If the NFM-P detects a port or VLAN range configuration mismatch in an MC synchronization group during NE discovery, the NFM-P raises an alarm.

44.2.2 MC synchronization and dual-homed L2/L3 CO

MC synchronization is typically used in a dual-homed L2 or L3 CO configuration. For example, an access node that aggregates several subscriber lines can be dual-homed to a redundant pair of

NEs. Dynamic subscriber-host state information on the NE must be synchronized with the redundant peer to ensure that service delivery in unaffected if a switchover occurs. See Chapter 78, “IES management” and Chapter 79, “VPRN service management” for more information about L2 and L3 CO dual homing.

MC synchronization for dual homing requires the configuration of protocol synchronization on the MC peer group that contains the redundant NEs. See 40.4 “To configure an MC peer group” (p. 1330) for information about configuring protocol synchronization on an MC peer group.

MC synchronization groups management procedures

44.3 MC synchronization groups management workflow and procedures

44.3.1 Stages

1

Create an MC peer group; see Chapter 40, “MC peer groups” .

2

Create an MC synchronization group, including MC peer synchronization ports or VLAN ranges; see 44.4 “To create an MC synchronization group” (p. 1376) .

3

Configure protocol synchronization for the MC synchronization group; see 44.5 “To configure protocol synchronization between MC peer group members” (p. 1378) .

44.4 To create an MC synchronization group

44.4.1 Steps

1

Choose Manage→Redundancy→Node Redundancy from the NFM-P main menu. The Manage Node Redundancy form opens.

2

Choose MC Peer Group (Multi-Chassis) from the drop-down menu and click Search. A list of MC peer groups is displayed.

3

Select an MC peer group and click Properties. The MC Peer Group (Edit) form opens.

4

Click on the Associated Groups tab.

5

Right-click on the MC Sync Group object in the navigation tree and choose Create MC Sync Group. The MC Sync Group (Create) form opens.

6

Configure the parameters.

7

Click Select beside the Port/LAG Name parameter in the First Element panel to specify a port, PW port, or LAG on the first NE.

Note: If you set the Sync Tag Config Level parameter to VLAN Range Level, only dot1q and QinQ-encapsulated Ethernet ports, PW ports, or LAGs in Access mode are listed.

8

Click Select beside the Port/LAG Name parameter in the Second Element panel to specify a port, PW port, or LAG on the first NE.

Note: If you set the Sync Tag Config Level parameter to VLAN Range Level, only dot1q and QinQ-encapsulated Ethernet ports, PW ports, or LAGs in Access mode are listed.

9

If you set the Sync Tag Config Level parameter to SDP Level, specify the SDP ranges that the MC synchronization group is to monitor.

Note: If the Synchronization Tag parameter is configured at the SDP level, a range cannot be configured for the SDP. The Synchronization Tag parameter should not be the same across different SDPs, whether at the SDP level or the Range level.

Use the following steps.

1. Enter the SDP ID in the SDP panel.
2. Click Apply.
3. Click on the First Site SDP Range Entries|Second Site SDP Range Entries tab.
4. Click Create. The SDP Range (Create) form opens.
5. Configure the parameters.
6. Click OK. The SDP Range (Create) form closes.
7. Repeat Step 9 4 to 6 to add another SDP range for the site, if required.
8. Repeat Step 9 for the other site, if required.

10

If you set the Sync Tag Config Level parameter to VLAN Range Level, specify the VLAN ranges that the MC synchronization group is to monitor.

Note: The VLAN ranges that you configure are applied to the configuration of each site in the MC synchronization group.

Use the following steps.

1. Click Apply.
2. Click on the First Site VLAN Entries tab.
3. Click Create. The VLAN Range (Create) form opens.

4. Configure the parameters.

   The Minimum Inner Encap Value and Maximum Inner Encap Value parameters are configurable only when the encapsulation type of the associated ports or LAGs is QinQ.

5. Click OK. The VLAN Range (Create) form closes.

11

Close the MC Sync Group (Create) form.

12

Close the MC Peer Group (Edit) form.

13

Close the Manage Node Redundancy form.

END OF STEPS

44.5 To configure protocol synchronization between MC peer group members

44.5.1 Steps

1

Choose Manage→Redundancy→Node Redundancy from the NFM-P main menu. The Manage Node Redundancy form opens.

2

Choose MC Peer Group (Multi-Chassis) from the drop-down menu and click Search. A list of MC peer groups is displayed.

3

Select an MC peer group and click Properties. The MC Peer Group (Edit) form opens.

4

Click on the Synchronize Protocols tab.

5

Configure the parameters.

6

Click OK.

7

Close the Manage Node Redundancy form.

END OF STEPS

44.6 To view the unmanaged MC synchronization peer of an NE

44.6.1 Purpose

Perform this procedure to view an MC synchronization peer when only one NE in the MC synchronization group is managed by the NFM-P.

Note: This procedure assumes that you have already configured an MC peer group with an associated MC synchronization group. If only one NE is managed by the NFM-P, you must create these objects from the CLI.

44.6.2 Steps

1

On the equipment view, right-click on the NE where you want to view an MC synchronization peer and choose Properties. The Network Element (Edit) form opens.

2

Click on the Redundancy tab, and then on the MC Peer tab.

3

Click Search. A list of MC peers is displayed.

4

Select an MC peer and click Properties. The MC Peer (Edit) form opens.

5

Click on the Synchronization Protocol tab.

6

Click Search. A list of MC synchronization peers is displayed.

7

Select an MC synchronization peer and click Properties. The MC Sync (Edit) form opens.

8

View the information, as required.

9

Close the MC Sync (Edit) form.

10

Close the MC Peer (Edit) form.

11

Close the Network Element (Edit) form.

END OF STEPS

44.7 To delete an MC synchronization group

44.7.1 Steps

1

Choose Manage→Redundancy→Node Redundancy from the NFM-P main menu. The Manage Node Redundancy form opens.

2

Choose MC Sync Group (Multi-Chassis) from the drop-down menu.

3

Click Search. A list of MC synchronization groups is displayed.

4

CAUTION

Service Disruption

Deleting an MC synchronization group that is associated with an MC ring group disables the protocol synchronization between the member sites in the MC ring group.

Select one or more MC synchronization groups in the list and click Delete.

5

Click Yes. The NFM-P deletes the MC synchronization group and the corresponding configuration on each member site.

6

Close the Manage Node Redundancy form.

END OF STEPS

45 MC ring groups

45.1 Overview

45.1.1 Purpose

This chapter describes MC ring groups and how to configure and manage them.

45.1.2 Contents

MC ring groups overview

45.2 MC ring groups overview

45.2.1 Overview

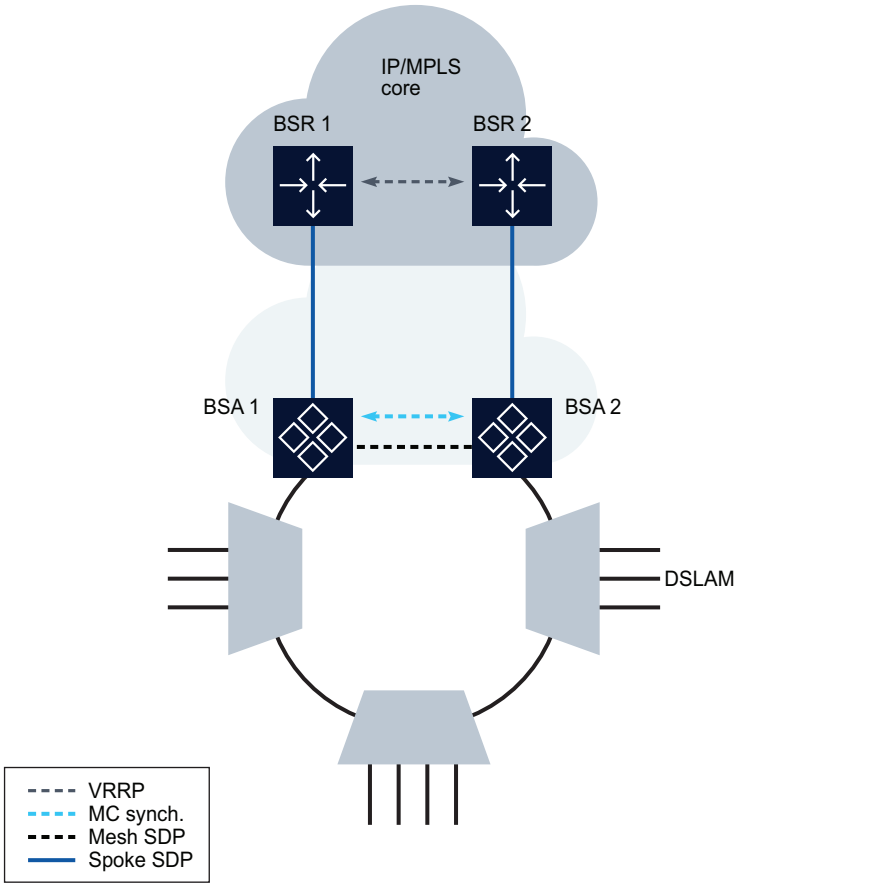
MC ring groups are an extension of dual-homing support that provides aggregation redundancy in networks that have multiple access nodes, called ring nodes in the context of MC ring groups, that are connected in a single ring.

The 7210 SAS, 7450 ESS, 7750 SR, and 7950 XRS support the creation of MC ring groups using Ethernet ports in Access mode.

Support for MC ring groups on the 7210 SAS varies depending on the chassis type and release; see the NE documentation for support information.

The following figure shows a simple subscriber aggregation network in which a single ring of access nodes, such as DSLAMs, is connected to a BSA in a VPLS. Each BSA is connected to an IES or VPRN L3 interface on a BSR using a spoke SDP. Each BSR L3 interface aggregates the subscriber traffic in one subnet.

Figure 45-1 Simple subscriber aggregation network



Note: BTV distribution is typically implemented in a separate VPLS that uses one SAP per access node.

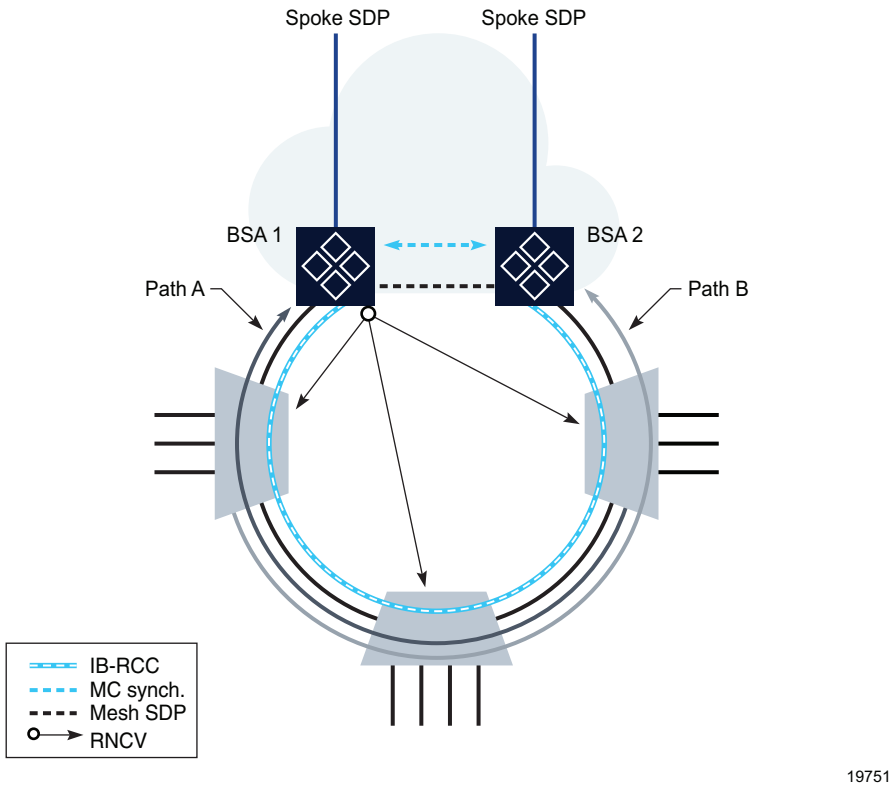
An MC ring group does not support a ring that has more than one break.

45.2.2 Steady-state condition

In an MC ring group, the operation of a typical dual-homed ring is as shown in Figure 45-2, “Dual-homed ring, steady-state condition” (p. 1384) . A steady-state condition is defined by the following.

- The participating BSAs have matching MC ring configurations.
- The In-Band Ring Control Connection, or IB-RCC, is operationally up.
- The MC ring is operationally up.

Figure 45-2 Dual-homed ring, steady-state condition



The IB-RCC is set up using a BFD session between IES or VPRN IP interfaces on BSA 1 and BSA 2. This connection requires a separate ring VLAN.

You can create an MC ring group only in an MC peer group. When only one peer in an MC peer group is managed by the NFM-P, you can configure node redundancy parameters only for the managed peer and only from the NE properties form. See Chapter 40, “MC peer groups” for information about MC peer groups.

In the steady state, the ring is fully closed and each ring node has two paths to the VPLS core; the paths are shown in as Path A and Path B in Figure 45-2, “Dual-homed ring, steady-state condition” (p. 1384) . To prevent a communication loop, a ring node can use only one path for VLAN traffic. The VLAN range can be explicitly assigned to Path B on each BSA; by default, the SAP uses Path A. The VLAN range assignment for each path must be the same on each BSA. A SAP in the conflict range is assigned to Path A, regardless of the local configuration.

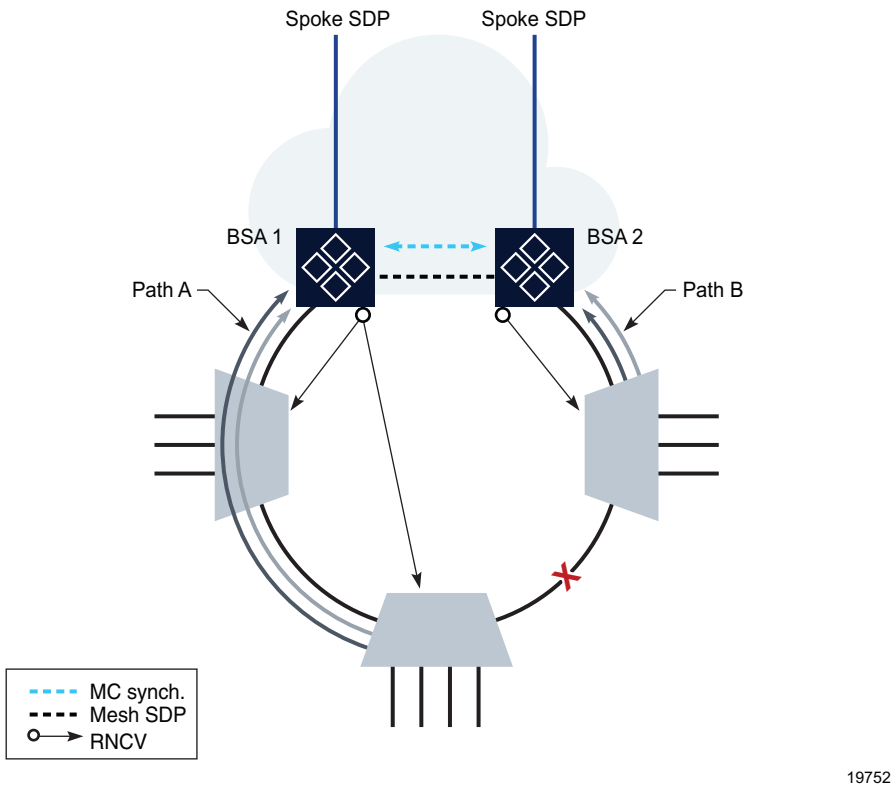
Each SAP in the path that ends on the master BSA is operationally up. Each subscriber-host forwarding database entry associated with the SAP points to the SAP. Each SAP in the path that ends on the standby BSA is operationally down. Each subscriber-host forwarding database entry associated with the SAP points to the mesh SDP that connects to the master BSA.

The master BSA periodically performs a Ring Node Connectivity Verification, or RNCV, check. The loss of connectivity to a ring node does not automatically trigger a switchover to the other path; if the IB-RCC BFD session is up, the ring is considered closed, and the master and standby BSA roles do not change.

45.2.3 Broken ring condition

A broken ring condition occurs when there is a link failure or ring node failure, as shown in the following figure. In this condition, the IB-RCC is operationally down. Each ring node has only one path to the VPLS core.

Figure 45-3 Dual-homed ring, broken-ring condition



Each BSA becomes the master for the ring nodes that it can reach, and performs as described in the steady-state condition. Each L2 SAP on each BSA is operationally up, except the SAPs that are explicitly excluded from the MC ring control.

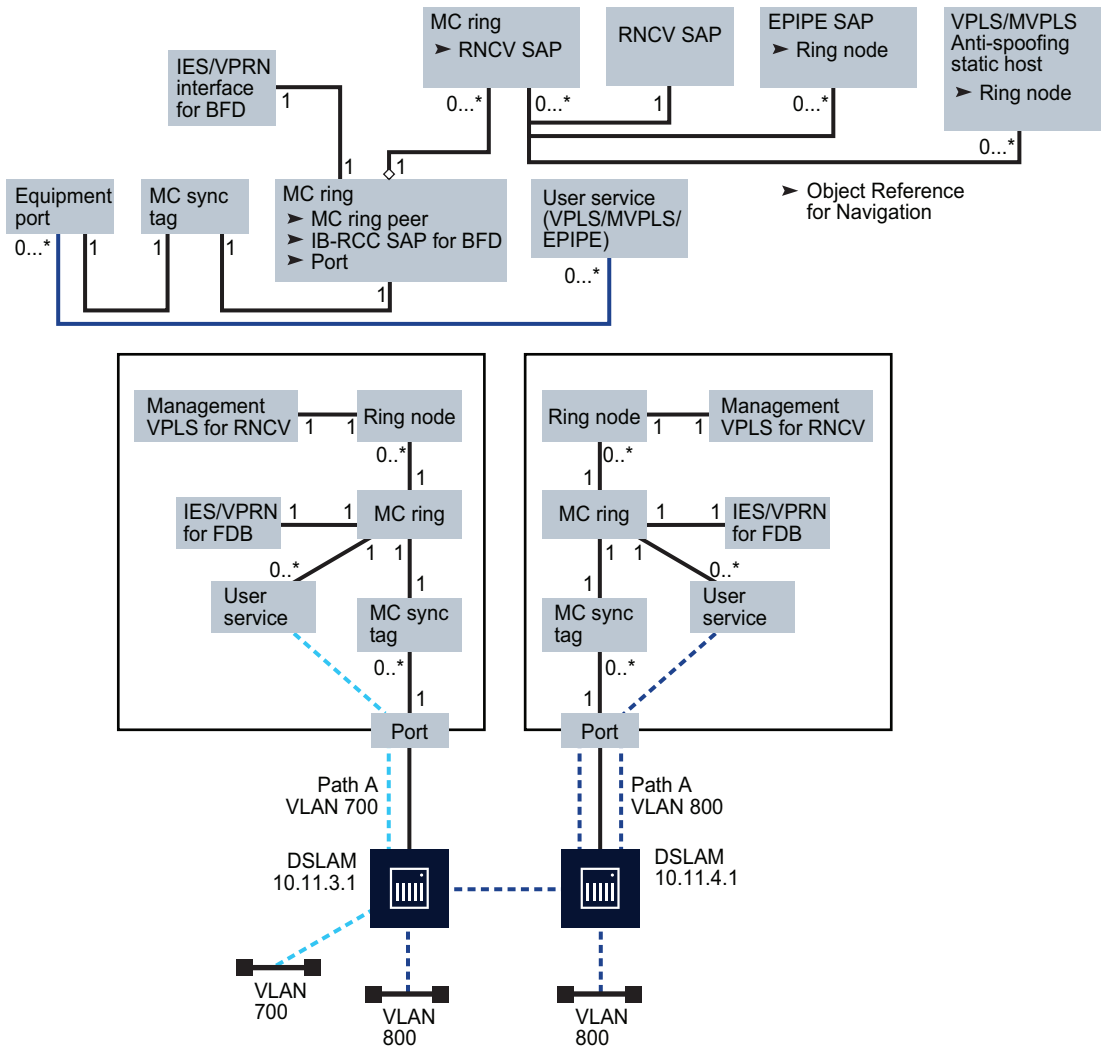
In the broken-ring condition, each BSA performs an RNCV check because each is a master. The forwarding database entry for each subscriber host behind an unreachable ring node points to the mesh SDP.

When the MC ring connectivity is restored, one BSA is the master for Path A and the other BSA is the master for Path B.

45.2.4 Object relationships

The following figure shows the MC ring and ring node object relationships with equipment and service objects.

Figure 45-4 MC ring group object relationships



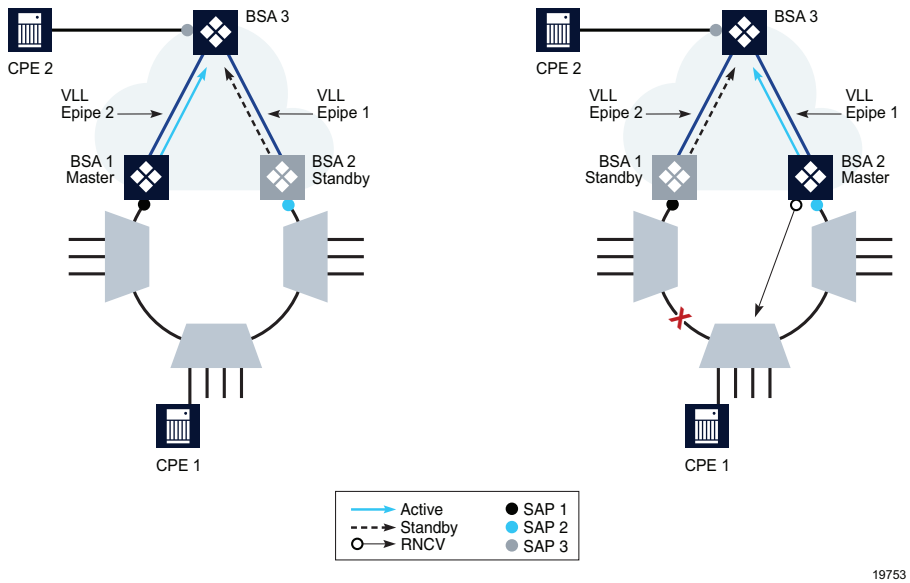
An MC ring has a one-to-one relationship with an MC synchronization tag. An MC ring uses one IES or VPRN service for IB-RCC. An MC ring can have multiple ring nodes, and each ring node can use only one SAP for RNCV.

When an MC ring group is correctly configured, each BSA L2 SAP is protected by the ring. The service that contains these protected SAPs is referred to as the user service. The service that is used for RNCV is an MVPLS that can also contain user SAPs and be a user service.

45.2.5 MC ring group and redundant VLL Epipe access

An MC ring group can connect to a VLL SAP to support redundant VLL Epipe access. The following figure shows a sample configuration using a VLL Epipe.

Figure 45-5 Dual-homed VLL Epipe configuration



CPE 1 connects to a ring node that has access to each BSA through a VLAN that is provisioned on each ring node. The SAP on each BSA uses the same VLAN tag.

In the closed ring on the left, BSA 1 is the master and sends an active status notification to BSA 3 on a VLL Epipe. BSA 2, the standby, sends a standby status notification. Based on this information, BSA 3 chooses a path to reach CPE 2.

In the broken ring on the right, the BSA that can use RNCV to reach CPE 1 becomes the master and sends an active status notification to BSA 3 on a VLL Epipe.

In each scenario, only one SAP is operationally up at a time, and each Epipe must be operationally up. If the ring node of CPE 1 is operationally down, neither BSA can reach the ring node, so each SAP and Epipe is operationally down.

45.2.6 MC ring groups and subscriber hosts

Each subscriber host on a SAP that is protected by an MC ring group must be associated with a ring node to determine whether the subscriber host is reachable by the BSA. Each VLL Epipe used for forwarding from an MC ring group must be explicitly configured with the name of a ring node in the MC ring. See 45.6 “To configure an MC ring group for redundant VLL Epipe access” (p. 1395)

for information about configuring VLL Epipes for use with an MC ring group.

When subscriber management is enabled on a VPLS SAP, each dynamic subscriber host is automatically associated with a ring node. Static hosts on a VPLS SAP require explicit configuration. The following must be true before you can turn up an MC ring on a VPLS SAP that has one or more static hosts, or turn up a static host o. a VPLS SAP in an operational MC ring:

- Residential subscriber management is enabled.
- The following are configured on the static host:
  - the name of a ring node in the MC ring group
  - subscriber identification
  - a subscriber profile
  - an SLA profile

MC ring group management workflow and procedures

45.3 Workflow to manage MC ring groups

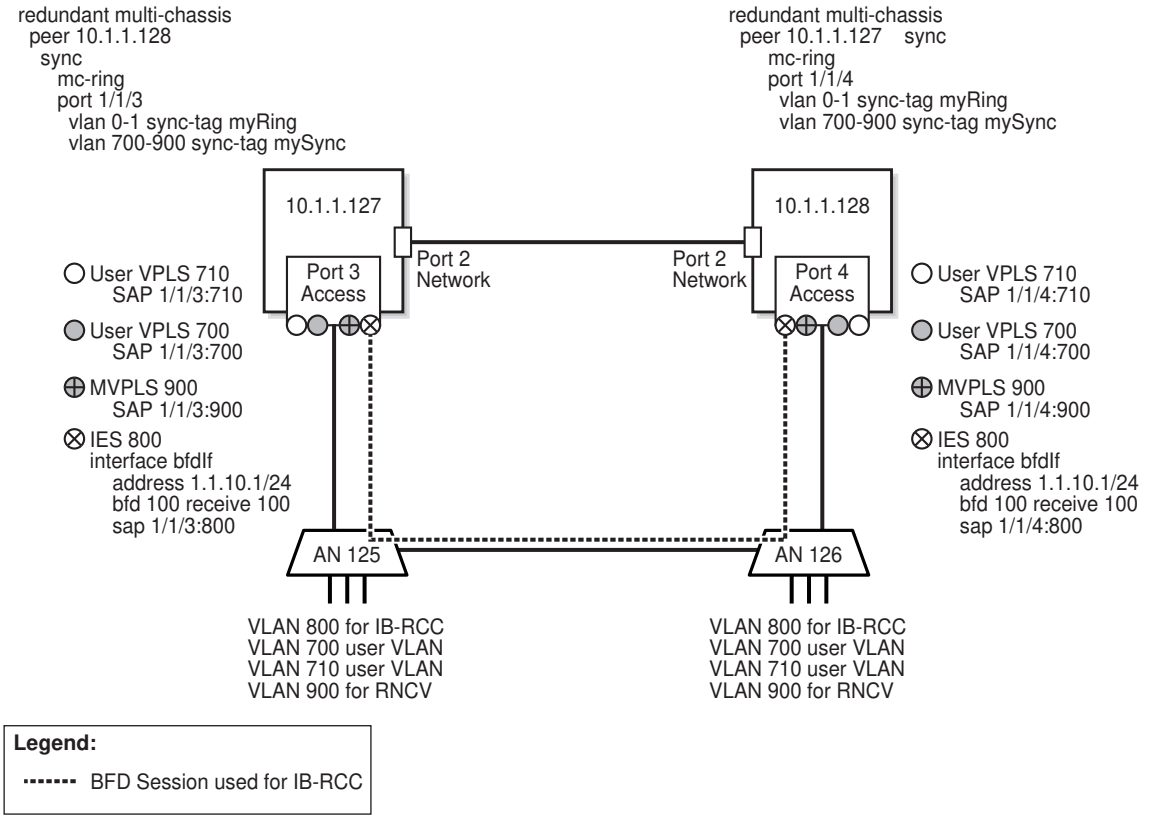
45.3.1 Stages

NE preconfiguration

1

Configure physical connectivity between the two BSAs and the ring nodes, as shown in Figure 45-6, “MC ring group preconfiguration” (p. 1389) . Each port must be operationally up.

Figure 45-6 MC ring group preconfiguration



2

Configure a routing protocol on each BSA to enable IP communication; see Chapter 28, “Routing protocol configuration” for information about configuring routing protocols.

3

Configure an MVPLS for RNCV on the BSAs; see Chapter 77, “VPLS management ” for information about configuring MVPLS.

4

Create an MC peer group that has the two BSAs as members and has MC ring synchronization enabled; see Chapter 40, “MC peer groups” for information about MC peer groups.

5

In the MC peer group, create an MC synchronization group that specifies each BSA access port. The MC synchronization group can synchronize the port or a VLAN range. See Chapter 44, “MC synchronization groups” for information about MC synchronization groups.

6

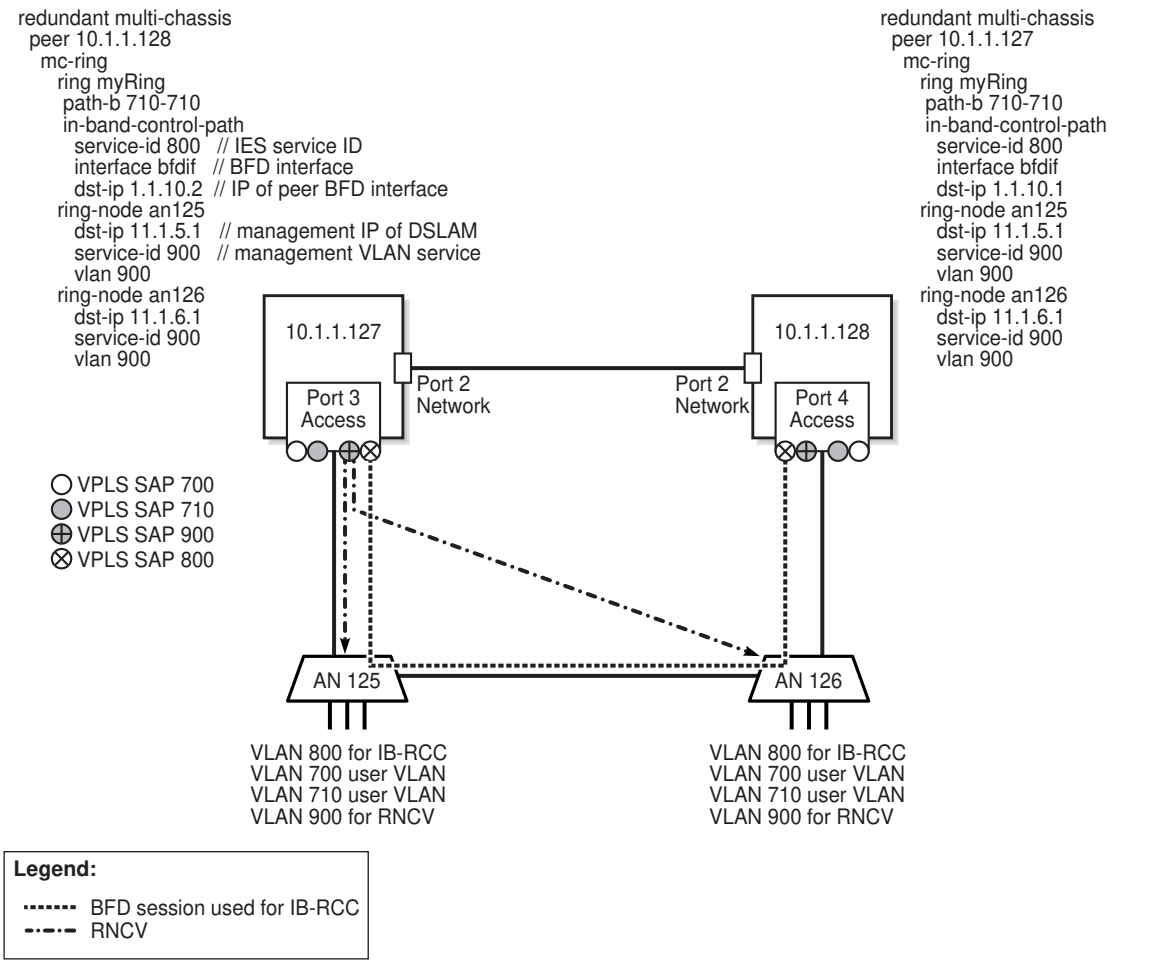
Configure each ring node with the VLAN tag used for BFD to enable BFD communication through the ring and make each BSA SAP operational.

MC ring group configuration

7

Create an MC ring group that contains the BSAs, which are shown as 10.1.1.127 and 10.1.1.128 in Figure 45-7, “MC ring configuration” (p. 1391) . For each ring node within the ring group, you must specify the management IP address of a ring node as the destination IP address and assign one VLAN for connectivity checking, which is shown in Figure 45-7, “MC ring configuration” (p. 1391) as VLAN 900; see 45.4 “To create an MC ring group” (p. 1392) for more information.

Figure 45-7 MC ring configuration



19759

8

Create the user VPLS and assign a SAP to each of the two BSA access ports. You can configure a protecting SAP on each BSA to provide SAP-level redundancy, if required; see Chapter 77, “VPLS management ” for information about protecting SAPs.

9

If the VPLS is to send traffic to an IES or a VPRN service, perform the following steps.

1. Create a spoke SDP from each VPLS site in the MC ring group to the IES or VPRN service.
2. Configure traffic forwarding to the IES or VPRN service; see 45.5 “To configure L3 forwarding from a VPLS or MVPLS to an IES or VPRN service” (p. 1394) .

10

If the VPLS is to send traffic to redundant VLL Epipes, perform the following steps.

1. Create a redundant VLL Epipe from each VPLS site in the MC ring group to the BSA that is the common endpoint of the VLL Epipes.
2. Configure traffic forwarding to each VLL Epipe service; see 45.6 “To configure an MC ring group for redundant VLL Epipe access” (p. 1395) .

11

Turn up the MC ring.

At this point, the following statements apply to the Figure 45-7, “MC ring configuration” (p. 1391) configuration.

- VPLS SAP 700 is operationally up on BSA 10.1.1.127 and operationally down on BSA 10.1.1.128.
- VPLS SAP 710 is operationally down on BSA 10.1.1.127 and operationally up on BSA 10.1.1.128.
- The operational state of the ring is Connected.

To test the configuration, you can shut down an access-node port in the ring to break the ring. As a result, the BSA SAPs should remain operationally up, but the operational state of the ring changes to Broken.

45.4 To create an MC ring group

Note: You cannot create an MC ring SAP on a VPLS site that is the endpoint of redundant spoke SDPs.

45.4.1 Steps

1

Choose Manage→Redundancy→Node Redundancy from the NFM-P main menu. The Manage Node Redundancy form opens.

2

Choose MC Peer Group (Multi-Chassis) from the drop-down menu and click Search. A list of MC peer groups is displayed.

3

Select an MC peer group and click Properties. The MC Peer Group (Edit) form opens.

4

Click on the Associated Groups tab.

5

Right-click on the MC Ring Group object and choose Create MC Ring Group. The MC Ring Group (Create) form opens.

6

Configure the parameters.

7

Click Apply.

8

Click Properties in the Multi-Chassis Ring on First Site panel. The MC Ring (Edit) form opens.

9

Configure the parameters.

10

Create one or more ring nodes, as required.

Perform the following steps:

1. Click on the Components tab.
2. Right-click on the MC Ring object and choose Create MC Ring Node. The MC Ring Node (Create) form opens.
3. Configure the parameters.
4. Click OK to save your changes and close the form.

11

Configure a VLAN range for traffic that is to use the non-default path through the MC ring, if required.

Perform the following steps:

1. Click on the Path B VLAN Range tab.
2. Click Create. The Path B VLAN Range (Create) form opens.
3. Configure the parameters.
4. Click OK to save your changes and close the form.

12

Configure a VLAN range for traffic that is not to be protected by the MC ring, if required.

Perform the following steps:

1. Click on the Exclude VLAN Range tab.
2. Click Create. The Path B VLAN Range (Create) form opens.

3. Configure the parameters.
4. Click OK to save your changes and close the form.

13

Click OK to save your changes and close the MC Ring (Edit) form.

14

Click Properties in the Multi-Chassis Ring on Second Site panel. The MC Ring (Edit) form opens.

15

Repeat Step 9 to Step 13 .

16

Click OK to save your changes and close the MC Ring Group (Create) form.

END OF STEPS

45.5 To configure L3 forwarding from a VPLS or MVPLS to an IES or VPRN service

45.5.1 Purpose

Perform this procedure to configure MC ring group traffic forwarding through a BSA spoke SDP to a BSR L3 access interface in an IES or VPRN service, as shown in Figure 45-1, “Simple subscriber aggregation network” (p. 1383) .

45.5.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Click Search. A list of services is displayed.

3

Select a VPLS or MVPLS and click Properties. The service properties form opens.

4

Click on a site in the service navigation tree. The site properties form opens.

5

Click on the Default Gateway tab.

6

Configure the parameters, which specify the IP and MAC addresses of the default gateway to which the VPLS is to forward L3 traffic.

7

Click OK to save your changes and close the site properties form.

8

Click OK to save your changes and close the service properties form.

END OF STEPS

45.6 To configure an MC ring group for redundant VLL Epipe access

45.6.1 Purpose

Perform this procedure to configure traffic forwarding from a BSA SAP in an MC ring group through a VLL Epipe to a BSA SAP outside the ring group, as shown in Figure 45-5, “Dual-homed VLL Epipe configuration” (p. 1387) .

45.6.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Click Search. A list of services is displayed.

3

Select the appropriate VLL Epipe service and click Properties. The Epipe Service (Edit) form opens.

4

Right-click on an L2 access interface in the service navigation tree and click Properties. The L2 Access Interface (Edit) form opens.

5

Configure the MC Ring Node parameter by clicking Select or by typing the name of a ring node that terminates on the port associated with the L2 access interface.

6

Click OK to save your changes and close the L2 Access Interface (Edit) form.

7

Click OK to save your changes and close the Epipe Service (Edit) form.

END OF STEPS

45.7 To turn up the MC rings in an MC ring group

45.7.1 Purpose

Note: You cannot administratively enable an MC ring group in one operation; you must turn up the MC rings in the MC ring group individually.
If a Problems Encountered form is displayed when you try to turn up an MC ring, you can perform one or both of the following to view information about the problem.

- Select the listed problem and click Properties.
- View the Operational State and Failure Reason indicators on the State tab of the MC ring properties form.

The NFM-P performs a series of checks to determine whether an MC ring can be turned up. The checks include verifying the following:

- The synchronization tag is configured on the BSA.
- The VLAN-level synchronization tag is valid.
- The IES or VPRN interface for the IB-RCC is configured.
- BFD is enabled on the IB-RCC interface.
- The IES or VPRN interface is operationally up.
- The IB-RCC interface is not in use by another MC ring.
- The IB-RCC interface is on the port used for MC synchronization.
- The IB-RCC destination IP address is configured.
- The IB-RCC destination IP address is not the same as the IB-RCC source IP address.
- The IB-RCC destination IP address is not in the same subnet as the IB-RCC source IP address.
- The MVPLS or VPLS site is not an endpoint for redundant spoke SDPs.

45.7.2 Steps

1

Choose Manage→Redundancy→Node Redundancy from the NFM-P main menu. The Manage Node Redundancy form opens.

2

Choose MC Ring Group (Multi-Chassis) from the drop-down menu and click Search. A list of MC ring groups is displayed.

3

Select an MC ring group and click Properties. The MC Ring Group (Edit) form opens.

4

Perform one of the following.

a. Turn up the MC ring using the MC ring properties form.

Note: Using this method enables you to view real-time MC ring status information while the NFM-P turns up the MC ring.

Perform the following steps:

1. Click Properties beside the Site ID parameter in the Multi-Chassis Ring on First Site panel. The MC Ring (Edit) form opens.
2. Click on the State tab.
3. Set the Administrative State parameter to Up.
4. Click Apply. The NFM-P attempts to turn up the MC ring.
5. View the dynamically updated Operational State indicator.
6. Close the MC Ring (Edit) form.
7. Click Properties beside the Site ID parameter in the Multi-Chassis Ring on Second Site panel. The MC Ring (Edit) form opens.
8. Repeat Step 4 a 2 to 6 .

b. Turn up the MC ring using the navigation tree.

Perform the following steps:

1. Click on the Components tab.
2. Right-click on the first site object and choose Turn Up. The NFM-P tries to turn up the MC ring.
3. Right-click on the second site object and click Turn Up. The NFM-P tries to turn up the MC ring.

5

Close the MC Ring Group (Edit) form.

END OF STEPS

45.8 To view the operational status of MC ring group components

45.8.1 Steps

1

Choose Manage→Redundancy→Node Redundancy from the NFM-P main menu. The Manage Node Redundancy form opens.

2

Choose MC Ring Group (Multi-Chassis) from the drop-down menu and click Search. A list of MC ring groups is displayed.

3

Select an MC ring group and click Properties. The MC Ring Group (Edit) form opens.

4

Click Properties beside a site that hosts an MC ring. The MC Ring (Edit) form opens.

5

Click on the State tab.

6

View the dynamically updated Operational State indicator.

The Operational State is one of the following:

- Unknown—cannot determine the operational state
- Shut Down—MC ring administratively down
- Config Error—MC ring misconfigured
- No Peer—peer MC ring not configured
- Connected—MC ring operational
- Broken—RNCV check fails
- Local Broken—MC ring site cannot connect to a ring node
- Conflict—MC ring configuration conflicts with another configuration
- Testing Ring—RNCV check in progress
- Peer Down—peer MC ring site inoperable
- Waiting For Peer—peer MC ring site initializing

7

Click on the Components tab.

8

Right-click on a ring node object and choose Properties. The MC Ring Node (Edit) form opens.

9

Click on the State tab.

10

View the dynamically updated information in the Local Operational State and Remote Operational State fields.

The Operational State is one of the following:

- Unknown—cannot determine operational state
- Not Provisioned—ring node configuration incomplete
- Config Error—ring node misconfigured
- Not Tested—no RNCV check result available
- Testing—RNCV check in progress
- Connected—ring node operational
- Disconnected—cannot reach ring node

11

Close the MC Ring Node (Edit) form.

12

Close the MC Ring (Edit) form.

13

Close the MC Ring Group (Edit) form.

END OF STEPS

45.9 To configure an MC ring peer on one NE

45.9.1 Purpose

Perform this procedure to configure an MC ring peer when only one NE in the MC ring is managed by the NFM-P.

Note: This procedure assumes that you have already configured an MC peer group with an associated MC ring. If only one NE is managed by the NFM-P, you must create these objects from the CLI.

45.9.2 Steps

1

On the equipment view, right-click on the NE where you want to configure an MC ring peer and choose Properties. The Network Element (Edit) form opens.

2

Click on the Redundancy tab.

3

Click on the MC Peer tab.

4

Click Search. A list of MC peers is displayed.

5

Select an MC Peer and click Properties. The MC Peer (Edit) form opens.

6

Click on the MC Rings tab.

7

Click Search. A list of MC rings is displayed.

8

Select an MC ring and click Properties. The MC Ring (Edit) form opens.

9

Configure the parameters.

10

Create one or more ring nodes, if required.

Perform the following steps:

1. Click on the Components tab.
2. Right-click on the MC Ring object and choose Create MC Ring Node. The MC Ring Node (Create) form opens.
3. Configure the parameters.
4. Click OK to save your changes and close the MC Ring Node (Create) form.

11

Configure a VLAN range for traffic that is to use the non-default path through the MC ring, if required.

Perform the following steps:

1. Click on the Path B VLAN Range tab.
2. Click Create. The Path B VLAN Range (Create) form opens.
3. Configure the parameters.
4. Click OK to save your changes and close the Path B VLAN Range (Create) form.

12

Configure a VLAN range for traffic that is not to be protected by the MC ring, if required.

Perform the following steps:

1. Click on the Exclude VLAN Range tab.
2. Click Create. The Exclude VLAN Range (Create) form opens.
3. Configure the parameters.
4. Click OK to save your changes and close Exclude VLAN Range (Create) form.

13

Close the MC Ring (Edit) form.

14

Close the MC Peer (Edit) form.

15

Close the Network Element (Edit) form.

END OF STEPS

45.10 To delete an MC ring group

CAUTION

Service Disruption

Deleting an MC ring group removes all child objects associated with the MC ring group, such as the MC rings and ring nodes.

Note: You must set the administrative state of an MC ring to Down before you can delete the MC ring.
Before you can set the administrative state of an MC ring to Down, you must administratively disable each VPLS or MVPLS SAP in the ring, regardless of the path used by each.

45.10.1 Steps

1

Choose Manage→Redundancy→Node Redundancy from the NFM-P main menu. The Manage Node Redundancy form opens.

2

Choose MC Ring Group (Multi-Chassis) from the drop-down menu and click Search. A list of MC ring groups is displayed.

3

Select an MC ring group and click Properties. The MC Ring Group (Edit) form opens.

4

Click Properties beside the Site ID parameter in the Multi-Chassis Ring on First Site panel. The MC Ring (Edit) form opens.

5

Click on the State tab.

6

Set the Administrative State parameter to Down.

7

Click Apply. The NFM-P shuts down the MC ring.

8

Close the MC Ring (Edit) form.

9

Click Properties beside the Site ID parameter in the Multi-Chassis Ring on Second Site panel. The MC Ring (Edit) form opens.

10

Repeat Step 5 to Step 8 .

11

Select the MC ring group and click Delete.

12

Click View Dependencies. A Warning form opens.

13

View the dependency information.

14

Select the I understand the implications of this action check box.

15

Click Yes. The NFM-P deletes the MC ring group and the associated configuration on each member NE.

16

Close the Manage Node Redundancy form.

END OF STEPS

46 Synchronization management

Synchronization management overview

46.1 NFM-P synchronization manager

46.1.1 Overview

The NFM-P synchronization manager provides a centralized view of timing synchronization across the network. The centralized view provides a common list of master and slave synchronization peers in a synchronization domain. The view includes a correlated list of alarms against synchronization objects in the domain, such as PTP clocks, ports, and peers.

You can use the synchronization manager to assign IP path monitors to peers between NEs configured with IEEE 1588 PTP clocks. The synchronization manager provides navigation to related NFM-P objects, such as NEs that are configured with IEEE 1588 PTP clocks, and to related CPAM objects, such as IP path monitors.

Note: The synchronization manager can be used to view and monitor IEEE 1588 PTP clocks. You can configure timing synchronization and IEEE 1588 PTP clocks through the NFM-P NE properties forms or through the device CLI.

46.1.2 Synchronization domains

Synchronization domains allow you to view and manage the PTP peers or SyncE sites in a domain. You can use synchronization domains to assign IP path monitors to PTP peers. You can also filter unmonitored peers and navigate to associated IP path monitors.

When the NFM-P discovers a PTP peer or SyncE site, it is assigned to a synchronization domain based on the domain ID. When the NFM-P discovers a PTP peer or SyncE site with a domain ID that is not shared with an existing synchronization domain, a synchronization domain with that domain ID is automatically created. The domain ID is configured on the IEEE 1588 PTP clock.

The following events can result in the creation of a synchronization domain.

- An NE is discovered with configured IEEE 1588 PTP clocks.
- An IEEE 1588 PTP clock is created on a discovered NE.
- The domain ID on an IEEE 1588 PTP clock is modified.

You cannot create synchronization domains manually, and you can delete a synchronization domain only when the domain does not contain peers or SyncE sites. Alarms generated for a PTP clock, port, or peer are propagated to the appropriate synchronization domain.

46.1.3 Synchronization groups

You can create synchronization groups to view a subset of PTP peers separately from the rest of the synchronization domain. A synchronization domain can contain up to 500 synchronization groups. When you create the group, you choose NEs configured with IEEE 1588 PTP clocks and

the NFM-P generates a list of constituent peers from the NEs. All of the path monitoring functionality that is available at the synchronization domain level is also available at the synchronization group level.

46.1.4 Peer remote site ID

When the NFM-P discovers a PTP peer, the peer IP address is used to determine the system IP address of the far-end NE. The IP address is displayed in the synchronization manager as the peer remote site ID. If the NFM-P discovers a system or network IP address that matches the peer IP address of a discovered PTP peer, the peer remote site ID is recalculated. The peer remote site ID is set to 0.0.0.0 if it cannot be mapped to a managed NE in the network or if it maps to more than one managed NE.

46.1.5 Timing synchronous links

The synchronization manager lists all timing synchronous links in the network related to a selected PTP peer or SyncE site. The list includes links that are not currently in use. You can click the Find Sync Time Sources button on the PTP peer or SyncE site properties form to view a list of timing synchronous links in the network that are currently being used by the selected site.

From the physical topology map, you can right-click an NE and select Highlight Sync Time Sources to view a graphical representation of the timing synchronous links currently being used by the selected NE.

46.1.6 IP path monitors

You can use the synchronization manager to assign unidirectional and bidirectional IP path monitors to PTP peers. The PTP Peers tabs on the synchronization domain and synchronization group forms include an Unmonitored tab that displays peers that are not assigned an IP path monitor. You can navigate to the IP path monitor object from the synchronization manager.

Alarms that are generated for IP path monitor objects, such as reachability, OAM and path change alarms, are propagated to the respective PTP peers. See the *NSP NFM-P Control Plane Assurance Manager User Guide* for more information about IP path monitors.

46.1.7 SyncE

The synchronization manager supports SyncE. The NFM-P automatically assigns NEs with Sync-E enabled to the default Sync-E synchronization domain. You can view SyncE sites and associated daughter cards, including correlated alarms. Both the far end and near end NEs must be managed by the NFM-P for SyncE to work.

The properties forms for SyncE sites includes a check box that indicates if the site is also enabled with PTP. The properties forms for PTP peers includes a check box that indicates if the peer is also enabled with SyncE. This flag is processed only if there is a valid peer remote site ID.

46.2 Synchronization topology

46.2.1 Overview

You can use the NFM-P physical topology map to view a graphical presentation of SyncE and PTP peers in your network. The synchronization topology offers snapshot view of timing sources as well

as the quality of timing in the network.

The SyncE highlights on the physical topology map are not updated dynamically.

Perform one of the following to refresh the graphical presentation:

- De-select and re-select the highlight session from the Highlight Sessions tab in the map legend
- Draw a new sync source highlight session

46.2.2 Timing sources highlight

You can use the physical topology map to highlight the timing sources for a selected NE. Right-click the NE and select Highlight Sync Time Sources. PTP timing source links are displayed as a dashed line and SyncE timing source links are displayed as a solid line. An arrow indicates the directional path of the timing source.

Note: Before using the timing source highlight feature, you must ensure that the physical topology is displaying physical links between the NEs.

Note: The topology map displays up to 20 hops for a timing source highlight. If the timing source exceeds 20 hops, you can use the Find Sync Time Sources button on the PTP peer or SyncE site properties form to generate a complete list of timing sources.

Figure 46-1 PTP timing source highlight

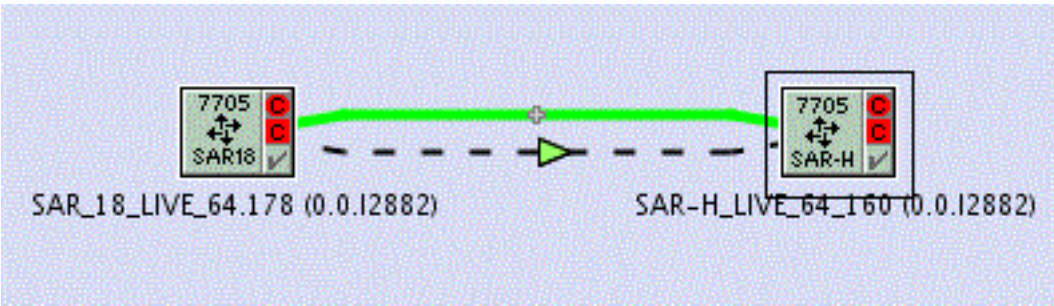


Figure 46-2 SyncE timing source highlight

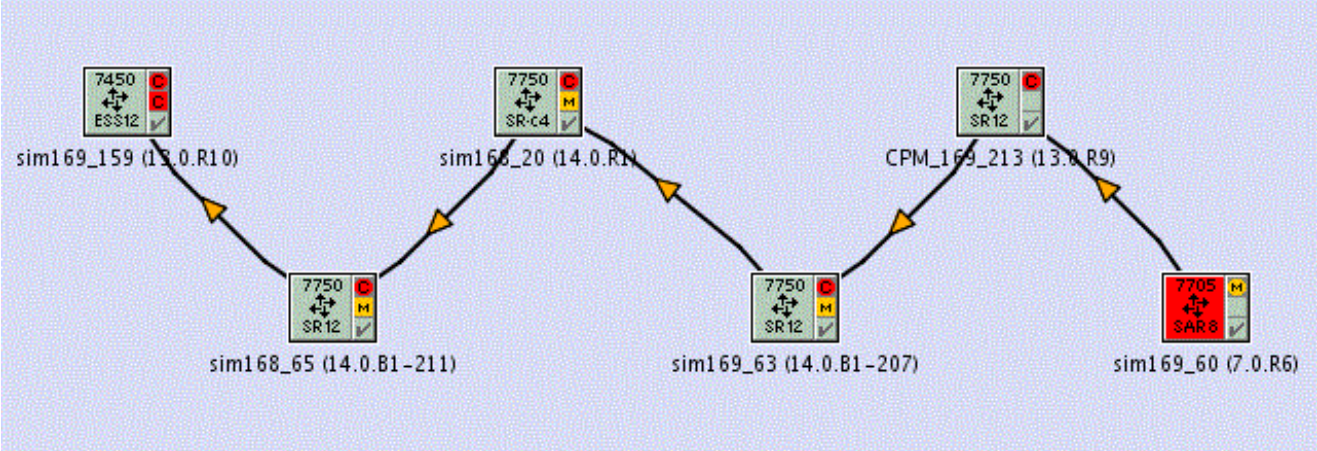


46.2.3 Timing quality

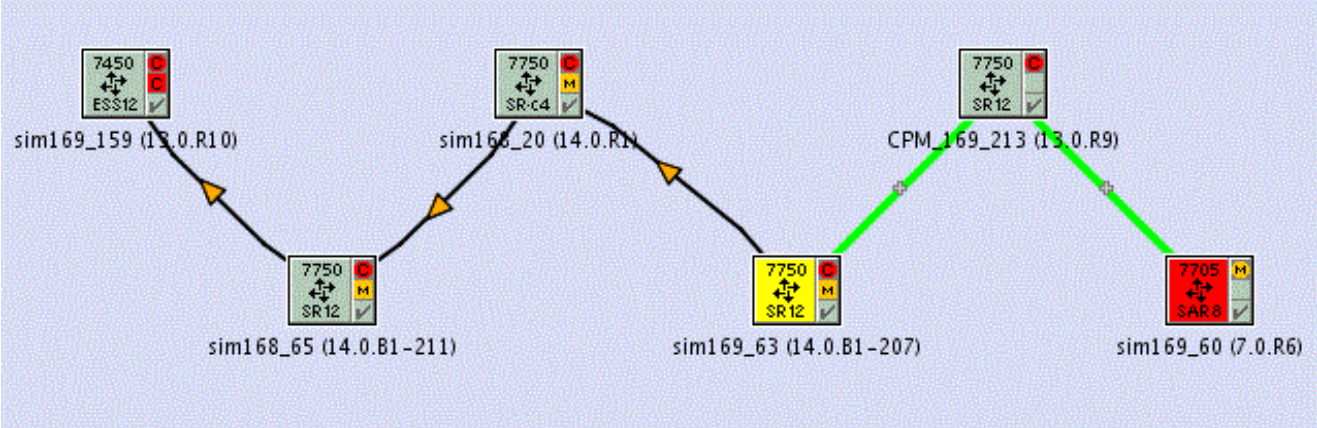
You can use the NFM-P physical topology map to view a graphical presentation of timing quality in your network. Right-click on the topology map and select Quality of Timing→Color Quality of Timing. The SyncE sites and PTP peers are colored based on the quality of the timing source.

The following colors are used to represent timing quality:

- Grey — reachable; or master-locked; or slave
- Yellow — resyncing; or master holdover; or acquiring
- Purple — suspended
- Red — unreachable; or resync failed; or master free run; or not present

In the following figure, sim169_60 is in free run, sim169_63 is in holdover, and all other NEs are master-locked.

Figure 46-3 Timing quality coloring



Synchronization management workflow

46.3 Workflow for synchronization management

46.3.1 General information

This workflow assumes that PTP peers are configured. See “Configuring shelf objects using the NFM-P” (p. 453) for more information about configuring timing and IEEE 1588 PTP clocks.

46.3.2 Stages

1

Configure synchronization domains and create synchronization groups. See 46.4 “To configure a synchronization domain and create synchronization groups” (p. 1411) .

2

Create unidirectional and bidirectional IP path monitors, as required. See 46.5 “To create IP path monitors for PTP peers” (p. 1412) .

3

View IP path monitors, as required. See 46.6 “To view an IP path monitor from the synchronization manager” (p. 1414) .

4

Perform path monitoring procedures, as required. See the *NSP NFM-P Control Plane Assurance Manager User Guide*.

5

Perform synchronization topology monitoring procedures, as required. See 46.8 “To use the synchronization topology map” (p. 1417).

Synchronization management procedures

46.4 To configure a synchronization domain and create synchronization groups

Note: A synchronization domain is created automatically when a new IEEE 1588 PTP clock with a unique domain ID is created or discovered. You cannot create synchronization domains manually.

46.4.1 Steps

1

Choose Tools→Synchronization Manager from the main menu. The Synchronization Manager form opens.

2

Configure the filter criteria, if required, and click on the Search button.

3

Choose a synchronization domain and click on the Properties button. The Synchronization Domain (Edit) form opens with the General tab displayed.

4

Configure the parameters:

- Displayed Name
- Description

5

Click on the Sync Groups tab button.

6

Click on the Create button. The Synchronization Group (Create) form opens with the General tab displayed.

7

Configure the parameters:

- Group ID
- Auto-Assign ID
- Displayed Name
- Description

8

Click on the Network Elements tab button.

9

To add NEs to the synchronization group:

1. Click on the Add button. The Select Network Elements form opens.
2. Configure the filter criteria, if required, and click on the Search button.

   Note:

   Only NEs with configured IEEE 1588 PTP clocks are displayed.
3. Choose one or more NEs and click on the OK button. The Select Network Elements form closes.

10

Click on the OK button. A dialog box opens.

11

Click on the OK button to confirm the changes. The Synchronization Group (Create) form closes.

12

Repeat Step 6 to Step 11 to create more synchronization groups, as required.

13

Click on the Apply button. A dialog box opens.

14

Click on the OK button. The Synchronization Domain (Edit) form closes.

15

Close the Synchronization Manager form.

END OF STEPS

46.5 To create IP path monitors for PTP peers

46.5.1 Steps

1

Choose Tools→Synchronization Manager from the main menu. The Synchronization Manager form opens.

2

Configure the filter criteria, if required, and click on the Search button.

3

Choose a synchronization domain and click on the Properties button. The Synchronization Domain (Edit) form opens with the General tab displayed.

4

Perform one of the following:

a. To create IP path monitors at the synchronization domain level, click on the PTP Peers tab button.

b. To create IP path monitors at the synchronization group level:

   1. Click on the Sync Groups tab button.
   2. Configure the filter criteria, if required, and click on the Search button.
   3. Choose a synchronization group in the list and click on the Properties button. The Synchronization Group (Edit) form opens with the General tab displayed.
   4. Click on the PTP Peers tab button.

5

Under the Unmonitored tab, perform one of the following:

a. To create unidirectional IP path monitors, click on the IP tab button.

b. To create bidirectional IP path monitors, click on the Bidirectional IP tab button.

6

Configure the filter criteria, if required, and click on the Search button.

7

Choose one or more peers.

8

Click on the Create Path Monitor button. The NFM-P creates an IP path monitor and the chosen peer is removed from the list.

Note: The IP Path Monitors are created only for PTP peers for which the peer remote site ID is resolved and mapped to a CPAM-managed router.

9

Close the Synchronization Group (Edit) form, if applicable.

10

Close the Synchronization Domain (Edit) form.

11

Close the Synchronization Manager form.

END OF STEPS

46.6 To view an IP path monitor from the synchronization manager

46.6.1 General information

Perform this procedure to navigate to an assigned IP path monitor object from the synchronization domain or synchronization group forms.

Note: You can also view the properties of an IP path monitor from the Synchronization component tree of an NE. See 46.7 “To use the Synchronization component tree” (p. 1415) for more information.

46.6.2 Steps

1

Choose Tools→Synchronization Manager from the main menu. The Synchronization Manager form opens.

2

Configure the filter criteria, if required, and click on the Search button.

3

Choose a synchronization domain and click on the Properties button. The Synchronization Domain (Edit) form opens with the General tab displayed.

4

Perform one of the following:

a. To view IP path monitors at the synchronization domain level, click on the PTP Peers tab button.

b. To view IP path monitors at the synchronization group level, perform the following:

1. Click on the Sync Groups tab button.
2. Configure the filter criteria, if required, and click on the Search button.
3. Choose a synchronization group and click on the Properties button. The Synchronization Group (Edit) form opens with the General tab displayed.
4. Click on the PTP Peers tab button.

5

Click on the All tab button.

6

Configure the filter criteria, if required, and click on the Search button.

7

Perform one of the following:

a. To view a unidirectional IP path monitor:
   1. Choose one or more monitored peers and click on the IP Path Monitors button. A dialog box opens.
   2. Click on the Yes button. The IP Path Monitor (Edit) form opens with the General tab displayed. If you specified more than one peer in 1 , several forms open.
   3. View the IP path monitor, as required. See the *NSP NFM-P Control Plane Assurance Manager User Guide* for more information about IP path monitors.
   4. Close the IP Path Monitor (Edit) form.

b. To view a bidirectional IP path monitor, perform the following:
   1. Choose one or more monitored peers and click on the Bidirectional IP Path Monitors button. A dialog box opens.
   2. Click on the Yes button. The Bidirectional IP Path Monitor (Edit) form opens with the General tab displayed. If you specified more than one peer in 1 , several forms open.
   3. View the bidirectional IP path monitor, as required. See the *NSP NFM-P Control Plane Assurance Manager User Guide* for more information about bidirectional IP path monitors.
   4. Close the Bidirectional IP Path Monitor (Edit) form.

8

Close the Synchronization Group (Edit) form, if applicable.

9

Close the Synchronization Domain (Edit) form.

10

Close the Synchronization Manager form.

END OF STEPS

46.7 To use the Synchronization component tree

46.7.1 General information

Perform this procedure to access the Synchronization component tree of an IEEE 1588 PTP synchronization-enabled NE. The component tree provides a hierarchical view of PTP Clocks, PTP Ports, PTP Peers, and Path Monitors associated with the NE.

You can also use the Synchronization component tree to create or delete IEEE 1588 PTP Clocks, as well as create IP Path Monitors.

46.7.2 Steps

1

Perform one of the following:

a. Right-click on an NE in the Equipment or Routing navigation tree or in any NE list form and choose Properties from the contextual menu. The Network Element (Edit) properties form opens.

b. Right-click on an NE in the topology map and choose Properties from the contextual menu. The Network Element (Edit) properties form opens.

c. Choose Tools→Synchronization Manager from the main menu. The Synchronization Manager form opens.

1. Configure the filter criteria, if required, and click on the Search button.
2. Choose a Synchronization Domain and click on the Properties button. The Synchronization Domain (Edit) form opens, with the General tab displayed.
3. If you want to access the Synchronization component tree from the synchronization group level, perform 4 and 5 . Otherwise proceed to 6 .
4. Click on the Sync Groups tab and click on the Search button.
5. Choose a Synchronization Group and click on the Properties button. The Synchronization Group (Edit) form opens, with the General tab displayed.
6. Click on the PTP Peers tab button. A list of IEEE 1588 PTP Peers appears in the Unmonitored sub-tab.
7. Click the All sub-tab and choose a PTP peer from the list, then click on the NE Properties button. The associated Network Element (Edit) properties form of the selected PTP Peer opens.

2

Perform one or more of the following from the Synchronization item in the navigation tree:

a. View properties of existing PTP Clocks, PTP Ports, PTP Peers, and Path Monitors associated with the NE by expanding the Synchronization item in the component tree to the required level. Click on an item in the tree to display its properties in the form. See 46.6 “To view an IP path monitor from the synchronization manager” (p. 1414) for more information on viewing IP Path Monitors.

b. To create a new PTP Clock on the NE, right-click the IEEE 1588 PTP item under Synchronization. The IEEE PTP Clock (Create) form opens. See “Configuring shelf objects using the NFM-P” (p. 453) for procedural information on creating IEEE 1588 PTP Clocks and PTP Ports.

c. To create a new PTP Peer for an IEEE PTP Clock. See “Configuring shelf objects using the NFM-P” (p. 453) for procedural information.

d. To create a new Path Monitor, right-click the required port under Synchronization and choose

either Create IP Path Monitor or Create Bidirectional IP Path Monitor from the contextual menu. See 46.5 “To create IP path monitors for PTP peers” (p. 1412) for more information.

3

Close the Synchronization Group (Edit) form, if applicable.

4

Close the Synchronization Domain (Edit) form, if applicable.

5

Close the Synchronization Manager form, if applicable.

END OF STEPS

46.8 To use the synchronization topology map

46.8.1 Steps

Open a physical topology map

1

Choose Tools→Synchronization Manager from the main menu. The Synchronization Manager form opens.

2

Click Sync Timing Topology View. The Physical Topology map opens.

View timing synchronization sources

3

Right-click an NE and select Highlight Sync Time Sources.

4

A dialog confirms that the synchronization timing source highlight displays a snapshot of network timing. Click Yes.

PTP timing source links are displayed as a dashed line and SyncE timing source links are displayed as a solid line. An arrow indicates the directional path of the timing source.

View quality of timing

5

Right-click the topology map and select Quality of Timing→Color Quality of Timing.

The SyncE sites and PTP peers are colored based on the quality of the timing source.

END OF STEPS

47 Cellular domain management

47.1 Overview

47.1.1 Cellular domains

The NFM-P supports the management of cellular domains that group together devices such as the 7705 SAR-Hm for remote management. A cellular domain groups devices that have similar cellular network characteristics. If devices with dual SIM cards are in use, the cellular domain groups devices with the same primary and backup cellular network.

All NEs in a cellular domain must be running the same NE software release.

Note: All NEs in the domain must have the same combination of carriers. If, for example, two NEs have SIM cards for the same carriers but NE1 will use Carrier A as primary and NE2 will use Carrier B as primary, the two NEs must be in separate domains.

A cellular domain provides the following:

- a management domain for a group of cellular-connected NEs with common management attributes
- automatic discovery protocol (ADP), which facilitates remote device discovery and management
- multiple head-end nodes, which are used to reach the NEs in the cellular domain
- definition of an optional in-band management VPRN service of the cellular domain used to manage the NEs
- optional NGE domain used to secure the NEs cellular interface for all NEs in the cellular domain
- wireless carrier redundancy with optional dual SIM operation
- chassis-level security using a common SIM PIN (Personal Identification Number) per carrier for all NEs in a domain

A cellular domain acts as a template for ADP device discovery within one or more predefined subnets, initial configuration, and encryption of the NEs in the domain using NGE.

After the ADP process completes, the NEs in one or more predefined subnets are included in the cellular domain and managed using the cellular domain configurations. You can add new NEs to the domain by re-enabling ADP, which enables the deployment of the required configuration, for example, BGP or NGE, to the devices.

Note: An NE can belong to only one cellular domain.

Dual SIM deployment

The NFM-P supports the use of two SIM cards in a 7705 SAR-Hm, each with a different wireless carrier, for WAN redundancy. One SIM is active at a time.

Switching from one SIM to the other can be automatic or manual. With automatic switchover, you can choose which SIM is primary and secondary, and configure SIM switchover criteria. For example, the BGP operational state associated with the cellular port can be used as a criterion for

determining when a SIM switchover should occur. If the BGP operational state is down for a specified interval, then a SIM switchover occurs.

A SIM switchover is service affecting. Overly frequent switchovers will impact continuous service operation.

Dual SIM deployment is configured at the cellular domain level. All NEs in a dual SIM domain must have two working SIM cards.

The NFM-P does not support conversion of a single SIM cellular domain to a dual SIM cellular domain.

Head-end nodes

Each cellular domain must have at least one head-end node. A single SIM domain can have from one to four head-end nodes; a dual SIM domain can have from one to eight.

Head-end nodes serve as an intermediary for communication with the NFM-P, terminate Layer 2 and Layer 3 services, forward services to other NEs, and optionally define the gateway sites used by the NGE domain associated with the cellular domain. Each head-end node in a cellular domain must also be a gateway site to the NGE domain, if NGE is in use.

A head-end node can be a VSR, 7705 SAR, or 7750 SR, and must be discovered and managed by the NFM-P to be included in a cellular domain. If NGE is required, the head-end node cannot be a 7750 SR.

47.1.2 Cellular domain operation modes

A cellular domain in single SIM layout has the following operation modes:

- static cellular system mode — in-band management via 7705 SAR-Hm PDN interface
- static cellular interface mode — in-band management via a VPRN service and a private system IP address on the 7705 SAR-Hm
- dynamic cellular interface mode — in-band management via a VPRN service and a private system IP address on the 7705 SAR-Hm

In a dual SIM layout, both SIMs automatically operate in dynamic cellular interface mode.

In any operation mode, an operator-created XML file can be used to specify the devices for discovery.

In static or dynamic interface mode, if the ADP System IP Address parameter is set to something other than Use XML, you can also specify a pool of IP addresses for assignment to the discovered devices.

Static system mode

In static system mode, ADP can be configured to do one of the following when an SNMPv2 trap is received from a 7705 SAR-Hm in an ADP subnet:

- Learn the system address and IMSI of the 7705 SAR-Hm:
  The NFM-P adds the device to the associated cellular domain and initiates the ADP.
- Verify the system address of the 7705 SAR-Hm:

If the IMSI and system address match a device specified in an operator-created XML file, the NFM-P adds the device to the cellular domain and initiates the ADP. “Specifying devices using an XML file” (p. 1422) describes how to structure and import the XML file.

Note: When ADP is used in static system mode, the system address of a 7705 SAR-Hm must match the cellular interface address.

Static interface mode

In static interface mode, ADP does one of the following:

- imports an operator-created XML file that specifies each 7705 SAR-Hm device to discover

  When an SNMPv2 trap is received from a 7705 SAR-Hm, the NFM-P initiates the ADP for the device if the IMSI value matches an entry in the file. “Specifying devices using an XML file” (p. 1422) describes how to structure and import the XML file.
- assigns an IP address from a user-specified pool of addresses

Note: The NFM-P reuses IP addresses in a pool if the IP address is not used when the ADP Domain site is deleted and assigned.

To avoid issues when reusing IP addresses, the IP address should be deleted from the 7705 SAR-Hm and the node should be unmanaged and deleted from NFM-P before deleting the ADP domain site.

When the addresses in an IP-address pool are exhausted, the NFM-P raises an alarm, and ADP discovery is halted. In such a case, you can add a new system IP pool to resume ADP discovery.

Note: If a subnet has an associated IP-address pool, and an IP address is associated with the device IMSI in an ADP XML file, the IP address in the XML file is assigned to the device.

Note: When ADP is used in static interface mode, the system address of a 7705 SAR-Hm must be unique and different from the cellular interface address.

Dynamic interface mode

In dynamic interface mode, ADP does one of the following:

- imports an operator-created XML file that specifies each 7705 SAR-Hm device to discover

  When an SNMPv2 trap is received from a 7705 SAR-Hm, the NFM-P initiates the ADP for the device if the IMSI value matches an entry in the file. “Specifying devices using an XML file” (p. 1422) describes how to structure and import the XML file.
- assigns a system IP address from a user-specified pool of addresses

Note: The NFM-P reuses IP addresses in a pool if the IP address is not used when the ADP Domain site is deleted and assigned.

To avoid issues when reusing IP addresses, the IP address should be deleted from the 7705 SAR-Hm and the node should be unmanaged and deleted from NFM-P before deleting the ADP domain site.

When the addresses in a System IP-address pool are exhausted, the NFM-P raises an alarm, and ADP discovery is halted. In such a case, you can add a new system IP pool to resume ADP discovery.

Note: If a subnet has an associated IP-address pool, and an IP address is associated with the device IMSI in an ADP XML file, the IP address in the XML file is assigned to the device.

Specifying devices using an XML file

Identifiers for 7705 SAR-Hm devices can be specified in an XML file, and imported for use in either operation mode. The XML file requires an ADP element and one node element for each device to discover. Each node element has IMSI, systemName, and systemAddress attributes.

Note: The systemAddress attribute is optional, depending on the IP allocation configuration and the operation mode of the cellular domain. The systemName attribute is also optional.

In both static and dynamic cellular interface mode, the systemAddress is the private IP address reachable via the in-band VPRN service.

The following is an example of an ADP XML file:

```
<?xml version="1.0" encoding="UTF-8"?>
<ADP>
<node IMSI="310150123456720"
systemAddress="10.10.10.20"
systemName="test"/>
</ADP>
```

47.5 “To configure a cellular domain with single SIM deployment” (p. 1440) and 47.6 “To configure a cellular domain with dual SIM deployment” (p. 1444) describe how to specify the devices for ADP discovery using an XML file.

47.1.3 Domain subnets

You can create separate subnets in a cellular domain. A domain subnet represents a group of NEs with a cellular interface IP address that exists with the specified subnet. For each subnet in a domain, a BGP dynamic neighbor is created on each head-end node in the domain. The dynamic neighbor can accept remote 7705 SAR-Hm peers as they become available. The deletion of a subnet also deletes the BGP dynamic neighbor from all head-end node BGP groups.

Note: If the head-end node is a 7705 SAR, BGP neighbors are not created automatically when subnets are added. The 7705 SAR does not support dynamic neighbors. Static neighbors must be manually created.

ADP must be enabled on a subnet that has new devices to discover. ADP is initiated based on the cellular domain operation mode; see 47.1.11 “ADP discovery process” (p. 1429).

Note: You cannot delete a subnet that has ADP enabled at the domain or subnet level.

47.1.4 7705 SAR-Hm security during ADP

For additional security, each new 7705 SAR-Hm includes an information card that names the chassis serial number and a unique administrator password. During cellular domain configuration, you must specify the serial number and password of each such device to enable ADP access to the device.

A cellular domain can also contain older devices that have a common default administrator password. To support such devices, the cellular domain configuration must include the default password for ADP communication with the older devices.

The administrative account credentials for a device in a cellular domain must meet the following requirements.

- The User Name value on the NE User properties form must match the User Name value for CLI and NETCONF access in the ADP mediation security policy.
- The Password value for console or FTP access on the NE User properties form must match the Password value for CLI and NETCONF access in the ADP mediation security policy.

  To simplify the configuration, you can use the same value for the SNMPv3 user authentication and privacy passwords.

Configuring secure 7705 SAR-Hm ADP

During cellular domain configuration, you can specify the serial numbers and passwords manually, or import the passwords from a file, as described in 47.3 “To create an ADP password mapping file” (p. 1435).

47.1.5 Cellular domain security with NGE

You can secure a cellular domain by binding the cellular domain to an NGE domain. The encryption status of PDN interfaces in the cellular domain is determined by the encryption status of the gateway interfaces of the gateway sites of the NGE domain.

Each head-end node in each cellular domain that belongs to the NGE domain must also be a gateway site in the NGE domain. The NEs in each cellular domain of an NGE domain are listed as sites in the NGE domain. Multiple cellular domains can point to the same NGE domain.

You can unbind a cellular domain from an NGE domain if the NGE domain is not encrypting. Before the cellular domain can be removed, the RI NGE encryption on each 7705 SAR-Hm NE in the cellular domain must be stopped.

47.1.6 Enhanced NE security mode

To prevent unwanted tampering with security settings on any 7705 SAR-Hm, you can enable enhanced NE security mode, which protects all 7705 SAR-Hm devices in the network using stringent security constraints that cannot be altered by an NFM-P operator. Attempts to do so are blocked, and generate NFM-P alarms.

Note: Enabling enhanced NE security mode affects each 7705 SAR-Hm in the managed network. Also, in order to disable the function, you must first unmanage each managed NE of any type in the entire network.

When enhanced NE security mode is enabled, the NFM-P enforces the following security constraints for each 7705 SAR-Hm device:

- The enabled SSH versions cannot include SSHv1.
- Exponential backoff must be enabled.
- The password policy must include specific criteria.

Note: The function does not validate any password, only the conformance of the local NE password policy.

47.4 “To enable enhanced NE security mode” (p. 1437) describes how to configure and enable the mechanism.

Note: The local and global NE password policy definitions are verified against the required password criteria before being applied to the NEs.

The SAR-Hm Enhanced Security indicator on the NFM-P System Preferences form shows whether enhanced NE security mode is enabled.

Implementation

If enhanced NE security mode is enabled, the NFM-P raises an alarm against any 7705 SAR-Hm whose configuration violates any listed security constraint. The alarm is raised regardless of whether a device is discovered before or after enhanced NE security mode is enabled. An alarm is also raised if a managed NE configuration is changed via CLI in a way that violates a constraint.

When you invoke the ADP process and enhanced NE security mode enabled, the NFM-P first verifies the password of the SNMPv3 user in the cellular domain mediation policy against the required password complexity rules. If the password violates any complexity rule, ADP does not proceed.

After ADP completes:

- Any client GUI configuration that attempts to enable SSH1 on an NE is blocked. If the configuration is performed using a CLI, the NFM-P raises an alarm.
- Any client GUI attempt to disable exponential backoff is blocked, and an attempt via CLI causes the NFM-P to raise an alarm.
- An error message is displayed if an NFM-P operator attempts to distribute an NE security policy or password policy to a 7705 SAR-Hm.

Note: The NFM-P does not initiate any configuration change to resolve an alarm raised because of a constraint violation. The alarm condition must be resolved by an NFM-P operator, or via the NE CLI, depending on the nature of the violation.

47.1.7 Management of remote 7705 SAR-Hm NEs

The 7705 SAR-Hm is a small form factor wireless router that extends IP/MPLS services over secure 3G/LTE wireless networks using cellular wireless infrastructure and WLAN technology. The 7705 SAR-Hm is available in several variants that have different cellular-interface radio capabilities. The cellular interface is the primary network port for WAN connectivity.

A 7705 SAR-Hm can be deployed in a remote location to perform wireless aggregation of traffic that is forwarded as IP packets to the cellular domain head-end node. In such a deployment, the cellular domain head-end node routes the traffic through a dedicated VPRN that you can optionally secure using NGE. See the *7705 SAR-Hm Main Configuration Guide* for additional functional, operational, and deployment information.

7705 SAR-Hm discovery, configuration, and management

You can use the NFM-P to perform the following discovery, configuration, and management functions for 7705 SAR-Hm devices.

Note: NFM-P management of remotely deployed 7705 SAR-Hm devices is limited to IPv4 only.

- Initiate ADP for the discovery of each 7705 SAR-Hm in a cellular domain. For the static cellular interface mode of operation, the NFM-P creates a management VPRN service for in-band 7705 SAR-Hm management.
- Upgrade the radio card firmware on 7705 SAR-Hm, Release 15.0 R6 and later, automatically during ADP.
- Create and manage 7705 SAR-Hm devices in cellular domains. Each 7705 SAR-Hm in a domain connects to the same head-end nodes and is part of the same NGE domain.
- Add the 7705 SAR-Hm devices that are going to be discovered to a cellular domain by importing an XML file that lists the SIM IMSI, and optionally, the system IP, of each device to discover in the domain.
- Move 7705 SAR-Hm NEs in or out of a cellular domain, or from one cellular domain to another.
- Globally apply/deploy a new security PIN to all 7705 SAR-Hm devices in a cellular domain during the ADP, or from domains that contain discovered devices, to overwrite any pre-existing/default PINs applied to the device. When a PIN is configured during the domain creation, all subsequent devices added to the domain using ADP have the same PIN applied to them.
- Create a security association between the SIM, IMEI, and the chassis identifier of each managed 7705 SAR-Hm. The NFM-P interprets a subsequent unexpected identifier change as a potential security violation, and alerts an operator.
- Configure polling in a cellular domain to monitor 7705 SAR-Hm reachability and system uptime. The polling interval is configurable in order to minimize traffic between the NFM-P and a large-scale 7705 SAR-Hm deployment.

47.1.8 In-band management using VPRN

When the cellular interface on a 7705 SAR-Hm is operating in static or dynamic cellular interface mode, the NFM-P can reach the NE system IP address through an in-band management VPRN service. For this mode of operation, the system IP address for NE management is private and differs from the cellular interface IP address. The system IP address must be advertised from the 7705 SAR-Hm to the head-end node by the in-band management VPRN service.

Routing in the private IP/MPLS network past the head-end node must allow management traffic to reach the head-end node, which then sends the management traffic over the VPRN to the 7705 SAR-Hm. Operators are responsible for configuring and ensuring connectivity to the NSP past the head-end node. This configuration is not described by this guide.

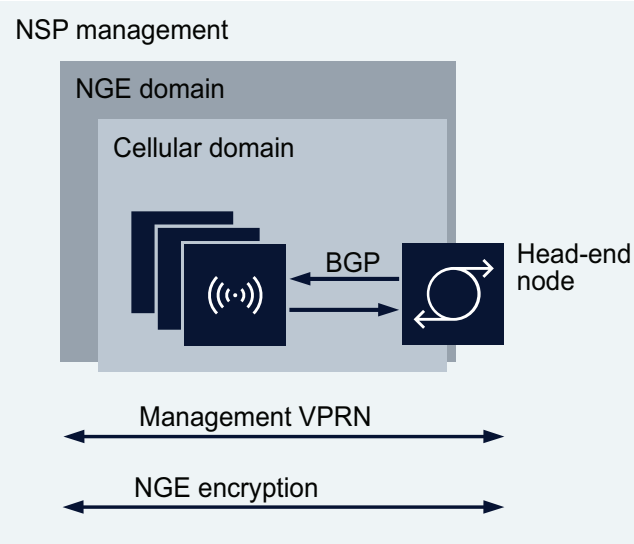
Each head-end node in a cellular domain must belong to the same VPRN service, which requires the following configuration:

- Route Distinguisher
- Route Target
- SNMP Community
- Auto-Bind Tunnel with GRE, and the resolution status set to Any Filter
- Autonomous System

Note: You can associate one VPRN service with only one cellular domain. If multiple head-end nodes are present in the domain, all head-end nodes must have the same VPRN service ID.

Figure 47-1, “Cellular domain management” (p. 1425) shows the scope of cellular domain management.

Figure 47-1 Cellular domain management



28135

47.1.9 Configuring polling for devices in cellular domains

During a system uptime poll of the NEs in a cellular domain, the NFM-P verifies the SIM information, IMEI, and chassis ID against the stored values. If a discrepancy is found, the NFM-P suspends management of the NE and disables resynchronization for the NE.

System uptime polling is performed in the following scenarios:

- during the initial ADP process
- if the dynamic BGP state of a head-end node changes

- at the operator-specified polling interval

As part of the cellular domain creation, a BGP group is configured on each head-end node. To monitor NE reachability in a cellular domain, the NFM-P polls the status of each BGP session between the head-end nodes and the managed NEs in the domain. Such a reachability check limits the traffic between the NFM-P and the managed NEs.

47.1.10 Device discovery and deployment using ADP

The NFM-P uses ADP, which is called ADP-Hm in the device documentation, to discover the remote devices in a cellular domain subnet. ADP provides all initialization and commissioning functions automatically for a newly installed device. After one or more SIMs is installed on a device and the device is turned up, ADP configures the cellular interface, establishes connectivity to the NFM-P, and waits for the NFM-P to complete the discovery and configuration of the device.

ADP automatically creates an NFM-P discovery rule to track the managed state of each NE in a cellular domain, and to initiate ADP when new devices in a cellular domain subnet are available for discovery. The NFM-P scans the network periodically for new devices, as specified by the discovery rule scan interval, which is the time between scans. To reduce the amount of network-management traffic in a cellular domain, you can configure the scan interval in the discovery rule for the subnet to be greater than the global scan interval defined in the NFM-P mediation configuration. The scan interval in a discovery rule overrides the scan interval in the NFM-P mediation configuration.

7705 SAR-Hm discovery prerequisites

The prerequisites for NFM-P discovery of a 7705 SAR-Hm using ADP are the following.

- The NFM-P manages one or more VSR, 7750 SR, or 7705 SAR head-end nodes that are to be included in the cellular domain.
- One or more valid SIM cards are inserted into the 7705 SAR-Hm.
- If dual SIM layout will be used:
  - the SIMs must be from two different carriers, with different HPLMNs
  - a PDN must be configured for each SIM

    The system assigns the PDN profile of the carrier to the port if the carrier IMSI prefix matches the port IMSI.

    For example, if carrier 2 has IMSI prefix 2121 configured and Port 1/1/1 IMSI is 2121xxxxxxxx the PDN profile configured in carrier 2 will be assigned to Port 1/1/1.
  - firmware for both carriers must be available in the NFM-P
- You have determined which ADP discovery method to use; the following are available:
  - one-step — all device configuration is performed automatically at the remote site after the device is turned up
  - two-step — NSP security configuration is performed at the customer staging facility; network configuration is performed automatically at the remote site after the device is turned up
- A route exists from the VPRN service to the cellular domain head-end node that is reachable by the NFM-P.
- A route exists from the cellular domain head-end node to each device that is to be discovered. For initial installation of a 7705 SAR-Hm cellular domain, IP addresses are typically allocated from a /24 or /18 address range.

- A default APN or Virtual Private Network (VPN) service has been procured from the service provider by the operator for the SIMs that are installed in the 7705 SAR-Hm. For a private cellular network, the operator can choose to use an APN if needed.

  If a static IP address is required for the IMSI associated with a SIM, the address can be allocated using one of the following methods:
  - by direct Home Subscriber Server (HSS) allocation, such as when a mobile carrier assigns an IP address
  - by deferred IP allocation; when the 7705 SAR-Hm first connects and authenticates with an HSS, the default APN associated with the service indicates that the IP allocation is deferred to an enterprise RADIUS AAA DHCP server. After the PGW learns the static IP address from the server, the PGW sends the address to the 7705 SAR-Hm in the PDP address IE after the default bearer is established.
- The PGW to which the 7705 SAR-Hm connects is configured with additional Protocol Configuration Options (PCOs) for the APN.

  The PCO must include the following two values:
  - dns-server-ipv4 primary – for example, config/mobile/pdn/apn/pco/dnsserveripv4/primary
  - dns-server-ipv4 secondary – for example, config/mobile/pdn/apn/pco/dnsserveripv4/backup
- Primary and secondary DNS servers are configured to resolve the NFM-P primary and standby main server IP addresses.
- An NFM-P cellular domain is configured with the required ADP operational settings and subnets for 7705 SAR-Hm discovery; see 47.1.1 “Cellular domains” (p. 1419) for information.

Offline NE handling during the ADP process

The ADP process cannot be completed when the 7705 SAR-Hm or the domain head-end node has an SNMP timeout or is not reachable.

When ADP starts, the online status of all the configured head-end nodes is checked. The ADP cannot start if none of the head-end nodes is online. ADP remembers the list of online head-end nodes and this list is used for the entire ADP process, rather than the list of configured head-end nodes. For ADP to succeed, at least one head-end node must be up during the entire ADP process. If all head-end nodes on the online head-end nodes list go down during the ADP process, ADP will fail.

When ADP with NGE configured is enabled, inbound ACL entries are created on the head-end nodes. The list of online head-end nodes is only updated when ADP is started and when outbound entries are added or removed. If any head-end node goes offline when ADP is in an initiating state, for example, adding inbound ACL entries to head-end nodes, the list of online head-end nodes may not be updated. This may cause ADP to fail or not start.

An OfflineDuringAdp alarm will be raised if a head-end node becomes offline during ADP. When a head-end node is marked as offline, its status will not be changed during the ADP process. If any offline head-end node becomes online during ADP, this head-end node will have no affect on the ongoing ADP process.

When the head-end node comes back online, you must manually fix the mismatched configuration and clear the alarm.

If any 7705 SAR-Hm becomes offline during ADP, ADP will fail for that 7705 SAR-Hm only. ADP will continue for all other online 7705 SAR-Hm NEs.

47.1.11 ADP discovery process

The following are the ADP operational phases:

- Network Discovery
- NFM-P Discovery
- 7705 SAR-Hm Discovery
- NFM-P Configuration

Phase 1 — Network Discovery

When a 7705 SAR-Hm initially boots, it runs the application load, executes the configuration file, which is empty, then checks the BOF to determine if ADP is enabled and needs to run.

If ADP is enabled on the NE, the NE performs the following:

- initializes the cellular interface using SIM1 for connectivity
- configures a PDN context with the default PDN profile
- after the cellular interface connects to the network, configures a PDN router interface to operate in dynamic cellular interface mode
- creates a loopback interface with a default name for the PDN interface, for example, “pdn1-loopback”; no IP address is assigned to the interface because it operates in dynamic cellular interface mode
- uses the loopback interface as the unnumbered interface for the PDN router interface

If the LTE network authenticates and accepts the new NE, a default bearer is established and the following are provided to the NE for the default APN to which the NE connects:

- cellular interface IP address
- DNS server IP addresses

Phase 2 — NFM-P Discovery

During the NFM-P discovery phase, the 7705 SAR-Hm sends DNS query messages to the DNS server addresses discovered in the previous phase.

The following NFM-P URLs are set in the BOF by default for the auto-discover function:

- auto-discover private.nokia.nsp.primary.nms
- auto-discover private.nokia.nsp.secondary.nms

Note: The names can also be set to the following:

- a different URL, if required
- an IP address, which eliminates the requirement for a DNS server

The 7705 SAR-Hm regularly sends a DNS query message until a DNS query response message that contains an NFM-P main server IP address is received. If no DNS query response message is received, ADP times out and reboots the device, after which ADP restarts the network discovery process.

Phase 3 — 7705 SAR-Hm Discovery

After the 7705 SAR-Hm receives one or more NFM-P server IP address, the 7705 SAR-Hm configures SNMPv2 trap destinations to the NFM-P server addresses using log ID 1.

ADP enables NetConf over SSHv2 and searches the user database for a user with access to NetConf. If none is found, NetConf access is given to the admin user.

The 7705 SAR-Hm initiates an SNMP trap poll that sends a notification to the NFM-P every 15 seconds for 30 minutes. If the ADP is not completed within the 30 minute interval, ADP will time out and begin again.

The 7705 SAR-Hm then sends an SNMPv2 Hello request, after which the NFM-P completes the device configuration, as described in the next phase.

Phase 4— NFM-P Configuration

In this phase, the NFM-P secures the 7705 SAR-Hm and completes the device configuration. During the configuration process, the 7705 SAR-Hm regularly sends an SNMPv3 trap to the NFM-P. When the configuration is complete, the NFM-P disables ADP on the NE.

47.1.12 ADP discovery methods

To meet differing security requirements, the following ADP discovery methods are available:

- one-step — all device configuration is performed automatically at the remote site after the device is turned up; the ADP process is active at the remote site from start to finish
- two-step:
  - NFM-P configures critical network and security parameters on device at the customer staging facility
  - remaining NE configuration is performed automatically after the device is installed and powered on at the remote site

During the ADP process with Dynamic Cellular IP mode, the NE can become unreachable at any time because the IP address that was used during the auto-discover process may change. The NE is at risk until the default in-band managed service is enabled and its configuration saved on the NE. Until then, the NFM-P relies on the IMSI value as the identifier for a particular NE. If the NE reboots during ADP and comes back, the SNMP trap hello message will indicate the IMSI and the cellular interface IP the NFM-P should be using to reach the NE and complete ADP.

Note: The NFM-P performs device configuration saves frequently during the process, regardless of the method used.

When the actions associated with either method are complete, the NFM-P does the following:

- stops the ADP process on the NE by executing an “ADP complete” command on the NE
- disables ADP in the NE BOF and clears the DNS entries on the NE so that a new discovery process cannot occur

One-step ADP discovery

In one-step ADP discovery, the 7705 SAR-Hm is turned up and ADP on the device completes the entire discovery and configuration process.

After the NFM-P receives an SNMPv2 trap and verifies the IMSI, and optionally, the system IP, the NFM-P uses NetConf over SSHv2 to configure the SNMPv3 user and parameters, including the required encryption and authentication keys. The configuration is based on the NFM-P mediation security policy associated with the cellular domain.

The NFM-P then completes the remainder of the device configuration:

- creates a strict security association between the 7705 SAR-Hm chassis information, IMEI, and SIM; the SIM cannot be inserted into another NE and managed by the NFM-P without operator intervention
- configures user names, passwords, scopes of control, and associated profiles
- downloads the required 7705 SAR-Hm software load, and resets the NE to apply the new load
- If NGE is required, configures NGE on the cellular interface by binding it into the NGE domain. If NGE is not required, this step is skipped. If the NGE domain is not encrypting, then the cellular interface is not enabled for encryption.
- if the cellular domain operation mode is Static Cellular Interface Mode or Dynamic Cellular Interface Mode, performs the following on each head-end node in the cellular domain to establish an in-band management service:
  - configures a BGP session to each head-end node in the cellular domain
  - configures an in-band management VPRN service used by the NFM-P to manage the 7705 SAR-Hm in-band over the GRE tunnels in the cellular network; the VPRN service can optionally be NGE-encrypted for secure NE management
  - if the 7705 SAR-Hm is running a release prior to 19.5, the NFM-P configures the GRT with static routes towards the VPRN over the PXC port to reach the primary and secondary NSP servers. The 7705 SAR- Hm system IP needs to be imported into BGP by configuring a static route in the VPRN for the system IP. This will allow the system IP to be reachable via the VPRN service from the head-end nodes. The VPRN static route for the system IP will point towards the PXC that will reach the GRT. At this point all NFM-P traffic can be routed over the VPRN service once the NFM-P starts using the new system IP address to manage the NE instead of the cellular interface IP address.
  - if the 7705 SAR-Hm is running release 19.5 or later, the NFM-P configures a GRT leak in the VPRN to leak the 7705 SAR-Hm system IP to the base routing of the 7705 SAR-Hm. This will allow the system IP to be reachable via the VPRN service from the head-end nodes. At this point all NFM-P traffic can be routed over the VPRN service once the NFM-P starts using the new system IP address to manage the NE instead of the cellular interface IP address.

After the NFM-P completes the ADP process, the 7705 SAR-Hm Status and Alarm LEDs indicate that the ADP process is complete. The NE is securely managed by the NFM-P and ready for service.

Two-step ADP discovery

In two-step ADP discovery, the 7705 SAR-Hm is powered on first in a staging area for the initial NFM-P security configuration, then a second time at the remote site to complete the remaining configuration tasks, as described in the following sequence:

1. The 7705 SAR-Hm is powered on for the first time and the NFM-P does the following:

   Note: ADP for the subnet must be enabled on the NFM-P during this step.

- creates a strict security association between the 7705 SAR-Hm chassis information, IMEI, and SIM; the SIM cannot be inserted into another NE and managed by the NFM-P without operator intervention
- configures user names, passwords, scopes of command, and associated profiles
- downloads the required 7705 SAR-Hm software load, and resets the NE to apply the new load
- stops the ADP process on the NE by executing an “ADP complete” command on the NE

The 7705 SAR-Hm Status LED turns solid green and the Alarm LED continues to blink. The 7705 SAR-Hm has completed step one and can be powered off and shipped to the remote site for installation.

2. After the 7705 SAR-Hm is installed and powered on at the remote site, the following occur:

   Note: ADP for the subnet must be enabled on the NFM-P during this step.

- The 7705 SAR-Hm regularly sends SNMPv3 traps to the NFM-P to indicate that the ADP process can resume.
- The NFM-P downloads the NGE key group of the NGE domain associated with the cellular domain, if NGE is to be used, and configures the key group on the 7705 SAR-Hm cellular interface.
- If the cellular domain mode is Static Cellular Interface Mode or Dynamic Cellular Interface Mode, the NFM-P performs the following on each head-end node in the cellular domain to establish an in-band management service:
  - configures a BGP session to each head-end node in the cellular domain
  - configures an in-band management VPRN service used by the NFM-P to manage the 7705 SAR-Hm in-band over the GRE-IMPLS tunnels in the cellular network; the VPRN service can optionally be NGE-encrypted for secure NE management

After the NFM-P completes the ADP process, the 7705 SAR-Hm Status and Alarm LEDs indicate that the ADP process is complete. The NE is securely managed by the NFM-P and ready for service.

47.2 Workflow to manage cellular domain devices

47.2.1 Stages

1

Review and complete the required prerequisites to allow the NFM-P to discover the required devices using ADP; see “7705 SAR-Hm discovery prerequisites” (p. 1427).

2

For the NEs in a cellular domain that are assigned a unique administrator password, create an XML file that maps each chassis serial number to each unique password, as described in 47.3 “To create an ADP password mapping file” (p. 1435).

3

If you want to automatically apply a specific configuration to discovered NEs in a cellular domain, create a post-discovery action. See 9.5 “Post-discovery actions on discovered NEs” (p. 282) in Chapter 9, “Device discovery” for information.

4

Create an SNMPv3 NE user account; see the procedure to configure a user account on a manage device in the *NSP System Administrator Guide*.

Note: The user requires console, FTP, SNMP, and NetConf access.

Note: If enhanced NE security mode is enabled, or you intend to enable the function, the user password must adhere to the password criteria specified in 47.4 “To enable enhanced NE security mode” (p. 1437).

Note: You must not specify AES-256 as the Privacy Protocol in the user SNMPv3 configuration.

5

Create a software upgrade policy in which the Software Download and Activate Image parameters are enabled, and the Software Upgrade parameter is disabled; see 26.5 “To configure a software upgrade policy” (p. 776).

6

Create a mediation security policy that specifies the following; see 9.17 “To configure device mediation” (p. 301) for information:

- SNMPv3 user: the new user created in Stage 4.
- CLI user: must be the same as the SNMPv3 user
- SSH for CLI access
- Secure FTP

Note: You must enable NetConf in the mediation policy, and specify the SNMPv3 user in the NetConf section of the mediation policy. The NetConf credentials are available from technical support.

7

If required, enable enhanced NE security mode; see

8

Create a carrier VPRN with static routes to and from the 7705 SAR-Hm; see 79.5 “To create a VPRN service” (p. 2534) and 79.57 “To configure static routes on a VPRN site” (p. 2621); ensure that the service is configured as described in 47.1.8 “In-band management using VPRN” (p. 1425).

9

Configure a PDN profile policy that specifies each cellular interface used to connect 7705 SAR-Hm mobile data users to the network; see 69.2 “To configure a PDN Profile policy for a 7705 SAR-Hm” (p. 1901).

10

If NGE security is required, create an NGE domain that includes the cellular domain head-end nodes as the NGE domain gateway sites; see 82.10 “Workflow for NGE management using NFM-P” (p. 2727).

11

If required, upgrade 7705 SAR-Hm radio card firmware; see 26.12 “To upgrade 7705 SAR-Hm radio card firmware” (p. 790).

12

Create a cellular domain that has the cellular domain head-end node as the head end, and includes each 7705 SAR-Hm device; see 47.5 “To configure a cellular domain with single SIM deployment” (p. 1440) or 47.6 “To configure a cellular domain with dual SIM deployment” (p. 1444).

13

If you intend to discover the devices listed in an XML file, import the file to the cellular domain that is to include the devices, as described in 47.5 “To configure a cellular domain with single SIM deployment” (p. 1440) or 47.6 “To configure a cellular domain with dual SIM deployment” (p. 1444); see “Specifying devices using an XML file” (p. 1422) for information about the XML file format.

14

If the head-end node is a 7705 SAR, create BGP peers in the domain BGP group; see 28.33 “To configure peer-level BGP” (p. 927).

15

Enable ADP on one or more selected cellular domain subnets, and monitor the discovery process; see 47.7 “To enable and monitor the ADP discovery process” (p. 1448).

16

If you are using the two-step ADP method, perform the following steps after the first step ADP is completed:

1. Check the LED status of each device to be discovered, as described in the device documentation, to ensure that the first ADP step is complete.
2. Disable ADP on the cellular domain subnet that includes the devices; see 47.11 “To disable ADP” (p. 1454).
3. Deliver the devices to the remote installation site.
4. Enable ADP on the cellular domain subnet that contains the devices.

5. Install and turn up each 7705 SAR-Hm that is to complete the ADP process at the remote site.
6. Monitor the ADP process using the NFM-P, as described in 47.7 “To enable and monitor the ADP discovery process” (p. 1448), and by checking the device LEDs, as described in the device documentation.

17

Disable ADP on the cellular domain subnets that no longer require ADP for device discovery; see 47.11 “To disable ADP” (p. 1454).

18

Apply a new security PIN to all NEs in a cellular domain, as required; see 47.10 “To configure a new PIN value for a cellular carrier” (p. 1452).

19

If dual SIM deployment is in use, configure the Cellular tab of the MDA on each 7705 SAR-Hm; see 15.78 “To configure an MDA” (p. 536).

20

Configure polling for the NEs in the cellular domain; see 8.12 “To configure polling for a 7705 SAR-Hm” (p. 264).

47.3 To create an ADP password mapping file

47.3.1 Purpose

Perform this procedure to create a file that facilitates the entry of 7705 SAR-Hm serial number and password information for the devices in a cellular domain.

The XML file that you create is imported during cellular domain configuration. The file maps the chassis serial number of each device in the cellular domain to the unique administrator password of the device.

47.3.2 Steps

1

Use a plain-text editor to create a file that contains the following XML header:

```
<?xml version="1.0" encoding="UTF-8"?>
<ADPSerialNumbers>
```

2

For each device that has a unique password associated with the chassis serial number, add a line below the header in the following format:

```
<node serialNumber="serial_number" password="password"/>
```

where

serial_number is the chassis serial number

password is the unique administrator password

3

When you are finished adding entries, add the following XML footer to the end of the file:

```
</ADPSerialNumbers>
```

The file reads as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<ADPSerialNumbers>
<node serialNumber="SN_1" password="password_1"/>
<node serialNumber="SN_2" password="password_2"/>
.
.
.
<node serialNumber="SN_n" password="password_n"/>
</ADPSerialNumbers>
```

where

SN_1 to *SN_n* are the chassis serial numbers

password_1 to *password_n* are the administrator passwords

4

Save and close the file using a .xml filename extension.

5

Transfer the XML file to the client GUI station that is to be used for the cellular domain configuration.

END OF STEPS

47.4 To enable enhanced NE security mode

47.4.1 Purpose

CAUTION

Irreversible Configuration Change

Enabling enhanced NE security mode affects each 7705 SAR-Hm in the managed network; disabling the function requires that you unmanage each managed NE of any type in the entire network.

If you are not absolutely certain that you want to enable enhanced NE security mode, do not perform the procedure.

CAUTION

Service Disruption

Modifying the server configuration can have serious consequences including service disruption.

Contact technical support before you attempt to modify the server configuration.

Perform this procedure to enable the stringent security measures of NFM-P enhanced NE security mode.

47.4.2 Steps

Configure SNMPv3 user password

1

For enhanced NE security mode, the password of the SNMPv3 NE user must conform to specific criteria.

If the user password does not currently conform to the following criteria, change the password to meet the criteria:

- 10 or more characters in length
- does not include the username
- includes 3 or fewer consecutive instances of the same character
- includes 1 or more lower-case characters
- includes 1 or more upper-case characters
- includes 1 or more numeric characters

1. Choose Administration→Security→NE User Configuration from the NFM-P main menu. The NE User Configuration form opens.
2. Select the ADP SNMPv3 user and click Properties. The NE User (Edit) form opens.
3. Configure the Password and Confirm Password parameters using a value that meets the required criteria.

4. Click OK to save your changes and close the form.

2

The password for SSH and FTP access in the ADP mediation security policy must match the password of the SNMPv3 NE user.

If the passwords do not match, update the password in the mediation security policy.

1. Choose Administration→Mediation from the NFM-P main menu. The Mediation (Edit) form opens.
2. Select the ADP mediation policy and click Properties. The Mediation Policy (Edit) form opens.
3. Configure the User Password and Confirm Password parameters in the CLI panel using the SNMPv3 NE user password.
4. Configure the User Password and Confirm Password parameters in the FTP panel using the SNMPv3 NE user password.
5. Click OK to save your changes and close the form.

Configure NE password policy

3

Choose Administration→Security→NE Password Policy from the NFM-P main menu. The NE Password Policy form opens.

4

Configure the following parameters using the values shown:

- Properties panel:
  - Lockout Time (minutes)—10
  - Minimum Length—10
  - Maximum Attempts—10 or fewer
  - Maximum Attempts Time (minutes)—10 or less
- Complexity Rules panel:
  - User Name Allowed in Password—False
  - Maximum Number Of Times Character Can Used Consecutively—3 or fewer
  - Minimum Number Of LowerCase Characters—1 or more
  - Minimum Number Of UpperCase Characters—1 or more
  - Minimum Number Of Numeric—1 or more

5

Click OK to save your changes and close the form.

Configure NE security policy

6

Choose Administration→Security→NE System Security from the NFM-P main menu. The NE System Security form opens.

7

Select one or more NEs and click Properties. A properties form opens.

8

Select the Exponential BackOff parameter.

9

Click on the Servers Configuration tab.

10

In the SSH Configuration panel, configure the SSH Version parameter by selecting Version 2 and deselecting the following:

- Version 1
- Version 1-2

11

Click OK to save your changes and close the form.

Configure NFM-P main servers

12

Perform the following steps on each main server station.

1. Log in as the nsp user on the main server station.
2. Open a console window.
3. Navigate to the /opt/nsp/nfmp/server/nms/config directory.
4. Create a backup copy of the nms-server.xml file.
5. Open the nms-server.xml file using a plain-text editor such as vi.
6. Locate the section that begins with following XML tag:

   ```
   <policyConfig
   ```

7. Insert the following line before the last line of the section, which ends with the /> tag:

   ```
   enhancedNESecurityMode="true"
   ```

8. Save and close the file.

13

On the standalone main server, or the primary main server in a redundant system, enter the following:

```
bash$ /opt/nsp/nfmp/server/nms/bin/nmsserver.bash read_config ↵
```

The NFM-P puts the configuration change into effect.

14

Close the open console windows.

END OF STEPS

47.5 To configure a cellular domain with single SIM deployment

47.5.1 Steps

1

Choose Manage→Cellular Domains from the NFM-P main menu. The Cellular Domain Manager form opens.

2

Click Create. The Cellular Domain [Create | Edit] form opens.

3

Configure the Name parameter.

4

Configure the Sim Layout parameter to Single SIM.

For dual SIM, see 47.6 “To configure a cellular domain with dual SIM deployment” (p. 1444).

5

Configure the Operation Mode parameter. See 47.1.2 “Cellular domain operation modes” (p. 1420) for information about operation modes.

6

Configure the ADP Process parameter to specify one-step or two-step discovery.

7

Configure the ADP System IP Address parameter.

8

If the cellular domain includes any older NEs that are factory-shipped with a default administrator password, configure the Default ADP-Hm admin Password parameter using the administrator password that is common to the NEs.

9

Specify one or more head-end nodes for the cellular domain, as required.

1. Click Create in the Head-End Nodes panel. The Head-End Node [Create] form opens.
2. Click Select and choose a managed NE.
3. Configure the parameters.
4. Click OK. The Head-End Node [Create] form closes, and the NE is listed in the Head-End Nodes List.

10

Click Select in the Mediation Security panel and choose the required SNMPv3 mediation security policy.

11

Click Select in the PDN Profile panel and choose the required PDN Profile policy.

12

Click Select in the Software panel and choose the required software and firmware upgrade policy.

During software upgrade, if the 7705 SAR-Hm has a later image than that mentioned in the domain, the node software is not changed with the version mentioned in the domain since it is already running a latest image.

Unlike software upgrade, there is no version check of the current 7705 SAR-Hm firmware. The firmware image mentioned in the domain is pushed down to the node even if it is an older image.

Leave the firmware image empty if you want to skip the firmware upgrade.

13

If required, configure the Firmware Version parameter.

For the 7705 SAR-Hm, use a format that is aligned with the Sierra Wireless web portal, [VENDOR NAME]<space>[FIRMWARE_SUFFIX]<space>[PRI]. For example: GENERIC 02.24.03.00 002.026_000

For the 7705 SAR-Hmc, use a format such as this example: CAT4_GS_BYPASS_0.3.3.9_V1.9

14

Configure the Software Version parameter using the string that identifies the software release to which the devices are to be upgraded; for example, TiMOS-B-*RR*.*r* R*n*.

15

If NGE is to be used, click Select in the NGE Domain panel and choose the required NGE domain.

16

Configure the parameters in the PIN Security panel.

17

Configure the parameters in the BGP Configuration panel.

18

If required, use the Select button in the Post Discovery Action panel to choose a post-discovery action for NEs in the cellular domain.

Note: The post-discovery action is performed on the NEs only when the ADP process for each NE in the cellular domain is complete.

19

If the Operation Mode parameter is set to Static Cellular Interface or Dynamic Cellular Interface, perform the following steps.

1. Click on the VPRN tab.
2. Use the Select button to specify the VPRN service to associate with the cellular domain.

20

Click Apply.

21

Click OK. The Cellular Domain [Edit] form refreshes and displays additional tabs.

22

If the Operation Mode is set to Static Cellular System, add new devices to the cellular domain, as required.

1. Click on the Sites tab.
2. Click Add→Add New Sites. The Domain Site [Create] form opens.
3. Configure the parameters.

   You can configure the System Name parameter. When the 7705 SAR-Hm is discovered, the system name appears as the shelf name in the NFM-P GUI. However, all main references such as alarms are based on the site name.
4. Click OK. The Domain Site [Create] form closes.

23

Add subnets to the domain, as required.

1. Click on the Subnets tab.

2. Configure the parameters.
3. Click OK.

24

If any NEs in the cellular domain have unique administrator passwords, click on the Serial Number Data tab. Otherwise, go to Step 26.

25

Perform one of the following.

a. Import the passwords from a file created as described in 47.3 “To create an ADP password mapping file” (p. 1435).
   1. Click Import Serial Numbers. A file browser form opens.
   2. Use the form to choose the password file and click Open. The passwords are imported, and the NE serial numbers are listed on the form.

b. Manually add one or more passwords; perform the following steps for each NE.

1. Click Create. The Serial Number Data (Create) form opens.
2. Configure the Serial Number and Password parameters using the NE values.
3. Save the changes and close the form.

26

If any head-end node in the domain is a 7705 SAR, configure BGP peers on the head-end node BGP group; see 28.33 “To configure peer-level BGP” (p. 927).

27

If the Operation Mode is set to Static Cellular Interface or Dynamic Cellular Interface, or the Operation Mode is set to Static Cellular System and the ADP System IP Address parameter is set to Use XML, import a list of devices.

1. Create an XML file that lists each 7705 SAR-Hm to be discovered. See “Specifying devices using an XML file” (p. 1422) for information about the file format.
2. Click on the Sites tab.
3. Click on the Import Sites button. The Open File browser form opens.
4. Navigate to the XML file that specifies the devices to discover.
5. Select the file and click Open. The devices specified in the file are added to the Domain Site list.

28

If the Operation Mode is set to Static Cellular Interface or Dynamic Cellular Interface, and the ADP System IP Address parameter is set to Verify and Allocate from Pool, define one or more System IP address pools to provide a sufficient number of IP addresses for all devices that are to be discovered in the cellular domain subnets.

Note: The NFM-P does not reuse any IP address in a pool. Ensure that the System Prefix value that you specify allocates a sufficient range of addresses for the subnet.

1. Click on the System IP Pool tab.
2. Click Create. The System IP Pool [Create] form opens.
3. Configure the System Address and System Prefix parameters.

29

Click OK to save your changes and close the open forms, as required.

END OF STEPS

47.6 To configure a cellular domain with dual SIM deployment

47.6.1 Steps

1

Choose Manage→Cellular Domains from the NFM-P main menu. The Cellular Domain Manager form opens.

2

Click Create. The Cellular Domain [Create | Edit] form opens.

3

Configure the Name parameter.

4

Configure the Sim Layout parameter to Dual SIM.

For single SIM, see 47.5 “To configure a cellular domain with single SIM deployment” (p. 1440).

5

Configure the ADP Process parameter to specify one-step or two-step discovery.

6

Configure the ADP System IP Address parameter.

7

Configure the carrier details. Perform the following for each carrier:

1. Click Create in the Carriers panel. The Cellular Carrier (Create) form opens.
2. Configure the Name parameter.
3. Click Select in the PDN Profile panel and choose the required PDN Profile policy.
4. Configure the Firmware Version parameter.

For the 7705 SAR-Hm, use a format that is aligned with the Sierra Wireless web portal, [VENDOR NAME]<space>[FIRMWARE_SUFFIX]<space>[PRI]. For example: GENERIC 02.24.03.00 002.026_000

For the 7705 SAR-Hmc, use a format such as this example: CAT4_GS_BYPASS_0.3.3.9_V1.9

5. Configure the parameters in the PIN Security panel.
6. Configure other parameters in the General tab as required.
7. In the IMSI Prefix tab, enter the IMSI prefixes that need to be matched for the carrier.
8. Click OK to close the form.
9. Repeat this step to configure the second carrier.

8

Specify the head-end nodes. An NE can serve as the head-end node for one carrier or both.

Perform the following for each head-end node:

1. Click Create. The Head-End Node [Create] form opens.
2. Click Select in the Head-End Node panel and choose a managed NE.
3. Configure the parameters.
4. Click OK. The Head-End Node [Create] form closes, and the NE is listed in the Head-End Nodes List.

9

Click Select in the Mediation Security panel and choose the required SNMPv3 mediation security policy.

10

Configure the Software Version parameter using the string that identifies the software release to which the devices are to be upgraded; for example, TiMOS-B-*RR*.*r* R*n*.

11

Click Select in the Software and Firmware Upgrade Policy panel and choose the required software and firmware upgrade policy.

Associate a non default SR Software Upgrade Policy. Ensure that Software Download and Activate Image is Enabled under SR Based Setting and Firmware Download and Firmware Activate is Enabled under Firmware Settings.

During software upgrade, if the 7705 SAR-Hm has a later image than that mentioned in the domain, the node software is not changed with the version mentioned in the domain since it is already running a latest image.

Unlike software upgrade, there is no version check of the current 7705 SAR-Hm firmware. The firmware image mentioned in the domain is pushed down to the node even if it is an older image.

Leave the firmware image empty if you want to skip the firmware upgrade.

12

Verify that the correct software and firmware images are imported.

13

If NGE is to be used, click Select in the NGE Domain panel and choose the required NGE domain.

14

Configure the parameters in the BGP Configuration panel.

15

If required, use the Select button in the Post Discovery Action panel to choose a post-discovery action for NEs in the cellular domain.

Note: The post-discovery action is performed on the NEs only when the ADP process for each NE in the cellular domain is complete.

16

In the VPRN tab, use the Select button to specify the VPRN service to associate with the cellular domain.

17

Click Apply.

18

Click OK. The Cellular Domain [Edit] form refreshes and displays additional tabs.

19

If the ADP System IP Address parameter is set to something other than Use XML, define one or more IP address pools to provide a sufficient number of IP addresses for all devices that are to be discovered in the cellular domain subnets.

Note: The NFM-P does not reuse any IP address in a pool. Ensure that the System Prefix value that you specify allocates a sufficient range of addresses for the subnet.

1. Click on the System IP Pool tab.
2. Click Create. The System IP Pool [Create] form opens.
3. Configure the System Address and System Prefix parameters.

20

Add subnets to the domain as required. Perform the following for each carrier:

1. Click on the Subnets tab.
2. Click Create and configure the parameters.
3. Click OK. The subnet is created with ADP off.

21

Add new devices to the cellular domain, as required.

1. Select the carrier to which the subnet is applicable.
2. Click on the Sites tab.
3. Click Add→Add New Sites. The Domain Site [Create] form opens.
4. Configure the parameters.

   You can configure the System Name parameter. When the 7705 SAR-Hm is discovered, the system name appears as the shelf name in the NFM-P GUI. However, all main references such as alarms are based on the site name.
5. Click OK. The Domain Site [Create] form closes.

22

If any NEs in the cellular domain have unique administrator passwords, click on the Serial Number Data tab. Otherwise, go to Step 24.

23

Perform one of the following.

a. Import the passwords from a file created as described in 47.3 “To create an ADP password mapping file” (p. 1435).
   1. Click Import Serial Numbers. A file browser form opens.
   2. Use the form to choose the password file and click Open. The passwords are imported, and the NE serial numbers are listed on the form.

b. Manually add one or more passwords; perform the following steps for each NE.

1. Click Create. The Serial Number Data (Create) form opens.
2. Configure the Serial Number and Password parameters using the NE values.
3. Save the changes and close the form.

24

If any head-end node in the domain is a 7705 SAR, configure BGP peers on the head-end node BGP group; see 28.33 “To configure peer-level BGP” (p. 927).

25

If the ADP System IP Address parameter is set to Use XML, import a list of devices.

1. Create an XML file that lists each 7705 SAR-Hm to be discovered. See “Specifying devices using an XML file” (p. 1422) for information about the file format.
2. Click on the Sites tab.
3. Click on the Import Sites button. The Open File browser form opens.
4. Navigate to the XML file that specifies the devices to discover.
5. Select the file and click Open. The devices specified in the file are added to the Domain Site list.

26

Click OK to save your changes and close the open forms, as required.

END OF STEPS

47.7 To enable and monitor the ADP discovery process

47.7.1 Before you begin

Ensure the NEs support a valid combination of authentication and privacy protocols. See the NE documentation or 9.11 “To enable SNMPv3 management of a device” (p. 291) to review the disallowed combinations.

47.7.2 Steps

1

Choose Manage→Cellular Domains from the NFM-P main menu. The Cellular Domain Manager form opens.

2

Click Search and choose a cellular domain. The Cellular Domain [Edit] form opens.

3

Select the Enable ADP parameter.

4

Click Apply. The ADP process begins.

5

Monitor the ADP process for a site, if required.

1. Click on the Sites tab. Each 7705 SAR-Hm in the cellular domain is listed.
2. Select a site and click Properties. The Domain Site [Edit] form opens.
3. View the Operation and Status indicators in the Status panel. When the ADP process for the site is complete, the Operation indicator displays ADP Complete, and the Status indicator reads Success or Failure, depending on the outcome.

   If the process fails, see 47.8 “Workflow to recover from ADP discovery failure” (p. 1449).

   If the process is successful, the State indicator in the ADP panel reads Managed.
4. Close the Domain Site [Edit] form.

6

Close the open forms, as required.

END OF STEPS

47.8 Workflow to recover from ADP discovery failure

47.8.1 Process

If the NSP host server restarts or switches over to a redundant server during ADP, the ADP process will fail. In this scenario, NFM-P will show ADP Off. To recover from an ADP failure due to a restart or switchover, perform Stage 1 through Stage 3. For any other ADP failure, perform Stage 4 through Stage 6.

Scenario 1: ADP failure caused by an NSP host server restart or switchover

1

Perform the following in the NFM-P:

a. If an NGE domain is created in the cellular domain and the NGE domain is encrypted, create inbound and outbound ACL IP exception filters on the head-end nodes; see 51.7 “To configure an ACL IP exception filter policy” (p. 1683). Apply the new ACL IP exception filters to the gateway interfaces in the NGE domain.

- For an inbound IP exception filter, the Source IP parameter must be set to the subnet IP address of the cellular domain. The Destination IP must be set to the IP address of the active NSP host server.
- For an outbound IP exception filter, the Source IP parameter is set to the IP address of the active NSP host server. The Destination IP is set to the IP address of the 7705 SAR-Hm to be discovered.

b.

Delete the failed sites from the cellular domain:

1. Choose Manage→Cellular Domains from the NFM-P main menu. The Cellular Domain Manager form opens.
2. Click Search and choose the cellular domain that initiated the failed ADP operation. The Cellular Domain [Edit] form opens.
3. Click on the Sites tab.
4. Choose a site from the list and click Delete.
5. Repeat for all sites in the domain for which ADP failed.

c. If the NE is already in a managed state, delete it from the NFM-P discovery manager; see 9.37 “To delete a device from the managed network” (p. 325).

d. Delete the rule element corresponding to the NE from discovery rules created by ADP for the domain; see 9.23 “To configure a discovery rule” (p. 310).

e. If the ADP System IP Address parameter is set to Verify, reload the XML file to the cellular domain.

2

Perform the following on the NE. See the NE documentation for more information.

a. Establish an SSHv2 session to the NE from either a terminal window or the NFM-P.

b. Restore the BOF file to factory default.

c. Delete the existing 7705 SAR-Hm config file.

d. Reboot the NE.

3

Perform the following in the NFM-P:

a.

If ACL IP exception filters were created in Stage 1 a

1. Remove the ACL IP exception filter from the gateway interfaces in the NGE domain.
2. Delete both inbound and outbound ACL IP exception filters; see 51.7 “To configure an ACL IP exception filter policy” (p. 1683).

b. Enable ADP; see 47.7 “To enable and monitor the ADP discovery process” (p. 1448).

Scenario 2: Other ADP failure

4

Perform the following in the NFM-P:

a. Disable ADP; see 47.11 “To disable ADP” (p. 1454).

b. If an NGE domain is created in the cellular domain and the NGE domain is encrypted, create inbound and outbound ACL IP exception filters on head-end nodes; see 51.7 “To configure an ACL IP exception filter policy” (p. 1683). Apply the new ACL IP exception filters to the gateway interfaces in the NGE domain.

- For an inbound IP exception filter, the Source IP parameter must be set to the subnet IP address of the cellular domain. The Destination IP must be set to the IP address of the active NSP host server.
- For an outbound IP exception filter, the Source IP parameter is set to the IP address of the active NSP host server. The Destination IP is set to the IP address of the 7705 SAR-Hm to be discovered.

c.

Delete the failed sites from the cellular domain:

1. Choose Manage→Cellular Domains from the NFM-P main menu. The Cellular Domain Manager form opens.
2. Click Search and choose the cellular domain that initiated the failed ADP operation. The Cellular Domain [Edit] form opens.
3. Click on the Sites tab.
4. Choose a site from the list and click Delete.
5. Repeat for all sites in the domain for which ADP failed.

d. If the NE is already in a managed state, delete it from the NFM-P discovery manager; see 9.37 “To delete a device from the managed network” (p. 325).

e. Delete the rule element corresponding to the NE from discovery rules created by ADP for the domain; see 9.23 “To configure a discovery rule” (p. 310).

f. If the ADP System IP Address parameter is set to Verify, reload the XML file to the cellular domain.

5

Perform the following on the NE. See the NE documentation for more information.

a. Establish an SSHv2 session to the NE from either a terminal window or the NFM-P.

b. Restore the BOF file to factory default.

c. Delete the existing 7705 SAR-Hm config file.

d. Reboot the NE.

6

Perform the following in the NFM-P:

a.

If ACL IP exception filters were created in Stage 4b:

1. Remove the ACL IP exception filter from the gateway interfaces in the NGE domain.
2. Delete both inbound and outbound ACL IP exception filters; see 51.7 “To configure an ACL IP exception filter policy” (p. 1683).

b. Enable ADP; see 47.7 “To enable and monitor the ADP discovery process” (p. 1448).

47.9 To move a 7705 SAR-Hm NE in or out of a cellular domain

47.9.1 Purpose

Use this procedure to add or remove a 7705 SAR-Hm NE from a cellular domain. Adding an NE may be required when a managed NE is to be included in the domain, but has been deployed using a method other than ADP, or when an NE is to be moved from one cellular domain to another.

47.9.2 Steps

1

Choose Manage→Cellular Domains from the NFM-P main menu. The Cellular Domain Manager form opens.

2

Select a cellular domain and click Properties. The Cellular Domain [Edit] form opens.

3

Click on the Sites tab.

4

To add an NE to the domain, click Add→Add Managed Sites. The Add Managed Sites-Select Sites form opens.

Click Search to list all available NEs, select an NE, and click OK.

Note: The following conditions are required to successfully add the 7705 SAR-Hm NE to the cellular domain:

- The NE must be in one of the domain subnets and not already in a cellular domain.
- If the domain is in Cellular Interface mode, the NE must be part of the VPRN service for in-band management.
- The NE must use the same mediation security policy, PDN profile policy, and software version that is used in cellular domain configuration.
- The NE must have the domain BGP Group configured on its routing instance, with the same AS number as the domain.
- The NE must have a BGP peer to the domain head-end node.
- If NGE is in use, the NE and its PDN interface must be in the NGE domain. The NE must appear in the Sites tab, and the PDN interface must appear in the L3 interfaces tab.
- If dual SIM is in use, the NE must have the same combination of cellular carriers as the other NEs in the domain.

5

To remove an NE from the domain, click Search to list all available NEs, select an NE, and click Delete.

6

Close the open forms, as required.

END OF STEPS

47.10 To configure a new PIN value for a cellular carrier

47.10.1 When to use

Each new 7750 SAR-Hm node that is discovered by the NFM-P may have a default PIN applied to each SIM for security and access rights.

The PIN is configured on a per carrier basis. If a single SIM layout is in use, a single PIN is configured for the domain and applied to all sites. In a dual SIM layout, a PIN is configured for each carrier and applied to all sites for the SIM that applies to that carrier.

You can globally apply and deploy a new security PIN during the ADP or from domains that contain discovered nodes. When a PIN is configured during the domain creation, all subsequent nodes added to the domain through the ADP will have the new PIN applied for the carrier.

Note: Before starting this procedure, you must first create the cellular domain and at least one 7705-SAR Hm node must be present in the domain; see 47.5 “To configure a cellular domain with single SIM deployment” (p. 1440) or 47.6 “To configure a cellular domain with dual SIM deployment” (p. 1444)..

47.10.2 Steps

1

Choose Manage→Cellular Domain from the NFM-P main menu. The Cellular Domain Manager form opens.

2

Click Search and choose the cellular domain that you want to configure a new PIN value for. The Cellular Domain [Edit] form opens.

3

On the General tab, disable the Enable ADP parameter.

4

If Dual SIM is in use, choose a carrier and click Properties. The Cellular Carrier (Edit) form opens.

5

Enter a new value for the New PIN parameter.

6

Click Apply to save the form and deploy the new PIN entry to all 7705 SAR-Hm nodes in the domain.

7

On the General tab, click the Enable ADP parameter if you want all subsequent nodes added to the domain to have the same PIN applied to them.

8

Close the form.

END OF STEPS

47.11 To disable ADP

47.11.1 Purpose

Perform this procedure after the ADP process has completed, or as part of recovery from ADP failure.

Caution: Do not disable ADP while ADP is in progress for any NEs. This could cause ADP to enter an indefinite state, requiring the failure recovery process to be restarted.

47.11.2 Steps

1

Choose Manage→Cellular Domains from the NFM-P main menu. The Cellular Domain Manager form opens.

2

Click Search and choose a cellular domain. The Cellular Domain [Edit] form opens.

3

Deselect the Enable ADP parameter.

4

Click Apply. The ADP process is disabled for the cellular domain.

5

Close the open forms, as required.

END OF STEPS

48 MACsec

48.1 MACsec

48.1.1 Overview

Media Access Control Security (MACsec) provides point-to-point, point-to-multipoint, and in-band security on Ethernet links between directly connected NEs or NEs connected over a Layer 2 cloud. MACsec uses MACsec Key Agreement (MKA) to signal data path encryption keys known as Security Association Keys (SAKs).

To use MACsec, you need to configure a global and a local connectivity association. A connectivity association creates secure channels for inbound and outbound traffic.

MACsec in NFM-P supports the static Connectivity Association Key (CAK) feature, which uses MKA and a Pre-Shared Key (PSK) to discover and authenticate peers. Static CAK uses two security keys to secure the Ethernet link: a CAK that secures control plane traffic, and an SAK that secures data plane traffic. Both keys are regularly exchanged between devices on each end of the Ethernet link to ensure link security. PSK is also used for encrypting SAKs between the key server and other peers in the MACsec connectivity association.

48.1.2 MACsec configuration components

The following need to be configured to use MACsec:

- Connectivity association: a global connectivity association configuration. The global configuration contains the static CAK.
- Connectivity association site: a local connectivity association configuration. The site contains parameters that must be synchronized to the global configuration, and parameters that can be changed on a local basis.
- Static CAK: the CAK contains the PSK and related information. A maximum of two PSKs can be configured at one time, and only one can be active at a time.
- PSKs: the PSKs contain the connectivity association name and CAK.
  - The global PSK is created under the global static CAK object.
  - The local PSK is created as part of the global PSK creation if the connectivity association site exists under the global connectivity association, or as part of distributing PSKs to sites.

  The NFM-P manages PSK generation and rekeying operations. PSK distribution uses SSH2.

48.1.3 MACsec interfaces

A MACsec port is an Ethernet port on a card that supports MACsec. A MACsec interface is a virtual sub-port, that is, a VLAN, on a MACsec port. MACsec port properties apply to all MACsec interfaces on the port. MACsec interface properties apply only to the interface.

MACsec is activated when MACsec interfaces are added to a connectivity association, and the interfaces, the ports, and the connectivity association are all in an administrative up state. If the

port, interface, or connectivity association is down, the MKA session providing encryption will end. A new session will be established when the port, interface, and connectivity association are all back up.

48.1.4 Key updates with offline nodes

A node is in offline mode if the NFM-P has lost connectivity to the node at the time of the action (global PSK creation, manual PSK distribution, scheduled rekey). A node is not in offline mode if it responds to SSH and SNMP requests.

By default, the key update process skips offline nodes. When the node is back online, you can manually distribute the new keys to the node or create a global key to be automatically distributed to all sites in the CA.

48.2 MACsec statistics

48.2.1 MACsec statistics overview

You can collect MKA session statistics for a port or subport on demand, and schedule statistics collection using a MIB entry policy. The statistics are displayed on the Statistics tab of the MACsec interface. See Chapter 9, “Device discovery” for information about configuring MIB entry policies.

MACsec statistics can be viewed and collected from the Statistics tab of the following object properties forms:

- MACsec interface
- MKA session
- MKA peer

See the Statistics search tool for detailed information about the statistics.

48.3 Workflow to configure MACsec

48.3.1 Stages

1

Verify that the discovery rule for each participating NE includes an SSH2 security access mediation policy; see 9.23 “To configure a discovery rule” (p. 310).

2

Create a global MACsec connectivity association; see 48.4 “To configure a global MACsec connectivity association” (p. 1457).

3

Create a local MACsec connectivity association; see 48.5 “To configure a local connectivity association” (p. 1458).

4

Create a global PSK; see 48.6 “To create a global PSK” (p. 1459).

5

Create a rekeying schedule; see 48.7 “To configure a rekeying schedule” (p. 1460).

6

Add interfaces to the MACsec connectivity association; see 48.8 “To add an interface to a MACsec connectivity association” (p. 1461).

After MACsec interfaces are added, the NE establishes an MKA session, discovers MACsec peers, and begins encrypting traffic between peers.

48.4 To configure a global MACsec connectivity association

48.4.1 Purpose

Perform this procedure to create a connectivity association for HSM key management.

Note: Before you can use an HSM for key management, you must add the HSM to the NFM-P configuration; see the procedure to add an HSM to the NFM-P in the *NSP System Administrator Guide*.

Note: The NFM-P does not store CAKs generated by an HSM.

48.4.2 Steps

1

Choose Manage → MACsec from the NFM-P main menu. The Manage MACsec form opens.

2

Click Create → Connectivity Association, or choose a connectivity association and click Properties. The Connectivity Association (Create|Edit) form opens.

3

Configure the required General parameters.

4

In the Keying Parameters panel, configure the Key Source parameter.

If you choose HSM, click the Select button and select an HSM.

5

Configure the required parameters for Static CAK.

6

Close the forms.

End of steps

48.5 To configure a local connectivity association

48.5.1 Purpose

Perform this procedure to add sites to a connectivity association and to configure local parameters. Parameter values are inherited from the global connectivity association by default. However, parameters with the Inherit Value check box can be configured with a value that is only applicable to the site.

48.5.2 Steps

1

Choose Manage → MACsec from the NFM-P main menu. The Manage MACsec form opens.

2

Choose a connectivity association and click Properties. The Connectivity Association (Edit) form opens.

3

Click on the Sites tab.

4

Click Add Site. The Select Site form opens. Click Search to populate the list.

5

Choose a site and click OK. The site is added to the connectivity association and appears in the list of sites.

6

To configure local parameters, choose the site from the Sites tab and click Properties. The Connectivity Association Site (Edit) form opens.

7

Configure local parameters as required.

Select the ANYSEC Reserved check box to enable ANYsec encryption. See 12.30 “To configure ANYsec encryption on an NE” (p. 366)

8

Click OK to close the Connectivity Association Site (Edit) form.

9

From the Sites tab, select the site and click Distribute PSKs to Sites.

Existing global PSKs are distributed to the site.

10

Close the forms.

END OF STEPS

48.6 To create a global PSK

48.6.1 Before you begin

Note: Distribution of a global PSK requires the `allow-immediate` parameter in the NE configuration to be set. If the parameter is set to `no-allow-immediate`, the PSK distribution will fail. See the NE documentation for more information about NE configuration.

48.6.2 Steps

1

Choose Manage → MACsec from the NFM-P main menu. The Manage MACsec form opens.

2

Choose a connectivity association and click Properties. The Connectivity Association (Edit) form opens.

3

Click on the Static CAK tab.

4

Click Create and choose an encryption type. The PSK is created.

The PSK will be automatically distributed to all the associated sites in the Connectivity Association.

5

Close the forms.

END OF STEPS

48.7 To configure a rekeying schedule

48.7.1 Purpose

Perform this procedure to configure PSK hitless rekeying.

A rekeying operation has the following stages:

- delete the old, inactive key, if it exists
- create and deploy a new key
- set the new key as active

When a rekeying operation is completed, the new key is displayed under the PSK list in the connectivity association. The status of the operation is displayed on the Rekey Schedule form Results tab. The status of the last operation is displayed on the Connectivity Association form General tab.

48.7.2 Steps

1

Choose Manage → MACsec from the NFM-P main menu. The Manage MACsec form opens.

2

Choose a connectivity association and click Properties. The Connectivity Association (Edit) form opens.

3

Click on the Rekey Schedule tab.

4

Click Create. The Rekey Schedule (Create) form opens.

5

Configure the required parameters.

6

In the Schedule panel, click Select and use the form that opens to choose or create a schedule.

7

Click OK. A rekeying scheduled task is created.

8

Close the forms.

END OF STEPS

48.8 To add an interface to a MACsec connectivity association

48.8.1 Steps

1

Choose Manage → MACsec from the NFM-P main menu. The Manage MACsec form opens.

2

Choose a connectivity association and click Properties. The Connectivity Association (Edit) form opens.

3

Click on the MACsec Interface tab.

4

Click Add. The Select MACsec Interface form opens.

5

Click Search to populate the list.

6

Perform one of the following:

a. Select an interface and click OK.

b. Create an interface.

1. Click Create. The MACsec Interface (Create) form opens.
2. Click Select to choose the site ID.
3. Click Select to choose the MACsec port.
4. Configure additional parameters as needed.
5. Click OK.

The new or selected MACsec interface is added to the connectivity association.

7

Close the forms.

END OF STEPS

Part V: Policy management

Overview

Purpose

This part provides information about policy management using the NFM-P.

Contents

49 Policies overview

49.1 Policies

49.1.1 Overview

The NFM-P supports the template-based creation of rules that govern how network traffic is handled and prioritized. These rules are referred to as policies. Policies provide a consistent, centralized configuration of common characteristics across multiple objects in the network. An NFM-P operator can distribute or delete policies on sites and NEs that are within their span of control.

You can assign policies to resources during service creation or modification. You can also assign policies to resources before or after you configure the service by choosing and modifying the resource from the Manage Equipment or Manage Services form.

Service and routing management policies are globally and seamlessly distributed to devices when they are used by resources on the device. They can also be manually distributed to devices. Subsequent changes to policies are distributed and affect all participating resources. Policy configurations can also be changed locally when you configure a network resource, for example, during service configuration or modification. These changes do not affect the global policy.

49.1.2 Global versus local policies

Policies are Global or Local in scope. Global policies are created using the NFM-P and are available for use throughout the network. Local policies are instances of global policies that are assigned to individual NEs and may contain properties applicable only to that NE.

When you modify and distribute a global policy using the NFM-P, the local policy definition is also updated, provided that its distribution mode is set to Sync With Global. This ensures that the policy instances are synchronized. If a local policy differs from the corresponding global policy because of changes to the global policy, a warning alarm is raised against the local policy. After a global policy is updated and distributed to the participating NEs, the NFM-P clears the mismatch alarms associated with the local policy.

When there is no global policy associated with a local policy, the NFM-P automatically creates a global policy that is identical to the first discovered local policy. If the local policy is incomplete, the NFM-P creates an incomplete global policy.

49.1.3 Global policies states

When you initially select a policy type under the main Policies menu, a selection window is displayed that lists all occurrences. You can choose to display Global or Local policies here. When you select Global, the menu bar over the list displays filterable and read-only parameters pertinent to the chosen policy type. The following read-only parameters describe the initialization phases of a Global policy:

- Discovery State

  The Discovery State parameter describes the state of the global policy during node discovery, or if a local policy on an NE is created or modified using CLI after the NE is discovered. The following may be displayed:
  - In Progress—the global policy is created as part of node discovery, and the policy definition is not yet complete.
  - Completed—the global policy is created as part of node discovery, and the global policy definition is successful and complete.
  - Failed—the global policy is created as part of node discovery, and the policy definition is not successful. This may occur because of an NFM-P server failure or activity switch. A failed global policy is updated during the next successful full NE resynchronization, or the policy can be manually synchronized with a specific local policy.
  - Initialized—the global policy is created by SNMP trap notification from a local policy that was created or modified on the NE by CLI after NE discovery. User may need to synchronize the global policy manually with the specific local policy. After such a policy synchronization on an “Initialized” global policy (using the NFM-P), the Discovery State for the global policy changes to “N/A”.
  - N/A (default)—the global policy is created or modified by an NFM-P user, and not as a result of NE discovery or CLI change.
- Last Sync Time

  The Last Sync Time field provides date and time information concerning the current state of an existing global policy that you are viewing.

  Note:

  This field displays “N/A” when you are first creating the global policy in the NFM-P.

  The Last Sync Time information field may denote any of the following timestamps:
  - the date and time when a policy that was created on an NE (using the CLI) was discovered by the NFM-P
  - the most recent date and time that the global policy was synchronized by the NFM-P with a corresponding local definition on an NE
  - N/A, indicating that the NFM-P has undergone an upgrade since the creation time of the global policy
- Last Sync From

  The Last Sync From field provides information concerning the origin of an existing global policy that you are viewing.

  Note:

This field displays “N/A” when you are first creating the global policy in the NFM-P, and then “admin” once the policy is initially applied.

The Last Sync From information field may denote any of the following origins:

- NFM-P user name (for instance, admin), indicating that the policy was created from the NFM-P
- System ID, indicating the NE from which the policy was learned by the NFM-P
- System ID, indicating the NE with which the policy was most recently synchronized by the NFM-P
- N/A, indicating that the NFM-P has undergone an upgrade since the creation of the global policy

Note: If you attempt to modify a global policy with an “In Progress” Discovery State, the following occurs:

- When discovery of the NE is ongoing, the modification fails.
- When discovery of the NE is completed, modifications using OSS proceed, although a warning appears and allows you to cancel the modification. If the modification is not canceled, the Discovery State is changed to N/A, and the global policy is not updated to match the local policy.
- When a global policy is modified, the Discovery State is reset to N/A.

At any time during discovery or a full resynchronization, you can use the SyncTo method from OSS or synchronize the global policy from any local policy.

When a discovery of an NE fails and there is no NFM-P server failure or activity switch, all global policies that are waiting for completion are changed to Failed for the Discovery State. If you start another full resynchronization of the failed NE, the NFM-P tries again to complete the global policies from the NE that is part of the resynchronization and which has the Failed or In Progress Discovery State. The NFM-P also attempts completion of the synchronization of global policies that have a Failed or an In Progress State until a server failure or an activity switch occurs.

The following table describes the recommended operator actions to recover global policies when the Discovery State remains In Progress or Failed.

Table 49-1 Actions to recover global policies

Discovery State	NFM-P server failure	NE state	Recovery action
In Progress/Failed	No	Resync Failed	Retry a full resynchronization or synchronization from another local policy
In Progress/Failed	No/Yes	Removed/Unmanaged	Synchronization from another local policy
In Progress/Failed	Yes	Resync Completed	Synchronization from another local policy
In Progress/Failed	Yes	Resync Failed	Retry a full resynchronization and synchronization from another local policy

49.1.4 Default global policy creation

When an NE is discovered, if a given global policy on the NE is not present in the NFM-P, then a non-empty global policy is created in the NFM-P. It has the same content as the originating NE's

policy. The local definition specific to the NE is set to “Sync With Global”, unless the originating policy is a routing policy, in which case the local definition is set to “Local Edit Only”.

When a global policy (other than a routing policy) is created using CLI on an NE already known to the NFM-P, the behavior is different. In this case, the NFM-P creates a new resynched global policy with only default mandatory values (for example, default queues). The NFM-P global policy does not contain objects specific to the NE-originated policy, such as filter entries. However, such objects are contained in the local definition specific to the NE. This local definition is set to “Local Edit Only”. In the case of a 7210 and 1830 Network policy, the local definition is set to “Sync With Global”, and the global policy created will be a copy of the local policy. For a CLI-created routing policy on a discovered NE, a non-empty global policy is created in the NFM-P. The global policy will be in sync with the local routing policy.

49.1.5 Policy audits

Nokia recommends that you change a policy on an NE using only the NFM-P or an OSS client. This ensures that there is no mismatch in policy IDs or policy configurations between the managed NEs and the NFM-P.

Creating or modifying a policy using a CLI may lead to inconsistencies in the policy configuration throughout the network.

Note: For policies that require you to enter a name to identify the policy, you cannot use “N/A” for the policy name; the term N/A is restricted.

Local changes to a policy may occur where users have permissions to access local policies using CLI. To identify local and global policy mismatches, you can perform a policy audit that compares the local and global instances of a policy, and then review the differences. Note however that the audit functionality is not applicable to non-modifiable default NFM-P policies. An audit can be performed on local policies of NEs that are in the user span of control.

You can audit all policies in the network or on selected NEs in the following ways:

- by policy group
- by policy type
- by global policy

If an entry exists in both the global and a local version of a policy but a field within that entry is different between the versions, then the audit indicates exactly which field is different. This includes missing entries as well. See 49.21 “To perform a policy audit for global policy” (p. 1498)
and 49.24 “To identify differences between a global and local policy or two local policies” (p. 1503) for information about identifying policy discrepancies using a policy audit.

If there is a mismatch between a local policy instance and the global instance, an alarm is raised against the local policy. The NFM-P clears the alarms from previous audits if the mismatch condition no longer exists.

Depending on the results of an audit, the mode of the local policy may change. If the audit discovers differences between the local and global policies, you can change the mode to allow only local configuration. When the audit discovers that the local policy and global policy match, the local mode can be changed to synchronize with global policies. For example, when you need the NFM-P to discover new NEs, set the mode parameter to local configuration only to ensure that unique

policies are not modified when a global policy is updated. The audit results can be reviewed to determine whether a policy should remain local.

49.1.6 Policy synchronization

Changes to a local policy made using CLI will not result in a change to the related global policy. If you perform a policy audit of managed NEs and identify that the policy configuration is modified and the policies are out of sync, you can initiate a policy synchronization of the global policy with a selected local policy.

You can also do the reverse action, namely, update the global policy with a local policy definition and then release and re-distribute the policy to all deployed NEs. To prevent a catastrophic deployment of an invalid policy, the NFM-P changes the global policy to draft mode, and it is not available for use until the policy is released. See 49.13 “To synchronize a policy” (p. 1487) for information about how to synchronize a policy.

49.1.7 Policy overrides

With some policy types, you can use the NFM-P to configure a policy override that allows you to change or override the default settings associated with the policy. Policy overrides are typically configured on the object to which the policy is assigned.

For policy types that allow multiple overrides to be configured, the Override Policy Items tab on the policy creation form displays all of the subordinate override policies that are configured on the policy. Each override policy is displayed on their own sub-tabs under the Override Policy Items tab. The override policies that appear on the GUI are dynamic, based on the policy type to be configured.

49.2 Policy distribution

49.2.1 General Information

The NFM-P creates a global policy in Draft mode. This is the mode used to configure a policy before distributing it to the NEs. Once a policy is configured and ready for distribution, you change its configuration mode to Released. Whether you’re dealing with a new or existing policy, changing its mode to Released opens the Distribute window. If the policy was previously distributed to a group of NEs, then only those NEs are shown in the Distribute window. By default, all the NEs are selected in the window. You can deselect the NEs you want, or use the current selection to distribute the policy. If the policy was not previously distributed, or its local versions are non-existent (deleted either by a user or an NE), then the Distribute window displays a list of compatible NEs. You must then select which NEs to distribute the policy to. Alternatively, you can use the drop-down menu in the Distribute window to select a Policy Distribute Group for the distribution.

The NFM-P also supports the partial distribution of global policies. Before a global policy is distributed to the NEs, the NFM-P determines whether the global policy, policy properties, and the policy entries are applicable for each NE to which the policy is to be applied. If an NE does not support the policy, property, or entry defined in a global policy, the policy is partially distributed to the NE. The inapplicable policy, property, or entry is not distributed to the NE. An alarm is not raised if a policy is partially distributed. When you use the NFM-P GUI or OSS, failure of distribution to an NE does not affect distribution to other NEs.

You can monitor policy distribution either in the Distribute window or by using the Task Manager. The NFM-P saves the latest released version of the global policy. If you select a Policy Distribute Group, the NEs contained within the group will be shown in the Selected Objects panel once the distribution begins. This allows you to monitor the distribution progress at the individual NE level.

You can also interrupt or completely stop an ongoing policy distribution. See 49.12 “To stop a policy distribution currently in progress” (p. 1486) for more information.

49.2.2 Distribution considerations

Consider the following before distributing policies using the NFM-P:

- A policy must first be released before it can be distributed to an NE.
- The default behavior when you release a policy for distribution is that the Distribute window opens and allows you to select the NEs required for distribution. Alternatively, you can enable a parameter setting in the System Preferences that will upon release of the global policy, automatically distribute it to NEs that already have local versions of the policy. See the *NSP System Administrator Guide* for more information on the use of the Auto Distribute Global Policy when Released parameter.
- Local NE versions of policies that use the Sync With Global distribution mode will allow the NE to receive the distribution of a global policy.
- Local NE versions of policies that use the Local Edit Only distribution mode will not allow the NE to receive the distribution of a global policy. You must ensure that the policy distribution mode for the local policy is set to Sync With Global if you want the NE to receive the distribution of a global policy.
- Local SR-family NE versions of policies that are changed using CLI can have their distribution modes automatically set to either Sync with Global or Local Edit Only. This is governed by the setting of the Switch Distribution Mode to Local Edit Only on CLI Change parameter in System Preferences. See the *NSP System Administrator Guide* for more information about the Local Edit Only function.
- When you distribute a policy to a 7705 SAR, all values within that policy must be supported by that 7705 SAR; otherwise, the distribution of the policy to that 7705 SAR is blocked.

49.2.3 Scaling policy deployments

The NFM-P allows policies to be distributed to numerous NE sites in a single operation. To accomplish this effectively, the NFM-P can use multiple deployers to distribute the policies. A deployer in this context is a thread within the NFM-P that executes a task. Releasing a large global policy to multiple NEs using only one deployer may degrade system performance. Scaling policy deployments using multiple deployers helps to maintain system performance.

To avoid or minimize system degradation, an operator can configure the maximum number of managed objects that a single deployer is allowed to send during policy distribution. The default value is 10,000 managed objects per deployer. A managed object in this context is basically a configuration entry within a policy. For example, in an ACL IP filter policy, each IP filter entry is considered to be one managed object. Therefore a single global policy can often contain numerous managed objects.

When an operator sets the “policyDistributionMaxObjectsPerDeployer” parameter to a desired value, the NFM-P uses this value, along with the actual number of managed objects in the policy to

be distributed, to calculate the maximum number of NE sites that can receive the policy per deployer. If the number of sites selected for the policy's distribution exceeds this number, additional deployer requirements are automatically calculated and used by the NFM-P. This applies to the distribution of single as well as multiple global policies. For a single global policy, the values are calculated as follows:

Maximum number of NE sites allowed per deployer = Maximum number of objects per deployer / Number of objects in the global policy to be distributed

Number of deployers used to distribute the global policy = Total number of local NE sites to receive the global policy / Maximum number of sites per deployer

For the distribution of multiple policies, the number of deployers required is determined on a per policy basis.

Table 49-2, "Example of policy deployment" (p. 1470) provides an example of deploying a single global policy that contains 1,000 managed objects. Note that if the maximum number of objects per deployer setting is less than the actual number of managed objects in the policy, the NFM-P will only use one deployer per site. However, if the setting for the maximum number of objects per deployer is very large, the NFM-P might use a single deployer for a very large number of sites, which could degrade system performance. See 49.10 "To configure the maximum number of policy objects per deployer" (p. 1483) for more information on configuring the maximum number of managed objects allowed per deployer.

Table 49-2 Example of policy deployment

Maximum number of managed objects allowed per deployer	Number of managed objects in a single global policy	Maximum number of NEs (sites) per deployer
0	—	All sites
1	—	1 site
500	1,000	1 site
1,000	1,000	1 site
5,000	1,000	5 sites
10,000	1,000	10 sites
100,000	1,000	100 sites

When configuring the "policyDistributionMaxObjectsPerDeployer" parameter, the user also has the option to set the value to "0" or "1". A value of "0" means that only one deployer will be used for all NE sites that are to receive the policy. A value of "1" means that one deployer per site will be used. When distributing global policies with a large number of managed objects to a large number of NEs, Nokia recommends setting a value between 2,000 and 100,000 for this parameter.

49.3 Policy types

49.3.1 General information

The following categories define the high-level policy management functionality on the NFM-P:

- **Service management policies**

  Service management policies specify how service traffic is handled by network resources such as interfaces, ports, daughter cards, and circuits. The policies can be used by multiple resources on multiple services. Examples of service management policies include QoS policies, access ingress/egress policies, MSAP policies, and network policies.

- **Routing management policies**

  Routing management policies specify routing configuration according to specifically defined parameters that override the default routing protocol decisions normally handled by the router. Routing management policies control the size and content of routing table, advertised routes, and best routes. Examples of routing management policies include routing policies (statement, prefix list, community, and damping), MPLS administrative group, and VRRP priority control-policies.

- **Network management policies**

  Network management policies specify how the NFM-P communicates with network resources, handles alarms, manages statistics used for billing, and stores information. Examples of network management policies include alarm, mediation, and accounting policies.

- **Security policies**

  Security policies specify how the NFM-P handles the user security measures required to protect all NFM-P data, software, and hardware and monitor the system/network for any security threats. This includes creating policies required to set up NFM-P user accounts and user groups with the required scope of command roles and span of control permissions and the ongoing monitoring and management of those accounts. Examples of security policies include NE DoS/DDoS protection policies, NE password policies, RADIUS, TACAC+, and AOS/PKI authentication policies, and format and range policies.

49.3.2 Policy information map

The following table provides a high-level navigation aid to help you locate policy information contained in this guide and other NFM-P customer documentation.

Table 49-3 Location of NFM-P policy information

Applicable device	Policy type	Location
All NEs supported by the NFM-P, except for the devices listed below	Device backup, deployment, and software upgrade Service management Routing management, and residential subscriber QoS, Filter, and Multicast Event	*NSP NFM-P Classic Management User Guide*
	NFM-P user security Device security Database File Size constraint, and format and range Ageout constraint IPDR File transfer Alarm settings	*NSP System Administrator Guide*
	Statistics Accounting and file	*NSP NFM-P Statistics Management Guide*
CPAM and 7701 CPAA	Backup MIB Non-routed edge discovery Size constraint, and retention OAM diagnostics, and RCA audits	*NSP NFM-P Control Plane Assurance Manager User Guide*
Wavence SM and Wavence SA	Wavence QoS Multicast CAC interface Radio interface queue map	*NSP Wavence Device Support Guide*

49.4 Workflow to configure, distribute, and manage policies

49.4.1 Core tasks

1

Before creating policies, review the default setting of NFM-P policy-related system preferences and customize them as required. For example, you can display or hide the policy names on policy configuration forms for certain types of local policies or enforce a restriction to the distribution mode for certain types of local policies that will permit local editing only. See the *NSP System Administrator Guide* for information about configuring policy-related system preferences.

2

Create the required policy; see Table 49-3, “Location of NFM-P policy information” (p. 1473) to help locate the appropriate policy information.

Note: For policies that require you to enter a name to identify the policy, you cannot use “N/A”, “n/a”, or “@” for the policy name; the term “N/A” is restricted. Creating a policy with “@” in the

name results in Template Inconsistent/Configuration Mismatch alarms, which do not clear after a synchronization with the global policy. Also, updating the name using node CLI as “N/A” is not valid.

3

Release and distribute the policies:

a. To release and distribute select policies; see 49.6 “To release and distribute a policy” (p. 1476).

b. As required, create a Policy Distribute Group to specify a group of NEs to distribute a policy to; see 49.7 “To create a policy distribution group” (p. 1478).

c. To distribute multiple policies using a Policy Distribute Group in one action; see 49.8 “To distribute multiple policies” (p. 1479).

4

As required, change the deployment settings for policy distribution:

a. Change the distribution mode of local policies to synchronize with a global policy or to change a global policy back to a local edit distribution mode; see 49.9 “To change the distribution mode of a policy” (p. 1482).

b. Change the maximum number of managed policy objects that a distribution deployer is allowed to send; see 49.10 “To configure the maximum number of policy objects per deployer” (p. 1483).

c. Change the default maximum number of tasks involved when a group of policies is distributed; see 49.11 “To configure the maximum number of tasks for distribution” (p. 1484).

5

As required, stop the distribution of the policy while it is in progress; see 49.12 “To stop a policy distribution currently in progress” (p. 1486).

6

As required, synchronize policies across all deployed NEs; see 49.13 “To synchronize a policy” (p. 1487).

7

Assign policies to resources during service configuration or modification. See Chapter 70, “Service management and QoS”for more information.

8

As required, configure a policy override that allows you to change default settings associated for the following policies:

a. AAA subscriber policy overrides; see 13.8 “To configure an AA subscriber policy override on an ISA-AA group or partition” (p. 421).

b. Port scheduler policy overrides; see 16.24 “To configure Ethernet ports” (p. 599).

c. HSMDA policy overrides; see 16.40 “To configure an HSMDA override” (p. 632).

d.

QoS policy overrides on:

- L2 or L3 access interfaces; see 50.97 “To configure QoS policy overrides on an L2 or L3 access interface” (p. 1654)
- access ingress meters for 7210 SAS; see 50.98 “To configure QoS policy overrides on access ingress meters for the 7210 SAS” (p. 1657).
- access ingress queues for 7210 SAS-X; see 50.99 “To configure QoS policy overrides on access ingress queues for a 7210 SAS-X” (p. 1659).

e. Epipe or Ipipe L2 access interface policy overrides; see 76.40 “To create a VLL L2 access interface on a terminating site” (p. 2174).

Incidental tasks

9

As required, manage NFM-P policies:

a. Enable or disable an exclusive policy editing restriction on one or more NEs or remove any exclusive edit locks that were previously set; see 12.18 “To configure an exclusive policy editing restriction on an NE” (p. 354).

b. Copy a policy; see 49.14 “To copy a policy” (p. 1488).

c. Modify a policy; see 49.15 “To modify a policy” (p. 1489) and 49.16 “To view local policy contents” (p. 1491).

d. Export existing global policies to a file in order to make them available for import elsewhere; see 49.17 “To export a policy” (p. 1492).

e. Import global policies from an exported policy file; see 49.18 “To import a policy” (p. 1493).

f. Delete a policy; see 49.19 “To delete a policy” (p. 1494).

49.5 Workflow to perform a policy audit

49.5.1 Stages

1

Complete one of the following to perform a policy audit:

a. To compare all local policies with the associated global policies for policy groups and types; see 49.20 “To perform a policy audit for policy groups and types” (p. 1495).

b. To compare all local policies with the associated global policy; see 49.21 “To perform a policy audit for global policy” (p. 1498).

c. To compare multiple global policies with same type; see 49.22 “To perform a policy audit for multiple global policies with same type” (p. 1499).

2

To schedule a policy audit to perform regular audits on selected policies and NEs; see 49.23 “To schedule a policy audit” (p. 1501).

3

As required, identify the differences between a global policy and a local policy or two local policies; see 49.24 “To identify differences between a global and local policy or two local policies” (p. 1503).

49.6 To release and distribute a policy

49.6.1 Purpose

Perform this procedure to release a policy for distribution when a policy is in the Draft configuration mode and to distribute a policy to individual NEs or to multiple NEs in a Policy Distribution Group.

Review the 49.2.2 “Distribution considerations” (p. 1470) information in this chapter before starting this procedure. This procedure assumes you have created the required policy before you start this procedure. Perform 49.7 “To create a policy distribution group” (p. 1478) first if you intend to distribute the policy using a Policy Distribution Group.

Note: You do not need to explicitly distribute a policy; a policy is distributed to a device when it is assigned to a resource on the device.

You can configure the NFM-P to automatically distribute policies to applicable NEs upon release. See the procedure to configure NFM-P system preferences in the *NSP System Administrator Guide* for more information.

49.6.2 Steps

Select a policy for release and distribution

1

Choose Policies→*Policy Type* from the NFM-P main menu, where *Policy Type* is the type of policy that you want to release and distribute. The appropriate policy manager form opens.

2

Click Search and select a policy.

3

Double-click on the policy to view or edit the current policy parameters, if required.

Note: If you change any parameters on a policy that is in a Released Configuration mode, the configuration mode changes back to Draft. You need to re-release the policy in order to distribute the policy changes.

4

Perform one of the following:

a. If the policy is in a Draft Configuration Mode, go to Step 5 .

b. If the policy is in a Released Configuration Mode, click Distribute. The Distribute Instance form opens. Go to Step 6 .

Note: The policy configuration mode is displayed in the Configuration Mode column on the policy manager form.

Release the policy

5

Perform one of the following to release the policy for distribution:

a. Click Properties. The policy configuration form opens.

1. Click Switch Mode beside the Configuration Mode parameter. A dialog box appears.
2. Click Yes. The policy configuration mode changes to Released and the Release Policy Instance form opens.

b. Click Release. The policy configuration mode changes to Released and the Release Policy Instance form opens.

Each NE that has a local definition of the policy with its Distribution Mode set to Sync with Global is listed in the Selected Objects panel. These are ready for distribution.

Additional NEs that are eligible for policy distribution are listed in the Available Objects panel.

Select the NEs for distribution

6

Select the NEs for distribution in the Available Object panel and click on the right-arrow button. The chosen object(s) moves to the Selected Objects panel and is ready for distribution.

Note: The Available Objects and Selected Objects panels contain a column titled Local Policy Exists. This indicates if local definitions of the policy already exist on the eligible NEs.

Distribute the policy

7

Perform one of the following to distribute the policy:

a. To distribute the policy to the individual NEs, go to Step 8.

b. To distribute the policy to multiple NEs in a Policy Distribution Group:

Note: If you use the Policy Distribution Group method to distribute the policy, no additional NEs can be added to the policy distribution unless you modify the Policy Distribution Group boundaries.

See 49.7 “To create a policy distribution group” (p. 1477) for information about configuring Policy Distribution Groups.

1. Select the Policy Distribute Group option from the drop-down menu and click Search. The available Policy Distribute Groups are displayed in the list.
2. Select the appropriate Policy Distribution Group; go to Step 8.

8

Close the form. The policy manager form reappears.

Verify the policy distribution

9

To view the NEs to which the policy has been distributed:

1. Choose a policy.
2. Click Properties. The policy configuration form opens.
3. Click on the Local Definitions tab to view the list of NEs to which the policy has been distributed.

10

Close the policy manager form.

END OF STEPS

49.7 To create a policy distribution group

49.7.1 Purpose

Perform this procedure to create a Policy Distribution Group to specify a group of NEs to which you want to distribute a policy to. Using a Policy Distribution Group simplifies the distribution process for a set group of NEs, and allows you to easily add or remove members.

49.7.2 Steps

1

Choose Policies→Policy Distribute Group from the NFM-P main menu.The Policy Distribute Group form opens.

2

Click Create. The Policy Distribute Group (Create) form opens.

3

Configure the required parameters.

4

Click on the Network Elements tab.

5

Click Add and choose the NEs that you want to include in the distribution group and click OK.

6

Save your changes and close the form.

END OF STEPS

49.8 To distribute multiple policies

49.8.1 Purpose

Use this procedure to distribute a group of policies in one action. When you distribute a group of global policies:

- The policies must all be of the same type.
- The same conditions and restrictions that apply to the distribution of a single policy exist. See 49.6 “To release and distribute a policy” (p. 1476) for more information.
- You can set a limit to the maximum number of tasks involved in the bulk policy distribution. Perform 49.11 “To configure the maximum number of tasks for distribution” (p. 1484) to set this limit.
- The default behavior when you release a policy for distribution is the Distribute window opens, and you select the NEs required for distribution. Alternatively, you can enable the Auto Distribute Global Policy when Released parameter in the System Preferences to automatically distribute the Global policy to NEs that already have a local version of the policy. See the *NSP System Administrator Guide* for more information.
- Local NE versions of policies that use the Sync With Global distribution mode will allow the NE to receive the distribution of a global policy. However, local NE versions of policies that use the Local Edit Only distribution mode will not allow the NE to receive the global policy. You must ensure that the policy distribution mode for the local policy is set to Sync With Global if you want the NE to receive the global policy distribution.
- Multiple distribution is currently not supported for routing or firewall policies.

49.8.2 Steps

1

Choose Policies→*Policy Type* from the NFM-P main menu, where *Policy Type* is the type of policy that you want to distribute. The appropriate policies manager form opens.

2

Choose Global from the Policy scope drop-down menu.

3

Click Search and select the policies that you want to release or distribute.

Note: If you select a combination of policies that are in Draft and Release mode, the Release and Distribute button will be disabled. The policies you select must be in one mode or the other.

4

Perform one of the following:

a. If the selected policies are in the Draft Configuration Mode, go to Step 5.

b. If the selected policies are in the Released Configuration Mode, go to Step 6.

5

When the selected policies are in the Draft Configuration Mode, the policies cannot be distributed to the NEs. You must first release the policies for distribution. Click Release. The Release form opens. Go to Step 9.

6

When the selected policies have previously been released (they are in the Released Configuration Mode) and you want to redistribute them, click Distribute. The Distribute form opens. The Network Elements (Network) option from the drop-down menu is displayed by default.

7

Perform one of the following:

a. If you want to select individual NEs for the distribution, go to Step 9.

b. If you want to use a policy distribution group for the distribution, go to Step 10 .

8

Click Distribute. The policy is distributed to the NEs.

A progress bar at the lower right of the GUI displays the overall distribution progress. Distribution states for individual NEs are shown in the Status column of the Selected Objects panel.

Note: Depending on the size of the policy, the number of NEs the policy is being distributed to, and the number of deployers used to distribute the policy, the progress bar status may not be noticeable and the policy may take considerable time to distribute. The progress bar reflects more than just the policy deployment; it also tracks the progression of the following events:

- polls the initial state of the NE to determine a baseline which is used to track the overall progression of the policy deployment on the NE
- the deployment of the policy to the NEs
- the resynchronization of the MIB tables that were changed on the NE

Note: If you are using a Policy Distribution Group for the distribution after you click the Distribute button, the NEs in the group are listed in the Available Objects panel. This allows you to monitor the distribution progress for specific NEs.

Note: Distribution failures are reported in a pop-up message. Distribution failures are also reported using JMS.

9

Select the NEs to release/distribute the policies to and click on the right-arrow. This moves the required row entries between the Available Objects and Selected Objects panels.

Observe the following behavior:

- The Available Objects panel is populated with a list of compatible NEs to which all the selected policies can be released/distributed.
- When local definitions exist, the list of NEs to which the policies have already been released and that have their Distribution Mode set to Sync with Global will appear in the Selected Objects panel. These are ready for distribution. Go to Step 11.

10

Select the Policy Distribute Group option from the drop-down menu and click Search. The available Policy Distribute Groups are displayed in the list.

Note: You cannot use a Policy Distribute Group and then add further individual NEs. See 49.7 “To create a policy distribution group” (p. 1478) for more information on Policy Distribute Groups.

11

Click Distribute to distribute the global policies to the selected devices.

If you are using a Policy Distribute Group for the distribution, once you click Distribute, the NEs contained in the group are listed in the Available Objects panel. This allows you to monitor the distribution progress for any specific NE.

A progress bar displays the overall percentage of distribution progress completion to the selected sites. Distribution states (In Progress, Succeeded, or Failed) for individual sites are shown in the Status column for the Selected Objects.

Note: Distribution failures are reported in a pop-up message. You can view the error message to determine the cause of the failure and which NE or NEs were affected. Distribution failures are also reported using JMS.

12

To stop the distribution of the policies, perform 49.12 “To stop a policy distribution currently in progress” (p. 1486).

13

Close the policy manager form.

END OF STEPS

49.9 To change the distribution mode of a policy

49.9.1 Purpose

Perform this procedure to change the distribution mode of local policies to synchronize them with a global policy or to change a global policy back to a local edit distribution mode.

49.9.2 Steps

1

Choose Policies→*Policy Type* from the NFM-P main menu where *Policy Type* is the type policy that you want to change the distribution mode of. The appropriate policy manager form opens.

2

Click Search and select a policy.

Note: The current policy distribution mode is displayed in the Distribution Mode column on the policy manager form.

3

Click Switch Distribution Mode. The Switch Distribution Mode - *Policy* form opens.

4

Choose one or more local definitions from the Available Local Policies list and click on the right-arrow. The definitions move to the Selected Local Policies panel.

5

Click Sync With Global or Local Edit Only to change the distribution mode of the policy. The Distribution Mode of the local definitions in the Selected Local Policies panel changes accordingly.

6

Save you changes and close the form. As required, distribute the policy to all participating NEs, as described in 49.6 “To release and distribute a policy” (p. 1476).

7

Close the policy manager form.

END OF STEPS

49.10 To configure the maximum number of policy objects per deployer

49.10.1 Purpose

Perform this procedure to set the maximum number of managed objects that can be distributed by one deployer. This in turn will determine how many deployers are used to distribute a global policy to a given set of NEs.

CAUTION

Service Disruption

Contact your Nokia technical support representative before you attempt to modify the nms-server.xml file.

Modifying the nms-server.xml file can have serious consequences that can include service disruption.

49.10.2 Steps

1

Log in to the NFM-P main server station as an admin user.

2

Navigate to the /opt/nsp/nfmp/server/nms/config directory.

3

Create a backup copy of the nms-server.xml file.

4

Open the nms-server.xml file using a plain-text editor.

5

Search for the following XML tag:

```
<policyConfig policyDistributionMaxObjectsPerDeployer="10000"/>
```

6

Change the number as required. An integer value of “0” or less specifies that only one deployer will be used to distribute a policy to all the NE sites. A value of “1” specifies that one deployer will be used per site. The default value is 10,000 managed objects per deployer. Nokia recommends that you configure the value between 2,000 and 100,000.

Refer to the section 49.2.3 “Scaling policy deployments” (p. 1470) for more information on setting the maximum number of managed objects per deployer.

7

Save and close the nms-server.xml file.

8

Open a console window.

9

Navigate to the /opt/nsp/nfmp/server/nms/bin directory.

10

If the main server is a standalone server, or the primary server in a redundant deployment, enter the following:

```
bash$ ./nmsserver.bash read_config ↲
```

The main server reads the nms-server.xml file and puts the configuration change into effect.

11

If the main server is the standby server in a redundant deployment, enter the following:

```
bash$ ./nmsserver.bash force_restart ↲
```

The main server restarts and puts the configuration change into effect.

12

Close the console window.

END OF STEPS

49.11 To configure the maximum number of tasks for distribution

49.11.1 Purpose

The NFM-P allows you to select multiple policies of the same type for bulk distribution. Perform this procedure to change the default maximum number of tasks involved when a group of policies is distributed.

CAUTION

Service Disruption

Contact your Nokia technical support representative before you attempt to modify the nms-server.xml file.

Modifying the nms-server.xml file can have serious consequences that can include service disruption.

49.11.2 Steps

1

Log in to the NFM-P main server station as the nsp user.

2

Navigate to the /opt/nsp/nfmp/server/nms/config directory.

3

Create a backup copy of the nms-server.xml file.

4

Open the nms-server.xml file using a plain-text editor.

5

Search for the following XML tag:

```
<policyConfig maxTasksForBulkDistribute="200000"/>
```

6

Change the number, as required. The default is 200,000. Nokia recommends that you configure the value between 1 and 200,000.

7

Save and close the nms-server.xml file.

8

Open a console window.

9

Navigate to the /opt/nsp/nfmp/server/nms/bin directory.

10

If the main server is a standalone server, or the primary server in a redundant deployment, enter the following:

```
bash$ ./nmsserver.bash read_config ↵
```

The main server reads the nms-server.xml file and puts the configuration change into effect.

11

If the main server is the standby server in a redundant deployment, enter the following:

```
bash$ ./nmsserver.bash force_restart ↵
```

The main server restarts and puts the configuration change into effect.

12

Close the console window.

END OF STEPS

49.12 To stop a policy distribution currently in progress

49.12.1 Purpose

This procedure presumes you have initiated the distribution of a policy as described in 49.6 “To release and distribute a policy” (p. 1476) . To stop an ongoing policy distribution process, you must be in the Release or Distribute window, depending on whether you are currently releasing a draft policy or distributing a released policy. Stopping the release and distribution of multiple policies is also supported using this procedure.

49.12.2 Steps

1

Click Stop Distribute in the Release or Distribute window to halt the currently ongoing process. A confirmation message appears.

2

Click Yes to stop the distribution.

When the distribution is stopped, the Status column in the Selected Objects pane is updated with the current task status.

The status will indicate Succeeded for the policies that were successfully deployed to the targeted NEs.

The status will indicate Aborted for those policies that were not distributed.

3

If you want to continue the distribution, click Re-enabled Distribute. The NFM-P takes the list of aborted tasks and invokes the distribute function on them again.

When the distribution action is complete, the Status column in the Selected Objects pane is updated.

4

Close the policy manager form.

END OF STEPS

49.13 To synchronize a policy

49.13.1 Purpose

You can use the Synchronize function to specify a local policy as global and re-distribute it to all deployed NEs. For example, if a policy is distributed to a wide range of devices and on one of these devices the policy was changed, you can use the Synchronize command to synchronize the policy on the device and on the NFM-P. You must then re-distribute the policy to all participating devices, as described in 49.6 “To release and distribute a policy” (p. 1476).

Note: When you synchronize a policy that is in Draft mode, the policy is not distributed to existing local definitions. When you synchronize a policy that is in Released mode, the NFM-P sets the policy to Draft mode. You must set the Configuration Mode parameter to Released to distribute the policy to existing local definitions. Only local policies that have the Distribution Mode parameter set to Sync With Global are affected.

49.13.2 Steps

1

Choose Policies→*Policy Type* from the NFM-P main menu, where *Policy Type* is the type of policy that you want to synchronize.

The Manage *Policy Type* form opens.

2

Choose Local or Global from the Policy scope drop-down menu. When you set it to Local, you can specify an NE using the Local Node IP Address parameter.

3

Click Search and choose the policy or policies that you want to synchronize.

4

Click Synchronize. The Synchronized - *Policy Type* form opens.

Note: The Synchronize function is available under the More Actions button. Do not confuse this with the Resync button. The Resync button on any property form is used to resynchronize the data in the NFM-P network model with the current state of the corresponding object.

5

Choose the NE to which the policy is to be synchronized from the Available Local Policies list and click on the right-arrow. The chosen NE moves to the Selected Source Local Policy panel of the form.

6

Configure the Resync Local Policy before synchronize? parameter as required.

7

Click Synchronize. The status of the synchronization process is displayed on the form.

8

Close the Synchronize - *Policy Type* form.

END OF STEPS

49.14 To copy a policy

49.14.1 Purpose

You can copy an existing policy and assign the copied version a unique policy ID. However, you cannot use this procedure to overwrite an existing policy.

49.14.2 Steps

1

Choose Policies→*Policy Type* from the NFM-P main menu, where *Policy Type* is the type of policy you want to copy. The *Policy Type* manager form opens.

2

Choose Global or Local from the Policy scope drop-down menu. If you set it to Local, you must specify a Local Node IP Address by clicking Select and then choosing the required NE. Click OK.

3

Click Search and choose the policy you want to copy.

4

Click Properties. The *Policy Type* (Edit) form opens.

5

Choose Copy and configure the warning message as required. The copied *Policy Type* (Create) form opens. The form is set as a global policy in draft mode, regardless of whether you initially chose a global or local policy to copy.

6

Configure the parameters as required.

Note: If you need to configure the policy ID manually, you must assign a unique value. The NFM-P does not allow you to use the same ID as the policy you originally copied.

7

Save your changes and close the forms.

END OF STEPS

49.15 To modify a policy

49.15.1 Purpose

Use this procedure to change existing policies and entries within policies using the NFM-P client GUI.

49.15.2 Steps

1

Choose Policies→*Policy Type* from the NFM-P main menu, where *Policy Type* is the type of policy that you want to edit. The *Policy Type* manager form opens.

2

Choose Global from the Policy scope drop-down menu.

3

Click Search and choose the policy that you want to modify.

4

Click Properties and perform one of the following:

a. If the policy configuration mode is set to Released, go to Step 5.

b. If the policy configuration mode is set to Draft, configure the parameters, as required, and go to Step 10.

5

Configure the parameters, if required. When you modify the configuration, the NFM-P changes the policy configuration mode to Draft.

6

When you modify filter entries for policies with filters, click on the appropriate tab and click Refresh to list the filter entries.

7

Save your changes.

8

Compare the global policy with the existing local definitions to verify whether you need to reset the policy configuration to the previously released global policy configuration. Perform 49.24 “To identify differences between a global and local policy or two local policies” (p. 1503) if required.

9

Click on the Action button and choose Reset to Released to reset the global policy configuration to the last released configuration of the policy and to cancel any modifications you entered in Step 5.

10

Click Switch Mode beside the Configuration Mode parameter. A dialog box appears.

11

Click Yes. The policy configuration mode changes to Released and the Release form opens.

The NEs that have a local definition of the policy set to Sync with Global are shown in the Selected Objects panel and are ready for distribution. You can select an NE and move it to the Available Objects panel by using the left-arrow. This will exclude it from distribution.

12

Click Distribute to distribute the policy locally to the devices listed in the Selected Objects panel.

A progress bar at the lower right of the GUI displays the overall percentage of distribution progress completion to the selected sites. Distribution states (In Progress, Succeeded, or Failed) for individual sites are shown in the Status column for the Selected Objects.

Note: Distribution failures are reported in a pop-up message. You can view the error message to determine the cause of the failure and which NE or NEs were affected. Distribution failures are also reported using JMS.

13

Click on the Local Definitions tab to view the local instances of the global policy, if required.

14

Save your changes and close the form.

END OF STEPS

49.16 To view local policy contents

49.16.1 Purpose

Use this procedure to view various contents of an existing local policy definition and any modifications you make to it before deploying the changes.

Use this procedure to view various contents of an existing local policy definition and any modifications you make to it before deploying the changes.

- QoS SAP ingress and QoS SAP egress polices
- ACL IP/IPv6 filters and ACL MAC filter policies
- Port list and Prefix lists
- All routing policies

  Note:

  Current and modified contents to VPLS (see 77.10 “To view VPLS contents” (p. 2260)), VLL (see 76.9 “To view VLL service contents” (p. 2126)), and VPRN services (see 79.8 “To view VPRN service contents” (p. 2537)) may also be viewed in a similar manner as described in this procedure for policies.

Two information views are available. The Committed info view displays the current contents of a policy, and the Committed menu item is always enabled. The Modified info view allows you to review any changes you make to a policy before committing them. Modified, created, and deleted attributes and objects are displayed.

49.16.2 Steps

1

Choose Policies→*Policy Type* from the NFM-P main menu, where *Policy Type* is the type of policy that you want to edit. The *Policy Type* manager form opens.

2

Choose Local from the Policy scope drop-down menu.

3

Click Search and select the policy that you want to view or modify.

4

Click Properties and perform one of the following:

a. To view the currently committed policy contents, go to Step 5 .

b. To view modified policy contents before committing any changes, go to Step 6 .

5

Click on the Action button and choose Show Info→Committed. A Committed Values form is displayed and shows various policy attributes that have been previously configured and saved

in the local policy. The information displayed in the form is similar to the information retrieved by running the “configure>*Policy Type #*”, where *Policy Type #* is the type of policy (followed by its Service ID) that you want to query on an NE.

6

Modify any policy parameters or objects, as required. Otherwise go to Step 9 .

7

Click on the Action button and choose Show Info→Modified. A Modified Values form is displayed. The table lists modified, created, and deleted actions, as well as specific attributes and objects, along with their old value, new value, and tab location. The Attribute Title corresponds to the attribute or object name acted upon by your current modifications. For created objects, the values of mandatory attributes are shown in comma-separated format.

8

Select an item in the Modified Values form and then click Show on Form. The policy form tab containing the changed item is displayed and the modified attribute is highlighted in blue.

9

Save your changes if required, and close the form.

END OF STEPS

49.17 To export a policy

49.17.1 Purpose

You can export existing global policies to a file in order to make them available for import elsewhere, for example, on another NFM-P server. The following types are available for export:

- SAP access ingress and access egress policies
- ACL filter policies (both IPv4 and IPv6)
- Accounting policies
- Scheduler policies
- All SR-based QoS policies
- All routing policies

See 49.18 “To import a policy” (p. 1493) for information about importing policies.

49.17.2 Steps

1

Choose Policies→*Policy Type* from the NFM-P main menu, where *Policy Type* is the type of policy you want to export. The *Policy Type* manager form opens.

2

Choose Global from the Policy scope drop-down menu.

3

Click Search and choose one or more policies you want to export.

4

Click Export Policy. The Export Global Policy Details form opens.

5

Choose the location to save the exported policy:

1. Choose Server or Local from the File Location menu.
   Policies saved to the server will be saved to /opt/nsp/nfmp/server/nms/bin/policyExport.
2. To save the policy locally, click Select and choose the file path.

6

Assign an Export File Name to the exported policies. You can also enter an optional description.

Note: If you selected more than one policy in Step 3, the exported xml file will contain all the selected policies.

7

Save your changes and close the form.

END OF STEPS

49.18 To import a policy

49.18.1 Purpose

You can import global policies from an exported policy file. The following types are available for import:

- SAP access ingress and access egress policies
- ACL filter policies (both IPv4 and IPv6)
- Accounting policies
- Scheduler policies
- All SR-based QoS policies
- All routing policies

Note: You can import global policies that have been exported on the same or lower release of the NFM-P.

See 49.17 “To export a policy” (p. 1492) for information about exporting policies.

49.18.2 Steps

1

Choose Policies→*Policy Type* from the NFM-P main menu, where *Policy Type* is the type of policy you want to import. The *Policy Type* manager form opens.

2

Choose Global from the Policy scope drop-down menu.

3

Click Import Policy and select an Import File Name.

4

Choose the location of the policy to import:

1. Choose Server or Local from the File Location menu.
2. If the policy is saved locally, click Select and choose the file path.

5

Click Preview List to see the global policies contained in the selected file.

6

Click the Override existing policies check box if you want the imported policies to overwrite existing global policies.

7

Save your changes and close the forms.

END OF STEPS

49.19 To delete a policy

49.19.1 Purpose

Each service SAP and network interface is associated, by default, with the appropriate ingress, egress, or network policy (ID 1). You can replace the default policy with a customer-configured policy, but you cannot entirely remove a QoS policy. When you remove a QoS policy from a SAP or IP interface, the policy association reverts to the default policy (ingress or egress policy ID 1). The default policy cannot be deleted.

A QoS, ACL, or an AA transit IP policy cannot be deleted until it is removed from the all SAPs or network ports where it is applied. When a policy is deleted, it is removed from the NFM-P, including the database and all devices.

Be aware when deleting a routing policy from an NE that is associated with one or more services. Multiple services on the NE may use the same policy.

49.19.2 Steps

1

Choose Policies→*Policy Type* from the NFM-P main menu, where *Policy Type* is the type of policy that you want to delete. The Manage *Policy Type* form opens.

2

Choose Local or Global from the Policy scope drop-down menu.

3

Click Search and choose the policy that you want to delete.

4

Click Delete. A confirmation message appears.

If you are trying to delete a global routing policy, the message informs you that the policy may currently be used by services or routing protocols. Some routing policies, such AS Paths and routing statements, contain a Policy Usage tab in their properties form. That tab allows you to view the services and routing protocols that currently use the policy you are attempting to delete (see 54.21 “To view routing policy usage” (p. 1767) for more information). If you proceed to delete the global policy, then all such local definitions of the policy will also be deleted.

The confirmation message also contains a check box that allows you to exclude a global policy that is currently used by a service or routing protocol. Configure this as required.

5

Click Yes or No to continue. The policy manager form reappears. If you chose to delete the policy, it is removed from the policy list.

END OF STEPS

49.20 To perform a policy audit for policy groups and types

49.20.1 Purpose

An audit compares all local policies with the associated global policies. A policy audit can be performed on all NEs in the network, or limited to a specific NE or group of NEs. All NEs are included in the audit unless they are explicitly chosen. A policy audit can be performed on policy groups and policy types. A policy audit cannot be started when another policy audit is in progress.

CAUTION

Service Disruption

If a policy type of global policy is not specified, all policies in the user span of control are included in the policy audit.

If NEs are not specified, all NEs that are in the users span of control are included in the policy audit.

Performing a policy audit may take one or more hours to complete.

Note: Validation is performed to prevent policies from being audited if the use span of control prohibits the operation.
If a user performs an audit on objects that are not within their span of control, the audit is aborted and a error message is displayed. The error message indicates which objects are prohibited.

49.20.2 Steps

1

Choose Tools→Policies Audit from the NFM-P main menu. The Policy Audit - audit status (Edit) form opens.

2

Configure the required parameters.

3

Perform one of the following steps:

a. To choose policy groups and policy types to be included in the audit, go to Step 4.

b. If all policy groups and policy types are included in the audit, go to Step 10 to configure which NEs to include in the audit.

c. If all policy groups and policy types and the entire network is included in the audit, go to Step 11.

4

Click on the Policy Group Selection tab.

5

Right-click on the Policy Audit icon and choose Select Policy Groups from the contextual menu. The Select Policy Groups form opens.

6

Select policy groups as required and click OK.The chosen policy group keys appear below the Policy Audit icon.

7

Perform one of the following steps:

a. To choose which policy types within the selected groups are included in the audit, go to Step 8.

b. If all policy types within the selected groups are included in the audit, go to Step 10.

8

Right-click on a policy group icon and choose Select Policy types. The Select Policy types - Policy Audit form opens.

9

Select the policy types as required and click OK. The chosen policy type icons appear below the Policy Audit icon.

10

Select NEs to include in the audit, if required:

1. Click on the Network Element Selection tab to select an NE, or group of NEs to be audit.
2. Click Add. The Select Site form opens.
3. Click Search and choose the NEs to be included in the audit.
4. Save your changes and close the form.

11

Click Start Audit to proceed with the policy audit. Click Stop Audit to interrupt the audit while it is in progress. A discrepancy between a global policy and a local instance of the policy generates an alarm. Monitor the dynamic alarm window to view alarms that are generated as a result of the policy audit.

12

Double-click on the alarm in the alarm window. The Alarm Info form opens.

13

Click View Alarmed Object. The Global Policy (Edit) form opens.

14

Perform Step 6 to Step 8 of 49.24 “To identify differences between a global and local policy or two local policies” (p. 1503) to locate the discrepancies between the local and global policies.

15

Close all open forms.

END OF STEPS

49.21 To perform a policy audit for global policy

49.21.1 Purpose

An audit compares all local policies with the associated global policy. A policy audit can be performed on all NEs in the network, or limited to a specific NE or group of NEs. All NEs are included in the audit unless they are explicitly chosen. A policy audit cannot be started when another policy audit is in progress.

CAUTION

Service Disruption

Performing this procedure is potentially service-affecting.

If NEs are not specified, all NEs that are in the users span of control are included in the policy audit.

Note: Validation is performed to prevent policies from being audited if the user span of control prohibits the operation.

If a user performs an audit on objects that are not within their span of control, the audit is aborted and a error message is displayed. The error message indicates which objects are prohibited.

49.21.2 Steps

1

Choose Policies→ *Policy_Type* from the NFM-P main menu, where *Policy_Type* is the type of policy that you want to audit. The appropriate policies manager form opens.

2

Click Search and choose a policy in the list.

3

Click Properties. The *Policy_Name* Global Policy (Edit) form opens.

4

Click on the Local Definitions tab. A list of local policies is displayed.

5

Perform one of the following:

a. To audit a specific local policy or a group of local policies, go to Step 6.

b. If all local policies in the list are included in the audit, go to Step 7.

6

Select one or multiple local policies that you want to include in the audit.

7

Click Policy Audit. A Policy Audit (Edit) form opens.

8

Click on the General tab.

9

Configure the required parameters.

10

Click Start Audit to proceed with the policy audit. Click Stop Audit to interrupt the audit while it is in progress. A discrepancy between a global policy and a local instance of the policy generates an alarm. Monitor the dynamic alarm window to view alarms that are generated as a result of the policy audit.

11

Double-click on the alarm in the alarm window. The Alarm Info form opens.

12

Click View Alarmed Object. The Global Policy (Edit) form opens.

13

Perform Step 6 to Step 8 of 49.24 “To identify differences between a global and local policy or two local policies” (p. 1503) to locate the discrepancies between the local and global policies.

14

Close all open forms.

END OF STEPS

49.22 To perform a policy audit for multiple global policies with same type

49.22.1 Purpose

An audit compares all local policies with the associated global policies. A policy audit can be performed on all NEs in the network, or limited to a specific NE or group of NEs. All NEs are included in the audit unless they are explicitly chosen. A policy audit can be performed on one or multiple global policies with the same type. A policy audit cannot be started when another policy audit is in progress.

CAUTION

Service Disruption

Performing this procedure is potentially service-affecting.

If NEs are not specified, all NEs that are in the users span of control are included in the policy audit.

Note: Validation is performed to prevent policies from being audited if the user span of control prohibits the operation.

If a user performs an audit on objects that are not within their span of control, the audit is aborted and a error message is displayed. The error message indicates which objects are prohibited.

49.22.2 Steps

1

Choose Policies→ *Policy_Type* from the NFM-P main menu, where *Policy_Type* is the type of policy that you want to audit. The appropriate policies manager form opens.

2

Click Search and choose one or multiple policies in the list.

3

Click Policy Audit. A Policy Audit (Edit) form opens.

4

Click Add and select a policy or multiple policies in the list.

5

Click OK. The Policy Audit (Edit) form refreshes with the selected policies.

6

Click on the General tab.

7

Configure the required parameters.

8

Perform one of the following:

a. To audit selected global policies on selected NEs, go to Step 9.

b. To audit selected global policies on the entire network, go to Step 10.

9

Select NEs to include in the audit, if required.

1. Click on the Network Element Selection tab to select an NE, or group of NEs to be audit.
2. Click Add.The Select Site form opens.
3. Click Search and choose the NEs to be included in the audit.
4. Save your changes and close the form.

10

Click Start Audit to proceed with the policy audit. Click Stop Audit to interrupt the audit while it is in progress. A discrepancy between a global policy and a local instance of the policy generates an alarm. Monitor the dynamic alarm window to view alarms that are generated as a result of the policy audit.

11

Double-click on the alarm in the alarm window. The Alarm Info form opens.

12

Click View Alarmed Object. The Global Policy (Edit) form opens.

13

Perform Step 6 to Step 8 of 49.24 “To identify differences between a global and local policy or two local policies” (p. 1503) to locate the discrepancies between the local and global policies.

14

Close all open forms.

END OF STEPS

49.23 To schedule a policy audit

49.23.1 Purpose

Perform this procedure to schedule a policy audit to perform regular audits on selected policies and NEs. Prior to scheduling a policy audit, you must first create the NFM-P-based schedule; see 5.6 “To configure an NFM-P-based schedule” (p. 193) .

An audit compares all local policies with the associated global policy. A policy audit can be performed on all NEs in the network, or limited to a specific NE or group of NEs. All NEs are included in the audit unless they are explicitly chosen. A policy audit cannot be started when another policy audit is in progress.

CAUTION

Service Disruption

Performing this procedure is potentially service-affecting.

If NEs are not specified, all NEs that are in the users span of control are included in the policy audit.

Note: Validation is performed to prevent policies from being audited if the user span of control prohibits the operation.

If a user performs an audit on objects that are not within their span of control, the audit is aborted and a error message is displayed. The error message indicates which objects are prohibited.

Note: You can configure the maximum number of scheduled audits that are stored for a local policy by setting the Max Number Of Audit Result stored per Local Policy parameter in the System Preferences. See the *NSP System Administrator Guide* for more information.

49.23.2 Steps

1

Choose Tools→Policies Audit from the NFM-P main menu. The Policy Audit (Edit) form opens.

2

Configure the required parameters.

3

Click Schedule Audit and choose Create. The Policy Audit Scheduled Tasks (Create) form opens.

4

Configure the required parameters.

5

Click Select in the Schedule panel and choose a schedule from the Select Schedule - Policy Audit Scheduled tasks form.

6

Click OK and close the form. The Policy Audit Scheduled Tasks (Create) form reappears.

7

Click on the Audit tab.

8

Select one or more policy types that you want to include in the audit from the Selected Policies panel.

9

Select one or more NEs that you want to include in the audit from the Selected NEs panel.

10

Click Apply. The Policy Audit Scheduled Tasks (Create) form is updated with the changes.

11

Click Start Audit or Stop Audit operations, as required. The User Activity displays the creation, modification, start and stop operations of the scheduled audit.

12

Once a scheduled policy audit is complete, click Schedule Audit and choose View from the menu to access the audit results. The Policy Audit Schedule Tasks list form opens.

13

Select a scheduled task from the list and click Properties.The Policy Audit Scheduled Tasks (Edit) form opens.

14

Click on the Audit Scheduled Task Results tab to view a list of results.

15

Select an entry and click Properties to review specific results. The Viewing Old Audit Result indicator determines if you are viewing the latest audit result or not.

16

Close all open forms.

END OF STEPS

49.24 To identify differences between a global and local policy or two local policies

49.24.1 Purpose

Global policies can be distributed to many varying NE types. Local policy audits are performed based on absolute database records. In some cases, this means that when you audit a local policy, a change may be indicated on the associated global policy that does not apply specifically to this local policy. The changed global property may simply not be relevant to the NE associated with this local policy.

For example, a Subscriber Profile global policy contains an HSMDA QoS tab. If a change has been made to a property on this tab in the global policy, but the local policy you are auditing applies to an NE that does not support HSMDA, then the following will occur. When you perform the local audit against the global policy, the global policy form will indicate that there is a difference between the two by displaying an arrow icon on its HSMDA QoS tab. However, since the local policy's NE does not support HSMDA, the local policy form will not display an HSMDA tab for you to compare with. Any such indicated global changes are irrelevant to the local policy and can be ignored.

49.24.2 Steps

1

Choose Policies→*Policy_type* from the NFM-P main menu, where *Policy_type* is the type of policy that you want to search for global and local differences. The Manage *Policy_type* form opens.

2

Choose Local from the Policy scope drop-down menu.

3

Click Select and choose a NE in the list and click OK.

4

Click Search and choose the local policy that you want to compare with another policy.

5

Click Properties. The *Policy_type* (Edit) form opens.

6

Click Local Audit On.

Note: You can cancel the local audit at any time by clicking on the Action button and choosing Local Audit Off on the *Policy_type* (Edit) form.

7

From the Policy scope drop-down menu:

a. Choose Global and click OK. The global opens for comparison.

b. Choose Local and perform the following:

1. Click Select to choose an NE. The Select a Network Element form opens.
2. Select the required NE from the list and click OK. The local policy opens for comparison.

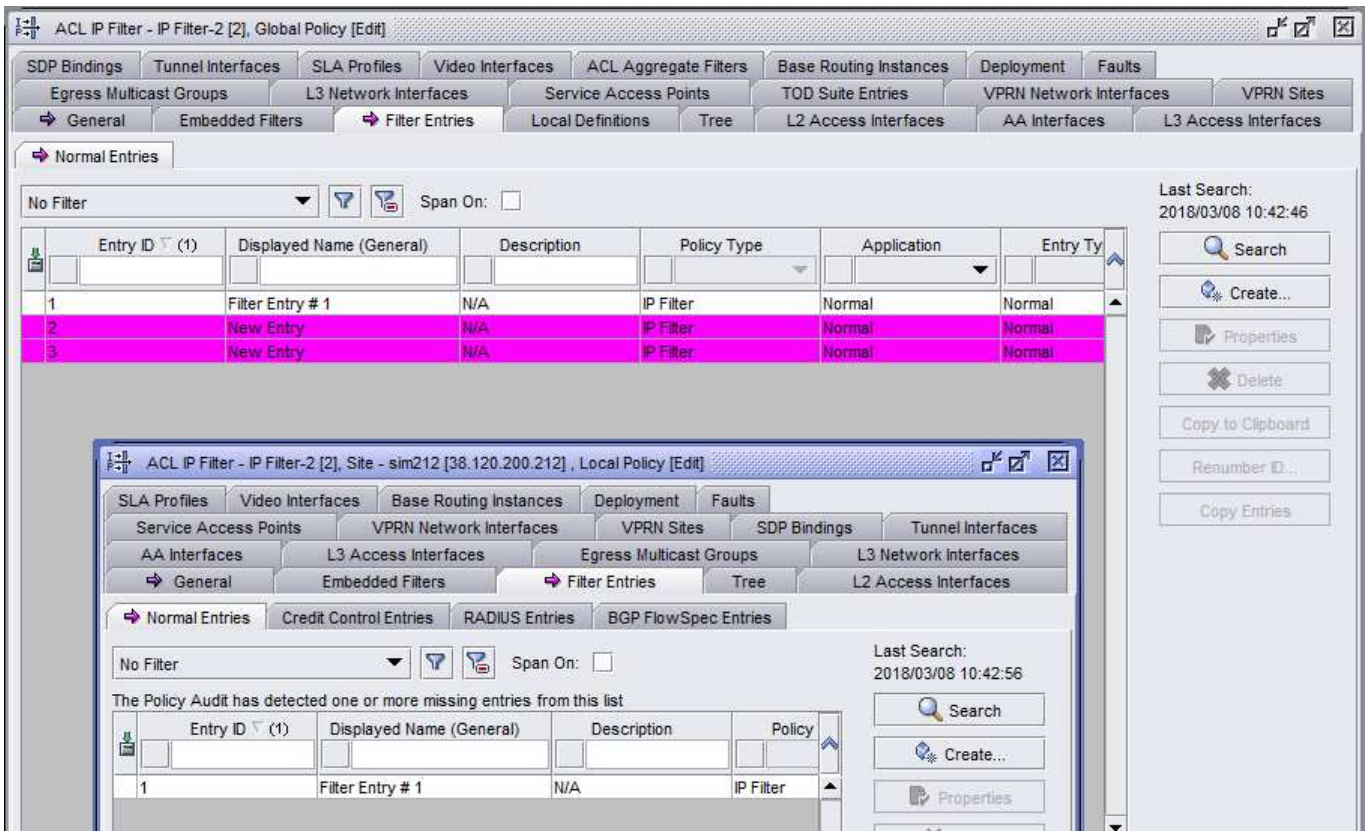
8

Perform one of the following steps, as applicable:

a. View the differences between the policies by clicking on the tabs that are highlighted with an

arrow icon, which indicates that differences exist between the forms. A purple arrow indicates that an attribute is set differently between the two audited forms. A pink arrow indicates that an attribute is missing. A purple arrow in a pink background rectangle indicates that both conditions are occurring. In lists, new entries are highlighted in pink and modified entries are highlighted in purple. Messages are also provided above a list to help isolate the differences on the affected form. The example shown in Figure 49-1, “Policy audit mismatches” (p. 1504) demonstrates some of these various conditions and indications.

Figure 49-1 Policy audit mismatches



b. For certain policy types, you can click on a Tree tab on the local or global policy form. New items are highlighted in pink text. Modified items in the tree are highlighted in purple text.

9

Close the local and global *Policy_type* (Edit) forms.

END OF STEPS

50 QoS policies

QoS policy types

50.1 Overview

50.1.1 General Information

QoS policies define how network traffic is shaped and queued on one or more NEs. You can use the NFM-P to create QoS policies that regulate data throughput on the following:

- equipment; for example, ports and MDAs
- routing and forwarding points; for example, access and network interfaces

The NFM-P provides QoS policies that are specific to 7210 SAS and 7250 IXR NEs.
See 50.23 “7210 SAS QoS policies” (p. 1528) and 50.24 “7250 IXR QoS policies” (p. 1534) in this chapter.

50.2 SAP access ingress policies

50.2.1 General Information

SAP access ingress policies are applied to access interfaces and specify QoS on ingress.

SAP access ingress policies define ingress service forwarding class queues and map flows to those queues. When an access ingress policy is created, it always has two queues defined that cannot be deleted: one for the default unicast traffic and one for the default multipoint traffic. These queues exist within the definition of the policy. The queues only get instantiated in hardware when the policy is applied to an access interface. In the case where the service does not have multipoint traffic, the multipoint queue is not instantiated.

In the simplest access ingress policy, all traffic is treated as a single flow and mapped to a single queue, and all flooded traffic is treated with a single multipoint queue.

The required SAP access ingress policy elements include:

- a unique access ingress policy ID
- an exclusive scope for one-time use, or a template scope for use with multiple SAPs and interfaces
- at least one default unicast forwarding class queue
- at least one multipoint forwarding class queue

The optional SAP access ingress policy elements include:

- additional unicast queues up to a total of 8 for each of the 8 forwarding classes
- 8 HSMDA queues that are automatically created when the policy is created; HSMDA queues are only used by HSMDA SAPs

- additional multipoint queues up to 3 per forwarding class for each type of multipoint traffic (broadcast, multicast and destination unknown unicast)
- QoS policy match criteria to map packets to a forwarding class
- A policer to control traffic flow rate
- A dynamic policer to specify traffic flow rate for dynamically-spawned policers

Each queue can have unique queue parameters to allow individual policing and rate shaping of the flow mapped to the forwarding class. Mapping flows to forwarding classes is controlled by comparing each packet to the match criteria in the policy.

There is one default SAP access ingress policy. The default policy gives all traffic equal priority with the same chance of being sent or dropped during periods of congestion.

Note: The NFM-P supports the configuration of HQoS scheduling mechanisms. HQoS provides the ability to rate limit across multiple queues from single or multiple access interfaces for a specific customer. The building blocks for HQoS include access ingress, access egress, and scheduler policies.

See 70.12 “Sample network QoS configuration” (p. 1942) for a sample service configuration using HQoS.

50.2.2 Policy override

You can override some or all settings associated with an access ingress policy on an L2 or L3 access interface, SLA profile, or subscriber profile. See 50.97 “To configure QoS policy overrides on an L2 or L3 access interface” (p. 1654).

Note: You can override SAP access ingress policies that have the Scope parameter set to template; see 50.28 “To configure a SAP access ingress policy” (p. 1538).

Tagged IP/IPv6 match entry overrides

In a SAP access ingress policy, you can assign a numbered tag identifier to IP and IPv6 match criteria entries. When the SAP access ingress policy is assigned to an L2 or L3 SAP, you can configure a QoS policy override to use the tag identifiers to select tagged entries with the same identifier. Any untagged entries in the policy are still valid on the SAP. The IP or IPv6 Criteria Type in the SAP access ingress policy must be set to Tagged Entries.

The following task flow lists the basic steps required to enable tagged IP/IPv6 match entry overrides.

1. Plan the match criteria and tag mapping as required.
2. Create a SAP access ingress policy and set the IP or IPv6 Criteria Type parameters in the policy to Tagged-Entries; see 50.28 “To configure a SAP access ingress policy” (p. 1538).
3. In the same policy, create IP or IPv6 match criteria entries and assign tag IDs to the entries.
4. Distribute the policy to NEs that support tagged match entries.
5. For the required L2/L3 SAPs, configure a QoS policy override to define the tag IDs to use on the SAP; see50.97 “To configure QoS policy overrides on an L2 or L3 access interface” (p. 1654).

50.2.3 Forwarding classes

The NFM-P supports the configuration of eight forwarding classes and class-based queuing or policing on the managed devices. Each forwarding class is only important in relation to other forwarding classes. A forwarding class provides NEs with a method to determine the relative importance of one packet over another packet in a different forwarding class.

Queues are created for a specific forwarding class to determine how the queue output is scheduled into the switch fabric and the type of parameters that the queue accepts. The forwarding class of the packet, and the in-profile and out-of-profile states, determine how the packet is queued and handled at each hop along its path to a destination egress point. Forwarding classes may also be associated with policers instead of queues. Eight forwarding classes are supported. The table below lists the default definitions for the supported forwarding classes.

Although all forwarding classes support profile marking, it is a good network engineering practise to ensure that all high priority forwarding classes are in-profile (CIR=PIR) and all low priority forwarding classes are out-of-profile (PIR > CIR=0). This way, distinguishing packets as in-profile or out-of-profile only occurs for assured class types.

Table 50-1 Forwarding classes

Forwarding class ID	Forwarding class name	Forwarding class designation	DiffServ name	Class type	Intended
7	Network control	nc	nc2	High priority	For network control traffic
6	High-1	h1	nc1		For a second network control class or delay/jitter sensitive traffic
5	Expedited	ef	ef		For delay/jitter sensitive traffic
4	High-2	h2	h2		For delay/jitter sensitive traffic
3	Low-1	l1	af2	Assured	For assured traffic; default priority for network management traffic
2	Assured	af	af1		For assured traffic
1	Low-2	l2	cs1	Best effort	For best effort traffic
0	be	be			

50.2.4 Forwarding subclasses

You can use forwarding subclasses for additional access ingress packet classification. One or more subclasses can be associated with each forwarding class. The designations for forwarding subclasses are the same as those for the forwarding classes listed in Table 50-1, “Forwarding classes” (p. 1509) . Each subclass assumes the behavior of its parent forwarding class. and in combination with the forwarding class provides a greater range of access ingress QoS classification possibilities.

50.2.5 Enabling ETH-LMM Y.173 statistics based on QoS forwarding classes

The ETH-LMM Y.1731 approach to Ethernet frame loss measurements allows for the collection of frame counters in order to determine the unidirectional frame loss between point-to-point ETH-CFM MEP peers. See the supported NE OAM and Diagnostics guide for more information about the ETH-LMM Y.1731 protocol.

You can enable the collection of ETH-LMM Y.1731 statistics on the NFM-P based on eight forwarding classes (either profile aware, or profile unaware) for the following Service types: EPIPE, VPLS, VPRN, and IES. Use the Collect ETH-LMM FC Stats parameter or Collect ETH-LMM FC Stats in Profile parameter on the supported Services navigation tree toolbar to enable ETH-LMM Y.1731 statistics collection as follows:

- Service Type→Sites→L2 or L3 Access Interfaces→SAP. On the Port OAM tab, ETH-CFM sub-tab, select the LMM Session Stats Collection panel and configure the parameters.
- Service Type→Sites→Spoke SDP Bindings. On the Service OAM tab, ETH-CFM sub-tab, select the LMM Session Stats Collection panel and configure the parameters.

See the XML API Reference for information about configurable parameters, their applicability, and the NFM-P GUI forms from which the parameters can be accessed.

50.2.6 Policers

You can add a policer to an access ingress policy to provide traffic flow limiting. Policers are associated with the forwarding classes defined in the access ingress policy. Policers can also be linked to a policer control policy, which maintains a hierarchy of multiple policer objects in the NFM-P system. Policers are linked to policer control policies by means of an arbiter. For more information, see 50.16 “Policer control policies” (p. 1524).

When policers are configured in an access ingress policy, they can be used to generate statistics. The type of statistics generated depends on the Stats Mode. The following table lists the options for counter allocation when generating statistics:

Table 50-2 Stats Mode options

Option	Description
No Override	The system does not override the value of Stats Mode set in the policer control policy.
Minimal	The system creates one offered-output counter in the network processor and one discard counter in the QChip. Packet priority, initial profile, and CIR profile output are ignored, and are not individually visible in the policer statistics. Use the Minimal option when only basic policer accounting is required.
No Stats	The system does not allocate any counters to the policer. The absence of counters does not affect the operation of the policer. Use the No Stats option when policer accounting is not required. You cannot enable this option if the policer has a parent arbiter assigned to it.

Table 50-2 Stats Mode options (continued)

Option	Description
Offered Limited Capped CIR	The system creates two offered-output counters in the network processor and two discard counters in the QChip. Use the Offered Limited Capped CIR option when ingress packets are being classified as either in-profile, or ignored when the traffic is in excess of CIR. Packet priority is ignored, and is not separated in the accumulated statistics.
Offered Limited Profile CIR	The system creates three offered-output counters in the network processor and three discard counters in the QChip. Use the Offered Limited Profile CIR option when ingress color-aware profiling is in use but packets are not being classified as in-profile. In most color-aware instances, only undefined and explicit out-of-profile packets are used in service offerings. If an in-profile classified packet is offered to the policer, it is included in the offered-undefined statistic. Packet priority is ignored, and is not separated in the accumulated statistics.
Offered Priority CIR	The system creates four offered-output counters in the network processor and four discard counters in the QChip. Use the Offered Priority CIR option when the ingress policer is used on a non-color-aware mode (all ingress packets have an undefined initial profile), but packet priority input and CIR state output visibility is required.
Offered Priority No CIR	The system creates two offered-output counters in the network processor and two discard counters in the QChip. Use the Offered Priority No CIR option when ingress packet priority (high profile and low profile classification) accounting is the primary requirement. The initial and output profile of the packets offered to the policer is ignored in the offered, discarded, and forwarded statistics. This mode does not inhibit the function of CIR on the ingress policer and it does not prevent explicit in-profile and out-of-profile classification for packets offered to the policer.
Offered Profile Capped CIR	The system creates three offered-output counters in the network processor and three discard counters in the QChip. Use the Offered Profile Capped CIR option when ingress packets are being marked as either in-profile, or out-of-profile when the traffic is in excess of CIR. Packet priority is ignored, and is not separated in the accumulated statistics.
Offered Profile CIR	The system creates four offered-output counters in the network processor and four discard counters in the QChip. The Offered Profile CIR option is similar to the Offered Limited Profile CIR option, except that it includes the in-profile packet classification along with the out-of-profile and undefined-profile classifications. As with the Offered Limited Profile CIR option, packet priority is ignored and not separated in the statistics.

Table 50-2 Stats Mode options (continued)

Option	Description
Offered Profile No CIR	The system creates two offered-output counters in the network processor and two discard counters in the QChip. Use the Offered Profile No CIR option when all ingress packets are either in-profile or out-of-profile. Undefined-profile packets are treated as offered out from a statistics perspective. Undefined-profile packets are affected by the current state of the policer's CIR and are output as either in-profile or out-of-profile, depending on the CIR output state. The offered, discarded, and forwarded statistics do not reflect this behavior because they are based on the initial profile of the packets.
Offered Total CIR	The system creates two offered-output counters in the network processor and two discard counters in the QChip. Use the Offered Total CIR option when ingress priority and initial profile visibility is not required, and CIR profiling is in use. In many cases, all packets offered to a policer are of one priority level and all have the same initial profile (in-profile, out-of-profile, or undefined-profile). This option is different from the Minimal option because it provides visibility into the policer's CIR output.

50.2.7 Traffic mapping

You can specify the mapping between the ingress traffic and the ingress queue. Mapping is optional and can be based on combinations of customer QoS marking (dot1p, DSCP, LSP-EXP, and Precedence), and IP criteria, Ipv6 criteria, or MAC criteria. See the table below.

Adding an LspExp rule to a policy forces packets that match the specified MPLS LSP EXP criteria to override the existing forwarding class and enqueuing priority, based on the parameters specified in the LspExp rule. This functionality allows geographically distributed ISP sites to establish site-to-site interconnection service through a backbone network using VPLS/VLL. Each ISP site PE router connects to a 7x50 Ethernet L2 SAP in the backbone network, and traffic is encapsulated in a VPLS/VLL service tunnel. A maximum of eight LspExp rules are allowed on a single access ingress policy.

Table 50-3 SAP access ingress policy traffic mapping

Tab	Function
Dot1p	Maps the dot1p value of the ingress traffic to the ingress queue ID
DSCP	Maps the DSCP value of the ingress traffic to the ingress queue ID
LspExp	Maps the EXP value of the ingress traffic to the ingress queue ID
Precedence	Maps the precedence value of the ingress traffic to the ingress queue ID
IP Match Criteria	Maps the IP Match Criteria of the ingress traffic to the ingress queue ID
IPv6 Match Criteria	Maps the IPv6 Match Criteria of the ingress traffic to the ingress queue ID

Table 50-3 SAP access ingress policy traffic mapping (continued)

Tab	Function
MAC Match Criteria	Maps the MAC Match Criteria of the ingress traffic to the ingress queue ID

50.3 SAP access egress policies

50.3.1 General Information

SAP access egress policies are applied to access egress interfaces and specify QoS on egress.

SAP access egress policies define egress service queues and map forwarding class flows to queues. In the simplest access egress policy, all forwarding classes are treated like a single flow and mapped to a single queue.

The required SAP access egress policy elements include:

- a unique access egress policy ID
- at least one defined default queue
- an exclusive scope for one-time use, or a template scope for use with multiple SAPs and interfaces

The optional SAP access egress policy elements include:

- additional queues up to a total of 8 separate queues for each of the 8 supported forwarding classes
- IEEE 802.1p priority value remarking based on forwarding class
- a policer to control traffic flow rate
- a dynamic policer to specify traffic flow rate for dynamically-spawned policers
- a policer to specify the high drop tail and high plus drop tail burst size (by percentage) from the specified MBS

Each queue in a policy is associated with one or more of the supported forwarding classes. Each queue can have its individual queue parameters allowing individual rate shaping of the forwarding classes mapped to the queue. More complex service queuing models are supported, where each forwarding class is associated with a dedicated queue.

The forwarding class determination per service egress packet is determined at ingress. If the packet ingresses the service on the same managed device, the service ingress classification rules determine the forwarding class of the packet. If the packet was received over a service tunnel, the forwarding class is marked in the tunnel transport encapsulation.

There is one default SAP access egress policy. The default policy gives all traffic equal priority with the same chance of being sent or dropped during periods of congestion.

50.3.2 Policy override

You can override some or all settings associated with an access egress policy on an L2 or L3 access interface, SLA profile, or subscriber profile. See 50.97 “To configure QoS policy overrides on an L2 or L3 access interface” (p. 1654) for more information.

Note: You can override SAP access egress policies that have the Scope parameter set to template. See 50.30 “To configure a SAP access egress policy” (p. 1550) for more information.

50.3.3 Policers

You can add a policer to an access egress policy to provide traffic flow limiting. Policers are associated with the forwarding classes defined in the access ingress policy. Policers can also be linked to a policer control policy, which maintains a hierarchy of multiple policer objects in the NFM-P system. Policers are linked to policer control policies by means of an arbiter. For more information, see 50.16 “Policer control policies” (p. 1524).

When policers are configured in an access egress policy, they can be used to generate statistics. The type of statistics generated depends on the Stats Mode. Table 50-2, “Stats Mode options” (p. 1510) lists the options for counter allocation when generating statistics.

50.3.4 Traffic mapping

You can specify the mapping between the egress traffic and the egress queue. Mapping is optional and can be based on combinations of customer QoS marking (dot1p, DSCP and precedence), IP/IPv6 criteria, or MAC criteria, as shown in the following table.

Table 50-4 SAP access egress policy traffic mapping

Tab	Function
Dot1p	Maps the dot1p value of the egress traffic to the egress queue ID
DSCP	Maps the DSCP value of the egress traffic to the egress queue ID
Precedence	Maps the precedence value of the egress traffic to the egress queue ID
IP Match Criteria	Maps the IP Match Criteria of the egress traffic to the egress queue ID
IPv6 Match Criteria	Maps the IP Match Criteria of the egress traffic to the egress queue ID

Adding an LspExp rule to a policy forces packets that match the specified MPLS LSP EXP criteria to override the existing forwarding class and enqueuing priority, based on the parameters specified in the LspExp rule. This functionality allows geographically distributed ISP sites to establish site-to-site interconnection service through a backbone network using VPLS/VLL. Each ISP site PE router connects to a 7x50 Ethernet L2 SAP in the backbone network, and traffic is encapsulated in a VPLS/VLL service tunnel. A maximum of eight LspExp rules are allowed on a single access ingress policy.

50.4 ATM QoS policies

50.4.1 General Information

ATM QoS policies are used to specify how ATM traffic is managed, by using ATM traffic descriptors such as service category and shaping. You can create up to 2000 ATM QoS policies per router. ATM QoS policies are assigned to access interfaces.

The following table describes ATM service categories and typical applications:

Table 50-5 Service categories

Service category	Application
CBR	For applications such as voice and video that require high priority and have a known peak transmission rate. CBR guarantees bandwidth for constant bit rate traffic, very low cell loss, and very low delay. For circuit-switched data paths, the Service Category parameter is set to the CBR option and cannot be changed.
RT-VBR	For time-sensitive applications, such as voice and video, that have unpredictable, bursty traffic characteristics. Guarantees very low cell loss and very low delay. The NFM-P handles RT-VBR and NRT-VBR identically for routing and rerouting purposes, and uses both to calculate the total VBR bandwidth usage. You cannot exceed the physical speed of the ATM interface when setting the traffic descriptors.
NRT-VBR	For applications such as video and frame relay that have known or predictable traffic characteristics. Guarantees low cell loss and low delay. You cannot exceed the physical speed of the ATM interface when setting the traffic descriptors.
UBR	For applications that do not require guarantees of low cell loss or low delay. UBR paths emulate the connectionless services provided by conventional bridged and routed data networks.

50.5 Post Policer Mapping policies

50.5.1 General information

You can create a Post Policer Mapping policy to:

- change the access egress packet's forwarding class to redirect the packet to an alternate queue than the ingress forwarding class determination would have used
- change the access egress packet's profile (for example, in or out) to modify the congestion behavior within the egress queue

In both cases, egress marking decisions will be based on the new forwarding class and profile as opposed to the egress forwarding class or profile. The exception is when ingress remarking is configured. An ingress remark decision will not be affected by egress forwarding class or egress profile overrides.

See 50.36 "To configure a Post Policer Mapping policy" (p. 1563) for more information. Once configured, you can apply the Post Policer Mapping policy to a SAP Access Egress Policy; see 50.30 "To configure a SAP access egress policy" (p. 1550).

50.6 MC MLPPP ingress and egress QoS profiles

50.6.1 General Information

MC MLPPP ingress QoS profiles are used to configure the reassembly timeout for each of the four MLPPP classes. You can create up to 128 ingress QoS profiles per NE.

MC MLPPP egress QoS profiles are used to specify queue and queue scheduling parameters for each of the four MLPPP classes.

50.7 MCFR ingress and egress QoS profiles

50.7.1 General Information

MCFR ingress QoS profiles are used to configure the reassembly timeout for each of the four MLFR classes. You can create up to 128 ingress QoS profiles per NE.

MCFR egress QoS profiles are used to specify queue and queue scheduling parameters for each of the four MLFR classes.

50.8 Network policies

50.8.1 General information

Network policies are applied to network interfaces or access uplink ports and specify QoS on egress and ingress.

On ingress, a network policy maps incoming DSCP and EXP values to forwarding class and profile state for traffic received from the core network. On egress, the policy maps forwarding class and profile state to DSCP and EXP values for traffic to be transmitted into the core network.

50.9 Network queue policies

50.9.1 General information

Network queue policies are applied to network ports, uplink ports, or daughter cards.

Network queue policies determine:

- the default burst allocations for queues based on the queue’s forwarding class
- the CIR, PIR, FIR, and burst size parameters for the queue

Note: You cannot use the same network queue policy on devices at different releases.

For network egress, a network burst policy is associated with the network port buffer pool. For network ingress, the network burst policy is associated the network ingress buffer pool of the daughter card.

Network queue policies support multipoint queues and a variable number of forwarding classes. When you want to deploy a network queue policy to devices of different types, you may need to create an instance of the policy for each NE type. Policies that are configured for multipoint queues

and a variable number of forwarding classes are deployed only to devices that support the functionality. Modification of an existing policy results in automatic deployment to participating NEs, so must be done with consideration of the policy features and devices involved.

CIR, PIR, and FIR

CIR defines the rate that packets are considered in-profile by the system. In-profile packets are preferentially queued by the system at egress and at subsequent next-hop devices on which the packet can traverse. To be properly handled as in- or out-of-profile throughout the network, the packets must be marked accordingly for profiling at each hop.

PIR specifies the peak information rate for an ingress or egress daughter card queue to transmit packets through the switch fabric or out an egress interface. On ingress, the PIR defines the maximum rate at which the queue can transmit packets through the switch fabric. On egress, the PIR defines the maximum rate at which the queue can transmit packets out an egress interface. The specified PIR value does not guarantee that the queue can transmit at the intended rate. The actual rate sustained by the queue can be limited by oversubscription factors or the available bandwidth.

FIR configuration allows the scheduling priority to be modified independently from the marking/drop precedence of the packets being scheduled from the queue. Specifically, a higher queue scheduling priority can be assigned without modifying the queue's CIR.

Burst size

The burst size for a queue determines whether the queue has exhausted its reserved buffer pool space while queuing packets. When the queue has exceeded the amount of buffer pool space considered in reserve for the queue, it must contend with other queues for the available shared buffer space in the buffer pool. Access to this shared pool space is controlled by the RED slope.

Two RED slopes are maintained in each buffer pool. A high-priority slope is used by in-profile packets. A low-priority slope is used by out-of-profile packets. All nc forwarding class packets are considered in-profile. Assured packets are handled by their in-profile and out-of-profile markings. All be packets are considered out-of-profile.

Premium queues should be configured such that the committed burst size is sufficient to prevent shared buffering of packets. This is handled by the CIR scheduling of premium queues and the overall small amount of traffic on the class. Premium queues in a properly designed system drain before all others, limiting their buffer utilization. The RED slopes detect congestion conditions and work to discard packets and slow down random TCP session flows through the queue.

The resultant committed burst size can be larger than the maximum burst size. This results in a portion of the committed burst size for the queue unused and should be avoided.

50.10 Shared-queue policies

50.10.1 General Information

A shared-queue policy can be applied to daughter cards for optional use by SAPs. The NFM-P provides one shared-queue policy for all eight default queues. Each queue is associated with a default forwarding class.

Shared-queue QoS policies can be implemented to facilitate queue consumption on a daughter card; for example, when VPLS, IES, and VPRN services are scaled on one card. Instead of allocating multiple hardware queues for each unicast queue that is defined in an access ingress policy, SAPs with the shared-queuing feature enabled only allocate one hardware queue for each unicast queue.

However, the total amount of traffic throughput at ingress is reduced because ingress packets that are serviced by a shared-queuing SAP are recirculated for additional processing. This can reduce the available bandwidth by half. Shared queuing can also add latency. Network planners should consider these restrictions when they try to scale services on one daughter card.

The following table lists the queue IDs used by the NFM-P to identify the shared-queue types.

Table 50-6 Shared queue types

Shared-queue ID	Shared-queue type
1 to 8	Unicast
9 to 16	Multicast
17 to 25	Broadcast
26 to 32	Unknown

Note: Queue IDs 9 to 32 are also known as multipoint shared queues.

50.10.2 Shared policer output queue

To support hierarchical policing, a default policer output queue policy is applied automatically to each IOM that supports ingress policing. In the NFM-P, this shared policer output queue is modeled in the same manner as the existing default shared queue, except that it has only 16 queues.

50.10.3 Multipoint shared-queue policies

Multipoint shared queues minimize the number of multipoint queues that are created for the following:

- ingress VPLS, IES, or VPRN SAPs
- ingress subscriber SLA profiles

Typically, ingress multipoint packets are handled by multipoint queues that are created for each SAP or subscriber SLA profile instance. In some cases, the number of SAPs or SLA profile instances are sufficient for the in-use multipoint queues to represent many thousands of queues on an ingress forwarding plane. If multipoint shared queuing is enabled for the SAPs or SLA profile instances on the forwarding plane, the multipoint queues are not created. Instead, the ingress multipoint packets are handled by the unicast queue that is mapped to the forwarding class of the multipoint packet.

Multipoint shared queues are a superset of shared queuing. With shared queuing on a SAP or SLA profile instance, only unicast packets are processed twice; once for the initial service-level queuing and a second time for switch fabric destination queuing. Shared queuing does not affect multipoint

packet handling. Multipoint packet handling in normal service queuing is the same as shared queuing. Shared queuing for unicast packets is automatically enabled when you enable multipoint shared queuing.

The NFM-P supports multipoint shared-queue policies for the following services on the 7750 SR, 7450 ESS:

- Layer 2: VPLS and MVPLS
- Layer 3: IES and VPRN

See the following chapters for more information about enabling multipoint shared queues for a service:

- Chapter 77, “VPLS management ” for VPLS and MVPLS
- Chapter 78, “IES management” for IES
- Chapter 79, “VPRN service management” for VPRN

You can also enable multipoint shared queues in an existing shared-queue policy. See the procedures in this chapter for more information about editing shared-queue policies.

50.11 Slope policies

50.11.1 General Information

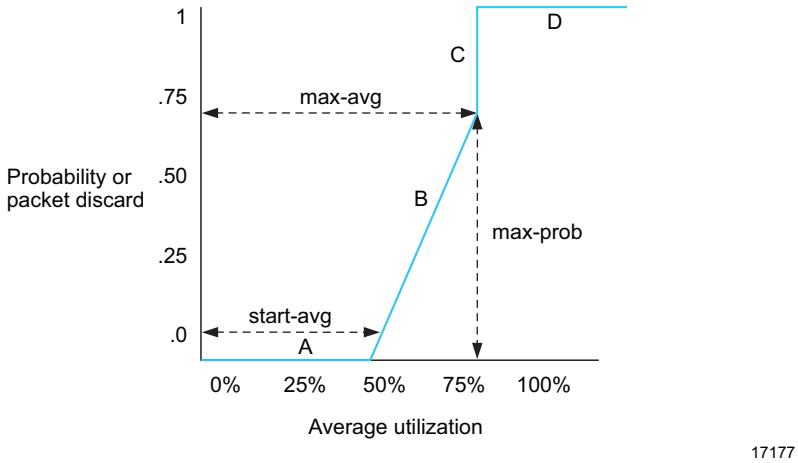
Slope policies are applied to access ports, network ports, and network daughter cards.

Slope policies define weighted RED (WRED) slope characteristics for buffer pools. Low-priority and high-priority slopes are specified when you configure a slope policy. If a slope policy is not explicitly specified, a default policy is applied.

Each buffer pool supports a high-priority, a low-priority RED slope, an Exceed Slope, and a HighPlus Slope. The high-priority RED slope manages access to the shared portion of the buffer pool for the high-priority or in-profile packets. The low-priority RED slope manages access to the shared portion of the buffer pool for low-priority or out-of-profile packets. The Exceed slope handles the exceeded profile traffic congestion control at the pool and megapool level. The Exceed slope is only used for exceed profile traffic when it is not shutdown. The defaults for the Exceed slope parameters should be set so that they are lower than the low slope in the slope hierarchy. Finally, the HighPlus Slope handles the inplus profile traffic congestion control. A HighPlus Slope policy can be applied to pool-per-queue queues in an egress queue group template, which in turn can be applied at a network egress port. The HighPlus Slope is also supported in a slope policy applied to the egress WRED megapool. The values for the HighPlus Slope parameters should be set so that they are higher than the High Slope in the slope hierarchy. By default, the Low, High, Exceed, and HighPlus slopes are initially disabled.

A RED slope is a graph with an X (horizontal) and Y (vertical) axis. The X axis plots the percentage of shared buffer utilization, from 0 to 100%. The Y axis plots the probability of packet discard marked from 0 to 1. The slope is defined as four sections, as shown in the following figure.

Figure 50-1 RED slope characteristics



Section A is (0, 0) to (start-avg, 0). For this part of the slope, the packet discard value is always zero, which prevents the RED function from discarding packets when the shared buffer average utilization falls between 1 and start-avg.

Section B is (start-avg, 0) to (max-avg, max-prob). This part of the slope is linear where packet discard probability increases from zero to max-prob.

Section C is (max-avg, max-prob) to (max-avg, 1). This part of the slope shows the instantaneous increase of packet discard probability from max-prob to one. A packet discard probability of one results in an automatic discard of the packet.

Section D is (max-avg, 1) to (100%, 1). On this part of the slope, the shared buffer average utilization value of max-avg to 100% results in a packet discard probability of one.

50.12 HSMDA WRED slope policies

50.12.1 General Information

HSMDA WRED slope policies controls the management of the HSMDA queue depth. The polices are applied to queues defined in the SAP ingress and SAP egress QoS to provide congestion control. Congestion control includes a defined maximum depth that the queue can reach when packets and RED of congestion and slope-based discards based on queue depth are accepted.

Note: HSMDA is only supported on 7750 SR-7/12/12e and 7450 ESS-7/12, Release 20.10 and earlier. The NFM-P does not support HSMDA WRED slope policies on other NEs.

50.13 Scheduler policies

50.13.1 General Information

Scheduler policies determine the order in which queues are serviced. All ingress and egress queues operate within the context of a scheduler. Multiple queues share the same scheduler. Schedulers control the data transfer between the following queues and destinations:

- service ingress queues to switch fabric destinations
- service egress queues to access egress ports
- network ingress queues to switch fabric destinations
- network egress queues to network egress interfaces

The are two types of scheduler policies:

- single-tier, in which queues are scheduled based on the forwarding class of the queue and the operation state of the queue relative to the queue CIR and PIR
- hierarchical or multi-tier, which allow the creation of a hierarchy of schedules where queues or other schedulers are scheduled by superior schedulers

Scheduler policies are applied to access ingress and access egress interfaces.

50.13.2 Single tier schedulers

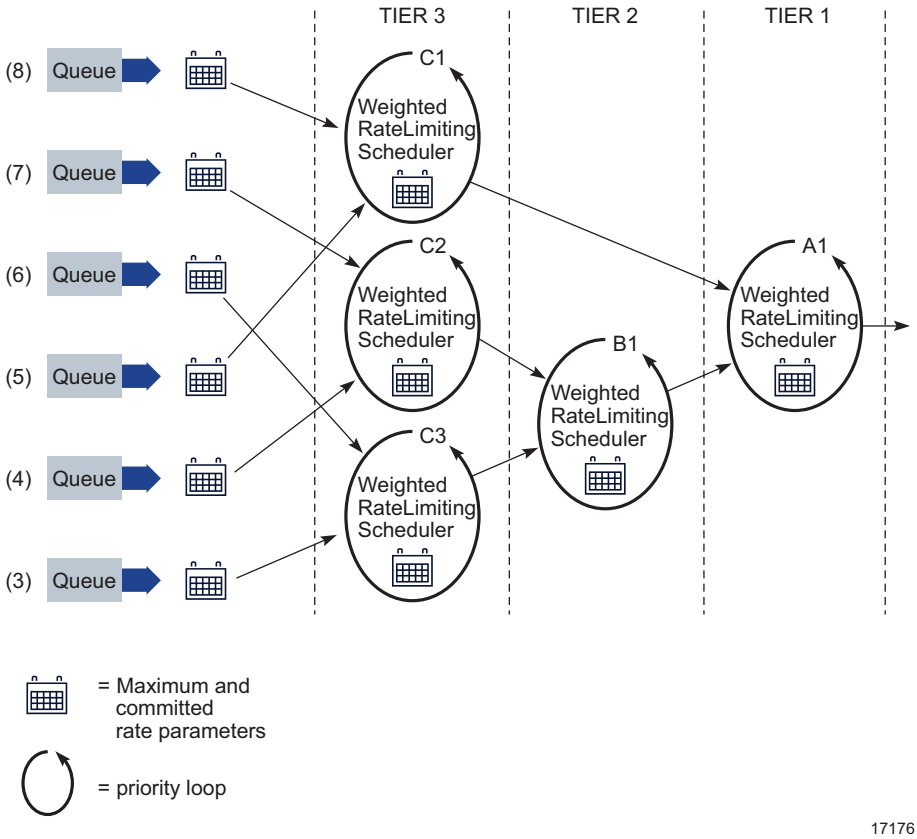
Single-tier scheduling is the default method of scheduling queues. Queues are scheduled with single-tier scheduler policies when no explicit hierarchical scheduler policy is defined or applied. In single-tier scheduling, queues are scheduled based on the forwarding class of the queue and the operational state of the queue relative to the queue CIR and PIR.

50.13.3 Hierarchical schedulers

Hierarchical scheduler policies are used for access ingress and access egress queues. Hierarchical scheduler policies allow you to create a hierarchy of schedulers where queues and other schedulers are scheduled by superior schedulers.

Virtual schedulers are created within the context of a hierarchical scheduler policy. A hierarchical scheduler policy defines the hierarchy and parameters for each scheduler. A scheduler is defined in the context of a tier. The tier level determines the scheduler's position in the hierarchy. Three tiers of virtual schedulers are supported, as shown in the following figure:

Figure 50-2 Hierarchical scheduler and queue association



Tier 1 schedulers are defined without a parent scheduler. A scheduler can enforce a maximum rate of operation for all child queues and associated schedulers.

You can create a tier 2 scheduler without a parent tier 1 scheduler or a tier 3 scheduler without a parent tier 2 scheduler.

During configuration of the hierarchical scheduler, you can assign numerical level and weight values to the tier 2 or tier 3 child scheduler, to specify a priority level in comparison with other child schedulers of the same parent scheduler. The level value determines relative importance when tier 2 or tier 3 schedulers are contending for bandwidth. The higher the number, the higher the priority level of the child scheduler bandwidth request.

Child schedulers with a level value lower than other child schedulers do not receive bandwidth until all child schedulers with a higher level have reached their maximum bandwidth allocation, or have no packets to pass.

When two child schedulers have the same level value, the weight value determines which scheduler first receives bandwidth.

50.13.4 Policy override

You can override some or all settings associated with an ingress or egress scheduler policy on an L2 or L3 access interface or subscriber profile. See 50.97 “To configure QoS policy overrides on an L2 or L3 access interface” (p. 1654) for more information.

50.14 Port scheduler policies

50.14.1 General Information

Port scheduler policies determine the virtual scheduling of egress ports by allocating HQoS bandwidth based on the available bandwidth at the egress port level. A port scheduler is defined in the context of a tier. The tier level determines the position of the port scheduler in the hierarchy.

The first tier of the scheduling hierarchy manages the total frame bandwidth that the port scheduler allocates to the eight priority levels. The second tier receives bandwidth from the first tier in two priorities—a within-CIR distribution, and an above-CIR distribution. The within-CIR distribution of the second tier provides bandwidth to the third tier within-CIR distributions for each of the eight priority levels. The above-CIR distribution of the second tier provides bandwidth to the above-CIR distribution of the third tier for each of the eight priority levels.

Up to eight groups can be defined within each port scheduler policy. A group has a rate, an optional cir-rate, and inherits the highest scheduling priority of its member levels. In essence, a group receives bandwidth from the port and distributes it within the member levels of the group according to the weight of each level. Each level will compete for bandwidth within the group based on its weight under congestion situation. If there is no congestion, a priority level can achieve up to its rate (cir-rate) worth of bandwidth. One or more levels can map to the same group.

Note: When the agg-rate-limit is applied to queues of a subscriber which are mapped to different priority levels in the same weighted scheduler group, the bandwidth distribution to the queues will be based on the priority of the level.

Orphan queues or schedulers that are not explicitly associated with the port scheduler receive bandwidth after all parented queues and schedulers are allocated bandwidth.

Port scheduler policies are configured on ports and channels.

50.14.2 Policy override

You can override some or all port scheduler settings associated with an access egress queue policy on an L2 or L3 access interface or SLA profile. See 50.97 “To configure QoS policy overrides on an L2 or L3 access interface” (p. 1654) for more information.

50.15 HSMDA scheduler policies

50.15.1 General Information

HSMDA scheduler policies controls the scheduling of a set of HSMDA scheduler classes. The policies are assigned to egress HSMDA ports, and the ingress control scheduler between the HSMDA and ingress forwarding plane. The policies assigned to HSMDA egress ports define how all queues associated with the egress port are scheduled. Scheduler policies assigned to the ingress

control scheduler between the HSMDA and ingress forwarding plane define how all ingress queues on the HSMDA, regardless of the ingress port, are scheduled.

Note: HSMDA is only supported on 7750 SR-7/12/12e and 7450 ESS-7/12, Release 20.10 and earlier. The NFM-P does not support HSMDA scheduler policies on other NEs.

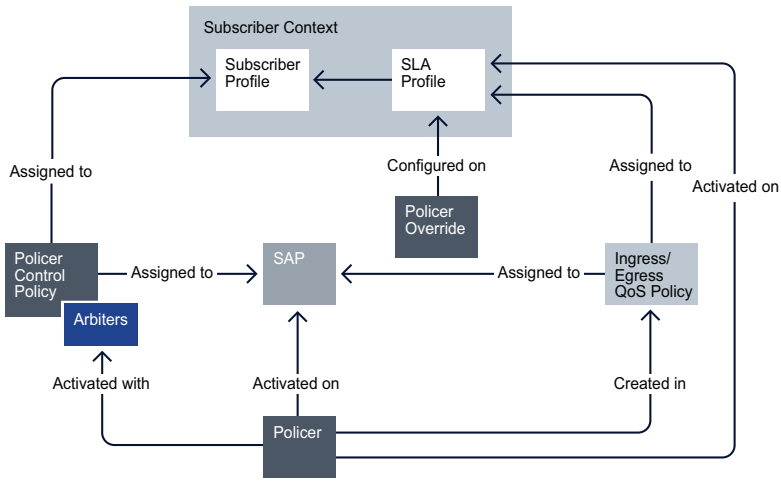
50.16 Policer control policies

50.16.1 General Information

Policer control policies allow you to create a control framework, under which policer objects associated with SAPs or subscriber contexts are configured with traffic control parameters. The policer object is applied to the SAP or subscriber context as part of an access ingress policy or access egress policy. The policer control policy is also applied to the SAP or subscriber context. The policer control policy provides the control framework, and policers are associated with the framework by means of arbiters.

When a policer control policy is applied to a SAP or subscriber context, the system creates a parent policer that is bandwidth limited by the policy's maximum bandwidth rate, as defined under the root arbiter. In addition to the root arbiter, the policy may also contain user defined child arbiters that provide bandwidth control for subsets of child policers.

Figure 50-3 Policer association with SAPs and user contexts under policer control hierarchy



A policer is created as part of an access ingress or access egress policy. The policer is configured with a parent arbiter name. When a policy containing a policer is applied to a SAP, the system scans the available arbiters on the SAP. If an arbiter exists with a name that matches the Parent Arbiter parameter on the policer, a policer to arbiter association is established and the policer becomes part of the policer control hierarchy.

In the case of subscriber contexts, the policer control policy is applied to the sub profile used by the subscriber. The system creates a unique policer control hierarchy for each subscriber associated

with the sub profile. An access ingress or access egress policy containing a policer is applied to the subscriber SLA profile. The combination of the sub profile and SLA profile at the subscriber level provides the system with the information required to create the policer control hierarchy instance for the subscriber context.

50.26 “Workflow to configure policer control hierarchy” (p. 1535) describes the high-level steps to configure a policer control hierarchy.

50.17 Buffer pool policies

50.17.1 General Information

There are two types of buffer pool policies:

- **HSMDA policies:** The high scale Ethernet MDA (HSMDA) pool policy can be assigned to an ingress or egress HSMDA to control how buffers are distributed between HSMDA queues. HSMDA pool policies do not apply to ports.

  Note: HSMDA is only supported on 7750 SR-7/12/12e and 7450 ESS-7/12, Release 20.10 and earlier. The NFM-P does not support HSMDA pool policies on other NEs.

- **Named buffer pool policies:** Named buffer pool policies allows you to create named pools to override the default buffer pool behavior by creating and allocating ingress and egress queues. Named pools are configured in the named buffer pool policy and are applied at the MDA and/or port ingress and egress level.

  Named pools can be further defined in Q1 pools configuration. You can configure and assign queue pools to the following policies:

  - SAP Access Ingress
  - SAP Access Egress
  - Network Queue
  - Shared Queue

  When a policy is associated at the MDA level, named pools defined in the policy allow queues from any port to be associated. When a policy is associated at the port level, named pools are only available to queues associated with that port. A named pool policy that is currently applied to a MDA or port can be deleted after all association between the policy and the MDA or port have been removed.

  When buffer pools are created, renamed or deleted, queues mapped to the pools are moved to default pools. When a queue is moved, traffic that was destined for the queue is temporarily moved to a fail over queue. After the old queue is drained, and the new queue is created and associated with the buffer pool, the saved statistics are loaded to the new queue and traffic is moved from the fail over queue to the new queue.

  50.27 “Workflow to configure a named buffer pool” (p. 1537) describes the high-level steps to configure Named Buffer Pools and Q1 pools.

50.18 HS QoS policies

50.18.1 General Information

HS QoS policies allow you to configure and manage ESM and services using the HSQ IOM4-e-HSMDA on the 7750 SR, Release 20.10 and earlier. There are four types of HS QoS policies:

- **HS Attachment policy:** The high scale (HS) Attachment policy defines how queues map to the scheduling classes associated with the HS port scheduler policy. The HS Attachment policy also defines how multiple queues collapse into WRR (weighted round robin) groups allowing multiple queues to map to a single scheduling class. See 50.69 “To configure a HS Attachment policy” (p. 1612).
- **HS Pool policy:** The high scale (HS) Pool policy is used to control how buffers are distributed to root-tier and mid-tier buffer pools and how mid-tier buffer pools attach to root-tier buffer pools. The HS pool policy is applied to the Forwarding Plane at the IOM level on a 7750 SR node. See 50.70 “To configure a HS Pool policy” (p. 1613).
- **HS Port Pool policy:** The high scale (HS) Port Pool policy is used to control how buffers are distributed to port-class buffer pools and how port-class buffer pools attach to mid-tier buffer pools. The HS port pool policy is applied to an HSQ (IOM4-e-HSMDA) egress port on a 7750 SR, Release 20.10 and earlier. See 50.71 “To configure a HS Port Pool policy” (p. 1614).
- **HS Scheduler policy:** The high scale (HS) Scheduler policy defines the scheduling behavior of each HS scheduler class for all queues associated to an HSQ (IOM4-e-HSMDA) egress port on a 7750 SR, Release 20.10 and earlier, including specifying the Max. rate, scheduling class type (rate/group), bandwidth rate, and weight-in-group. See 50.73 “To configure a HS Scheduler policy” (p. 1616).

50.19 Queue Group policies

50.19.1 General Information

There are three types of Queue Group policies:

- **Queue Group Ingress Template policies:** are used for Access Ingress Queue Group creation on Ethernet access ports; see 50.74 “To configure a queue group ingress template policy” (p. 1617).
- **Queue Group Egress Template policies:** are used for Access Egress Queue Group and Network Egress Queue Group creations on Ethernet ports; see 50.75 “To configure a queue group egress template policy” (p. 1619).

  Queue Group template policies allow you to define the queuing and parenting structure for queue groups on Ethernet ports. The policy defines the number and types of queues within the port queue group, and provides the default queue parameters. Queue Group Template policies are not applicable to L3 interfaces associated with HSMDA ports.

  Queue Group Template policies are used in the following network applications:
  - Access SAP queue group applications
  - Network port queue groups for network interfaces
- **Queue Group Redirect List policies:** are used to provide QoS control to map IPv4 and IPv6 traffic using a single VXLAN or VXLAN GPE Virtual Network Identifier (VNI) to an ingress access

queue group instance or a port access egress queue group instance. Each entry in the redirect list policy matches to a specific VNI which then maps it to a specific queue group instance. A maximum of 16 match statements can be configured in a queue group redirect list. Queue Group Redirect List policies are supported on both egress/ingress physical interfaces (SAPs) that support IES or VPRN services. See 50.76 “To configure a queue group redirect list policy” (p. 1624).

See Chapter 71, “Queue groups” for more information about queue groups, the associated network components, and typical applications.

50.19.2 Default policer queue group

The system maintains a special default egress queue group template policy that is applied automatically to all Ethernet ports. The default policer-output-queues policy is configured with two queues:

- Queue 1: configured with a forwarding class value of Best Effort.
- Queue 2: configured with a forwarding class value of Expedite.

All other parameters are default. You cannot delete the default policer-output-queues policy.

50.20 FP Resource policies

50.20.1 General information

Forwarding Plane Resource policies allow custom allocation of card slot resources to queues. By default, ingress and egress queues are each allocated 50% of the queue resources on a forwarding plane. FP Resource policies allow you to configure custom ingress queue resources in a range of 4% to 97%. The corresponding percentage remaining is allocated to egress queues. See 50.72 “To configure an FP Resource policy” (p. 1615).

FP Resource policies are assigned to forwarding planes on the card slot properties form; see 15.59 “To assign an FP Resource policy to a forwarding plane” (p. 519).

50.21 Queue depth monitoring

50.21.1 General information

Queue depth monitoring provides insight into traffic flows on queues, which can help to fine-tune port service allocations and QoS policies, for capacity planning and SLA compliance.

The NFM-P supports the configuration of queue depth monitoring using overrides for access ingress, access egress, and network egress queue groups, and for L2 and L3 access egress interfaces.

- For egress queue group overrides on Ethernet ports, see 16.37 “To add a queue group to an Ethernet port” (p. 627).
- For QoS policy overrides for L2 and L3 access egress interfaces, see 50.97 “To configure QoS policy overrides on an L2 or L3 access interface” (p. 1654).

Configuration includes options for fast polling, which can provide more accurate results, and for violation thresholds, which generate notifications when exceeded. Depth monitoring results and notifications are not available in the NFM-P, but can be obtained from NEs using CLI or telemetry, depending on NE version and release support. See the NE documentation for more information.

50.22 7705 SAR fabric profiles

50.22.1 General Information

Each daughter card in a 7705 SAR can have two assigned fabric profiles, one for access ingress and one for network ingress. These policies are assigned from the Daughter Card tab of a daughter card slot properties form.

A 7705 SAR fabric profile includes a mode, which cannot be changed after profile creation, and one or more shaping rates. The mode types are Aggregate and Destination. In Aggregate mode, one rate defines the maximum fabric shaping rate that is distributed to each daughter card slot. In Destination mode, there is one fabric shaping rate for each daughter card slot.

In Destination mode, there is also a multi-point shaping rate that is distributed to each daughter card slot.

50.23 7210 SAS QoS policies

50.23.1 General Information

The NFM-P provides QoS policies that are specific to 7210 SAS NEs. Some of these policies also apply to 7250 IXR devices, as indicated by the menu name of the policy. QoS policy information that is specific to the 7210 SAS may not necessarily apply for other devices.

QoS policies for the 7210 SAS accommodate multiple different 7210 SAS chassis types. See 6.5 “7210 SAS” (p. 216) in Chapter 6, “Device support” for more information about 7210 SAS chassis types. Not all chassis types support all policies, or all configurations within a policy. For information about chassis support for a specific policy, see Table 50-7, “7210 SAS QoS policies” (p. 1531).

For some 7210 SAS QoS policies and functions, device system resources must be appropriately allocated. See 6.5.13 “System resource profile” (p. 220) in Chapter 6, “Device support” and the NE documentation for more information.

Some 7210 SAS QoS functions and settings are not configured within the policy framework. Instead, they are configured as device or port properties, or during SAP configuration. For an overview of the tasks required to configure QoS on 7210 SAS NEs using the NFM-P, see 70.15 “Sample QoS configuration on the 7210 SAS” (p. 1954) .

You can override the settings for meters and queues in access ingress policies that are assigned to access interfaces. For information about policy overrides for access ingress meters on 7210 SAS NEs, see 50.98 “To configure QoS policy overrides on access ingress meters for the 7210 SAS” (p. 1657). For information about policy overrides for access ingress queues on 7210 SAS-X NEs, see 50.99 “To configure QoS policy overrides on access ingress queues for a 7210 SAS-X” (p. 1659).

On supporting 7210 SAS NEs, you can override the settings for queues in port access egress policies that are assigned to access ports; see 50.100 “To configure QoS policy overrides on port access egress queues for a 7210 SAS” (p. 1660).

A GQP can be used to assign 7210 and 1830 SAP access ingress policies and 7210 SAP access egress policies to access interfaces; see 50.96 “To configure a Generic QoS Profile” (p. 1649). GQPs are assigned using the XML API.

When a GQP is used to assign ingress and egress policies to 7210 SAS NEs that do not support QoS policy overrides, an API may be used to provide GQP overrides that change QoS values (CIR, PIR, CBS, MBS). The API creates a new “dynamic” local policy that is outside the NFM-P policy management. Local policy forms remain visible in the NFM-P GUI, and display the Policy Mode parameter, set to dynamic. This indicates that the QoS values are set by the GQP override API, and not from the GUI, CLI, or OSS.

See the 7210 SAS documentation for more information about 7210 SAS QoS and QoS policies.

50.23.2 Table-based ingress classification on the 7210 SAS

The NFM-P supports the configuration of table-based ingress classification on supporting 7210 SAS NEs. When table classification is enabled, ingress DSCP bits are mapped to FCs and profiles using hardware tables instead of CAM resources. The DSCP mappings are configured in a 7210/7250 DSCP classification policy.

You can enable table-based ingress classification for the following:

- L2 interfaces on VPLS and VLL Epipe services. The 7210/7250 DSCP classification policy is assigned to the SAP Access Ingress policy on the interface.
- L3 interfaces on IES and VPRN services. The 7210/7250 DSCP classification policy is assigned to the SAP Access Ingress policy on the interface.
- RVPLS on L3 interfaces. The 7210/7250 DSCP classification policy is assigned to the interface using the Routed VPLS tab of the properties form for the interface. On the form, the 7210/7250 DSCP classification policy is called the Routed Override QoS Policy.
- Ethernet ports. The 7210/7250 DSCP classification policy is assigned to the port using the Policies tab of the port properties form. When table-based classification is enabled on a port, all SAPs on the port use the 7210/7250 DSCP classification policy assigned to that port. You can configure a default FC for ingress packets that do not have a DSCP value.

See the NE documentation for more information about table-based classification.

50.23.3 Workflow to configure table-based DSCP ingress classification

The following workflow outlines the basic steps required to configure table-based ingress DSCP classification.

1

Configure a 7210/7250 DSCP classification policy; see 50.85 “To configure a 7210/7250 DSCP classification policy” (p. 1638). Distribute the policy to the required NEs.

2

If you are configuring table-based ingress classification on interfaces, assign the 7210/7250 DSCP classification policy to a 7210, 7250 and 1830 SAP Access Ingress policy; see 50.29 “To configure a 7210, 7250, and 1830 SAP Access Ingress policy” (p. 1544). Distribute the policy to the required NEs.

3

Configure table-based ingress classification on interfaces, and assign the 7210, 7250 and 1830 SAP Access Ingress policy from Stage 2 to those interfaces.

See the relevant procedure for the service type:

- VLL: 76.43 “To assign ingress and egress QoS policies to a VLL L2 access interface on a 7210 SAS site” (p. 2184)
- VPLS: 77.70 “To assign ingress and egress QoS policies to a VPLS L2 access interface on a 7210 SAS site” (p. 2343)
- IES: 78.33 “To assign ingress and egress QoS policies to an IES L3 access interface on a 7210 SAS site” (p. 2479)
- VPRN: 79.90 “To assign ingress and egress QoS policies to a VPRN L3 access interface on a 7210 SAS site” (p. 2665)

4

Configure table-based ingress classification for RVPLS on L3 interfaces, and assign the 7210/7250 DSCP classification policy from Stage 1 to those interfaces.

See the relevant procedure for the service type:

- IES: 78.30 “To bind an IES L3 access interface to a VPLS site or VPLS I-site” (p. 2475)
- VPRN: 79.98 “To bind a VPRN L3 access interface to a VPLS site or VPLS I-site” (p. 2673)

5

Configure table-based ingress classification for Ethernet ports, and assign the 7210/7250 DSCP classification policy from Stage 1 to those ports. See 16.45 “To assign QoS policies to a 7210 SAS Ethernet port” (p. 636).

50.23.4 7210 SAS QoS policies

The following table describes the QoS policies specific to the 7210 SAS.

Table 50-7 7210 SAS QoS policies

QoS policy	Assigned to (in Procedure #)	Supported 7210 SAS chassis types	For policy configuration, see
7210, 7250 and 1830 SAP Access Ingress	L2 access interfaces in: • VLL (76.43 “To assign ingress and egress QoS policies to a VLL L2 access interface on a 7210 SAS site” (p. 2184)) • VPLS (77.70 “To assign ingress and egress QoS policies to a VPLS L2 access interface on a 7210 SAS site” (p. 2343)) L3 access interfaces in: • IES (78.33 “To assign ingress and egress QoS policies to an IES L3 access interface on a 7210 SAS site” (p. 2479)) • VPRN (79.90 “To assign ingress and egress QoS policies to a VPRN L3 access interface on a 7210 SAS site” (p. 2665))	All 7210 SAS chassis types	50.29 “To configure a 7210, 7250, and 1830 SAP Access Ingress policy” (p. 1544)
7210 and 1830 Port Access Egress	Access ports (16.45 “To assign QoS policies to a 7210 SAS Ethernet port” (p. 636))	7210 SAS-D 7210 SAS-Dxp 7210 SAS-E 7210 SAS-M 7210 SAS-Mxp 7210 SAS-S 7210 SAS-Sx 7210 SAS-T 7210 SAS-R 7210 SAS-X	50.31 “To configure a 7210 and 1830 port access egress policy” (p. 1556)
7210 SAP Access Egress	L2 access interfaces in: • VLL (76.43 “To assign ingress and egress QoS policies to a VLL L2 access interface on a 7210 SAS site” (p. 2184)) • VPLS (77.70 “To assign ingress and egress QoS policies to a VPLS L2 access interface on a 7210 SAS site” (p. 2343)) • Mirror Service destinations (93.10 “To create an L2 access interface on a destination site” (p. 3174)) L3 access interfaces in: • IES (78.33 “To assign ingress and egress QoS policies to an IES L3 access interface on a 7210 SAS site” (p. 2479)) • VPRN (79.90 “To assign ingress and egress QoS policies to a VPRN L3 access interface on a 7210 SAS site” (p. 2665))	7210 SAS-K 7210 SAS-Mxp 7210 SAS-R 7210 SAS-X	50.32 “To configure a 7210 SAP access egress policy” (p. 1558)

Table 50-7 7210 SAS QoS policies (continued)

QoS policy	Assigned to (in Procedure #)	Supported 7210 SAS chassis types	For policy configuration, see
7210 and 1830 Network	Network ports (16.45 “To assign QoS policies to a 7210 SAS Ethernet port” (p. 636)) Network interfaces[1] (27.17 “To create an L3 network interface on a routing instance” (p. 856) , 27.18 “To configure L3 network interfaces” (p. 863))	All 7210 SAS chassis types	50.42 “To configure a 7210 and 1830 network policy” (p. 1571)
7210 and 1830 Network Queue	Network ports (16.45 “To assign QoS policies to a 7210 SAS Ethernet port” (p. 636))	All 7210 SAS chassis types	50.47 “To configure a 7210 and 1830 network queue policy” (p. 1583)
7210 and 1830 Slope	Egress ports in any mode (16.24 “To configure Ethernet ports” (p. 599)) Queues, during queue configuration in: • 7210 and 1830 SAP Access Ingress policies (50.29 “To configure a 7210, 7250, and 1830 SAP Access Ingress policy” (p. 1544)) • 7210 SAP Access Egress policies (50.32 “To configure a 7210 SAP access egress policy” (p. 1558)) • 7210 and 1830 Network Queue policies (50.47 “To configure a 7210 and 1830 network queue policy” (p. 1583)) • 7210 and 1830 Network policies (50.42 “To configure a 7210 and 1830 network policy” (p. 1571))	7210 SAS-D 7210 SAS-Dxp 7210 SAS-E 7210 SAS-K 7210 SAS-M 7210 SAS-S 7210 SAS-Sx 7210 SAS-T	50.50 “To configure a 7210 and 1830 slope policy” (p. 1589)
7210 and 7250 Queue Management	Queues, during queue configuration in: • 7210 and 1830 SAP Access Ingress policies (50.29 “To configure a 7210, 7250, and 1830 SAP Access Ingress policy” (p. 1544)) • 7210 and 1830 Port Access Egress policies (50.31 “To configure a 7210 and 1830 port access egress policy” (p. 1556)) • 7210 SAP Access Egress policies (50.32 “To configure a 7210 SAP access egress policy” (p. 1558)) • 7210 and 1830 Network Queue policies (50.47 “To configure a 7210 and 1830 network queue policy” (p. 1583))	7210 SAS-Mxp 7210 SAS-R 7210 SAS-X	50.52 “To configure a 7210 and 7250 Queue Management policy” (p. 1592)
7210, 7250, and 1830 Port Scheduler[2]	Egress ports in any mode (16.45 “To assign QoS policies to a 7210 SAS Ethernet port” (p. 636))	7210 SAS-D 7210 SAS-Dxp 7210 SAS-E 7210 SAS-M 7210 SAS-S 7210 SAS-Sx 7210 SAS-T	50.60 “To configure a 7210, 7250 and 1830 Port Scheduler policy” (p. 1601)

Table 50-7 7210 SAS QoS policies (continued)

QoS policy	Assigned to (in Procedure #)	Supported 7210 SAS chassis types	For policy configuration, see
7210/7250 Dot1p	Ingress policies: • 7210 and 1830 SAP Access Ingress policies (50.29 “To configure a 7210, 7250, and 1830 SAP Access Ingress policy” (p. 1544)) • 7210 and 1830 Network policies (50.42 “To configure a 7210 and 1830 network policy” (p. 1571))	7210 SAS-K	50.84 “To configure a 7210/7250 Dot1p classification policy” (p. 1637)
7210/7250 DSCP	Ingress policies: • 7210 and 1830 SAP Access Ingress policies (50.29 “To configure a 7210, 7250, and 1830 SAP Access Ingress policy” (p. 1544)) • 7210 and 1830 Network policies (50.42 “To configure a 7210 and 1830 network policy” (p. 1571)) Ethernet ports; see 16.45 “To assign QoS policies to a 7210 SAS Ethernet port” (p. 636) RVPLS on L3 access interfaces: • 78.30 “To bind an IES L3 access interface to a VPLS site or VPLS I-site” (p. 2475) • 79.98 “To bind a VPRN L3 access interface to a VPLS site or VPLS I-site” (p. 2673)	7210 SAS-K 7210 SAS-Mxp 7210 SAS-R	50.85 “To configure a 7210/7250 DSCP classification policy” (p. 1638)
7210/7250 MPLS LSP-EXP	7210 and 1830 Network policies (50.42 “To configure a 7210 and 1830 network policy” (p. 1571))	7210 SAS-K12 7210 SAS-K30 ETR	50.86 “To configure a 7210/7250 MPLS LSP-EXP classification policy” (p. 1639)
7210 FC Meter Map	7210,7250 and 1830 SAP Access Ingress policies (50.29 “To configure a 7210, 7250, and 1830 SAP Access Ingress policy” (p. 1544))	7210 SAS-Mxp	50.87 “To configure a 7210 FC Meter Map policy” (p. 1640)
7210 Remarking	Egress policies: • 7210 and 1830 Port Access Egress policies (50.31 “To configure a 7210 and 1830 port access egress policy” (p. 1556)) • 7210 SAP Access Egress policies (50.32 “To configure a 7210 SAP access egress policy” (p. 1558)) • 7210 and 1830 Network policies (50.42 “To configure a 7210 and 1830 network policy” (p. 1571))	7210 SAS-K 7210 SAS-Mxp 7210 SAS-R 7210 SAS-S 7210 SAS-Sx 7210 SAS-T 7210 SAS-X	50.80 “To configure a 7210 remarking policy” (p. 1630)

Table 50-7 7210 SAS QoS policies (continued)

QoS policy	Assigned to (in Procedure #)	Supported 7210 SAS chassis types	For policy configuration, see
7210 MPLS LSP-EXP Mapping	7210 and 1830 Network policies of network interface type (50.42 “To configure a 7210 and 1830 network policy” (p. 1571)) NEs, using the NE properties form	7210 SAS-M 7210 SAS-Mxp 7210 SAS-R 7210 SAS-S 7210 SAS-Sx 7210 SAS-T 7210 SAS-X	50.83 “To configure a 7210 MPLS LSP-EXP Mapping policy” (p. 1635)
7210 Multipoint Bandwidth management	7210 SAS-X NEs, using the NE global properties (52.16 “To configure a 7210 multipoint bandwidth management policy” (p. 1725))	7210 SAS-X	52.16 “To configure a 7210 multipoint bandwidth management policy” (p. 1725)

Notes:

1. The 7210 SAS-M (in network mode), 7210 SAS-Mxp, 7210 SAS-R,7210 SAS-S, 7210 SAS-Sx, 7210 SAS-T (in network mode), and 7210 SAS-X support 7210 and 1830 network policies on network interfaces. The policy must be of network interface type.
2. The 7210 SAS-K, 7210 SAS-Mxp, 7210 SAS-R and 7210 SAS-X do not use scheduler policies. Egress scheduling for these devices is defined by the port bandwidth and by user-configured settings in access egress and network queue policies, port properties, and SAP configuration. See 70.15 “Sample QoS configuration on the 7210 SAS” (p. 1954) in Chapter 70, “Service management and QoS”.

50.24 7250 IXR QoS policies

50.24.1 7250 IXR QoS policy support

If you are creating or synchronizing QoS policies for the 7250 IXR with SR OS, the following NFM-P QoS policies apply:

- SAP Access Ingress; see 50.28 “To configure a SAP access ingress policy” (p. 1538)
- Shared policer; see 50.101 “To configure a shared policer policy” (p. 1661)
- 7250 SROS Queue Management; see 50.53 “To configure a 7250 SROS Queue Management policy” (p. 1593)
- 7250 SROS VLAN QoS; see 50.54 “To configure a 7250 SROS VLAN QoS policy” (p. 1594)
- 7250 SROS Port QoS; see 50.61 “To configure a 7250 SROS Port QoS policy” (p. 1603)
- 7250 SROS Remarking; see 50.82 “To configure a 7250 SROS Remarking policy” (p. 1634)
- 7250 SROS Network Ingress; see 50.43 “To configure a 7250 SROS Network Ingress policy” (p. 1575)

- 7250 SROS Ingress Classification; see 50.45 “To configure a 7250 SROS Ingress Classification policy” (p. 1579)

For supporting chassis variants and releases of the 7250 IXR, the NFM-P supports the following SROS FC mapping policies for ingress classification:

- 7250 SROS Dot1p FC Mapping
- 7250 SROS DSCP FC Mapping
- 7250 SROS LSP-EXP FC Mapping

See 50.44 “To configure FC mapping policies for ingress classification on the 7250 IXR” (p. 1577).

For supporting chassis variants and releases of the 7250 IXR, the NFM-P supports the following SROS FC mapping policies for egress remarking:

- 7250 SROS FC Dot1p Mapping
- 7250 SROS FC DSCP Mapping
- 7250 SROS FC LSP-EXP Mapping

See 50.81 “To configure FC mapping policies for egress remarking on the 7250 IXR” (p. 1632).

For more information about FC mapping policy support on the 7250 IXR, see the NE documentation.

50.25 OmniSwitch QoS policies

50.25.1 General Information

OmniSwitch QoS provides a way to control traffic flows through the switch based on configured policies. The control may be simple such as allowing or denying traffic, or complicated such as remapping 802.1p bits from a Layer 2 network to ToS values in a Layer 3 network.

The OmniSwitch supports the following types of QoS policies:

- basic QoS—to control traffic prioritization and bandwidth shaping
- ACLs—for Layer 2, 3, and 4 filtering

A QoS policy contains a condition and an action. The condition specifies parameters that the switch checks in incoming traffic flows, such as the destination address or ToS bits. The action specifies what the switch does with traffic that matches the condition; for example, the switch may queue the traffic flow with a higher priority or reset the ToS bits.

Ethernet service policies are used to create UNI and SAP profiles. The profiles are applied to stacked VLAN SAPs and UNIs to control traffic and specify options to manage certain traffic types.

50.26 Workflow to configure policer control hierarchy

50.26.1 Requirements

This workflow assumes that the following components already exist:

- a policer control policy

- an access ingress or access egress policy
- a subscriber
- an access interface or SAP

50.26.2 Stages

1

Configure arbiters in a policer control policy. See 50.62 “To configure a policer control policy” (p. 1604) for more information.

1. Create arbiters.
2. Configure parent/child relationships between arbiters to build a policer control hierarchy.

2

Configure a policer in a SAP access ingress or access egress policy. See 50.28 “To configure a SAP access ingress policy” (p. 1538) and 50.29 “To configure a 7210, 7250, and 1830 SAP Access Ingress policy” (p. 1544) for more information.

1. Create a policer to configure traffic control parameters.
2. Assign a parent arbiter to the policer to associate it with the hierarchy configured in the policer control policy.

3

Assign the policer control policy to a subscriber that is configured with a SAP access ingress or access egress policy that includes a policer. See 64.4 “To configure a subscriber profile” (p. 1840) for more information.

4

As required, assign the policer control policy to an access interface or SAP that is configured with a SAP access ingress or access egress policy that includes a policer.

a. For an IES L3 access interface, see 78.28 “To configure an L3 access interface on an IES site” (p. 2472) for more information.

b. For an IES SAP, see 78.19 “To configure a group interface on an IES” (p. 2449) for more information.

c. For a VPLS L2 access interface, see 77.67 “To create a VPLS or MVPLS L2 access interface” (p. 2332) for more information.

d. For a VPLS B-L2 access interface, see 77.87 “To create a VPLS or MVPLS B-L2 access interface” (p. 2366) for more information.

e. For a VPLS I-L2 access interface, see 77.88 “To create a VPLS I-L2 access interface” (p. 2372) for more information.

f. For a VPRN L3 access interface, see 79.83 “To configure an L3 access interface on a VPRN site” (p. 2656) for more information.

g. For a VPRN SAP, see 79.37 “To configure a group interface on a VPRN” (p. 2586) for more information.

50.27 Workflow to configure a named buffer pool

50.27.1 Stages

1

Configure a named pool buffer Policy. See 50.67 “To configure a named buffer pool policy” (p. 1610) for more information.

2

Enable named pool to be configured for a port or MDA. See 15.67 “To enable named pool mode” (p. 526) for more information.

3

Apply a named pool policy to an MDA. See 15.78 “To configure an MDA” (p. 536) for more information.

4

Apply a named pool policy to a port. See 16.24 “To configure Ethernet ports” (p. 599) for more information.

5

Configure Q1 pools. See 50.68 “To configure Q1 pools” (p. 1611) for more information.

6

Assign Q1 pools to SAP access ingress policies. See 50.28 “To configure a SAP access ingress policy” (p. 1538) for more information.

7

Assign Q1 pools to SAP access egress policies. See 50.30 “To configure a SAP access egress policy” (p. 1550) for more information.

8

Assign Q1 pools to network queue policies. See 50.46 “To configure a network queue policy” (p. 1581) for more information.

9

Assign Q1 pools to shared queue policies. See 50.48 “To modify a shared-queue policy” (p. 1585) for more information.

QoS policies procedures

50.28 To configure a SAP access ingress policy

50.28.1 Before you begin

A SAP access ingress policy defines forwarding for traffic entering from a service. The policy is assigned to L2 access interfaces on VPLS and VLL services, and to L3 access interfaces on IES and VPRN services. See the following procedures, according to the service type:

- for VLL: 76.42 “To assign ingress and egress QoS policies to a VLL L2 access interface” (p. 2181)
- for VPLS: 77.69 “To assign QoS policies or to enable a MAC override address to a VPLS or MVPLS L2 access interface” (p. 2340)
- for IES: 78.32 “To assign ingress and egress QoS policies to an IES L3 access interface” (p. 2477)
- for VPRN: 79.89 “To assign ingress and egress QoS policies to a VPRN L3 access interface” (p. 2662)

50.28.2 Steps

1

Choose Policies→QoS→SROS QoS→Access Ingress→SAP Access Ingress from the NFM-P main menu. The SAP Access Ingress Policies form opens.

2

Click Create or choose a policy and click Properties. The SAP Access Ingress Policy (Create|Edit) form opens.

3

Configure the required general parameters.

If you are configuring a SAP access ingress policy for tagged IP/IPv6 match entry overrides, set the IP/IPv6 Criteria Type parameters to Tagged-Entries. Tag IDs are configured in Step 13. See 50.2.2 “Policy override” (p. 1508).

If you are configuring a SAP access ingress policy for the 7250 IXR, select a 7250 SROS Ingress Classification policy in the Ingress Classification Policy panel; see50.45 “To configure a 7250 SROS Ingress Classification policy” (p. 1579). If you do not select a user-configured 7250 SROS Ingress Classification policy, a default policy is applied.

Note: For some of the general parameters, additional fields will be displayed when certain selections are made. For example, when setting the IP Criteria Type and IPv6 Criteria Type to VXLAN-VNI and then clicking Apply, the Match Criteria field is displayed, and shows a value of None.

Note: NEs that support next-generation CLI use the policy name as the key identifier for internal system reference. For policies on these NEs, you must configure a policy name (typically the service name or a numerical string). Policy IDs are also supported. You must configure a numerical range on the NE for auto-assigned policy IDs; see 12.65 “To configure an Auto-ID range for policies” (p. 395).

Note: For some of the following steps, the tabs are not available until after the policy is created. Click Apply if required to create the policy and make all tabs available.

4

Enable the Policers HQoS Manageable parameter if the policers in this policy are to be managed by the Hierarchical QoS process.

5

Configure access ingress queues.

1. Click on the Queues tab.

   The NFM-P provides two default queues — a default unicast queue (ID 1) and a default multipoint queue (ID 11). You cannot delete the default queues.

   You can add queues up to a total of 32.
2. Click Create or choose a queue and click Properties. The Queue (Create|Edit) form opens.
3. Configure the required general parameters.

   Before you can configure the Pool Name parameter, you must create a Q1 pool; see 50.68 “To configure Q1 pools” (p. 1611).
4. Select a slope policy.
5. Select an advanced configuration policy.
6. Click on the CIR/PIR/FIR tab and configure the required parameters.

   You can configure the CIR, PIR, and FIR as a rate or as a percentage, depending on the option selected for the Rate Type parameter.

   Ensure that the CIR value is lower than the PIR value.
7. Click on the Burst Size tab and configure the required parameters.

   Deselect the Default check box for each parameter that you need to configure.

   Ensure that the Committed Burst Size (kb) value is lower than the Maximum Burst Size (bytes) value.
8. Save your changes and close the form.

6

Configure a dynamic policer.

1. Click on the Dynamic Policer tab and configure the required general parameters.
2. Select a Parent Arbiter.

3. Click on the Burst Size tab and configure the Committed Burst Size and Maximum Burst Size parameters.

   Deselect the Default check box for each parameter that you need to configure.

   Ensure that the Committed Burst Size value is lower than the Maximum Burst Size value.

7

Configure ingress policers.

1. Click on the Policer tab.
2. Click Create or choose a policer and click Properties. The Access Ingress Policer (Create|Edit) form opens.
3. Configure the required general parameters.
4. Select a Parent Arbiter and an Advanced Configuration Policy.
5. Select a Scheduler Parent if required, and then configure the parameters in the Scheduler Association panel.
6. Click on the CIR/PIR tab and configure the required parameters.

   You can configure the CIR and PIR as a rate or as a percentage, depending on the option selected for the Rate Type parameter.

   Ensure that the CIR value is lower than the PIR value.
7. Click on the Burst Size tab and configure the required parameters.

   Deselect the Default check box for each parameter that you need to configure.
8. Save your changes and close the form.

8

Configure forwarding classes.

1. Click on the Forwarding Classes tab.
2. Click Create or choose a forwarding class and click Properties. The Forwarding Class (Create|Edit) form opens.
3. Configure the Forwarding Class parameter.
4. Perform any of the following:
   - If you need to configure a queue group for one or more traffic types, complete substeps 5 and 6 .
   - If you need to configure queues for one or more traffic types, complete substep 6 .
   - If you need to configure policers for one or more traffic types, complete substeps 7,8, and 9.
5. In the Traffic Control panel, select the Use Queue Group option for any of the Unicast, Broadcast, Multicast, and Unknown traffic type parameters.

   In the Queues panel, select a queue group template policy.

   When the Use Queue Group option is selected in the global policy, the Queue ID, Multipoint Queue ID, Broadcast Queue ID, and Unknown Queue ID parameters, if selected, are

validated against the specified Queue Group Template Policy. The Queue ID is validated against the local queues for each local policy instance.

6. In the Queues panel, configure the parameters:
   - Queue ID

     The parameter must be set to a unicast ID. Set the parameter to 0 if you want the default queue ID to be used.
   - Multipoint Queue ID

     The parameter must be set to a multicast ID. Set the parameter to 0 if you want the default queue ID to be used.
   - Broadcast Queue ID

     The parameter must be set to a multicast ID. Set the parameter to 0 if you want the default queue ID to be used.
   - Unknown Queue ID

     The parameter must be set to a multicast ID. Set the parameter to 0 if you want the default queue ID to be used.
7. In the Traffic Control panel, select the Use Policer option for any of the Unicast, Broadcast, Multicast, and Unknown traffic type parameters.
8. In the Policers panel, for each traffic type configured with the Use Policer option, configure the corresponding Policer ID parameter.

   The FP Redirect Group, Multipoint FP Redirect Group, Broadcast FP Redirect Group, and Unknown FP Redirect Group parameters are displayed only when the associated traffic types in the Traffic Control panel are configured to use policers.
9. Select a policer for each Policer ID parameter. The policer must exist in the SAP access ingress policy from Step 7 .
10. Configure the required remaining parameters.

    The In Precedence parameter is configurable when the In Remark parameter is set to precedence.

    The Out Precedence parameter is configurable when the Out Remark parameter is set to precedence.

    The In DSCP parameter is configurable when the In Remark parameter is set to dscp.

    The Out DSCP parameter is configurable when the Out Remark parameter is set to dscp.
11. Click on the Sub Classes tab to configure subclasses for the forwarding class.
12. Click Create or choose a sub class and click Properties. The Forwarding Sub Class (Create|Edit) form opens.
13. Configure the required parameters.

    The In Precedence parameter is configurable when the In Remark parameter is set to precedence.

    The Out Precedence parameter is configurable when the Out Remark parameter is set to precedence.

    The In DSCP parameter is configurable when the In Remark parameter is set to dscp.

    The Out DSCP parameter is configurable when the Out Remark parameter is set to dscp.
14. Save your changes and close the forms.

9

Map ingress dot1p bits.

1. Click on the Dot1p tab.
2. Click Create or choose a Dot1p entry and click Properties. The Dot1p (Create|Edit) form opens.
3. Configure the required parameters.
4. Save your changes and close the form.

10

Map ingress DSCP bits.

1. Click on the DSCP tab.
2. Click Create or choose a DSCP entry and click Properties. The Dscp (Create|Edit) form opens.
3. Configure the required parameters.
4. Save your changes and close the form.

11

Map ingress Precedence bits.

1. Click on the Precedence tab.
2. Click Create or choose a Precedence entry and click Properties. The Precedence (Create|Edit) form opens.
3. Configure the required parameters.
4. Save your changes and close the form.

12

Map ingress LSP EXP bits.

1. Click on the LspExp tab.
2. Click Create or select an LspExp entry and click Properties. The Lsp Exp (Create|Edit) form opens.
3. Configure the required parameters.
4. Save your changes and close the form.

13

Configure match criteria. Perform any the following:

Note: If you configure MAC match criteria entries, you cannot configure IPv4 or IPv6 match criteria entries. Conversely, when no MAC match criteria entries are configured, you can configure both IPv4 and IPv6 entries.

a. Configure IPv4 match criteria.

1. Click on the IP Match Criteria tab.
2. Click Create or choose an entry and click Properties. The IP Match (Create|Edit) form opens.
3. Configure the required parameters.

   You can configure the Tag ID parameter only when the IP/IPv6 Criteria Type is set to Tagged-Entries in Step 3.

   If you set the IP/IPv6 Criteria Type to Tagged-Entries, you cannot enable the Destination Port parameter in the Port Properties panel.

   The Source Port and Destination Port parameters are available only when the Protocol parameter value is TCP, UDP, or UDPTCP (*).

   The VXLAN-VNI Properties panel is only displayed when the Protocol parameter value is set to UDP (17). You can then configure the required Operator parameter.

   To configure some parameters, you must select the check box for the parameter.

   The Src Mask and Src Net Mask parameters are mutually exclusive.

   The Source IP and Source IP Prefix parameters are mutually exclusive.

   The Dst Mask and Dst Net Mask parameters are mutually exclusive.

   The Destination IP and Destination IP Prefix parameters are mutually exclusive.
4. In the IP Properties panel, select QoS IP Prefix List policies, as required.

   - For the Source IP Prefix and Destination IP Prefix parameters, enable the checkbox and click Select. The Select [Source|Destination] IP Prefix form opens.

   - Click Create, or click Search and choose an existing QoS IP Prefix list policy.

   See 50.33 “To configure a QoS prefix list policy” (p. 1561).
5. Select a bypass policer, if required.

   The bypass policer must be local to the SAP (that is, it cannot be part of a queue group), and it must already be created within the SAP ingress policy, as described in Step 7 .
6. Save your changes and close the form.

b. Configure MAC match criteria.

1. Click on the MAC Match Criteria tab.
2. Click Create or choose an entry and click Properties. The MAC Match (Create|Edit) form opens.
3. Configure the required parameters.

   The parameters that are available vary depending on the option selected for the Frame Type parameter.

   To configure some parameters, you must select the check box for the parameter.
4. Select a bypass policer, if required.

   The bypass policer must be local to the SAP (that is, it cannot be part of a queue group), and it must already be created within the SAP ingress policy, as described in Step 7 .
5. Save your changes and close the form.

c. Configure IPv6 match criteria.

1. Click on the IPv6 Match Criteria tab.
2. Click Create or choose an entry and click Properties. The IPv6 Match form opens.
3. Configure the required parameters.

   The Source Port and Destination Port parameters appear only when the Protocol parameter value is TCP, UDP, or UDPTCP (*).

   The VXLAN-VNI Properties panel is only displayed when the Protocol parameter value is set to UDP (17). You can then configure the required Operator parameter.

   To configure some parameters, you must select the check box for the parameter.

   The Src Mask and Src Net Mask parameters are mutually exclusive.

   The Dst Mask and Dst Net Mask parameters are mutually exclusive.
4. In the IP Properties panel, select QoS IP Prefix List policies, as required.

   - For the Source IPv6 Prefix and Destination IPv6 Prefix parameters, enable the checkbox and click Select. The Select [Source|Destination] IPv6 Prefix form opens.

   - Click Create, or click Search and choose an existing QoS IP Prefix list policy.

   See 50.33 “To configure a QoS prefix list policy” (p. 1561).
5. Select a bypass policer, if required.

   The bypass policer must be local to the SAP (that is, it cannot be part of a queue group), and it must already be created within the SAP ingress policy, as described in Step 7 .
6. Save your changes and close the form.

14

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.29 To configure a 7210, 7250, and 1830 SAP Access Ingress policy

50.29.1 Purpose

A 7210, 7250 and 1830 SAP Access Ingress policy defines forwarding for traffic entering from a service. The policy specifies the following:

- an FC and profile for packets, based on MAC and IP match criteria, or dot1p or DSCP classification
- a default FC and profile for packets that do not meet any of the match criteria
- mapping of FCs to ingress meters or queues
- ingress meters, with rate values (CIR, PIR), burst sizes, and algorithm modes
- ingress queues, with rate values (CIR, PIR), scheduler priority values, and assigned queue management or slope policies

Meters are defined for unicast and multipoint traffic, and are mapped to FCs according to the user-

defined configuration in the policy. The maximum number of meters supported on a local policy varies depending on the chassis type.

The 7210 SAS-K and 7210 SAS-X support ingress queues. The 7210, 7250 and 1830 SAP Access Ingress policy allows the creation of up to eight queues per SAP, and maps the queues to FCs according to the user-defined configuration in the policy. For the 7210 SAS-K, unicast and multicast ingress queues are configured in the policy. For the 7210 SAS-X, ingress multipoint traffic is handled separately; see 52.16 “To configure a 7210 multipoint bandwidth management policy” (p. 1725) .

The 7210, 7250 and 1830 SAP Access Ingress policy is assigned to L2 access interfaces on VPLS and VLL services, and to L3 access interfaces on IES and VPRN services. See the following procedures, according to the service type:

- 76.43 “To assign ingress and egress QoS policies to a VLL L2 access interface on a 7210 SAS site” (p. 2184) for VLL
- 77.70 “To assign ingress and egress QoS policies to a VPLS L2 access interface on a 7210 SAS site” (p. 2343) for VPLS
- 78.33 “To assign ingress and egress QoS policies to an IES L3 access interface on a 7210 SAS site” (p. 2479) for IES
- 79.90 “To assign ingress and egress QoS policies to a VPRN L3 access interface on a 7210 SAS site” (p. 2665) for VPRN

The NFM-P provides one default 7210, 7250 and 1830 SAP Access Ingress policy (policy ID 1). The default policy cannot be deleted or modified, and is assigned to an interface unless a user-defined policy is explicitly assigned. The default policy defines two default meters, one for unicast traffic (Meter 1) and one for multipoint traffic (Meter 11). The default meters map all packets to the *be* (best effort) FC.

MAC and IP match criteria entries consume NE system resources. The system resource profile for a 7210 SAS NE that uses the policy must be configured appropriately. See 6.5.13 “System resource profile” (p. 220) in Chapter 6, “Device support” for more information.

You can override the settings for meters and queues in access ingress policies that are assigned to access interfaces. For information about policy overrides for access ingress meters on 7210 SAS NEs, see 50.98 “To configure QoS policy overrides on access ingress meters for the 7210 SAS” (p. 1657) . For information about policy overrides for access ingress queues on 7210 SAS-X NEs, see 50.99 “To configure QoS policy overrides on access ingress queues for a 7210 SAS-X” (p. 1659) .

The 7210, 7250 and 1830 SAP Access Ingress policy is supported on all 7210 SAS chassis types. If you are configuring a SAP access ingress policy for a 7250 IXR, see 50.28 “To configure a SAP access ingress policy” (p. 1538). For more information about QoS policy support on the 7250 IXR, see 50.24 “7250 IXR QoS policies” (p. 1534).

Support for specific parameters and features depends on the chassis type. Local definitions of the policy do not necessarily support all configurations in the global policy. See the NE documentation for more information.

50.29.2 Steps

1

Choose Policies→QoS→SROS QoS→Access Ingress→7210, 7250 and 1830 Access Ingress Policies from the NFM-P main menu. The 7210, 7250 and 1830 Access Ingress Policies form opens.

2

Click Create, or choose a policy and click Properties. The 7210, 7250 and 1830 SAP Access Ingress Policy (Create|Edit) form opens.

3

Configure the required parameters on the General tab.

To avoid deployment errors, configure the Number of QoS Classifiers parameter to coordinate with the system resource profile settings for the NE. See 6.5.13 “System resource profile” (p. 220) in Chapter 6, “Device support” . The combined SAP-based allocations must not exceed the system allocations. See the NE documentation for more information.

For supporting 7210 SAS-Mxp NEs, table-based ingress classification is available using an assigned FC Meter Map policy. You must set the Use SVC Meter Pool to True, and assign an FC Meter Map policy in the Classification Type panel.

You can configure the IPV6 Match Criteria type parameter only when the Allow any IPV6 Match parameter is set to true.

You cannot change the setting of the MAC Match Criteria type, IP Match Criteria type, or IPV6 Match Criteria type parameters when entries exist for that match type. You must delete the entries first, and release the global policy.

You cannot set the IP MAC Match Criteria type parameter to None, or change it from None, when entries exist. You must delete the entries first, and release the global policy.

You cannot change the setting of the IP MAC Match Criteria type parameter when the policy is assigned to an access interface.

When the IP MAC Match Criteria type parameter is set to IP First or MAC first, the Allow any IPV6 Match parameter must be set to false.

4

If you are configuring a policy for the 7210 SAS-K, select a Dot1p classification policy in the Classification Type panel. See 50.84 “To configure a 7210/7250 Dot1p classification policy” (p. 1637) for information about 7210 Dot1p classification policies.

The classification policies selected in the Classification Type panel apply only to the 7210 SAS-K. For 7250 IXR classification configuration, you must select an Ingress CoS classification policy in the Ingress CoS Classification panel; see Step 6.

5

If you are configuring a policy for the 7210 SAS-K, or for table-based classification on supporting chassis types, select a DSCP classification policy in the Classification Type panel.

See 50.85 “To configure a 7210/7250 DSCP classification policy” (p. 1638) for information about 7210 DSCP classification policies.

The classification policies selected in the Classification Type panel apply only to the 7210 SAS-K. For 7250 IXR classification configuration, you must select an Ingress CoS classification policy in the Ingress CoS Classification panel; see Step 6.

6

If you are configuring a policy for the 7250 IXR, or for table-based classification on supporting chassis types, select a 7250 Ingress CoS classification policy in the Ingress CoS Classification panel. See 50.89 “To configure a 7250 Ingress CoS policy” (p. 1642) for information about 7250 Ingress CoS policies.

You cannot select a 7250 Ingress CoS policy that contains a 7210/7250 MPLS LSP-EXP policy.

7

If you are configuring a policy for a 7210 SAS-Mxp that supports 7210 Meter Map policies, perform the following:

1. Set the User SVC Meter Pool parameter to True. FC-Meter-Map parameters appear on the form.

   The Number of QoS Classifiers parameter supported value is 2.
2. Select a 7210 FC Meter Map policy in the Classification Type panel. See 50.87 “To configure a 7210 FC Meter Map policy” (p. 1640);
3. Go to Step 16.

8

Configure ingress meters.

The 7250 IXR NEs use the term “policer” internally, but the NFM-P policy configuration uses the term “meter”. When you configure a 7210, 7250 and 1830 SAP Access Ingress policy for 7250 IXR NEs, meters configured in the policy correspond to policers in 7250 IXR NEs.

The Number of QoS Classifiers parameter, configured in Step 3 , affects the number of meters available.

Perform the following:

1. Click on the Meter tab.
2. Select a meter and click Properties, or click Create. The Meter form opens.
3. Configure the required parameters on the General tab.

   You cannot choose ID values 1 or 11 for user-configured meters; these ID values are used by default meters.

   Note:

   To enable hierarchical ingress policing (H-metering), set the Rate Mode parameter to trTCM (RFC 4115).
4. Click on the CIR/PIR and Burst Size tabs and configure the required parameters.
5. Save your changes and close the form.

9

Configure ingress queues.

The Number of QoS Classifiers parameter, configured in Step 3 , affects the number of queues available.

1. Click on the Queues tab.
2. Select a queue and click Properties, or click Create. The Queue form opens.
3. Configure the required queue identification parameters.
4. Select a queue management policy in the Queue Management Policy panel. See 50.52 “To configure a 7210 and 7250 Queue Management policy” (p. 1592) for information about queue management policies.
5. Select a slope policy in the Slope Policy panel. See 50.50 “To configure a 7210 and 1830 slope policy” (p. 1589) for information about slope policies.
6. Configure the scheduling parameters in the Port Parent panel.
7. Configure the rate parameters in the CIR/PIR panel.
8. Click on the Burst Size tab and configure the required parameters.
9. Save your changes and close the form.

   Note:

   You can configure queues in the policy anytime, but when the policy is assigned to an interface, the system resource profile for the 7210 SAS NE must allocate sufficient resources to the Queues function. See 12.50 “To configure the global system resource profile on a 7210 SAS or 7250 IXR” (p. 380) .

10

Click on the Forwarding Classes tab.

11

Select a forwarding class and click Properties, or click Create. The Forwarding Class form opens.

12

Configure the Forwarding Class parameter, if required.

13

Map the FC to a queue or meter. Perform one of the following:

a. Assign a queue or queues to the forwarding class.

   1. Select a queue for each of the required queue types in the Queue panel. To create queues, see Step 9 .
   2. Save your changes and close the form.

b. Assign a meter or meters to the forwarding class.

1. Select a meter for each of the required meter types in the Meter panel. To create meters, see Step 4 .
2. Save your changes and close the form.

You can also select meters or queues by directly entering the meter or queue ID.

14

Repeat Step 11 to Step 13 for each forwarding class that you need to configure.

15

Configure match criteria entries.

Note: The Number of QoS Classifiers parameter, configured in Step 3 , affects the maximum number of entries available.
MAC and IP match criteria entries consume NE system resources. The system resource profile for a 7210 SAS NE must be configured appropriately. See 6.5.13 “System resource profile” (p. 220) in Chapter 6, “Device support” .

Perform any of the following:

a. Associate forwarding classes with MAC match criteria.

1. Click on the MAC Match Criteria tab.
2. Select an entry in the list and click Properties, or click Create. The MAC Match form opens.
3. Configure the required parameters.

   You can configure the Source MAC, Destination MAC, and Ether Type parameters only when the MAC Match Criteria type parameter is set to Any in Step 3 .
4. Save your changes and close the form.

b. Associate forwarding classes with IP or IPv6 match criteria.

1. Click on the IP Match Criteria tab or IPv6 Match Criteria tab.
2. Select an entry in the list and click Properties, or click Create. The IP Match or IPv6 Match form opens.
3. Configure the required parameters.

   You can configure the Fragment parameter only when the IP Match Criteria type parameter is set to Any in Step 3 .

   You can configure the Protocol, Source IP, Src Mask, Destination IP, and Dst Mask parameters only when the IP Match Criteria type parameter is set to Any in Step 3 .

   You can configure the Source Port, Port Src, Destination Port, and Port Dst parameters only when the IP Match Criteria type parameter is set to Any in Step 3 and the Protocol parameter is set to TCP or UDP.

   You can configure parameters in only one of the DSCP and IP Precedence panels. When you configure one panel, the other is not available.
4. Save your changes and close the form.

16

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.30 To configure a SAP access egress policy

50.30.1 Steps

1

Choose Policies→QoS→SROS QoS→Access Egress→SAP Access Egress from the NFM-P main menu. The SAP Access Egress Policies form opens.

2

Click Create, or choose a policy in the list and click Properties. The SAP Access Egress Policy (Create|Edit) form opens.

3

Configure the required general parameters.

Note: For some of the following steps, the tabs are not available until after the policy is created. Click Apply if required to create the policy and make all tabs available.

Note: NEs that support next-generation CLI use the policy name as the key identifier for internal system reference. For policies on these NEs, you must configure a policy name (typically the service name or a numerical string). Policy IDs are also supported. You must configure a numerical range on the NE for auto-assigned policy IDs; see 12.65 “To configure an Auto-ID range for policies” (p. 395).

4

Enable the Policers HQoS Manageable parameter if the policers in this policy are to be managed by the Hierarchical QoS process.

5

If the SAP access egress policy requires the forwarding class to be changed to an alternate queue than the ingress forwarding class determination would have used, or you need to modify the forwarding profile to modify the congestion behavior of the egress queue, select a policy in the Post Policer Mapping Policy panel.

6

Click Select in the HS panel to associate an alternate HS Attachment Policy other than the default policy. The Select HS Attachment Policy – Egress Queue Group Template Policy form opens.

7

Select the required HS Attachment Policy and click OK.

8

If you are creating a 7705 SAR MC MLPPP access egress policy, configure the Use As Multiclass MLPPP Policy For 7705 SAR parameter and select a WRR Policy in the Egress HSMDA panel.

9

Configure HSMDA queues.

1. Click on the HSMDA Queues tab. Eight default queues are displayed.
2. Choose a queue and click Properties. The Access Egress HSMDA Queue (Create) form opens.
3. Configure the required general parameters.
4. Select a slope policy in the Slope Policy panel.
5. Click on the PIR/Burst Size tab and configure the required parameters.

   To configure the parameters, deselect the MAX or Default check boxes as required.
6. Save your changes and close the forms.

10

Configure access egress queues.

1. Click on the Queues tab.

   The NFM-P provides a default egress queue (ID 1). You can modify the default queue but you cannot delete queue ID 1.
2. Click Create, or choose a queue and click Properties. The Queue (Create|Edit) form opens.

   You can create up to eight queues.
3. Configure the required general parameters.

   Note:

   You must enable the Use WRED Queue parameter to display and configure additional parameters associated with a WRED queue.
4. Select a Slope Policy, Pool Name, Advanced Configuration Policy, and Scheduler.

   Before you can select a Pool Name, you must create a Q1 pool; see 50.68 “To configure Q1 pools” (p. 1611) .

   Scheduler selection is available when the Port Parent parameter is set to false.

   The hardware aggregate shaper scheduler policy can be supported using Shaper Weight and Scheduler Class parameters. See 50.64 “To configure a Hardware Aggregate Shaper Scheduler policy” (p. 1608).
5. Click on the CIR/PIR tab and configure the required parameters.

You can configure the CIR and PIR as a rate or as a percentage, depending on the option selected for the Rate Type parameter.

6. Click on the Burst Size tab and configure the required parameters.

   Deselect the Default check box for each parameter that you need to configure.

   Ensure that the Committed Burst Size (KB) value is lower than the Maximum Burst Size (bytes) value.
7. Click on the HSQ tab if required and configure the required parameters. You can only configure HSQ on default queue entries 1 to 8.
8. Select a HS WRED Slope Policy if required and click OK.

   Note: To configure the parameters on the HS WRED Slope Policy Properties form, you must first create a HS WRED Slope policy. See 50.49 “To configure a WRED slope policy” (p. 1587).
9. Save your changes and close the form.

11

Configure a dynamic policer.

1. Click on the Dynamic Policer tab and configure the required general parameters.
2. Select a Parent Arbiter.
3. Click on the Burst Size tab and configure the Committed Burst Size and Maximum Burst Size parameters.

   Deselect the Default check box for each parameter that you need to configure.

   Ensure that the Committed Burst Size value is lower than the Maximum Burst Size value.

12

Configure egress policers.

1. Click on the Policer tab.
2. Click Create, or choose a policer and click Properties. The Access Egress Policer (Create|Edit) form opens.
3. Configure the general parameters.
4. Select a Parent Arbiter and an Advanced Configuration Policy.
5. Select a Scheduler Parent if required, and then configure the parameters in the Scheduler Association panel.

   Note:

   You cannot configure a Scheduler Parent and a Port Parent. They are mutually exclusive.
6. Set the Port Parent parameter to True if you need to create a port parent association for the policer, as opposed to a scheduler association. You can then configure the parameters in the Port Parent Association panel.
7. Click on the CIR/PIR tab and configure the required parameters.

You can configure the CIR and PIR as a rate or as a percentage, depending on the option selected for the Rate Type parameter.

8. Click on the Burst Size tab and configure the required parameters.

   Deselect the Default check box for each parameter that you need to configure.

9. Save your changes and close the form.

13

Configure forwarding classes. You can create up to eight forwarding classes.

1. Click on the Forwarding Classes tab.
2. Click Create, or choose a forwarding class and click Properties. The Forwarding Class (Create|Edit) form opens.
3. Configure the Forwarding Class parameter.
4. Complete one of the following for each Forwarding Class you configure:
   - If you need to configure a policer, set the Traffic Control parameter for the Use Policer option and go to 5 .
   - If you need to configure a local queue, set the Traffic Control parameter for the Use Queue option and configure the Port Redirect Queue Group parameter as required, then go to 9 .
   - If you need to configure a queue from a queue group, set the Traffic Control parameter to the Use Queue Group option and go to 7 .
5. In the Policers panel, select a policer.
6. Configure the Port Redirect Queue Group parameter as required. If you disable this parameter, then go to 7 . Otherwise go to 9 .
7. In the Queue Group panel, select a Queue Group Template Policy.
8. Configure the Instance ID parameter.
9. In the Queue panel, select a queue.

   Note:

   You cannot map a Forwarding Class to a non-existent or deleted Queue ID. Use the Select button to choose a Queue ID, as opposed to manually entering it in the Queue ID field.

   The queue you can select here is dependent on the Traffic Control parameter setting you chose in 4 , as follows:

   - Use Queue: If you specified this setting, then you can only select a locally-defined queue. The local queue in this context is either the default queue or one you created for this policy in Step 10 . The local queue you select here must be set to a unicast ID. The default ID for unicast queues is 1. Alternatively, you can manually enter 0 if you want the default Queue ID to be used.
   - Use Queue Group: If you specified this setting, then you can only select one of the queues defined in the Queue Group Template Policy you chose in 7 .

     Note:

     If the Use Queue Group option is enabled for the global policy, then the Queue ID you select is validated against the specified Queue Group Template Policy. The Queue ID is validated against the local queues for each local policy instance.

You cannot delete a Queue Group Template Policy that is referenced by a queue group.

- Use Policer: If you specified this setting and disabled the Port Redirect Queue Group parameter in 6 , then you can select one of the queues defined in the Queue Group Template Policy you chose in 7 . If you enabled the Port Redirect Queue Group parameter in 6 , then select the required local queue here.

10. In the Hsmda Queue panel, configure the Queue ID and Port Redirect Queue Group parameters, as required.
11. Configure the required parameters in the Dot1p and Properties panels.
12. Save your changes and close the form.

14

Configure IPv4 match criteria.

1. Click on the IP Match Criteria tab.
2. Click Create, or choose an entry and click Properties. The IP Match (Create|Edit) form opens.
3. Configure the required parameters.

   To configure some parameters, you must select the check box for the parameter.

   The Source Port and Destination Port parameters appear only when the Protocol parameter value is TCP, UDP, or UDPTCP (*).

   The Src Mask and Src Net Mask parameters are mutually exclusive.

   The Source IP and Source IP Prefix parameters are mutually exclusive.

   The Dst Mask and Dst Net Mask parameters are mutually exclusive.

   The Destination IP and Destination IP Prefix parameters are mutually exclusive.
4. In the IP Properties panel, select QoS IP Prefix List policies, as required.

   - For the Source IP Prefix and Destination IP Prefix parameters, enable the checkbox and click Select. The Select [Source|Destination] IP Prefix form opens.

   - Click Create, or click Search and choose an existing QoS IP Prefix list policy.

   See 50.33 “To configure a QoS prefix list policy” (p. 1561).
5. In the Bypass Policer panel, select a Policer and Queue and configure the Port Redirect Queue Group parameter, as required.

   Note:

   The bypass policer must be local to the SAP (that is, it cannot be part of a queue group), and it must already be created within the SAP egress policy, as described in Step 12 .
6. Save the changes and close the form.

15

Configure IPv6 match criteria.

1. Click on the IP Match Criteria tab.

2. Click Create, or choose an entry and click Properties. The IP Match (Create|Edit) form opens.
3. Configure the required parameters.

   To configure some parameters, you must select the check box for the parameter.

   The Source Port and Destination Port parameters appear only when the Protocol parameter value is TCP or UDP.

   The Src Mask and Src Net Mask parameters are mutually exclusive.

   The Dst Mask and Dst Net Mask parameters are mutually exclusive.
4. In the IP Properties panel, select QoS IP Prefix List policies, as required.

   - For the Source IPv6 Prefix and Destination IPv6 Prefix parameters, enable the checkbox and click Select. The Select [Source|Destination] IPv6 Prefix form opens.

   - Click Create, or click Search and choose an existing QoS IP Prefix list policy.

   See 50.33 “To configure a QoS prefix list policy” (p. 1561).
5. In the Bypass Policer panel, select a Policer and Queue and configure the Port Redirect Queue Group parameter, as required.

   Note:

   The bypass policer must be local to the SAP (that is, it cannot be part of a queue group), and it must already be created within the SAP egress policy, as described in Step 12 .
6. Save your changes and close the form.

16

Map DSCP values to FCs and profiles.

1. Click on the DSCP tab.
2. Click Create, or choose an entry and click Properties. The DSCP form opens.
3. Configure the required parameters.
4. Save your changes and close the form.

17

Map Precedence values to FCs and profiles.

1. Click on the Precedence tab.
2. Click Create, or choose an entry and click Properties. The Precedence form opens.
3. Configure the required parameters.
4. Save your changes and close the form.

18

Map dot1p values to FCs and profiles.

1. Click on the Dot1p tab.
2. Click Create, or choose an entry and click Properties. The Dot1p form opens.

3. Configure the required parameters.
4. Save your changes and close the form.

19

Configure the HSQ parameters if required to configure HS WRR Groups..

1. Click on the HS WRR Groups tab.
2. Choose an existing HS WRR group and click Properties. The HS WRR Group form opens.

   Note: You can only modify the existing WRR Group parameters; you cannot create new WRR Groups.
3. As required, modify the parameters.
4. Save your changes and close the form.

20

Configure Scheduler Class Elevation.

1. Click on the Scheduler Class Elevation tab.
2. Choose an existing Scheduler Class Elevation entry and click Properties. The Scheduler Class Elevation form opens.

   Note: You can only modify the existing Scheduler Class Elevation parameters; you cannot create new Scheduler Class Elevation entries.
3. As required, modify the parameters.
4. Save your changes and close the form.

21

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.31 To configure a 7210 and 1830 port access egress policy

50.31.1 Purpose

A 7210 and 1830 port access egress policy defines remarking values and queue rate and scheduling parameters for traffic that egresses the switch toward a service. The policy is assigned to access ports; see 16.45 “To assign QoS policies to a 7210 SAS Ethernet port” (p. 636) . Policy definitions are applied to all SAPs on the port.

You can enable or disable remarking in the policy. Remarking is configured per FC, or a 7210 remarking policy is assigned.

You can configure CIR and PIR for up to eight queues, and you can assign queue management policies to define slope and burst size parameters for queues. Queues are mapped to forwarding classes by default; the mapping is not user-configurable.

The NFM-P provides a default 7210 and 1830 port access egress policy (policy ID 1). The default policy cannot be modified or deleted, and policy ID 1 cannot be used by another policy. The default policy specifies dot1p remarking, a default remarking policy, and queue rates set to the port line rate. The default policy is assigned to access ports if no user-configured policy is assigned.

All 7210 SAS chassis types (except the 7210 SAS-K) support the 7210 and 1830 port access egress policy. Support for specific parameters and features varies, depending on the chassis type. Local definitions of the policy do not necessarily support all configurations in the global policy.

50.31.2 Steps

1

Choose Policies→QoS→SROS QoS→Access Egress→7210 and 1830 Port Access Egress from the NFM-P main menu. The 7210 and 1830 Port Access Egress Policies form opens.

2

Click Create or choose a policy and click Properties. The Port Access Egress Policy (Create|Edit) form opens.

3

Configure the required parameters on the General tab.

The Remarking Type parameter is configurable when the Egress Remark parameter is set to true.

4

Select a remarking policy, if required. See 50.80 “To configure a 7210 remarking policy” (p. 1630) for information about 7210 remarking policies.

Note: A 7210 remarking policy that is assigned to a 7210 and 1830 port access egress policy must be of one of the following types:

- DOT1P
- DSCP
- DOT1P - DSCP
- DOT1P - LSP-EXP SHARED

5

Configure port access egress queues.

1. Click on the Queues tab. A list of eight queues is displayed.
2. Choose a queue and click Properties. The Port Access Egress Queue form opens.
3. Configure the required parameters on the General tab.
4. Select a queue management policy, if required. See 50.52 “To configure a 7210 and 7250 Queue Management policy” (p. 1592) for information about 7210 queue management policies.

5. Click on the CIR/PIR tab and configure the required parameters.
6. Save the changes and close the form.

6

Assign remarking values to forwarding classes.

1. Click on the Forwarding Classes tab.
2. Choose an FC from the list and click Properties, or click Create. The Port Access Egress Forwarding Class form opens.
3. Configure the required parameters.

   For dot1p and DE remarking, settings for the Dot1p and Force DE value parameters take effect when the Mark DE bits parameter is set to true.
4. Save the changes and close the form.

7

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.32 To configure a 7210 SAP access egress policy

50.32.1 Purpose

A 7210 SAP access egress policy defines remarking and SAP egress queue parameters for traffic egressing the switch into a service.

For packets, the policy defines SAP-based remarking values using an assigned 7210 remarking policy.

For SAP-based egress queues, the policy defines:

- rate parameters
- scheduling priority values and weights
- slope parameters and burst size values, using an assigned queue management policy or slope policy

Egress queues are mapped to forwarding classes. For 7210 SAS-Mxp, 7210 SAS-R, and 7210 SAS-X devices, the mapping is static and not user-configurable. The mapping for these devices is not displayed in the NFM-P. The following table shows the system-defined mapping.

Table 50-8 7210 SAS system-defined FC-to-queue mapping

Forwarding class	Queue ID
nc	8
h1	7

Table 50-8 7210 SAS system-defined FC-to-queue mapping (continued)

Forwarding class	Queue ID
ef	6
h2	5
l1	4
af	3
l2	2
be	1

For the 7210 SAS-K, the FC-to-queue mapping is user-configurable. You must explicitly enable queues in policies distributed to the 7210 SAS-K, except for Queue 1 which is enabled by default. Only queues that are applicable are available for mapping to FCs.

The 7210 SAP access egress policy is assigned to L2 access interfaces on VPLS and VLL services, and to L3 access interfaces on IES and VPRN services. You can also assign the policy to destination L2 interfaces on mirror services. The 7210 SAP access egress policy is SAP-based, not port-based, and applies policy definitions only on the interfaces to which it is assigned. The policy is assigned to interfaces in the following procedures, according to the service type:

- 76.43 “To assign ingress and egress QoS policies to a VLL L2 access interface on a 7210 SAS site” (p. 2184) for VLL
- 77.70 “To assign ingress and egress QoS policies to a VPLS L2 access interface on a 7210 SAS site” (p. 2343) for VPLS
- 78.33 “To assign ingress and egress QoS policies to an IES L3 access interface on a 7210 SAS site” (p. 2479) for IES
- 79.90 “To assign ingress and egress QoS policies to a VPRN L3 access interface on a 7210 SAS site” (p. 2665) for VPRN
- 93.10 “To create an L2 access interface on a destination site” (p. 3174) for mirror services

The NFM-P assigns a default 7210 SAP access egress policy to an interface unless a user-configured policy is explicitly assigned. The default policy (policy ID 1) cannot be altered or deleted.

The 7210 SAP access egress policy is supported on the 7210 SAS-K, 7210 SAS-Mxp, 7210 SAS-R, and 7210 SAS-X. Support for specific parameters and features varies, depending on the chassis type. Local definitions of the policy do not necessarily support all configurations in the global policy. See the NE documentation for more information.

Note: For the 7210 SAS-Mxp, 7210 SAS-R, and 7210 SAS-X, access egress remarking is either SAP-based or port-based. L3 access egress remarking is always port-based. For the 7210 SAS-Mxp and 7210 SAS-R, L2 access egress remarking is always SAP-based.

For the 7210 SAS-X, to use the values configured in a 7210 SAP access egress policy for SAP-based remarking, you must enable the SAP QoS Marking parameter on the port properties form for access and hybrid ports; see 16.24 “To configure Ethernet ports” (p. 599) .

See the NE documentation for more information.

50.32.2 Steps

1

Choose Policies→QoS→SROS QoS→Access Egress→7210 SAP Access Egress from the NFM-P main menu. The 7210 SAP Access Egress Policies form opens.

2

Click Create or choose a policy and click Properties. The 7210 SAP Access Egress Policy (Create|Edit) form opens.

3

Configure the required parameters.

For 7210 SAS-K NEs, you must enable the Remarking Policy Applicable parameter to apply the remarking policy selected in Step 4 , or a default remarking policy is applied.

4

Select a remarking policy in the Remarking Policy panel. See 50.80 “To configure a 7210 remarking policy” (p. 1630) for more information about 7210 remarking policies.

5

Configure SAP egress queues.

1. Click on the Queues tab. Eight default queues are displayed.
2. Choose a queue and click Properties. The Queue, 7210 SAP Access Egress Policy form opens.
3. Configure the required parameters on the General tab.

   The Port Parent panel contains scheduling parameters.
4. Select a Queue Management Policy in the Queue Management Policy panel.
5. Select a Slope Policy in the Slope Policy panel.
6. Click on the CIR/PIR and Burst Size tabs and configure the required parameters.
7. Save your changes and close the form.

6

Click on the Forwarding Classes tab.

7

Map FCs to queues.

1. Click Create, or choose an FC from the list and click Properties. The Forwarding Class form opens.
2. Configure the Forwarding Class parameter and select queues as required.

   Queues are available only when the Queue Applicable parameter is enabled for the queue.

3. Save your changes and close the form.

8

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.33 To configure a QoS prefix list policy

50.33.1 Purpose

QoS IPv4 and IPv6 prefix lists are associated with the following QoS policies:

- SAP access ingress policies ; see 50.28 “To configure a SAP access ingress policy” (p. 1538).
- SAP access egress policies; see 50.30 “To configure a SAP access egress policy” (p. 1550).
- Network policies ; see 50.41 “To configure a QoS network policy” (p. 1568).

Various tabs on the QoS IP Prefix List form show the associations for lists in distributed policies.

50.33.2 Steps

1

Choose Policies→QoS→SROS QoS→QoS Match→ Prefix List from the NFM-P main menu. The QoS – Prefix Lists form opens.

2

Click Create, or choose a policy in the list and click Properties. The QoS – IP Prefix List (Create|Edit) form opens.

3

If you are creating a new policy, configure the IP Prefix List Name and IP Prefix List Type parameters, and click Apply.

4

Configure IP Prefix List members.

1. Click on the IP Prefix List Members tab.
2. Click Create, or choose an entry and click Properties. The QoS IP Prefix List Member form opens.
3. Configure the Prefix and Mask parameters.
4. Save your changes and close the form.

5

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To

release and distribute a policy" (p. 1568) to distribute the policy to NEs.

End of steps

50.34 To configure a QoS port list policy

50.34.1 Purpose

A QoS port list policy defines TCP/UDP ports or ranges of port values for use as IPv4 and IPv6 match criteria.

QoS port list policies are associated with QoS network policies; see 50.41 "To configure a QoS network policy" (p. 1568).

Tabs on the QoS - Port List form show the associations for lists in distributed policies.

50.34.2 Steps

1

Choose Policies→QoS→SROS QoS→QoS Match→QoS Port List from the NFM-P main menu. The QoS - Port List form opens.

2

Click Create, or choose a policy in the list and click Properties. The QoS - Port List (Create|Edit) form opens.

3

Configure the required parameters on the General tab.

4

Configure Port List members.

Port list policies can contain a maximum of 16 members.

1. Click on the Port List Members tab.
2. Click Create, or choose a member entry and click Properties. The Port List Member form opens.
3. For the Port parameter, choose EQUAL or RANGE in the drop-down, and configure the port value or values.
4. Save your changes and close the form.

5

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 "To release and distribute a policy" (p. 1476) to distribute the policy to NEs.

End of steps

50.35 To configure an ATM QoS policy

50.35.1 Steps

1

Choose Policies→QoS→SROS QoS→ATM QoS from the NFM-P main menu. The Manage ATM QoS Policies form opens.

2

Click Create or choose an ATM QoS policy and click Properties. The ATM QoS Policy (Create | Edit) form opens.

3

Configure the parameters on the General tab.

4

Click on the QoS tab and configure the required parameters.

5

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.36 To configure a Post Policer Mapping policy

50.36.1 Steps

1

Choose Policies→QoS→SROS QoS→Post Policer Mapping from the NFM-P main menu. The Post Policer Mapping Policy form opens.

2

Click Create or choose an Post Policer Mapping Policy and click Properties. The Post Policer Mapping Policy (Create | Edit) form opens.

3

Configure the parameters on the General tab.

4

Click on the Post Policer Mapping Entry tab and configure the required parameters.

5

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.37 To configure a MC MLPPP ingress QoS profile

50.37.1 Steps

1

Choose Policies→QoS→SROS QoS→MLPPP→Ingress QoS Profile from the NFM-P main menu. The Manage MLPPP Ingress QoS Profile form opens.

2

Click Create or choose an existing profile and click Properties. The MLPPP Ingress QoS Profile (Create | Edit) form opens.

Note: You can edit the properties of the default ingress MC profile, but you cannot delete the profile.

3

Configure the required parameters on the General tab and click Apply.

4

Click on the Classes tab.

5

Select a class in the list and click Properties. The MLPPP Ingress QoS Profile Class (Edit) form opens.

6

Configure the Reassembly Timeout (msec) parameter and click OK.

7

Repeat Step 5 and Step 6 for each class that you need to configure.

8

Save your changes and close the form.

END OF STEPS

50.38 To configure a MC MLPPP egress QoS profile

50.38.1 Steps

1

Choose Policies→QoS→SROS QoS→MLPPP→Egress QoS Profile from the NFM-P main menu. The Manage MLPPP Egress QoS Profile form opens.

2

Click Create or choose an existing profile and click Properties. The MLPPP Ingress QoS Profile (Create | Edit) form opens.

Note: You can edit the properties of the default egress MC profiles, but you cannot delete them.

3

Configure the required parameters on the General tab and click Apply.

4

Click on the Classes tab.

5

Select a class in the list and click Properties. The MlpppEgressQosProfileClass (Edit) form opens.

6

Configure the required parameters and click OK.

7

Repeat Step 5 and Step 6 for each class that you need to configure.

8

Click on the Forwarding Classes tab.

9

Select a forwarding class in the list and click Properties. The MlpppEgressQosProfileForwardingClass (Edit) form opens.

10

Configure the MLPPP Class parameter and click OK.

11

Repeat Step 9 and Step 10 for each forwarding class that you need to configure.

12

Save your changes and close the form.

END OF STEPS

50.39 To configure a MCFR ingress QoS profile

50.39.1 Steps

1

Choose Policies→QoS→SROS QoS→MCFR→Ingress QoS Profile from the NFM-P main menu. The Manage MCFR Ingress QoS Profile form opens.

2

Click Create or choose an existing profile and click Properties. The MCFR Ingress QoS Profile (Create | Edit) form opens.

Note: You can edit the properties of the default ingress MC profile, but you cannot delete the profile.

3

Configure the required parameters on the General tab and click Apply.

4

Click on the Classes tab.

5

Select a class in the list and click Properties. The MCFR Ingress QoS Profile Class (Edit) form opens.

6

Configure the Reassembly Timeout (msec) parameter and click OK.

7

Repeat Step 5 and Step 6 for each class that you need to configure.

8

Save your changes and close the form.

END OF STEPS

50.40 To configure a MCFR egress QoS profile

50.40.1 Steps

1

Choose Policies→QoS→SROS QoS→MCFR→Egress QoS Profile from the NFM-P main menu. The Manage MCFR Egress QoS Profile form opens.

2

Click Create or choose an existing profile and click Properties. The MCFR Egress QoS Profile (Create | Edit) form opens.

Note: You can edit the properties of the default egress MC profile, but you cannot delete the profile.

3

Configure the required parameters on the General tab and click Apply.

4

Click on the Classes tab.

5

Select a class in the list and click Properties. The MCFR Egress QoS Profile Class (Edit) form opens.

6

Configure the required parameters and click OK.

7

Repeat Step 5 and Step 6 for each class that you need to configure.

8

Save your changes and close the form.

END OF STEPS

50.41 To configure a QoS network policy

50.41.1 Steps

1

Choose Policies→QoS→SROS QoS→Network→Network from the NFM-P main menu. The Network Policies form opens.

2

Click Create, or choose a policy and click Properties. The Network Policy (Create|Edit) form opens.

3

Configure the required general parameters.

Note: To view or configure the NE policy name parameter, the Show Display Name of Form system preference must be enabled. See the procedure to configure NFM-P system preferences in the *NSP System Administrator Guide*.

Note: NEs that support next-generation CLI use the policy name as the key identifier for internal system reference. For policies on these NEs, you must configure a policy name (typically the service name or a numerical string). Policy IDs are also supported. You must configure a numerical range on the NE for auto-assigned policy IDs; see 12.65 “To configure an Auto-ID range for policies” (p. 395).

4

Configure the parameters in the Ingress panel and Egress panel.

5

If you are configuring a network policy for a 2-port ring adapter MDA on a 7705 SAR NE, perform the following:

1. Set the Network Policy Type for 7705 parameter to Ring. The Ring Dot1p tab becomes available, and other tabs are unavailable.
2. Click on the Ring Dot1p tab and choose an entry, or click Create. The Ring Dot 1 p (Create|Edit) form opens.
3. Configure the required parameters to map dot1p values to queues and profiles.
4. When you finish mapping the required queues, go to Step 11 .

6

Configure egress forwarding classes.

1. Click on the Egress Forwarding Classes tab. Eight default FCs are displayed.
2. Click Create, or choose an FC and click Properties. The Egress Forwarding Class (Create|Edit) form opens.
3. Configure the required parameters.

   Select the Use check box to configure the Queue ID and Policer ID parameters. A valid entry for the Queue ID parameter must be specified in the queue group template policy.
4. Save your changes and close the form.

7

Configure ingress forwarding classes.

1. Click on the Ingress Forwarding Classes tab. Eight default FCs are displayed.
2. Click Create, or choose an FC and click Properties. The Ingress Forwarding Class (Create|Edit) form opens.
3. Configure the required parameters.
4. Save your changes and close the form.

8

To configure the mapping of ingress or egress traffic markings to FCs and profiles, click on the appropriate tab. Mapping is optional and is based on combinations of customer QoS marking for LSP EXP, DSCP, Dot1p, and Precedence. Table 50-9, “Network policy traffic-mapping options” (p. 1568) describes the options.

Table 50-9 Network policy traffic-mapping options

Tab	Mapping
Ingress LSP EXP Bits	LSP EXP bits of the ingress traffic to an FC and profile
Ingress DSCP	DSCP of the ingress traffic to an FC and profile
Ingress Dot1p	Dot1p tag of the ingress traffic to an FC and profile
Egress DSCP	DSCP of the egress traffic to an FC and profile
Egress Precedence	Precedence value of the egress traffic to an FC and profile

Perform the following steps for each mapping that you want to configure.

1. Click on the required tab.
2. Click Create, or choose an entry and click Properties. A (Create|Edit) form opens.
3. Configure the required parameters.
4. Save your changes and close the form.

9

Configure ingress match criteria.

1. Click on the Ingress IP Match Criteria or the Ingress IPv6 Match Criteria tab, as required.
2. Click Create. The [IP|IPv6] Match (Create) form opens.
3. Configure the required parameters.

   Match entries are evaluated in numerical order based on the entry ID from the lowest to highest ID value. The first entry that matches all match criteria has its action performed.
4. In the IP Properties panel, select a QoS IP Prefix List policy, as required.

   - For the Source [IP|IPv6] Prefix or Destination [IP|IPv6] Prefix parameters, enable the check box and click Select. The Select [Source|Destination] IPv6 Prefix form opens.

The Source IP and Source IP Prefix parameters are mutually exclusive. The Destination IP and Destination IP Prefix parameters are mutually exclusive.

- Click Create, or click Search and choose an existing QoS IP Prefix list policy.

See 50.33 “To configure a QoS prefix list policy” (p. 1561).

You can assign only one QoS IP Prefix list policy per match entry, either as a Source IP Prefix or a Destination IP Prefix.

5. In the Port Properties panel, select a QoS port list policy, as required.

   - For the Source Port List or Destination Port List parameters, enable the check box and click Select. The Select [Source|Destination] Port List form opens.

   The Source Port and Source Port List parameters are mutually exclusive. The Destination Port and Destination Port List parameters are mutually exclusive.

   - Click Create, or click Search and choose an existing QoS port list policy.

   See 50.34 “To configure a QoS port list policy” (p. 1562).

   You can assign only one QoS port list policy per match entry, either as a Source Port List or a Destination Port List.

6. Save your changes and close the form. The new match criteria entry is displayed in the list.

Note: If required, you can renumber the IPv4 or IPv6 match criteria entries in the global policy or in a local definition. Select the entry on the Ingress IP Match Criteria or the Ingress IPv6 Match Criteria tab and click Renumber. The Renumber Entry ID form opens and displays the existing (Old) Entry ID. Configure a New Entry ID and click OK.

Note: The use of the Source IP Prefix parameter in the IP Properties panel within a single entry is mutually exclusive with the [Source|Destination] Port List parameters in the Port Properties panel.

10

Configure egress match criteria.

1. Click on the Egress IP Match Criteria or the Egress IPv6 Match Criteria tab, as required.
2. Click Create. The Egress IP Match or Egress IPv6 Match (Create) form opens, as appropriate.
3. Configure the required parameters.

   Match entries are evaluated in numerical order based on the entry ID from the lowest to highest ID value. The first entry that matches all match criteria has its action performed.

4. In the Port Properties panel, select a QoS port list policy, as required.

   - For the Source Port List or Destination Port List parameters, enable the check box and click Select. The Select [Source|Destination] Port List form opens.

   - Click Create, or click Search and choose an existing QoS port list policy.

   See 50.34 “To configure a QoS port list policy” (p. 1562).

   You can assign only one QoS port list policy per match entry, either as a Source Port List or a Destination Port List.

5. Save your changes and close the form. The new match criteria entry is displayed in the list.

Note: If required, you can renumber the IPv4 or IPv6 match criteria entries in the global policy or in a local definition. Select the entry on the Egress IP Match Criteria or the Egress IPv6 Match Criteria tab and click Renumber. The Renumber Entry ID form opens and displays the existing (Old) Entry ID. Configure a New Entry ID and click OK.

11

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.42 To configure a 7210 and 1830 network policy

50.42.1 Purpose

A 7210 and 1830 network policy defines forwarding for network traffic on both ingress and egress.

For ingress traffic, the policy associates dot1p, DSCP, or LSP-EXP bits to forwarding classes and profile states. The associations are either configured directly in the network policy, or by using an assigned Dot1p, DSCP, or MPLS LSP-EXP classification policy. For packets with no dot1p, DSCP, or LSP-EXP values, a user-defined default FC and profile are assigned.

FCs are mapped to ingress meters or queues. You can configure unicast and multipoint ingress meters. One default unicast meter and one default multipoint meter are provided within the policy. The FC-to-meter mapping is user-configurable. The network policy defines rate, burst size, and algorithm mode for ingress meters.

Ingress queues (supported on the 7210 SAS-K) are configured directly within the policy. Eight queues are provided by default. You can configure the following for network ingress queues:

- CIR and PIR as a percentage of port bandwidth
- scheduling and burst size parameters
- WRED slope parameters using an assigned slope policy; see 50.50 “To configure a 7210 and 1830 slope policy” (p. 1589)

Ingress queue-to-FC mapping is user-configurable.

For egress traffic, a network policy defines remarking behavior. Remarking is configured per FC, or a 7210 remarking policy is assigned to the network policy.

On egress, FCs are statically mapped to egress queues by default; the FC-to-queue mapping is not configurable. Rates and other parameters for egress queues are defined in a separate network queue policy; see 50.47 “To configure a 7210 and 1830 network queue policy” (p. 1583) .

There are two types of 7210 and 1830 network policies: port type and network interface type. Port-type network policies are assigned to network, hybrid, or L2 uplink ports; see 16.45 “To assign QoS policies to a 7210 SAS Ethernet port” (p. 636) . Network interface-type policies are assigned to L3 network interfaces; see 27.17 “To create an L3 network interface on a routing instance” (p. 856) and 27.18 “To configure L3 network interfaces” (p. 863) . For network interface-type policies, you can

select an MPLS LSP-EXP Profile. See 50.83 “To configure a 7210 MPLS LSP-EXP Mapping policy” (p. 1635) for information about creating an MPLS LSP-EXP Profile.

7210 and 1830 network policies are identified by both the Nw Mgr ID value and the Policy ID value. The Nw Mgr ID value is unique for all 7210 and 1830 network policies. The Policy ID value is unique for a policy type (port or network interface). It is possible to have two 7210 and 1830 network policies with the same Policy ID if one is a port-type policy and one is a network interface-type policy. However, each of these policies will have a different Nw Mgr ID.

The NFM-P provides two default 7210 and 1830 network policies. Ports use default network policy ID 1 and network interfaces use default network policy ID 2. You cannot modify or delete a default policy. A default network policy is assigned to a port or network interface unless a user-configured policy is explicitly assigned. For the 7210 SAS-K12 and 7210 SAS-K30 ETR, a default port-type policy for network ports is automatically created as Policy ID 2 when the device is discovered. An auto-assigned Nw Mgr ID value distinguishes it from the network interface default policy.

The 7210 and 1830 network policy is supported on all 7210 SAS chassis types. Support for specific parameters and features depends on the chassis type. Local definitions of the policy do not necessarily support all configurations in the global policy.

50.42.2 Steps

1

Choose Policies→QoS→SROS QoS→Network→7210 and 1830 Network from the NFM-P main menu. The 7210 and 1830 Network Policies form opens.

2

Perform one of the following:

a. Modify an existing policy. Select a policy and click Properties. The Network Policy (Edit) form opens.

b. Create a new policy.

   1. Click Create. The Network Policy (Create) form opens.
   2. Configure the Nw Mgr ID, Policy ID, and Type parameters.

      The Nw Mgr ID value is unique for all 7210 and 1830 network policies regardless of type. The Policy ID value is unique for policies within each type (port or network interface).
   3. Click Apply to create the policy. The Network Policy (Edit) form is displayed.

      Note:

      You cannot modify the Nw Mgr ID, Policy ID, or Type parameter after the policy is created.

3

Configure the required parameters on the General tab.

The Remarking Type parameter is configurable only when the Type parameter is set to Port and the Remarking parameter is set to true.

4

In the Classification Type panel, select a Dot1p, DSCP, or MPLS LSP-EXP classification policy, as required. See 50.84 “To configure a 7210/7250 Dot1p classification policy” (p. 1637), 50.85 “To configure a 7210/7250 DSCP classification policy” (p. 1638) or 50.83 “To configure a 7210 MPLS LSP-EXP Mapping policy” (p. 1635).

You can select Dot1p, DSCP, or MPLS LSP-EXP classification policies only for a port-type network policy.

5

Select an MPLS LSP-EXP Profile in the Ingress panel, if required.

You can select an MPLS LSP-EXP Profile only for a network interface-type policy.

Note: The MPLS LSP-EXP Profile defines how LSP-EXP bits are mapped to profile states on ingress. The MPLS LSP-EXP Profile is also referred to as an MPLS LSP-EXP Map policy. See 50.83 “To configure a 7210 MPLS LSP-EXP Mapping policy” (p. 1635) for more information about MPLS LSP-EXP Map policies.

6

Select a remarking policy in the Egress panel, if required. See 50.80 “To configure a 7210 remarking policy” (p. 1630) for information about creating a remarking policy.

7

Associate egress forwarding classes to dot1p, DE, DSCP, or LSP-EXP values.

1. Click on the Egress Forwarding Classes tab. Eight forwarding classes are listed with associated dot1p, DE, DSCP, or LSP-EXP values.

   Port-type policies display dot1p, DE, and DSCP values. Network interface-type policies display LSP-EXP values.
2. Choose a forwarding class and click Properties. The Egress Forwarding Class form opens.
3. Configure the required parameters.

   For dot1p and DE remarking for port-type network policies, settings for the Dot1p and Force DE value parameters take effect when the Mark DE bits parameter is set to true.
4. Save your changes and close the form.

8

If you are configuring a network interface-type policy, associate ingress LSP EXP values with forwarding classes and profiles. Otherwise, go to Step 9 .

1. Click on the Ingress LSP EXP Bits tab.
2. Choose an LSP EXP value from the list and click Properties, or click Create. The Network Ingress Lsp Exp, 7210 Network Policy form opens.
3. Configure the required parameters.
4. Save your changes and close the form.

5. Go to Step 11 .

9

If you are configuring a port-type policy, perform one of the following:

a. Associate ingress dot1p values with forwarding classes and profiles.
   1. Click on the Ingress Dot1p tab.
   2. Choose a dot1p value from the list and click Properties, or click Create. The Network Ingress Dot1p, Network Policy form opens.
   3. Configure the required parameters.
   4. Save your changes and close the form.

b. Associate ingress DSCP values with forwarding classes and profiles.
   1. Click on the Ingress DSCP tab.
   2. Choose a DSCP value from the list and click Properties, or click Create. The Network Ingress DSCP, Network Policy form opens.
   3. Configure the required parameters.
   4. Save your changes and close the form.

10

Configure ingress queues.

1. Click on the Queues tab.
2. Choose an ingress queue from the list and click Properties. The Network Ingress Queue, Network Policy form opens.
3. Configure the required parameters on the General tab.
4. Select a slope policy in the Slope Policy panel.
5. Click on the CIR/PIR and Burst Size tabs and configure the required parameters.
6. Save your changes and close the form.

11

Configure ingress meters.

1. Click on the Ingress Meter tab.
2. Choose an ingress meter from the list and click Properties, or click Create. The Network Ingress Meter, Network Policy form opens.
3. Configure the required parameters on the General tab.
4. Click on the CIR/PIR and Burst Size tabs and configure the required parameters.
5. Save your changes and close the form.

12

Map forwarding classes to queues or meters.

1. Click on the Ingress FC tab.
2. Choose an entry from the list and click Properties, or click Create. The 7210 Network Ingress Forwarding Class, Network Policy form opens.
3. Configure parameters and select queues, as required.
4. Save your changes and close the form.

13

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

End of steps

50.43 To configure a 7250 SROS Network Ingress policy

50.43.1 Purpose

A 7250 SROS Network Ingress policy defines forwarding for ingress traffic on a network interface.

The policy associates ingress Dot1p, DSCP, or LSP-EXP bits with forwarding classes and profiles, using an assigned 7250 SROS Ingress Classification policy.

The 7250 SROS Network Ingress policy also defines network ingress policers. Eight unicast policers, with IDs 1 to 8, exist by default and cannot be deleted. The CIR, PIR, and burst size values for these policers are user-configurable; if no user-configured values are defined, default values are used. You can configure up to eight additional policers for multicast, using IDs 9 to 16.

Ingress policers are mapped to FCs. The default mapping for unicast policers 1 to 8 is fixed, and not user-configurable. The mapping of FCs to multicast policers is user-configurable.

7250 SROS Network Ingress policies are assigned to L3 network interfaces; see 27.17 “To create an L3 network interface on a routing instance” (p. 856) and 27.18 “To configure L3 network interfaces” (p. 863).

7250 SROS Network Ingress policies are identified by the policy name; policy ID numbers are not used.

A default 7250 SROS Network Ingress policy is applied if no user-configured policy is explicitly assigned. The default policy cannot be modified or deleted.

For more information about QoS policy support on the 7250 IXR, see 50.24 “7250 IXR QoS policies” (p. 1534).

50.43.2 Steps

1

Choose Policies→QoS→SROS QoS→Network→7250 SROS Network Ingress from the NFM-P main menu. The 7250 SROS Network Ingress form opens.

2

Click Create, or choose a policy and click Properties. The 7250 SROS Network Ingress Policy (Create|Edit) form opens.

3

Configure the required parameters on the General tab.

4

In the Ingress Classification Policy panel, select a 7250 SROS Ingress Classification policy; see 50.45 “To configure a 7250 SROS Ingress Classification policy” (p. 1579).

5

Configure policers.

Policers 1 through 8 exist in the policy by default. Unicast traffic uses policers 1 to 8.

You can create additional policers 9 through 16. These additional policers can be mapped to FCs for multicast traffic only.

Click on the Policer tab and perform the following:

1. Choose a policer from the list and click Properties, or click Create. The Policer, 7250 SROS Network Ingress (Create|Edit) form opens.
2. Configure the required parameters on the General tab.
3. Click on the CIR/PIR and Burst Size tabs and configure the required parameters.
4. Save your changes and close the form.

6

To view the mapping of policers to forwarding classes, click on the Forwarding Classes tab.

The mapping of FCs to unicast policers 1 through 8 is fixed, and is not user-configurable.

The mapping of FCs to multicast policers is optional; see Step 7.

7

To configure the mapping of multicast policers to forwarding classes, click on the Forwarding Classes tab. For each required FC, perform the following:

1. Choose the forwarding class from the list and click Properties. The Network Ingress Forwarding Class (Create) form opens.
2. Configure the Multicast Policer ID parameter.

   You can enter a policer ID from 1 to 16. You can assign one of the policers that exist in the policy by default (1 to 8), or a user-created policer (9 to 16).
3. Save your changes and close the form.

8

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.44 To configure FC mapping policies for ingress classification on the 7250 IXR

50.44.1 Purpose

7250 SROS FC mapping policies for ingress classification associate Dot1p, DSCP, and LSP EXP CoS values with forwarding classes and profiles. A separate policy is configured for each classification type (Dot1p, DSCP, or LSP-EXP). For each policy, a default FC and profile action is configurable for ingress traffic that does not have a CoS value.

The policies are assigned to a 7250 SROS Ingress Classification policy; see 50.45 “To configure a 7250 SROS Ingress Classification policy” (p. 1579).

7250 SROS FC mapping policies are identified by the policy name; policy ID numbers are not used.

The NFM-P provides a default 7250 SROS Dot1p FC mapping policy. The default policy is not configurable, and cannot be deleted. The default policy is assigned to a 7250 SROS Ingress Classification policy when no user-configured policy is explicitly assigned.

7250 SROS FC mapping policies are not supported on all 7250 IXR chassis types and releases. For information about FC mapping policy support on the 7250 IXR, see the NE documentation.

For more information about QoS policy support on the 7250 IXR, see 50.24 “7250 IXR QoS policies” (p. 1534).

50.44.2 Steps

1

If required, configure a 7250 SROS Dot1p FC Mapping policy. Perform the following:

1. Choose Policies→QoS→SROS QoS→Ingress Classification→7250 SROS Dot1p FC Mapping from the NFM-P main menu. The 7250 SROS Dot1p FC Mapping form opens.
2. Click Create or choose an existing policy and click Properties. The 7250 SROS Dot1p FC Mapping (Create|Edit) form opens.
3. Configure the required parameters on the General tab.

   The default values are applied to ingress packets that do not have a CoS value.
4. Click on the Dot1p tab.
5. Click Create, or choose a mapping in the list. The Dot1p FC form opens.
6. Configure the mapping of Dot1p values, forwarding classes, and profiles.
7. Save your changes and close the form.
8. Repeat substep 5 to substep 7 to configure additional mappings, as required.

9. Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

2

If required, configure a 7250 SROS DSCP FC Mapping policy. Perform the following:

1. Choose Policies→QoS→SROS QoS→Ingress Classification→7250 SROS DSCP FC Mapping from the NFM-P main menu. The 7250 SROS DSCP FC Mapping form opens.
2. Click Create or choose an existing policy and click Properties. The 7250 SROS DSCP FC Mapping (Create|Edit) form opens.
3. Configure the required parameters on the General tab.

   The default values are applied to ingress packets that do not have a CoS value.
4. Click on the DSCP tab.
5. Click Create, or choose a mapping in the list. The DSCP FC form opens.
6. Configure the mapping of DSCP values, forwarding classes, and profiles.
7. Save your changes and close the form.
8. Repeat substep 5 to substep 7 to configure additional mappings, as required.
9. Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

3

If required, configure a 7250 SROS LSP EXP FC Mapping policy. Perform the following:

1. Choose Policies→QoS→SROS QoS→Ingress Classification→7250 SROS LSP EXP FC Mapping from the NFM-P main menu. The 7250 SROS LSP EXP FC Mapping form opens.
2. Click Create or choose an existing policy and click Properties. The 7250 SROS LSP EXP FC Mapping (Create|Edit) form opens.
3. Configure the required parameters on the General tab.

   The default values are applied to ingress packets that do not have a CoS value.
4. Click on the LSP-EXP tab.
5. Click Create, or choose a mapping in the list. The LSP-EXP FC form opens.
6. Configure the mapping of LSP-EXP values, forwarding classes, and profiles.
7. Save your changes and close the form.
8. Repeat substep 5 to substep 7 to configure additional mappings, as required.
9. Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.45 To configure a 7250 SROS Ingress Classification policy

50.45.1 Before you begin

A 7250 SROS Ingress Classification policy associates ingress Dot1p, DSCP, and LSP-EXP CoS values with forwarding classes and profiles. A default FC and profile action is configurable for ingress traffic that does not have a CoS value.

The policy is assigned to the following QoS policies:

- SAP Access Ingress policies configured for the 7250 IXR, see 50.28 “To configure a SAP access ingress policy” (p. 1538)
- 7250 SROS Network Ingress policies; see 50.43 “To configure a 7250 SROS Network Ingress policy” (p. 1575)

7250 SROS Ingress Classification policies are identified by the policy name; policy ID numbers are not used.

The NFM-P provides two default 7250 SROS Ingress Classification policies, one for SAP Access Ingress policies and the other for 7250 SROS Network Ingress policies. The default policies are not configurable, and cannot be deleted. A default policy is assigned to a SAP Access Ingress policy or 7250 SROS Network Ingress policy when no user-configured policy is explicitly assigned.

The 7250 IXR supports 7250 SROS Ingress Classification policies.

For more information about QoS policy support on the 7250 IXR, see 50.24 “7250 IXR QoS policies” (p. 1534).

50.45.2 Steps

1

Choose Policies→QoS→SROS QoS→Ingress Classification→7250 SROS Ingress Classification from the NFM-P main menu. The 7250 SROS Ingress Classification form opens.

2

Click Create, or choose an existing policy and click Properties. The 7250 SROS Ingress Classification Policy (Create|Edit) form opens.

3

Configure the required parameters on the General tab.

If you are configuring a policy for a 7250 IXR NE that supports SROS FC mapping policies for ingress classification, assign the FC mapping policies in the Properties panel, then go to Step 7.

For more information about SROS FC mapping policies, see 50.44 “To configure FC mapping policies for ingress classification on the 7250 IXR” (p. 1577).

4

Click on the Dot1p tab to associate ingress Dot1p values.

1. Click Create, or choose a Dot1p value from the list and click Properties. The Dot1p Forwarding Class form opens.
2. Configure the parameters.
3. Save your changes and close the form.

5

Click on the DSCP tab to associate ingress DSCP values.

1. Click Create, or choose a DSCP value from the list and click Properties. The DSCP Forwarding Class form opens.
2. Configure the parameters.
3. Save your changes and close the form.

6

Click on the LSP-EXP tab to associate ingress LSP-EXP values.

1. Click Create, or choose an LSP-EXP value from the list and click Properties. The LSP-EXP Forwarding Class form opens.
2. Configure the parameters.
3. Save your changes and close the form.

7

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.46 To configure a network queue policy

50.46.1 Purpose

Use this procedure to configure a network queue policy.

Note: You cannot use the same network queue policy on devices at different releases.

Note: HSMDA is only supported on 7750 SR-7/12/12e and 7450 ESS-7/12, Release 20.10 and earlier.

50.46.2 Steps

1

Choose Policies→QoS→SROS QoS→Network Queue→Network Queue from the NFM-P main menu. The Network Queue Policies form opens.

2

Click Create or choose a policy and click Properties. The Network Queue Policy (Create|Edit) form opens.

3

Configure the general parameters.

4

Click Select in the HS panel to associate an alternate HS Attachment Policy other than the default policy. The Select HS Attachment Policy – Egress Queue Group Template Policy form opens.

5

Select the required HS Attachment Policy and click OK.

6

Configure the Packet Byte Offset parameter in the Egress HSMDA panel.

7

Select a WRR policy in the WRR Policy panel and click Apply.

8

Click on the Egress HSMDA Queues tab. Eight default queues are displayed on the form.

9

Double-click on a queue in the list to configure a default Egress HSMDA queue. The Network Queue Egress HSMDA Queue (Edit) form opens with the General tab displayed.

10

Configure the WRR Weight parameter.

Note: The WRR Weight parameter is only displayed and configurable for Egress HSMDA Queues 1, 2, and 3.

11

Select a slope policy in the Slope Policy panel.

12

Click on the PIR/Burst Size tab and configure the parameters.

13

Configure the parameters and click OK.

You must deselect the associated Default check box to configure the Maximum Burst Size (bytes) or Burst Limit (bytes) parameter.

14

Click on the Queues tab. Two default queues are displayed on the form.

15

Perform one of the following:

a. To configure a default queue, double-click on a queue in the list. The Entry, Network Queue Policy (Edit) form opens with the General tab displayed.

b. To create a new queue, click Create. The Entry, Network Queue Policy (Create) form opens with the General tab displayed.

16

Configure the required parameters and select a slope policy in the Slope Policy panel.

17

Click on the CIR/PIR/FIR and Burst Size tabs and configure the required parameters.

18

Configure the HSQ parameters if required. You can only configure HSQ on default queue entries 1 to 8.

1. Click on the HSQ tab.
2. Configure the required parameters.
3. Click Select adjacent to the HS WRED Slope Policy parameter. The Select HS WRED slope Policy form opens.

   Note: To configure the HS WRED Slope Policy parameter, you must first create a HS WRED Slope policy. See 50.49 “To configure a WRED slope policy” (p. 1587).
4. Select the required policy and click OK.

19

Click OK. The Entry, Network Queue Policy configuration form closes and the Network Queue Policy (Create) form reappears with a list of the network queues displayed.

20

Click on the Forwarding Classes tab.

21

Double-click on an existing forwarding class or click Create to create a new forwarding class. The Forwarding Class, Network Queue Policy (Edit) form opens.

22

Configure the required parameters.

The Forwarding Class parameter can be configured only when you are creating a forwarding class network queue policy.

23

Configure the HSQ parameters if required to configure HS WRR Groups.

1. Click on the HS WRR Groups tab.
2. Choose an existing HS WRR group and click Properties. The HS WRR Group form opens.

   Note: You can only modify the existing WRR Group parameters; you cannot create new WRR Groups.
3. As required, modify the parameters.
4. Save your changes and close the form.

24

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.47 To configure a 7210 and 1830 network queue policy

50.47.1 Purpose

A 7210 and 1830 network queue policy defines the following for egress queues on a network-facing port:

- CIR and PIR as a percentage of port bandwidth
- scheduling priority mode and weight
- WRED slope parameters and burst size values, using an assigned queue management policy or slope policy
- burst size values; these are either system-defined, configured directly in the policy, or defined in an assigned queue management policy, depending on the NE

7210 and 1830 network queue policies are assigned to network-facing ports (network, L2 uplink, or hybrid ports); see 16.45 “To assign QoS policies to a 7210 SAS Ethernet port” (p. 636) . The supported port types vary, depending on the NE chassis type; see the NE documentation for more information.

7210 and 1830 network queue policies are identified by the policy name and description; policy ID numbers are not used.

The NFM-P provides default 7210 and 1830 network queue policies. A default policy is applied unless another network queue policy is explicitly assigned. The local definition of the default policy varies depending on the chassis type. See the 7210 SAS Quality of Service Guides for more information.

All 7210 SAS chassis types support the 7210 and 1830 network queue policy. Support for specific parameters and features varies, depending on the chassis type. Local definitions of the policy do not necessarily support all configurations in the global policy. See the NE documentation for more information.

50.47.2 Steps

1

Choose Policies→QoS→SROS QoS→Network Queue→7210 and 1830 Network Queue from the NFM-P main menu. The 7210 and 1830 Network Queue Policies form opens.

2

Click Create or choose a policy and click Properties. The Network Queue, Global Policy (Create|Edit) form opens.

3

Configure the required parameters on the General tab.

4

Configure the required queues.

1. Click on the Queues tab. Eight default queues are displayed.
2. Select a queue and click Properties. The NQueue Entry, Network Queue form opens.
3. Configure the required parameters.
4. Select a queue management policy in the Queue Management Policy panel. See 50.52 “To configure a 7210 and 7250 Queue Management policy” (p. 1592) for more information about queue management policies.
5. Select a slope policy in the Slope Policy panel. See 50.50 “To configure a 7210 and 1830 slope policy” (p. 1589) for more information about slope policies.
6. Configure the CIR and PIR for the queue. Click on the CIR/PIR tab and configure the parameters.
7. Configure burst size parameters for the queue. Click on the Burst Size tab and configure the parameters.
8. Save your changes and close the form.

5

Configure FC-to-queue mapping.

1. Click on the Forwarding Classes tab.
2. Click Create, or choose an FC and click Properties. The Forwarding Class form opens.

   The Create button is not available when the Displayed Name parameter on the General tab is set to default; see Step 3 .
3. Configure the required parameters.
4. Save your changes and close the form.

6

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.48 To modify a shared-queue policy

50.48.1 Purpose

You cannot create shared-queue policies. Instead, you modify the existing default policy (default or policer-output-queues). Modification of shared-queue policies is supported on the 7750 SR and 7450 ESS.

The default behavior automatically chooses the expedited or non-expedited nature of the queue based on the forwarding classes mapped to it. As long as all forwarding classes mapped to the queue are expedited (nc, ef, h1 or h2), the queue is treated as an expedited queue by the hardware schedulers. When any non-expedited forwarding classes are mapped to the queue (be, af, l1 or l2), the queue is treated as best effort (be) by the hardware schedulers.

50.48.2 Steps

1

Choose Policies→QoS→SROS QoS→Shared Queue from the NFM-P main menu. The Shared Queue Policies form opens.

2

Choose Local or Global from the Policy scope drop-down menu. When you choose Local, you can specify the Local Node IP Address parameter and choose a device by clicking Select and selecting a device in the list.

3

Choose a policy in the list and click Properties. The Shared Queue Policy (Edit) form opens with the General tab displayed.

4

Configure the Description parameter.

5

Click on the Queues tab.

The following table lists the queue IDs that are used by the NFM-P to identify the shared queue types.

Table 50-10 Shared queue types

Shared queue ID	Shared queue type
1 to 8	Unicast
9 to 16	Multicast
17 to 25	Broadcast
26 to 32	Unknown

There are 32 default queues displayed on the form. Configure the queues as required. Only 16 queues are available for the policer-output-queues policy.

1. Double-click on a queue in the list. The Queue configuration form opens with the General tab displayed.
2. Configure the Expedite and Pool Name parameters.

   Note:

   Before you can configure the Pool Name parameter, you must create a Q1 pool; see 50.68 “To configure Q1 pools” (p. 1611) .
3. Click on the CIR/PIR/FIR and Burst Size tables and configure the parameters.
4. Save your changes.

6

Click on the Forwarding Classes tab.

Default objects based on the eight forwarding classes are displayed on the form. You cannot associate different forwarding classes with the shared queues.

7

Select a forwarding class and click Properties. The Forwarding Class, Local Policy (Edit) form opens.

You can only configure a forwarding class if you chose Local in Step 2 .

8

Configure the required parameters and click OK.

9

Click on the L2 Interfaces or L3 Interfaces tab. (Applies to default shared queue policy only.)

10

Select an interface in the list and click Properties. The L2 or L3 Access Interface form opens with the General tab displayed.

11

Click on the QoS tab and configure the Use Multipoint Shared Queue parameter. (Applies to default shared queue policy only.)

12

Click OK. The Shared Queue Policy form reappears.

13

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.49 To configure a WRED slope policy

50.49.1 Steps

1

Choose Policies→QoS→SROS QoS→Slope→WRED Slope from the NFM-P main menu. The WRED Slope Policies form opens.

2

Click Create, or choose a policy in the list and click Properties. The WRED Slope Policy (Create|Edit) form opens.

3

Configure the required general parameters.

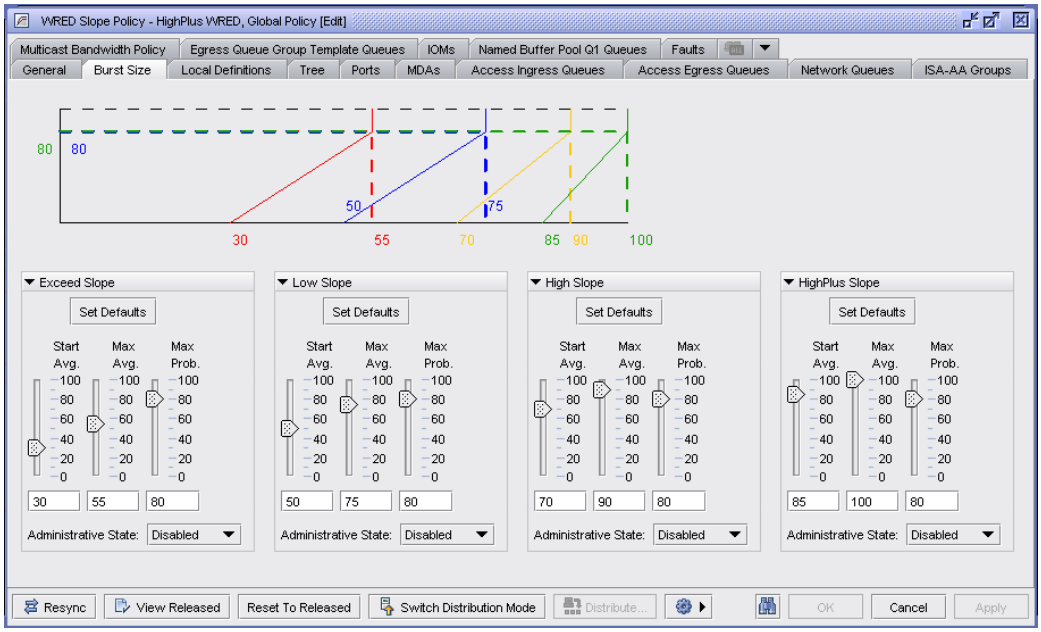
When packets are queued, shared buffer average utilization is calculated using the Time Average Factor for the buffer pool. The time average factor specifies the weighting between the previous shared buffer average utilization result and the new shared buffer utilization to determine the new shared buffer average utilization.

Note: The Time Average Factor parameter must be set to 3 on the 7705 SAR.

4

Click on the Burst Size tab. The Burst Size form opens, as shown in Figure 50-4, “Slope policy form - Burst Size” (p. 1588) .

Figure 50-4 Slope policy form - Burst Size



Each buffer pool supports a high-priority RED High Slope, a low-priority RED Low Slope, an Exceed Slope, and a HighPlus Slope. The High Slope manages access to the shared portion of the buffer pool for high-priority or in-profile packets. The Low Slope manages access to the shared portion of the buffer pool for low-priority or out-of-profile packets. The Exceed Slope handles the exceeded profile traffic congestion control at the pool and megapool level. The values for the Exceed Slope parameters should be set so that they are lower than the Low Slope in the slope hierarchy, as shown in the example above, specifically, Start Avg=30, Max Avg=55, and Max Prob=80. Finally, the HighPlus Slope handles the inplus profile traffic congestion control. A HighPlus Slope policy can be applied to pool-per-queue queues in an egress queue group template, which in turn can be applied at a network egress port. The HighPlus Slope is also supported in a slope policy applied to the egress WRED megapool. The values for the HighPlus Slope parameters should be set so that they are higher than the High Slope in the slope hierarchy, as shown in the example above, specifically, Start Avg=85, Max Avg=100, and Max Prob=80. See 50.11 “Slope policies” (p. 1519) in this chapter for more information.

5

Configure the parameters for the Exceed Slope, Low Slope, High Slope, and the HighPlus Slope.

6

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.50 To configure a 7210 and 1830 slope policy

50.50.1 Purpose

A 7210 and 1830 slope policy defines the values used for calculating drop precedence for egress queues in port buffer pools. Values are configured as drop rate percentages for each queue or as parameters for WRED slope calculations.

Note: The allocation of device memory for buffer pools and queues varies, depending on the chassis type. The slope calculation algorithm also varies by chassis type. See the NE documentation for more information.

The policy allows the configuration of the following slopes for a queue:

- High Slope (high priority TCP slope for in-profile packets)
- Low Slope (low priority TCP slope for out-of-profile packets)
- Non-TCP Slope

You can configure some 7210 SAS chassis types to use only TCP slopes (two slopes per queue). See 12.48 “To configure two WRED slopes on a 7210 SAS” (p. 379) .

You can also configure a High Ring Slope and a Low Ring Slope.

7210 and 1830 slope policies are identified by the policy name and description; policy ID numbers are not used.

The policy is assigned to egress buffer pools during port configuration; see 16.24 “To configure Ethernet ports” (p. 599) . The policy can also be assigned to queues in the following policies:

- 7210 and1830 SAP access ingress policy; see 50.29 “To configure a 7210, 7250, and 1830 SAP Access Ingress policy” (p. 1544)
- 7210 SAP access egress policy; see 50.32 “To configure a 7210 SAP access egress policy” (p. 1558)
- 7210 and 1830 network queue policy; see 50.47 “To configure a 7210 and 1830 network queue policy” (p. 1583)
- 7210 and 1830 network policy (port type); see 50.42 “To configure a 7210 and 1830 network policy” (p. 1571)

A default slope policy is applied if no policy is explicitly assigned.

The policy is supported on the 7210 SAS-D, 7210 SAS-Dxp, 7210 SAS-E, 7210 SAS-K, 7210 SAS-M, 7210 SAS-S, 7210 SAS-Sx, and 7210 SAS-T. Support for specific parameters and features varies, depending on the chassis type. Local definitions of the policy do not necessarily support all configurations in the global policy. See the NE documentation for more information.

The 7210 SAS-R and 7210 SAS-X do not support 7210 and 1830 slope policies; these devices use queue management policies instead. See 50.52 “To configure a 7210 and 7250 Queue Management policy” (p. 1592) .

50.50.2 Steps

1

Choose Policies→QoS→SROS QoS→Slope→7210 and 1830 Slope from the NFM-P main menu. The 7210 and 1830 Slope Policies form opens.

2

Click Create or choose a policy and click Properties. The WRED Slope Policy (Create|Edit) form opens.

3

Configure the required parameters on the General tab.

4

Configure drop rates for queues. Click on the Burst Size tab and configure the parameters in the Low Slope and High Slope panels.

5

Configure slope calculation values for queues.

1. Click on the Queue Slope tab. Eight default queues are displayed.
2. Choose a queue and click Properties. The Queue Slope, WRED Slope Policy form opens.
3. Configure the required parameters.
4. Save your changes and close the form.

6

Click on the Slope tab and configure the required parameters.

7

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.51 To configure an HSMDA WRED slope policy

50.51.1 Steps

1

Choose Policies→QoS→SROS QoS→Slope→HSMDA WRED Slope from the NFM-P main menu. The HSMDA Slope Policies form opens.

2

Click Create or choose a policy and click Properties. The HSMDA Slope Policy (Create|Edit) form opens.

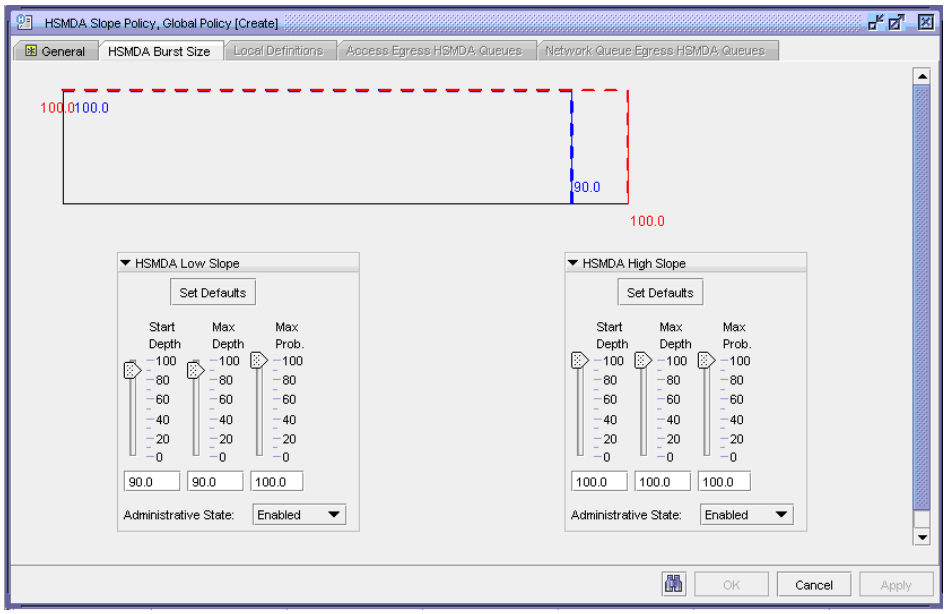
3

Configure the general parameters.

4

Click on the HSMDA Burst Size tab. The Burst Size form opens, as shown in Figure 50-5, “HSMDA Slope Policy form - Burst Size” (p. 1590) .

Figure 50-5 HSMDA Slope Policy form - Burst Size



Each buffer pool supports a high-priority RED slope and a low-priority RED slope. The high-priority RED slope manages access to the shared portion of the buffer pool for high-priority or in-profile packets. The low-priority RED slope manages access to the shared portion of the buffer pool for low-priority or out-of-profile packets. See 50.11 “Slope policies” (p. 1519) in this chapter for more information.

5

Configure the parameters for the Low Slope and the High Slope and click Apply. The HSMDA Slope Policy form is refreshed with additional buttons.

6

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.52 To configure a 7210 and 7250 Queue Management policy

50.52.1 Purpose

A 7210 and 7250 Queue Management policy defines parameters for calculating drop precedence for ingress or egress queues. The policy defines values for CBS and MBS, and for high and low WRED slope calculations.

7210 and 7250 Queue Management policies are assigned to queues during queue configuration in the following policies:

- 7210 and 1830 Access Ingress policy; see 50.29 “To configure a 7210, 7250, and 1830 SAP Access Ingress policy” (p. 1544)
- 7210 and 1830 Port Access Egress policy; see 50.31 “To configure a 7210 and 1830 port access egress policy” (p. 1556)
- 7210 SAP Access Egress policy; see 50.32 “To configure a 7210 SAP access egress policy” (p. 1558)
- 7210 and 1830 Network Queue policy; see 50.47 “To configure a 7210 and 1830 network queue policy” (p. 1583)
- 7210, 7250 and 1830 Port Scheduler policy; see50.60 “To configure a 7210, 7250 and 1830 Port Scheduler policy” (p. 1601)

The NFM-P assigns a default 7210 and 7250 Queue Management policy to a queue if no user-configured policy is explicitly assigned. The default policy cannot be deleted or modified. The default policy allocates the appropriate amount of CBS and MBS buffers based on whether the queue is associated with a SAP or a network port. The WRED slopes (high and low) are disabled in the default policy. If WRED is not configured in a 7210 and 7250 Queue Management policy, tail drop is used.

7210 and 7250 Queue Management policies are identified by the policy name and description; policy ID numbers are not used.

The 7210 and 7250 Queue Management policy is supported on the 7210 SAS-Mxp, 7210 SAS-R, and 7210 SAS-X.

If you are configuring a queue management policy for a 7250 IXR, see 50.53 “To configure a 7250 SROS Queue Management policy” (p. 1593). For more information about QoS policy support on the 7250 IXR, see 50.24 “7250 IXR QoS policies” (p. 1534).

Support for specific parameters and features varies, depending on the chassis type. Local definitions of the policy do not necessarily support all configurations in the global policy.

50.52.2 Steps

1

Choose Policies→QoS→SROS QoS→Slope→7210 and 7250 Queue Management from the NFM-P main menu. The 7210 and 7250 Queue Management Policies form opens.

2

Click Create, or choose a policy and click Properties. The 7210 and 7250 Queue Management Policy (Create|Edit) form opens.

3

Configure the required parameters.

4

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.53 To configure a 7250 SROS Queue Management policy

50.53.1 Purpose

A 7250 SROS Queue Management policy defines parameters for calculating drop precedence for egress queues. The policy defines values for Time Average Factor, MBS, and WRED slope calculations. If the slopes are not configured in the policy, the queue tail drops any excess traffic. The policy also defines a port speed value that supporting NEs use to internally optimize the allocation of virtual output queues in NE system memory.

7250 SROS Queue Management policies are assigned to queues in the following policies:

- 7250 SROS VLAN QoS policy; see 50.54 “To configure a 7250 SROS VLAN QoS policy” (p. 1594)
- 7250 SROS Port QoS policy; see 50.61 “To configure a 7250 SROS Port QoS policy” (p. 1603)

You can view the associated 7250 SROS VLAN QoS and 7250 SROS Port QoS policies using the 7250 SROS Queue Management policy properties form.

7250 Queue Management policies are identified by the policy name; policy ID numbers are not used.

The NFM-P provides a default 7250 SROS Queue Management policy. The default policy cannot be deleted or modified. The default queue management policy is assigned to queues in 7250 SROS VLAN QoS policies and 7250 SROS Port QoS policies if no user-configured queue management policy is explicitly assigned. The NFM-P default 7250 SROS Queue Management policy does not

assign a port speed. When the default policy is distributed to an NE that supports port speed configuration, the NE automatically assigns a port speed.

The 7250 IXR supports 7250 SROS Queue Management policies.

Support for specific parameters and features varies, depending on the chassis type and release. Local definitions of the policy do not necessarily support all configurations in the global policy.

For more information about QoS policy support on the 7250 IXR, see 50.24 “7250 IXR QoS policies” (p. 1534).

50.53.2 Steps

1

Choose Policies→QoS→SROS QoS→Slope→7250 SROS Queue Management from the NFM-P main menu. The 7250 SROS Queue Management form opens.

2

Click Create, or choose a policy and click Properties. The 7250 SROS Queue Management Policy (Create|Edit) form opens.

3

Configure the required parameters.

4

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.54 To configure a 7250 SROS VLAN QoS policy

50.54.1 Purpose

A 7250 SROS VLAN QoS policy defines queue parameters for VLAN egress queues. The policy allows configuration of CIR weight profiles, CIR/PIR values, and the assignment of 7250 SROS Queue Management policies.

The 7250 SROS VLAN QoS policy also allows viewing of the mapping of forwarding classes to queues. FCs are mapped to queues by default; the mapping is not user-configurable.

The 7250 SROS VLAN QoS policy allows the enabling or disabling of VOQ (Virtual Output Queue) statistics collection, for supporting 7250 IXR chassis types. Statistics collection is enabled using the Stat Mode parameter.

For supporting NEs, the policy allows configuration of a Packet Byte Offset value. See the NE documentation for more information about PBO on the 7250 IXR.

The 7250 SROS VLAN QoS policy is assigned to L2 access interfaces on VPLS and VLL services, to L3 access interfaces on IES and VPRN services, and to network interfaces. See the following procedures:

- for VLL: 76.42 “To assign ingress and egress QoS policies to a VLL L2 access interface” (p. 2181)
- for VPLS services: 77.69 “To assign QoS policies or to enable a MAC override address to a VPLS or MVPLS L2 access interface” (p. 2340)
- for IES: 78.32 “To assign ingress and egress QoS policies to an IES L3 access interface” (p. 2477)
- for VPRN: 79.89 “To assign ingress and egress QoS policies to a VPRN L3 access interface” (p. 2662)
- for L3 network interfaces: 27.17 “To create an L3 network interface on a routing instance” (p. 856) and 27.18 “To configure L3 network interfaces” (p. 863)

7250 SROS VLAN QoS policies are identified by the policy name; policy ID numbers are not used.

A default 7250 VLAN QoS policy is applied if no user-configured policy is explicitly used. The default policy cannot be deleted or modified.

The 7250 IXR supports 7250 SROS VLAN QoS policies. For more information about QoS policy support on the 7250 IXR, see 50.24 “7250 IXR QoS policies” (p. 1534).

Support for specific parameters and features varies, depending on the chassis type. Local definitions of the policy do not necessarily support all configurations in the global policy.

50.54.2 Steps

1

Choose Policies→QoS→SROS QoS→Slope→7250 SROS VLAN QoS from the NFM-P main menu. The 7250 SROS VLAN QoS form opens.

2

Click Create, or choose a policy and click Properties. The 7250 SROS VLAN QoS Policy (Create|Edit) form opens.

3

Configure the required parameters on the General tab.

For supporting NEs, you can configure the Packet Byte Offset parameter when QoS Packet Byte Offset is globally enabled in NE properties; see 12.67 “To globally enable or disable Packet Byte Offset on a 7250 IXR” (p. 396).

4

Configure CIR weight profiles.

CIR weight profiles configured in this step are used during CIR configuration in Step 6.

1. Click on the CIR Weight Profiles tab, choose a profile from the list, and click Properties. The VLAN QoS CIR Weight Profile, Site form opens.
2. Configure the parameters.
3. Save your changes and close the form.

5

Click on the Forwarding Classes tab to view the mapping of FCs to queues. The mapping is not user-configurable.

6

Configure queues.

1. Click on the Queues tab. Eight default queues are displayed.
2. Choose a queue and click Properties. The VLAN QoS Queue form opens.
3. Configure the required parameters on the General tab.
4. Select a 7250 SROS Queue Management policy in the Queue Management policy panel. For information about 7250 SROS Queue Management policies, see 50.53 “To configure a 7250 SROS Queue Management policy” (p. 1593).
5. Click on the CIR/PIR tab and configure the required parameters.

   CIR weight profiles selected in this step are configured in Step 4.
6. Save your changes and close the form.

7

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.55 To configure a scheduler policy

50.55.1 Steps

1

Choose Policies→QoS→SROS QoS→Scheduler→Scheduler from the NFM-P main menu. The Scheduler Policies form opens.

2

Click Create or choose a policy and click Properties. The Scheduler Policy (Create|Edit) form opens.

3

Configure the required parameters and click Apply.

4

Click on the Schedulers tab and click Create. The Entry, Scheduler Policy (Create) form opens.

The scheduler defines bandwidth control that limits each child (other schedulers and queues) that are associated with the scheduler.

5

Configure the required parameters.

The Limit Unused Bandwidth parameter appears only when the Tier parameter is set to 1.

The Parent Scheduler panel and its parameters appear only when the Port Parent parameter is set to false.

The Tier parameter identifies the level of hierarchy with which a group of schedulers is associated. A parent is tier 1. Children are tier 2. Grandchildren are tier 3. You can create a tier 2 child scheduler without creating a parent tier 1 scheduler, and you can create a grandchild tier 3 scheduler without creating a child tier 2 scheduler.

6

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.56 To create an Aggregation Scheduler

Note: You can create an Aggregation Scheduler when you have created two or more scheduler policies. See 50.13.3 “Hierarchical schedulers” (p. 1521) and 50.55 “To configure a scheduler policy” (p. 1596) in this chapter for more information.

50.56.1 Steps

1

Choose Manage→Service→Customers from the NFM-P main menu. The Manage Customers form opens.

2

Select a customer in the list and click Properties. The Customer (Edit) form opens.

3

Click on the Sites tab.

4

Select a site in the list and click Properties. The Site (Edit) form opens.

5

Click on the Aggregation tab and click Create. The Create Aggregation Scheduler step form opens.

6

Select a site in the list and click Next.

7

Configure the parameters in the Define Name step and click Next.

8

Select the assignment scope and click Next.

9

Select a port, card, or FPE and click Next.

10

Select an ingress and egress scheduler policy and click Next.

11

Configure the parameters in the Select Egress Aggregate Rate Limit step and click Next.

12

If you are creating an Aggregation Scheduler for an IOM3 port, go to Step 13 . Otherwise go to Step 14 .

13

Select an ingress and egress scheduler policy and click Next.

14

Select a time of day suite and click Finish.

The Aggregation Scheduler is listed in the Aggregation tab of the Site (Edit) form. It is also listed in the Aggregation Schedulers tab of the properties form for the specific object you assigned in Step 12 , either a card, port (including LAGs), or FPE.

15

Save your changes and close the forms.

END OF STEPS

50.57 To configure a port scheduler policy

50.57.1 Steps

1

Choose Policies→QoS→SROS QoS→Scheduler→Port Scheduler from the NFM-P main menu. The Port Scheduler Policies form opens.

2

Click Create or choose a policy and click Properties. The Port Scheduler (Create|Edit) form opens.

3

Configure the required parameters.

The Maximum Rate parameter is configurable when the MAX check box is deselected.

When the HQoS Algorithm parameter is set to the Above Offered Allowance Control option, the policy uses values configured in an Advanced Configuration policy; see 50.63 “To configure an Advanced Configuration policy” (p. 1606). The required Advanced Configuration policy must be distributed to the NE along with the Port Scheduler policy.

4

Click on the Group tab and click Create. The Port Scheduler Group (Create) form opens.

5

Configure the required parameters.

If you set the Rate Type parameter to kbps, the PIR (kbps) and CIR (kbps) parameters are configurable when the associated MAX check box is deselected.

6

Save your changes.

7

Click on the Level tab on the Port Scheduler (Create) form to configure the required levels.

Note: Contiguous mapping of levels to a group is enforced. Priority levels cannot be added to a group unless the resulting set of priority levels is contiguous. When a level is not explicitly mapped to any group, it maps directly to the root of the port scheduler at its own priority.

8

Associate a port scheduler group to a level:

1. Click Select in the Level panels to choose a port scheduler group from the list in the Select Group form. The port scheduler group must be preexisting on the port scheduler policy (as created in Step 4 to Step 6).
2. Configure the Weight in group parameter as required.

9

Configure the Rate Type, PIR, and CIR parameters for each level required.

The PIR and CIR parameters are configurable when the associated MAX check box is deselected.

10

Configure the required parameters in the Orphan panel.

11

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.58 To configure an HSMDA scheduler policy

50.58.1 Steps

1

Choose Policies→QoS→SROS QoS→Scheduler→HSMDA Scheduler from the NFM-P main menu. The HSMDA Scheduler Policies form opens.

2

Click Create or choose a policy and click Properties. The HSMDA Scheduler Policy (Create) form opens.

3

Configure the required general parameters.

4

Click on the HSMDA Group Rates tab and configure the required parameters for Group 1 and Group 2.

5

Click on the HSMDA Scheduler Classes tab and configure the parameters for classes 1 to 8.

The Group parameter must be configured with the same group (Group 1 or Group 2) for up to three sequential classes for each group. For example, when you configure Class 1 as Group 2, you can configure Class 2 and Class 3 as Group 2, but not as Group 1.

The Rate (Mbps) and Burst Limit (bytes) parameters are configurable when the Group parameter is set to None. The Weight parameter is configurable when the Group parameter is set to a value other than None.

6

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.59 To configure an HSMDA WRR policy

50.59.1 Steps

1

Choose Policies→QoS→SROS QoS→Scheduler→HSMDA WRR Policy from the NFM-P main menu. The HSMDA WRR Policies form opens.

2

Click Create or choose a policy and click Properties. The HSMDA WRR Policy (Create|Edit) form opens.

3

Configure the required parameters.

4

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.60 To configure a 7210, 7250 and 1830 Port Scheduler policy

50.60.1 Purpose

For 7210 SAS and 1830 PSS NEs, a 7210, 7250 and 1830 Port Scheduler policy defines the scheduling mode (algorithm type) used to determine the forwarding priority for egress queues. When a weighted algorithm is chosen, the policy allows the configuration of relative weights for up to eight queues.

The policy affects access egress and network (or L2 uplink) egress traffic, and is assigned to ports in any mode. For policy assignment on 7210 SAS NEs, see 16.45 “To assign QoS policies to a 7210 SAS Ethernet port” (p. 636). For policy assignment on 7250 IXR NEs, see 16.24 “To configure Ethernet ports” (p. 599).

The NFM-P provides a default 7210, 7250 and 1830 Port Scheduler policy. The default policy is applied unless a user-configured port scheduler policy is explicitly assigned. The default policy specifies the Strict scheduler mode and cannot be modified. Strict priority means that queues are serviced based on their queue ID number, with higher numbers serviced first.

The 7210, 7250 and 1830 Port Scheduler policies are identified by the policy name and description; policy ID numbers are not used.

The 7210, 7250 and 1830 Port Scheduler policy is supported on the 7210 SAS-D, 7210 SAS-Dxp, 7210 SAS-E, 7210 SAS-M, 7210 SAS-S, 7210 SAS-Sx, and 7210 SAS-T.

Support for specific parameters and features varies, depending on the chassis type. Local definitions of a policy do not necessarily support all configurations in the global policy. See the NE documentation for more information.

Note: For 7210 SAS devices that do not support 7210, 7250 and 1830 Port Scheduler policies, egress scheduling is defined by the port bandwidth, and by user-configured settings in access egress and network queue policies, port properties, and SAP configuration. See 70.15 “Sample QoS configuration on the 7210 SAS” (p. 1954) in Chapter 70, “Service management and QoS” .

The maximum bandwidth (line rate) for a port is either system-defined, or is configured using port level egress rate limiting.

50.60.2 Steps

1

Choose Policies→QoS→SROS QoS→Scheduler→ 7210, 7250 and 1830 Port Scheduler from the NFM-P main menu. The 7210, 7250 and 1830 Port Scheduler Policies form opens.

2

Click Create or choose a policy and click Properties. The Port Scheduler, Global Policy (Create|Edit) form opens.

3

Configure the required parameters on the General tab.

4

If you selected a value of Strict or RoundRobin for the Mode parameter, go to Step 6 .

5

If you selected a value of WeightedRoundRobin or WeightedDeficitRoundRobin for the Mode parameter, assign weight values to queues.

1. Click on the Queue Weights tab.
2. Configure the required parameters.
3. Go to Step 6.

6

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.61 To configure a 7250 SROS Port QoS policy

50.61.1 Purpose

A 7250 SROS Port QoS policy defines scheduler parameters for egress queues. The policy allows configuration of WRR weights, CIR and PIR values, and the assignment of 7250 SROS Queue Management policies.

The 7250 SROS Port QoS policy also allows viewing of the mapping of forwarding classes to queues. FCs are mapped to queues by default; the mapping is not user-configurable.

For supporting NEs, the policy allows configuration of a Packet Byte Offset value. See the NE documentation for more information about PBO on the 7250 IXR.

7250 SROS Port QoS policies are assigned to ports, using the Policies tab of the port properties form; see 16.24 “To configure Ethernet ports” (p. 599).

7250 SROS Port QoS policies are identified by the policy name; policy ID numbers are not used.

A default 7250 Port QoS policy is applied if no user-configured policy is explicitly used. The default policy cannot be deleted or modified.

For more information about QoS policy support on the 7250 IXR, see 50.24 “7250 IXR QoS policies” (p. 1534).

50.61.2 Steps

1

Choose Policies→QoS→SROS QoS→Scheduler→7250 SROS Port QoS from the NFM-P main menu. The 7250 SROS Port QoS form opens.

2

Click Create, or choose a policy and click Properties. The 7250 SROS Port QoS Policy, (Create|Edit) form opens.

3

Configure the required parameters on the General tab.

For supporting NEs, you can configure the Packet Byte Offset parameter when QoS Packet Byte Offset is globally enabled in NE properties; see 12.67 “To globally enable or disable Packet Byte Offset on a 7250 IXR” (p. 396).

4

Click on the Forwarding Classes tab to view the mapping of FCs to queues. The mapping is not user-configurable.

5

Click on the Queues tab to configure egress queues.

1. Choose a queue from the list and click Properties. The Port QoS Queue, 7250 SROS Port QoS (Create|Edit) form opens.
2. Configure the required parameters on the General tab.

   For the WRR Weight parameter, ID and weight values are configured in Step 6.
3. Select a 7250 SROS Queue Management policy. For information about 7250 SROS Queue Management policies, see 50.53 “To configure a 7250 SROS Queue Management policy” (p. 1593).
4. Click on the CIR/PIR tab and configure the required parameters.
5. Save your changes and close the form.

6

Click on the WRR Weights tab to configure multicast and unicast WRR weights for queues.

1. Choose a WRR Weight ID from the list and click Properties. The Port QoS WRR Weights, Site (Create|Edit) form opens.
2. Configure the required parameters.

   WRR IDs and weights configured in this step are used in Step 5 .
3. Save your changes and close the form.

7

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.62 To configure a policer control policy

50.62.1 Steps

1

Choose Policies→QoS→SROS QoS→Scheduler→Policer Control from the NFM-P main menu. The Policer Control Policies form opens.

2

Click Create or choose an existing policer control policy and click Properties. The Policer Control Policy (Create | Edit) form opens.

3

Configure the required parameters.

4

Click on the Arbiter tab.

1. Click Create. The Arbiter (Create) form opens.
2. Configure the required parameters.

   The Parent Arbiter parameter is configurable when the Tier parameter is set to 2.
3. Click OK. The Arbiter (Create) form closes.

5

Optionally, click on the Graphical Arbiters tab to view a graphical display of the arbiter hierarchy within the policer control policy. You can perform any of the following steps:

a. Right-click on the grid and select New Arbiter from the drop-down menu. The Arbiter (Create) form opens. You can create a new arbiter, as described in Step 4 .

b. Right-click on an arbiter object and select Edit from the drop-down menu. The Arbiter (Edit) form opens. You can change the arbiter, as described in Step 4 .

c. Right-click on an arbiter and select Remove from the drop-down menu. The arbiter object is removed from the hierarchy.

d. Click on a Tier 2 arbiter object and draw a line to a Tier 1 arbiter object. The Tier 1 arbiter becomes the parent of the Tier 2 arbiter.

6

Click on the Tree tab to view a hierarchical display of the policer control policy properties and sub components.

7

Click on the Priority Level tab to configure the MBS contribution for eight priority levels. For each level, configure the Cumulative MBS Contribution and Fixed MBS contribution parameters.

8

Click Apply.

9

Click Distribute to distribute the policy to NEs. See 49.6 “To release and distribute a policy” (p. 1476) for more information.

10

Click OK to save the policy and close the forms.

END OF STEPS

50.63 To configure an Advanced Configuration policy

50.63.1 Purpose

The Advanced Configuration policy allows for additional configurations to queues and policers in the access ingress/egress policies and the ingress/egress queue group templates. This extra configuration is subsequently applied by assigning the Advanced Configuration policy to a queue or policer.

The Advanced Configuration policy also provides bandwidth distribution values used by Port Scheduler policies to control the HQoS algorithm.

50.63.2 Steps

1

Choose Policies→QoS→SROS QoS→Scheduler→Advanced Configuration Policy from the NFM-P main menu. The Advanced Configuration Policy (Create) form opens.

2

Configure the required parameters.

3

Click on the Measured Offered Rate tab.

1. Configure the general parameters as required.
2. Configure the required parameters in the Measured Offered Rate Increase panel.

   The Value parameter will either be expressed as a kbps rate or a percentage, based on your choice of Rate Type.

The Default parameter causes the Value parameter to use whatever value is set for the entity in its own configuration form.

3. Configure the required parameters in the Granularity panel.

   The Value parameter will either be expressed as a kbps rate or a percentage, based on your choice of Rate Type.

   The Default parameter causes the Value parameter to use whatever value is set for the entity in its own configuration form.

4. Configure the required parameters in the Max Decrement panel.

   The Value parameter will either be expressed as a kbps rate or a percentage, based on your choice of Rate Type.

   The Default parameter causes the Value parameter to use whatever value is set for the entity in its own configuration form.

5. Click OK. The Arbiter (Create) form closes.

4

Click on the Bandwidth Distribution tab.

1. Configure the required general parameters.
2. Configure the required parameters in the Above Offered Cap panel.

   The Value parameter will either be expressed as a kbps rate or a percentage, based on your choice of Rate Type.

   The Default parameter causes the Value parameter to use whatever value is set for the entity in its own configuration form.

3. Configure the required parameters in the Granularity panel.

   The Value parameter will either be expressed as a kbps rate or a percentage, based on your choice of Rate Type.

   The Default parameter causes the Value parameter to use whatever value is set for the entity in its own configuration form.

4. Configure the required parameters in the Above Offered Allowance panel.

   The Above Offered Allowance settings are used by a Port Scheduler policy when its HQoS Algorithm parameter is set to the Above Offered Allowance Control option. See 50.57 “To configure a port scheduler policy” (p. 1599).

5

Click Apply.

A number of other tabs become active. These allow you to view where the policy is used, once it has been assigned to the various applicable entities.

6

Click on the General tab.

7

Click on the Switch Mode button beside the Configuration Mode parameter to distribute the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

8

Click OK to save the policy and close the form.

END OF STEPS

50.64 To configure a Hardware Aggregate Shaper Scheduler policy

50.64.1 Purpose

The Hardware Aggregate Shaper Scheduler policy improves reaction time and downstream bursts for aggregate-rate enforcement at subscriber level.

It improves on other deficiencies of traditional HQoS, such as potential for underrun during weight-based BW distribution between different queues.

50.64.2 Steps

1

Choose Policies→QoS→SROS QoS→Scheduler→Hardware Aggregate Shaper Scheduler from the NFM-P main menu. The Hardware Aggregate Shaper Scheduler form opens.

2

Click Create or choose an existing Hardware Aggregate Shaper Scheduler policy and click Properties. The Hardware Aggregate Shaper Scheduler Policy (Create) form opens.

3

Configure the required parameters on the General tab.

4

In the Group tab, click Create to enter the Displayed Name parameter.

5

Click OK to save changes.

6

Click the Scheduler Class tab to configure the scheduler class entries.

1. Choose a scheduler class from the list and click Properties. The Scheduler Class, Hardware Aggregate Shaper Scheduler Policy (Create) form opens.
2. Click Select to associate group name to the selected scheduler class.

7

Click OK to save the policy and close the form, or click Apply to save the policy.

See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.65 To configure a port policy

50.65.1 Steps

1

Choose Policies→QoS→SROS QoS→Scheduler→Port Policy from the NFM-P main menu. The Port Policies form opens.

2

Click Create or choose an existing port policy and click Properties. The Port Policy (Create | Edit) form opens.

3

Configure the required parameters.

4

Click Select in the Port Scheduler Policy panel and choose a Port Scheduler Policy, then click OK.

5

Click Apply.

6

Click Distribute to manually distribute the policy locally to devices. Policies are also automatically distributed to devices when they are used by resources on the device. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

7

Click OK to save the policy and close the forms.

END OF STEPS

50.66 To configure an HSMDA pool policy

Note: To associate an HSMDA buffer pool with an MDA, see 15.78 “To configure an MDA” (p. 536) .

50.66.1 Steps

1

Choose Policies→QoS→SROS QoS→Buffer Pool→HSMDA Pool from the NFM-P main menu. The Manage HSMDA Pool Policies form opens.

2

Click Create or choose an HSMDA pool policy and click Properties. The HSMDA Pool Policy (Create | Edit) form opens.

3

Configure the required parameters on the General tab.

4

Click on the Root Pools tab and configure the Allocation Weight parameter for root pools 1 to 8.

The Allocation Weight parameter is configurable when the Default check box is deselected.

5

Click on the Class Pools tab and configure the required parameters for root pools 1 to 8.

The Allocation Percent parameter is configurable when the Default check box is deselected.

6

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.67 To configure a named buffer pool policy

Note: To associate a Named Buffer Pool to an MDA, see 15.78 “To configure an MDA” (p. 536) .

50.67.1 Steps

1

Choose Policies→QoS→SROS QoS→Buffer Pool→Named Buffer Pool from the NFM-P main menu. The Named Buffer Pool Policies form opens.

2

Click Create or choose an existing named buffer pool policy and click Properties. The Named Pool Policy (Create | Edit) form opens.

3

Configure the required parameters.

4

To configure Q1 pools, perform Step 3 to Step 7 in 50.68 “To configure Q1 pools” (p. 1610) .

5

Click Apply.

6

Click Distribute to manually distribute the policy locally to devices. Policies are also automatically distributed to devices when they are used by resources on the device. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

7

Click OK to save the policy and close the forms.

END OF STEPS

50.68 To configure Q1 pools

50.68.1 Before you begin

You must configure a Q1 pool before you can assign the pool to an access ingress, access egress, network queue or shared queue policy.

50.68.2 Steps

1

Choose Policies→QoS→SROS QoS→Buffer Pool→Named Buffer Pool from the NFM-P main menu. The Manage Named Buffer Pool Policies form opens.

2

Click Create or choose a pool policy and click Properties. The Named Pool Policy (Create | Edit) form opens.

3

Click on Q1 Pool tab. A list of configured Q1 Pools is displayed.

4

Click Create or choose a Q1 pool and click Properties. The Q1 pool (Create | Edit) form opens.

5

Configure the required parameters.

6

Click Select beside the Displayed Name parameter and select a slope policy.

7

Save your changes and close the forms.

END OF STEPS

50.69 To configure a HS Attachment policy

50.69.1 Steps

1

Choose Policies→QoS→SROS QoS→HS QoS→HS Attachment policy from the NFM-P main menu. The HS QoS – Attachment Policy form opens.

2

Click Create or choose an existing HS attachment policy and click Properties. The HS Attachment Policy, Global Policy (Create | Edit) form opens.

3

Configure the required parameters on the General tab.

4

Click Apply to save the policy. Confirm the action.

5

As required, click on the Queue tab, select a default queue entry and click Properties to modify the parameters. By default, all queue entries have the same parameter settings applied to them. The HS Attachment Queue form opens.

6

Modify the parameters on the form as required and click OK to save the changes and close the form. The HS Attachment Policy, Global Policy (Create | Edit form reappears.

7

As required, click on the WRR Group tab, select an entry and click Properties to modify the parameters. By default, all entries have the same parameter settings applied to them. The HS Attachment WRR Group form appears.

8

Modify the parameters on the form as required and click OK to save the changes and close the form. The HS Attachment Policy, Global Policy (Create | Edit form reappears.

9

Click OK to save the policy and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

END OF STEPS

50.70 To configure a HS Pool policy

50.70.1 Steps

1

Choose Policies→QoS→SROS QoS→HS QoS→HS Pool policy from the NFM-P main menu. The HS QoS – Pool Policy form opens.

2

Click Create or choose an existing HS pool policy and click Properties. The HS Pool Policy, Global Policy (Create | Edit) form opens.

3

Configure the required parameters on the General tab.

4

As required, click on the Root-Tier Pool tab, select a default entry and click Properties to modify the parameters. By default, all entries have the same parameter settings applied to them. The HS Root Tier Pool form opens.

5

Modify the parameters on the form as required and click OK to save the changes and close the form. The HS Pool Policy, Global Policy (Create | Edit) form reappears.

6

As required, click on the Mid-Tier Pool tab, select a default entry and click Properties to modify the parameters. By default, all entries have the same parameter settings applied to them. The HS Mid Tier Pool form opens.

7

Modify the parameters on the form as required and click OK to save the changes and close the form. The HS Pool Policy, Global Policy (Create | Edit) form reappears.

8

Click OK to save the policy and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

9

As required, associate the HS Port policy to the Forwarding Plane at the IOM level on a 7750 SR node:

1. From the equipment view, navigate to a Forwarding Plane on a 7750 SR node (Node→Shelf→Card Slot→Forwarding Plane) and choose Properties. The Forwarding Plane [Edit] form opens.
2. On the General tab, choose a HS Pool policy in the HSQ panel to associate the policy with the Forwarding Plane and click OK.
3. Save your changes and close the form.

END OF STEPS

50.71 To configure a HS Port Pool policy

50.71.1 Steps

1

Choose Policies→QoS→SROS QoS→HS QoS→HS Port Pool policy from the NFM-P main menu. The HS QoS – Port Pool policy form opens.

2

Click Create or choose an existing HS port pool policy and click Properties. The HS Port Pool Policy, Global Policy (Create | Edit) form opens.

3

Configure the required parameters on the General tab.

4

As required, click on the Standard Port Class Pools tab, select a default entry and click Properties to modify the parameters. By default, all entries have the same parameter settings applied to them. The HS Port STD Class Port form opens.

5

Modify the parameters on the form as required and click OK to save the changes and close the form. The HS Port Pool Policy, Global Policy (Create | Edit) reappears.

6

As required, click on the Alternate Port Class Pools tab, select a Class pool entry and click Properties to modify the default parameters. By default, all entries have the same parameter settings applied to them. The HS Port ALT Class Port form opens.

7

Modify the parameters on the form as required and click OK to save the changes and close the form. The HS Port Pool Policy, Global Policy (Create | Edit) reappears.

8

Click OK to save the policy and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

9

As required, associate the HS Port Pool policy to a HSQ IOM4-e-HS MDA port on a 7750 SR node:

1. From the equipment view, navigate to a HSQ IOM4-e-HS MDA port on a 7750 SR node (Node→Shelf→Card Slot→Daughter Card→[Supported] Port) and choose Properties. The Physical Port [Edit] form opens.
2. On the General tab, choose a HS Port Pool policy in the HSQ panel to associate the policy with the port and click OK.
3. Save your changes and close the form.

END OF STEPS

50.72 To configure an FP Resource policy

50.72.1 Before you begin

Forwarding Plane Resource policies allow custom allocation of card slot resources to queues. By default, ingress and egress queues are each allocated 50% of the queue resources on a forwarding plane. FP Resource policies allow you to configure custom ingress queue resources in a range of 4% to 97%. The corresponding percentage remaining is allocated to egress queues.

FP Resource policies are assigned to forwarding planes on the card slot properties form of supporting NEs; see 15.59 “To assign an FP Resource policy to a forwarding plane” (p. 519)

50.72.2 Steps

1

Choose Policies→QoS→SROS QoS→FP Resource Policy from the NFM-P main menu. The FP Resource Policy form opens.

2

Click Create or choose an existing FP Resource policy and click Properties. The FP Resource Policy, Global Policy (Create | Edit) form opens.

3

Configure the required parameters on the General tab.

4

Save the policy and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

End of steps

50.73 To configure a HS Scheduler policy

50.73.1 Steps

1

Choose Policies→QoS→SROS QoS→HS QoS→HS Scheduler policy from the NFM-P main menu. The HS QoS – Scheduler Policy form opens

2

Click Create or choose an existing HS scheduler policy and click Properties. The HS Scheduler Policy, Global Policy (Create | Edit) form opens.

3

Configure the required parameters on the General tab.

4

Click Apply to save the policy. Confirm the action.

5

As required, click on the Scheduling Class tab, select a default entry and click Properties to modify the default parameters. By default, all entries have the same parameter settings applied to them. The HS Scheduling Classes form opens.

6

Modify the parameters on the form as required and click OK to save the changes and close the form. The HS Scheduler Policy, Global Policy (Create | Edit) form reappears..

7

As required, click on the Scheduling Group tab, select a default entry and click Properties to modify the default parameters. By default, all entries have the same parameter settings applied to them. The HS Scheduling Group form appears.

8

Modify the parameters on the form as required and click OK to save the changes and close the form. The HS Scheduler Policy, Global Policy (Create | Edit) form reappears.

9

Click OK to save the policy and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

10

As required, associate the HS Port Pool policy to a HSQ IOM4-e-HS MDA port on a 7750 SR node:

1. From the equipment view, navigate to a HSQ IOM4-e-HS MDA port on a 7750 SR node (Node→Shelf→Card Slot→Daughter Card→[Supported] Port) and choose Properties. The Physical Port [Edit] form opens.
2. On the General tab, choose a HS Scheduler policy in the HSQ panel to associate the policy with the port and click OK.
3. Save your changes and close the form.

END OF STEPS

50.74 To configure a queue group ingress template policy

50.74.1 Steps

1

Choose Policies→QoS→SROS QoS→Queue Group→Ingress Template from the NFM-P main menu. The Ingress Queue Group Template Policies form opens.

2

Click Create or choose an existing ingress queue group template policy and click Properties. The Ingress Queue Group Template (Create | Edit) form opens.

3

Configure the required parameters.

4

Click on the Queues tab.

5

Click Create or choose an existing queue and click Properties. The Ingress Queue (Create | Edit) form opens.

6

Configure the required parameters.

7

Configure the Named Buffer Pool parameter:

1. Click on Select adjacent to the Named Buffer Pool parameter. The Named Buffer Pool form opens.

   Note:

   To configure the Named Buffer Pool parameter, you must first create a Named Buffer Pool policy. See 50.67 “To configure a named buffer pool policy” (p. 1610) .
2. Select the required policy and click OK.

8

Configure the Scheduler parameter:

1. Click on Select adjacent to the Scheduler parameter. The Schedulers form opens.
2. Select the required scheduler and click OK.
3. Configure the required parameters in the Scheduler Association panel.

9

Configure the Advanced Configuration Policy Displayed Name parameter:

1. Click Select in the Advanced Configuration Policy panel. The Select Advanced Configuration Policy search form opens.
2. Select the required policy and click OK.

10

Configure the CIR/PIR/FIR parameters:

1. Click on the CIR/PIR/FIR tab.
2. Configure the required parameters.

   Ensure that the CIR value is lower than the PIR value.

11

Configure the Burst Size parameters:

1. Click on the Burst Size tab.
2. Configure the required parameters.

   The parameters are configurable when the Default check box above each is deselected.

   Ensure that the Committed Burst Size (kb) value is lower than the Maximum Burst Size (bytes) value.
3. Click OK.

12

Click on the Policers tab.

13

Click Create or choose an existing policer and click Properties. The Ingress Policer (Create | Edit) form opens.

14

Configure the required parameters.

15

Configure the Advanced Configuration Policy Displayed Name parameter:

1. Click Select in the Advanced Configuration Policy panel. The Select Advanced Configuration Policy search form opens.
2. Select the required policy and click OK.

16

Configure the CIR/PIR parameters:

1. Click on the CIR/PIR tab.
2. Configure the required parameters.

17

Configure the Burst Size parameters:

1. Click on the Burst Size tab.
2. Configure the required parameters.

   The parameters are configurable when the Default check box above each is deselected.
3. Click OK.

18

Click OK to save the policy and close the form.

END OF STEPS

50.75 To configure a queue group egress template policy

50.75.1 Steps

1

Choose Policies→QoS→SROS QoS→Queue Group→Egress Template from the NFM-P main menu. The Egress Queue Group Template Policies form opens.

2

Click Create or choose an existing egress queue group template policy and click Properties. The Egress Queue Group Template (Create | Edit) form opens.

3

Configure the required parameters.

4

Enable the Queues HQoS Manageable parameter if you intend to allow Hierarchical QoS management of the queues in this template.

5

To configure HSMDA queues, go to Step 6. To associate an HS Attachment Policy, go to Step Step 9. Otherwise, go to Step 14.

6

Configure the Packet Offset (bytes) and Low Burst Max Class parameters.

7

Click Select in the WRR Policy panel to associate a WRR Policy. The Select WRR Policy form opens.

8

Select the required WRR Policy and click OK.

9

Click Select in the HS panel to associate an alternate HS Attachment Policy other than the default policy. The Select HS Attachment Policy – Egress Queue Group Template Policy form opens

10

Select the required HS Attachment Policy and click OK.

11

Click on the HSMDA Queues tab.

12

Edit the HSMDA queues as required:

1. Select a queue from the list and click Properties.
2. Configure the required parameters.
3. Click Select and choose the required Slope Policy, then click OK.
4. Click on the PIR/Burst Size tab.

5. Configure the required parameters.

   The sliders can be configured when the checkboxes above them are disabled.

6. Click OK. The selected HSMDA queue is revised with your configuration changes.

13

Repeat Step 6 to Step 12 for any other required HSMDA queues.

14

Click on the Queues tab.

15

Click Create or choose an existing queue and click Properties. The Egress Queue (Create | Edit) form opens.

16

Configure the required parameters.

The Level, Weight, CIR Level, and CIR Weight parameters are configurable only if the Port Parent parameter is set to True.

17

Configure the Named Buffer Pool parameter:

1. Click on Select adjacent to the Named Buffer Pool parameter. The Named Buffer Pool form opens.

   Note:

   To configure the Named Buffer Pool parameter, you must first create a Named Buffer Pool policy. See 50.67 “To configure a named buffer pool policy” (p. 1610) .

2. Select the required policy and click OK.

18

Configure the Scheduler parameter:

1. Click on Select adjacent to the Scheduler parameter. The Schedulers form opens.

   Note:

   The Scheduler parameter is configurable only if you set the Port Parent parameter to False.

2. Select the required scheduler and click OK.
3. Configure the required parameters in the Scheduler Association panel.

19

Configure the Advanced Configuration Policy Displayed Name parameter:

1. Click Select in the Advanced Configuration Policy panel. The Select Advanced Configuration Policy search form opens.
2. Select the required policy and click OK.

20

Configure the WRED Queue parameters:

1. Select the Use WRED Queue parameter.
2. Click Select adjacent to the Displayed Name parameter. The Select WRED Queue Slope Policy form opens.

   Note:

   To configure a WRED Queue Slope policy, you must first create the policy. See 50.49 “To configure a WRED slope policy” (p. 1587).
3. Specify a filter to search for existing policy.
4. Select the required WRED Slope policy and click OK.

21

Configure the parameters in the Latency panel.

Enabling the Dynamic MBS parameter permits the dynamic modification of the MBS size of a queue in order to maintain the maximum latency for traffic in the queue, based on the queue’s admin PIR and configured MBS. The Queue Delay parameter allows you to configure the target queue delay for packets forwarded through the queue. It is used to determine the related queue parameters based on the PIR of the queue. If the No checkbox is selected, the determination of the queue parameters based on the queue delay is disabled.

22

Configure the CIR/PIR parameters:

1. Click on the CIR/PIR tab.
2. Configure the required parameters.

   The choice of CIP and PIR parameter definitions depends on the Rate Type parameter setting on the General tab.

23

Configure the Burst Size parameters:

1. Click on the Burst Size tab.
2. Configure the required parameters.

   The parameters are configurable when the Default check box above each is deselected.

24

Configure the HSQ parameters if required. You can only configure HSQ on default queue entries 1 to 8.

1. Click on the HSQ tab.
2. Configure the required parameters.
3. Click Select adjacent to the HS WRED Slope Policy parameter. The Select HS WRED slope Policy form opens.

   Note: To configure the HS WRED Slope Policy parameter, you must first create a HS WRED Slope policy. See 50.49 “To configure a WRED slope policy” (p. 1587).
4. Select the required policy and click OK.
5. Click OK. The Egress Queue form closes.

25

Click on the Forwarding Classes tab.

26

Click Create or choose an existing forwarding class and click Properties. The Forwarding Class (Create | Edit) form opens.

27

Configure the required parameters.

28

Click OK.

29

Click on the Policers tab.

30

Click Create or choose an existing policer and click Properties. The Egress Policer (Create | Edit) form opens.

31

Configure the required parameters.

32

Configure the Advanced Configuration Policy Displayed Name parameter:

1. Click Select in the Advanced Configuration Policy panel. The Select Advanced Configuration Policy search form opens.
2. Select the required policy and click OK.

33

Configure the CIR/PIR parameters:

1. Click on the CIR/PIR tab.
2. Configure the required parameters.

34

Configure the Burst Size parameters:

1. Click on the Burst Size tab.
2. Configure the required parameters.

   The parameters are configurable when the Default check box above each is deselected.
3. Click OK. The Egress Policer (Create | Edit) form closes.

35

Configure the HSQ parameters if required to configure HS WRR Groups.

1. Click on the HS WRR Groups tab.
2. Choose an existing HS WRR group and click Properties. The HS WRR Group form opens.

   Note: You can only modify the existing WRR Group parameters; you cannot create new WRR Groups.
3. As required, modify the parameters.
4. Save your changes and close the form.

36

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.76 To configure a queue group redirect list policy

50.76.1 Purpose

You can create a Queue Group Redirect List policy to provide QoS control to map IPv4 and IPv6 traffic using a single VXLAN or VXLAN GPE VNI to an ingress access queue group instance or a port access egress queue group instance. See 50.19 “Queue Group policies” (p. 1526) for more information.

After you create a queue group redirect list policy, you must release and distribute the policy, then associate the policy with an egress/ingress physical interface (SAP) that supports IES or VPRN services.

50.76.2 Steps

1

Choose Policies→QoS→SROS QoS→Queue Group→Redirect List from the NFM-P main menu. The Redirect List Queue Group Policies form opens.

2

Click Create or choose an existing queue group redirect list policy and click Properties. The Queue Group Redirect List Policy (Create | Edit) form opens.

3

Configure the required parameters.

4

Click on the Match tab and click Create. The Redirect List Match, Queue Group Redirect List Policy form opens.

5

Configure the required parameters.

6

Click OK to save the changes and close the form. The Queue Group Redirect List Policy (Create | Edit) form reappears.

7

Click OK to save the changes and close the form. The Redirect List Queue Group Policies form reappears.

Release and distribute the queue group redirect list policy to the NEs

8

To release and distribute the policy, click Search, select the newly created policy and click Properties. The Queue Group Redirect List Policy (Edit) form opens.

9

Perform the required steps in 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy.

Associate the queue group redirect list policy to an IES or VPRN ingress SAP

10

Create a queue group ingress template policy as described in 50.74 “To configure a queue group ingress template policy” (p. 1617) .

11

Perform the required steps in 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy.

12

Attach the newly created queue group ingress template policy to the forwarding plane of a card slot on the Access Ingress Queue Group tab; see 15.65 “To configure an ingress queue group on a forwarding plane” (p. 523).

13

Perform the following actions on the QoS tab associated with an ingress L3 access interface (SAP) that supports an IES or VPRN service; see78.32 “To assign ingress and egress QoS policies to an IES L3 access interface” (p. 2477).

1. Click Select to choose the queue group ingress template policy created in Step 10.
2. Click Select to choose the queue group redirect list policy created in Step 1 to Step 7.
3. Configure any other required parameters on the form and click OK to save your changes and close the form.

Associate the queue group redirect list policy to an IES or VPRN egress SAP

14

Create a queue group egress template policy as described in 50.75 “To configure a queue group egress template policy” (p. 1619) .

15

Perform the required steps in 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy.

16

Attach the newly created queue group egress template policy to the physical port on the Access Egress Queue Group tab; see 16.37 “To add a queue group to an Ethernet port” (p. 627).

17

Perform the following actions on the QoS tab associated with an egress L3 access interface (SAP) that supports an IES or VPRN service; see78.32 “To assign ingress and egress QoS policies to an IES L3 access interface” (p. 2477).

1. Click Select to choose the queue group ingress template policy created in Step 14.
2. Click Select to choose the queue group redirect list policy created in Step 1 to Step 7.
3. Configure any other required parameters on the form and click OK to save your changes and close the form.

END OF STEPS

50.77 To configure a 7705 SAR fabric profile

50.77.1 Steps

1

Choose Policies→QoS→SROS QoS→Fabric from the NFM-P main menu. The Fabric Profiles form opens.

2

Click Create or choose an existing fabric policy and click Properties. The Fabric (Create | Edit) form opens.

3

Configure the required parameters.

4

Click on the Rates tab. Perform one of the following:

a. If you chose Aggregate Mode in Step 3 , configure the parameters:
   - Aggregate Rate (kbps)
   - Unshaped SAP CIR (kbps)

b. If you chose Destination Mode in Step 3 , configure the Rate To MDA in kbps for each daughter card slot to set the fabric shaping rate to each daughter card.

   You can also configure the MultiPoint Rate (kbps) parameter for distribution to all of the daughter cards.

5

Click Apply. The form refreshes to enable the other tabs.

6

Click Distribute to distribute the policy to NEs. See 49.6 “To release and distribute a policy” (p. 1476) for more information.

7

Click OK to save the policy and close the form.

END OF STEPS

50.78 To configure a 7705 SAR security queue policy

50.78.1 Purpose

The security queue policy defines the queue type (Best Effort or Expedited) applied to 7705 SAR ingress traffic to deter DoS-like attacks from overwhelming the control plane, while ensuring that

critical control traffic such as signaling is always serviced in a timely manner. These queues are either fixed use (each queue handles a certain type of traffic which is not user-configurable) or fixed configuration (each queue is user-configurable; you can configure the CIR/PIR rate, burst size, and buffering capacity of each queue).

50.78.2 Steps

1

Choose Policies→QoS→SROS QoS→Security Queue from the NFM-P main menu. The Security Queue Policies form opens.

2

Click Create. The Security Queue Policy, Global Policy (Create) form opens.

3

Configure the general parameters and click Apply. The form refreshes to enable the other tabs.

4

Click on the Queue tab. Two default queues appear - Best Effort and Expedited.

5

Choose a default queue and click Properties.

6

Configure the MIN and MAX for the CIR (kbps), PIR (kbps), Committed Burst Size (KB), Maximum Buffer Size (KB), and Buffer Size (%), using the sliders.

The sliders are operational when the checkboxes are disabled.

7

Click Apply to save the policy, or click OK to save the policy and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

End of steps

50.79 To configure a 7705 SAR shaper policy

50.79.1 Purpose

All 7705 SAR devices have a default shaper QoS policy and an associated shaper group that cannot be modified. If you create a new shaper QoS policy, you can modify the associated default shaper group.

50.79.2 Steps

1

Choose Policies→QoS→SROS QoS→Shaper from the NFM-P main menu. The Shaper Policies form opens.

2

Click Create or choose an existing Shaper policy and click Properties. The Shaper Policy (Create | Edit) form opens.

3

Configure the required parameters.

4

Click OK and confirm.

5

Click Distribute to distribute the policy to NEs. See 49.6 “To release and distribute a policy” (p. 1476) for more information.

6

Select the newly-created policy in the Shaper Policies form and click Distribute to distribute the policy to NEs. See 49.6 “To release and distribute a policy” (p. 1476) for more information.

7

To modify a default shaper group, choose a newly-created policy from the Shaper Policies form and click Properties. The Shaper Policy, Global Policy (Edit) form opens.

8

Click on the Shaper Group tab.

9

Choose the default Shaper group and click Properties. The Shaper Group (Edit) form opens.

10

Configure the Description parameter and the MIN and MAX values for the PIR (kbps) and CIR (kbps) using the sliders.

The sliders are operational when the checkboxes are disabled.

11

Click OK to save your changes and close the forms.

END OF STEPS

50.80 To configure a 7210 remarking policy

50.80.1 Purpose

A 7210 remarking policy maps forwarding classes and profile states to dot1p, DE, DSCP, and LSP-EXP bit values for access egress or network egress traffic. Policies are created as one of the following types:

- DOT1P
- DSCP
- LSP-EXP
- DOT1P-DSCP
- DOT1P-LSP-EXP SHARED
- DOT1P-LSP-EXP
- DSCP-LSP-EXP
- DOT1P-LSP-EXP-DSCP

A 7210 remarking policy can be assigned to:

- a 7210 and 1830 port access egress policy; see 50.31 “To configure a 7210 and 1830 port access egress policy” (p. 1556) . The remarking policy must be of type DOT1P, DSCP, DOT1P-DSCP, or DOT1P-LSP-EXP SHARED.
- a 7210 SAP access egress policy; see 50.32 “To configure a 7210 SAP access egress policy” (p. 1558) . The remarking policy must be of type DOT1P, DSCP, DOT1P-DSCP, or DOT1P-LSP-EXP SHARED.
- a 7210 and 1830 network policy; see 50.42 “To configure a 7210 and 1830 network policy” (p. 1571) . If the network policy is of port type, the remarking policy must be of type DOT1P, DSCP, DOT1P-DSCP, DOT1P-LSP-EXP, DOT1P-LSP-EXP-DSCP, or DSCP-LSP-EXP. If the network policy is of network interface type, the remarking policy must be of type LSP-EXP or DOT1P-LSP-EXP SHARED.

The NFM-P provides two default remarking policies:

- policy ID 1: DOT1P-DSCP type
- policy ID 2: DOT1P-LSP-EXP SHARED type

Policy ID 1 is the default for port-type network policies; policy ID 2 is the default for network interface-type network policies. Default policies cannot be deleted or modified. A default 7210 remarking policy is assigned unless a user-configured remarking policy is explicitly assigned. You can view the default mapping of FCs and profiles to dot1p, DSCP, and LSP-EXP bit values by clicking on the Forwarding Classes tab of the properties form for the default policy.

The 7210 remarking policy is supported on the 7210 SAS-K, 7210 SAS-Mxp, 7210 SAS-R, 7210 SAS-S, 7210 SAS-Sx, 7210 SAS-T, and 7210 SAS-X. Support for specific parameters and features varies, depending on the chassis type. Local definitions of a policy do not necessarily support all configurations in the global policy. See the NE documentation for more information.

Note: To avoid synchronization and deployment errors when you create remarking policies using a CLI on the 7210 SAS-X, Nokia recommends that you create each remarking policy separately and allow at least three seconds between each policy creation.

50.80.2 Steps

1

Choose Policies→QoS→SROS QoS→Egress Remarking→7210 Remarking from the NFM-P main menu. The 7210 Remarking Policies form opens.

2

Click Create or choose an existing policy and click Properties. The 7210 Remarking Policy (Create| Edit) form opens.

3

Configure the required parameters on the General tab and click Apply.

Note: You cannot modify the Type parameter after the policy is created.

4

Configure the mapping of forwarding classes, profiles, and remark values:

1. Click on the Forwarding Classes tab.
2. Choose a forwarding class and click Properties. The 7210 Remark Forwarding Class form opens.
3. Configure the required parameters.

   The available parameters vary, depending on the remarking policy type and the settings for other parameters on the form.

   For DOT1P and DOT1P-DSCP remarking policy types, settings for the Dot1p and Force DE value parameters take effect when the Mark DE bits parameter is set to true.
4. Save your changes and close the form.

5

Click Distribute to distribute the policy to NEs. See 49.6 “To release and distribute a policy” (p. 1476) for more information.

6

Click Apply to save the policy or click OK to save the policy and close the form.

END OF STEPS

50.81 To configure FC mapping policies for egress remarking on the 7250 IXR

50.81.1 Purpose

7250 SROS FC mapping policies for egress remarking associate Dot1p, DSCP, and LSP-EXP CoS values with forwarding classes and profiles. A separate policy is configured for each classification type (Dot1p, DSCP, or LSP EXP).

The policies are assigned to a 7250 SROS Egress Remarking policy; see 50.82 “To configure a 7250 SROS Remarking policy” (p. 1634).

7250 SROS FC mapping policies are identified by the policy name; policy ID numbers are not used.

The NFM-P provides a default 7250 SROS FC Dot1p mapping policy. The default policy is not configurable, and cannot be deleted. The default policy is assigned to a 7250 SROS Egress Remarking policy when no user-configured policy is explicitly assigned.

7250 SROS FC mapping policies are not supported on all 7250 IXR chassis types and releases. For information about FC mapping policy support on the 7250 IXR, see the NE documentation.

For more information about QoS policy support on the 7250 IXR, see 50.24 “7250 IXR QoS policies” (p. 1534).

50.81.2 Steps

1

If required, configure a 7250 SROS FC Dot1p Mapping policy. Perform the following:

1. Choose Policies→QoS→SROS QoS→Egress Remarking→7250 SROS FC Dot1p Mapping from the NFM-P main menu. The 7250 SROS FC Dot1p Mapping form opens.
2. Click Create or choose an existing policy and click Properties. The 7250 SROS FC Dot1p Mapping (Create|Edit) form opens.
3. Configure the Displayed Name parameter on the General tab.
4. Click on the FC Classification tab.
5. Choose a forwarding class in the list and click Properties. The FC Dot1p form opens.
6. Configure the mapping of forwarding classes, profiles, Dot1p values, and DE values.

   Settings for the Force DE value parameter take effect when the Mark DE bit parameter is set to true.
7. Save your changes and close the form.
8. Repeat substep 5 to substep 7 to configure additional FCs, as required.
9. Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

2

If required, configure a 7250 SROS FC DSCP Mapping policy. Perform the following:

1. Choose Policies→QoS→SROS QoS→Egress Remarking→7250 SROS FC DSCP Mapping from the NFM-P main menu. The 7250 SROS FC DSCP Mapping form opens.
2. Click Create or choose an existing policy and click Properties. The 7250 SROS FC DSCP Mapping (Create|Edit) form opens.
3. Configure the Displayed Name parameter on the General tab.
4. Click on the FC Classification tab.
5. Choose a forwarding class in the list, or click Create. The FC DSCP form opens.
6. Configure the mapping of forwarding classes, profiles, and DSCP values.
7. Save your changes and close the form.
8. Repeat substep 5 to substep 7 to configure additional FCs, as required.
9. Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

3

If required, configure a 7250 SROS FC LSP EXP Mapping policy. Perform the following:

1. Choose Policies→QoS→SROS QoS→Egress Remarking→7250 SROS FC LSP EXP Mapping from the NFM-P main menu. The 7250 SROS FC LSP EXP Mapping form opens.
2. Click Create or choose an existing policy and click Properties. The 7250 SROS FC LSP EXP Mapping (Create|Edit) form opens.
3. Configure the Displayed Name parameter on the General tab.
4. Click on the FC Classification tab.
5. Choose a forwarding class in the list, or click Create. The FC LSP EXP form opens.
6. Configure the mapping of forwarding classes, profiles, and LSP-EXP values.
7. Save your changes and close the form.
8. Repeat substep 5 to substep 7 to configure additional FCs, as required.
9. Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

End of steps

50.82 To configure a 7250 SROS Remarking policy

50.82.1 Before you begin

A 7250 SROS Remarking policy maps forwarding classes and profile states to Dot1p, DSCP, DE, and LSP-EXP values for egress traffic.

The 7250 SROS Remarking policy is assigned to L2 access interfaces on VPLS and VLL services, to L3 access interfaces on IES and VPRN services, and to network interfaces. See the following procedures:

- for VLL: 76.42 “To assign ingress and egress QoS policies to a VLL L2 access interface” (p. 2181)
- for VPLS: 77.69 “To assign QoS policies or to enable a MAC override address to a VPLS or MVPLS L2 access interface” (p. 2340)
- for IES: 78.32 “To assign ingress and egress QoS policies to an IES L3 access interface” (p. 2477)
- for VPRN: 79.89 “To assign ingress and egress QoS policies to a VPRN L3 access interface” (p. 2662)
- for L3 network interfaces: 27.17 “To create an L3 network interface on a routing instance” (p. 856)and 27.18 “To configure L3 network interfaces” (p. 863)

7250 SROS Remarking policies are identified by the policy name; policy ID numbers are not used.

The NFM-P provides three default 7250 SROS Remarking policies:

- access default, for L2 and L3 access interfaces
- network default, for network interfaces
- push-implicit-null-default, for PHP network interfaces

Note: The push-implicit-null-default policy is supported only for releases earlier than 22.2 R1 on the IXR nodes.

The default policies are not configurable. A default policy is assigned if no user-configured 7250 SROS Remarking policy is explicitly assigned.

For more information about QoS policy support on the 7250 IXR, see 50.24 “7250 IXR QoS policies” (p. 1534).

50.82.2 Steps

1

Choose Policies→QoS→SROS QoS→Egress Remarking→7250 SROS Remarking from the NFM-P main menu. The 7250 SROS Remarking form opens.

2

Click Create, or choose an existing policy and click Properties. The 7250 SROS Egress Remark Policy (Create|Edit) form opens.

3

Configure the required parameters on the General tab.

If you are configuring a policy for a 7250 IXR NE that supports SROS FC mapping policies for egress remarking, assign the FC mapping policies in the Properties panel, then go to Step 5.

For more information about SROS FC mapping policies, see 50.81 “To configure FC mapping policies for egress remarking on the 7250 IXR” (p. 1632).

4

Click on the Forwarding Classes tab to configure remarking values for FCs.

1. Choose a forwarding class and click Properties. The Egress Remark Forwarding Class form opens.
2. Configure the required parameters.
3. Save your changes and close the form.

5

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.83 To configure a 7210 MPLS LSP-EXP Mapping policy

50.83.1 Purpose

A 7210 MPLS LSP-EXP Mapping policy defines a local mapping of forwarding classes to MPLS LSP-EXP bits for traffic ingressing the switch from an MPLS network. The policy is used primarily for an RSVP LSP with FRR one-to-one. For LDP LSPs, or when using FRR facility, the use of a single MPLS LSP-Exp Map policy for all IP interfaces is recommended.

The policy is assigned to a network policy of network interface type; see 50.42 “To configure a 7210 and 1830 network policy” (p. 1571) . You can also assign the policy to an NE using the NE properties form. The 7210 MPLS LSP-EXP Mapping policy is called an MPLS LSP-EXP Profile when it is assigned to a network policy or NE.

The LDP Local FC parameter must be set to true in NE properties in order for 7210 MPLS LSP-EXP Mapping policy local definitions to take effect.

The NFM-P provides one default MPLS LSP-EXP Mapping policy (policy ID 1). The default policy cannot be modified or deleted. In the default policy, EXP bit values 0 and 2 are out-of-profile. The other six EXP bit values (1, 3, 4, 5, 6, 7) are in-profile.

The MPLS LSP-EXP Mapping policy is supported on the following MPLS-enabled 7210 SAS devices:

- 7210 SAS-M (in network mode)
- 7210 SAS-Mxp
- 7210 SAS-R

- 7210 SAS-S
- 7210 SAS-Sx
- 7210 SAS-T (in network mode)
- 7210 SAS-X

50.83.2 Steps

1

Set the LDP Local FC parameter to true.

Note: For 7210 SAS NEs, the LDP Local FC parameter is read-only and is set to true.

Perform the following:

1. Right-click on a 7210 SAS NE in the navigation tree and choose Properties. The Network Element (Edit) form opens.
2. Click on the LDP QoS Config tab and configure the LDP Local FC parameter, as required.
3. Save your changes and close the form.

2

Choose Policies→QoS→SROS QoS→Network→7210 MPLS LSP-EXP Mapping from the NFM-P main menu. The 7210 MPLS LSP-EXP Map Policies form opens.

3

Click Create or choose a policy and click Properties. The 7210 MPLS LSP-Exp Map, Global Policy (Create|Edit) form opens.

4

Configure the required parameters on the General tab.

5

Map profile states to MPLS LSP-EXP bits.

1. Click on the MPLS LSP-Exp Bits tab.
2. Select an LSP EXP bit and click Properties. The MPLS LSP-Exp Map Profile form opens.
3. Configure the Profile parameter.
4. Save your changes and close the form.

6

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.84 To configure a 7210/7250 Dot1p classification policy

50.84.1 Purpose

A 7210/7250 Dot1p classification policy associates ingress dot1p values, forwarding classes, and profiles. The policy is assigned to 7210,7250 and 1830 SAP Access Ingress policies, 7210 and 1830 Network policies, and 7250 Ingress CoS policies.

The NFM-P provides a default 7210/7250 Dot1p classification policy. The default policy is applied if no user-configured policy is explicitly assigned.

The 7210 SAS-K supports 7210/7250 Dot1p classification policies assigned to access ingress and network policies on the device.

50.84.2 Steps

1

Choose Policies→QoS→SROS QoS→Ingress Classification→7210/7250 Dot1p from the NFM-P main menu. The 7210/7250 Dot1p form opens.

2

Click Create or choose an existing policy and click Properties. The Dot1p Classification Policy (Create|Edit) form opens.

3

Configure the required parameters on the General tab.

The values configured in the Default Forwarding Class panel are applied to packets that do not match any of the associations on the Dot1p Classification tab; see Step 5.

4

Click on the Dot1p Classification tab.

5

Associate dot1p bits with FCs and profiles:

1. Click Create, or choose an existing entry and click Properties. The Ingress Dot1p, Dot1p Classification Policy (Create) form opens.
2. Configure the required parameters.
3. Save your changes.

6

Save your changes and close the forms.

END OF STEPS

50.85 To configure a 7210/7250 DSCP classification policy

50.85.1 Purpose

A 7210/7250 DSCP classification policy associates ingress DSCP values with forwarding classes and profiles. The policy is assigned to 7210, 7250 and 1830 SAP Access Ingress policies, 7210 and 1830 Network policies, and 7250 Ingress CoS policies. For table-based DSCP ingress classification, the policy is assigned to Ethernet ports and L3 interfaces configured for RVPLS; see 50.23.2 “Table-based ingress classification on the 7210 SAS” (p. 1529).

The NFM-P provides a default 7210/7250 DSCP classification policy. The default policy is applied if no user-configured policy is explicitly assigned.

The 7210 SAS-K supports 7210/7250 DSCP classification policies assigned to access ingress and network policies on the device.

The 7210 SAS-Mxp and 7210 SAS-R support 7210/7250 DSCP classification policies assigned to access ingress policies, access ports, and L3 access interfaces configured for RVPLS.

50.85.2 Steps

1

Choose Policies→QoS→SROS QoS→Ingress Classification→7210/7250 DSCP from the NFM-P main menu. The 7210/7250 DSCP form opens.

2

Click Create or choose an existing policy and click Properties. The DSCP Classification Policy (Create|Edit) form opens.

3

Configure the required parameters on the General tab.

The values configured in the Default Forwarding Class panel are applied to packets that do not match any of the associations on the Ingress DSCP tab; see Step 5.

4

Click on the Ingress DSCP tab.

5

Associate DSCP bits with FCs and profiles.

1. Click Create, or choose an existing entry and click Properties. The Ingress DSCP, DSCP Classification (Create) form opens.
2. Configure the required parameters.
3. Save your changes.

6

Save your changes and close the forms.

END OF STEPS

50.86 To configure a 7210/7250 MPLS LSP-EXP classification policy

50.86.1 Purpose

A 7210/7250 MPLS LSP-EXP classification policy associates network ingress LSP-EXP values with forwarding classes and profiles. The policy is assigned to 7210 and 1830 network policies, and 7250 Ingress CoS policies.

The NFM-P provides a default 7210/7250 MPLS LSP-EXP classification policy. The default policy is applied if no user-configured policy is explicitly assigned.

The 7210 SAS-K12 and 7210 SAS-K30 ETR support MPLS LSP-EXP classification policies assigned to network policies on the device.

50.86.2 Steps

1

Choose Policies→QoS→SROS QoS→Ingress Classification→7210/7250 MPLS LSP-EXP from the NFM-P main menu. The 7210/7250 MPLS LSP-EXP form opens.

2

Click Create or choose an existing policy and click Properties. The MPLS LSP-EXP Classification Policy (Create|Edit) form opens.

3

Configure the required parameters on the General tab.

The values configured in the Default Forwarding Class panel are applied to packets that do not match any of the associations on the Ingress LSP-EXP tab; see Step 5.

4

Click on the Ingress LSP-EXP tab.

5

Associate LSP-EXP bits with FCs and profiles.

1. Click Create, or choose an existing entry and click Properties. The Ingress LSP-EXP, MPLS LSP-EXP Classification Policy (Create) form opens.
2. Configure the required parameters.
3. Save your changes.

6

Save your changes and close the forms.

End of steps

50.87 To configure a 7210 FC Meter Map policy

50.87.1 Purpose

A 7210 FC Meter Map policy is assigned to a 7210, 7250 and 1830 SAP Access Ingress policy; see 50.29 “To configure a 7210, 7250, and 1830 SAP Access Ingress policy” (p. 1544).

Service meters for SAP ingress provide an option to use meter resources from the ingress service-meter pool, which provides a larger number of meters/policers for use by access SAPs. This option is available only with table-based classification; it is not available when CAM-based classification is used. The Use SVC Meter Pool parameter must be set to true in the 7210, 7250 and 1830 SAP Access Ingress policy.

Note: Table-based classification uses meters from either the TCAM pool or the service meter pool, based on the SAP ingress policy type. If the SAP ingress policy is configured to use the use-svc-meter-pool parameter, the policy uses the service meter pool, otherwise the policy uses the TCAM meter pool.

7210 FC Meter Map policy attached to the 7210 SAP-ingress QoS policy supports only DSCP and Dot1p classifications. For the Policy ID parameter, the configurable values are 1 or 2. The default policy uses an ID values of 1; a user-defined policy uses an ID value of 2.

50.87.2 Steps

1

Choose Policies→QoS→SROS QoS→Ingress Classification→7210 FC Meter Map from the NFM-P main menu. The 7210 FC Meter Map form opens.

2

Click Create or choose an existing policy and click Properties. The FC-meter-map (Create|Edit) form opens.

3

Configure the required parameters on the General tab.

4

Map FCs to meters.

1. Click on the Forwarding Classes tab.
2. Choose an FC in the list, or click Create. The Forwarding Class (Create|Edit) form opens.
3. Configure the Forwarding Class parameter and select the meter or meters to map to that forwarding class.

4. Click Apply to save the mapping and map another FC, or click OK to save your changes and close the form.
5. Save your changes and close the forms.

5

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.88 To configure a 7210 Port Access Ingress Policy

50.88.1 Purpose

7210 Port Access Ingress Policy allows you to access ports as layer 2 uplinks. As a result, you can apply a single port-based access-ingress policy on ingress of an access port instead of using per SAP ingress policies. This allows a single policy definition to be used to classify and rate-limit all traffic received over access ports.

Meters are mapped to FCs according to the user-defined configuration in the policy. The maximum number of meters supported on a local policy varies depending on the chassis type.

50.88.2 Steps

1

Choose Policies→QoS→SROS QoS→Access Ingress→7210 Port Access Ingress Policy from the NFM-P main menu. The 7210 Port Access Ingress form opens.

2

Click Create or choose an existing policy and click Properties. The 7210 Port Access Ingress Policy (Create|Edit) form opens.

3

Configure the required parameters on the General tab.

4

Configure ingress meters.

The Number of QoS Classifiers parameter, configured in Step 3 , affects the number of meters available.

Perform the following:

1. Click on the Meter tab.
2. Select a meter and click Properties, or click Create. The Meter form opens.
3. Configure the required parameters on the General tab.

You cannot choose ID values 1 or 9 for user-configured meters; these ID values are used by default meters.

4. Configure the CIR/PIR parameters:
   a. Click on the CIR/PIR tab.
   b. Configure the required parameters.
5. Configure the Burst Size parameters:
   a. Click on the Burst Size tab.
   b. Configure the required parameters.
      The parameters are configurable when the Default check box above each is deselected.
   c. Click OK.

5

Click on the Forwarding Classes tab.

6

Click Create or choose an existing forwarding class and click Properties. The Forwarding Class (Create | Edit) form opens.

7

Configure the required parameters and click OK.

8

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.89 To configure a 7250 Ingress CoS policy

50.89.1 Before you begin

A 7250 Ingress CoS policy associates ingress CoS values with forwarding classes and profiles, using selected classification policies. The 7250 Ingress CoS policy provides a container for various combinations of ingress classification policies.

Before you configure a 7250 Ingress CoS policy, configure the following polices as required:

- 7210/7250 Dot1p classification policy; see 50.84 “To configure a 7210/7250 Dot1p classification policy” (p. 1637)
- 7210/7250 DSCP classification policy; see 50.85 “To configure a 7210/7250 DSCP classification policy” (p. 1638)
- 7210/7250 MPLS LSP-EXP classification policy; see 50.86 “To configure a 7210/7250 MPLS LSP-EXP classification policy” (p. 1639)

The 7250 Ingress CoS policy is assigned to 7210,7250 and 1830 SAP Access Ingress policies; see 50.29 “To configure a 7210, 7250, and 1830 SAP Access Ingress policy” (p. 1544).

You cannot assign a 7250 Ingress CoS policy to a 7210,7250 and 1830 SAP Access Ingress policy if the 7250 Ingress CoS policy contains a 7210/7250 MPLS LSP-EXP classification policy.

The NFM-P provides two default 7250 Ingress CoS policies, with policy IDs 1 and 2. The default policies are not configurable. Default policy 1 is assigned to 7210,7250 and 1830 SAP Access Ingress policies when no user-configured policy is explicitly assigned. Default policy 2 is assigned to 7250 Network Ingress policies when no user-configured policy is explicitly assigned.

If you are configuring an ingress classification policy for a 7250 IXR with SR OS, see 50.45 “To configure a 7250 SROS Ingress Classification policy” (p. 1579). For more information about QoS policy support on the 7250 IXR, see 50.24 “7250 IXR QoS policies” (p. 1534).

50.89.2 Steps

1

Choose Policies→QoS→SROS QoS→Ingress Classification→7250 Ingress CoS from the NFM-P main menu. The 7250 Ingress CoS form opens.

2

Click Create, or choose an existing policy and click Properties. The Ingress CoS Classification Policy (Create|Edit) form opens.

3

Configure the required parameters on the General tab.

4

In the Classification policies panel, select the required classification policies:

- Dot1p Classification
- DSCP classification
- LSP-EXP Classification

See 50.89.1 “Before you begin” (p. 1642) for information about classification policies.

If you are configuring a 7250 Ingress CoS policy for a 7210,7250 and 1830 SAP Access Ingress policy, do not select an LSP-EXP Classification policy.

5

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.90 To configure an OmniSwitch AOS QoS Network Group policy

50.90.1 Purpose

Perform this procedure to create or modify an AOS QoS Network Group policy. You can select network group policies to define a Source Network Group or Destination Network Group during configuration of IP match criteria in an AOS QoS Condition policy; see 50.92 “To configure an OmniSwitch QoS Condition policy ” (p. 1645).

50.90.2 Steps

1

Choose Policies→QoS→AOS QoS Policies from the NFM-P main menu. The AOS QoS Policies form opens.

2

Click Create→QoS Network Group, or choose QoS Network Groups (AOS QoS) from the object drop-down menu and select a Network Group, then click Properties. The AOS QoS Network Group - Global Policy (Create|Edit) form opens.

3

If you are creating an AOS QoS Network Group policy, configure the Displayed Name parameter.

4

Click on the Network Group Element tab and choose an item from the list, or click Create. The QoS Network Group Element (Create|Edit) form opens.

5

Configure the required parameters and click OK.

6

Create additional network group elements as required.

7

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.91 To configure an OmniSwitch AOS QoS MAC Group policy

50.91.1 Purpose

Perform this procedure to create or modify an AOS QoS MAC Group policy. You can select MAC group policies to define a Source MAC Group or Destination MAC Group during configuration of MAC match criteria in an AOS QoS Condition policy; see 50.92 “To configure an OmniSwitch QoS Condition policy ” (p. 1645).

50.91.2 Steps

1

Choose Policies→QoS→AOS QoS Policies from the NFM-P main menu. The AOS QoS Policies form opens.

2

Click Create→QoS MAC Group, or choose QoS MAC Groups (AOS QoS) from the object drop-down menu and select a MAC Group, then click Properties. The AOS QoS MAC Group - Global Policy (Create|Edit) form opens.

3

If you are creating an AOS QoS MAC Group policy, configure the Displayed Name parameter.

4

Click on the MAC Group Element tab and choose an item from the list, or click Create. The QoS MAC Group Element (Create|Edit) form opens.

5

Configure the required parameters and click OK.

6

Create additional MAC group elements as required.

7

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.92 To configure an OmniSwitch QoS Condition policy

Note: OmniSwitch QoS policies consist of a condition and an action. You must configure at least one condition and one action before you can create a policy.

50.92.1 Steps

1

Choose Policies→QoS→AOS QoS Policies from the NFM-P main menu. The AOS QoS Policies form opens.

2

Click Create→QoS Condition or choose an AOS QoS condition and click Properties. The AOS QoS Condition - Global Policy (Create | Edit) form opens.

3

Configure the Displayed Name parameter.

4

Click on the Filter Properties tab and configure the required parameters in the Port Match Criteria panel.

5

Click on the Layer 2 tab and configure the required parameters.

In the MAC Match Criteria panel, click Select to choose an AOS QoS MAC Group policy for the Source MAC Group and Destination MAC Group; see 50.91 “To configure an OmniSwitch AOS QoS MAC Group policy” (p. 1645).

6

Click on the Layer 3 tab and configure the required parameters.

In the IP Match Criteria panel, click Select to choose an AOS QoS Network Group policy for the Source Network Group and Destination Network Group; see50.90 “To configure an OmniSwitch AOS QoS Network Group policy” (p. 1644).

7

Click on the Layer 4 tab and configure the IP Protocol parameter, if required.

8

If you set the IP Protocol to a value other than HOPOPT (0) in the previous step, configure the required parameters in the IP Port Match Criteria panel.

9

Save your changes and close the forms.

END OF STEPS

50.93 To configure an OmniSwitch QoS policy action

Note: OmniSwitch QoS policies consist of a condition and an action. You must configure at least one condition and one action before you can create a policy.

50.93.1 Steps

1

Choose Policies→QoS→AOS QoS Policies from the NFM-P main menu. The AOS QoS Policies form opens.

2

Click Create→QoS Action or choose an AOS QoS action and click Properties. The AOS QoS Action - Global Policy (Create | Edit) form opens.

3

Configure the required parameters.

Note: You cannot use DSCP and ToS parameters in the same action.
You cannot use Maximum Bandwidth (Kbps) and Information Rate and Burst Size parameters in the same action.

4

Save your changes and close the form.

END OF STEPS

50.94 To create an OmniSwitch QoS policy

Note: OmniSwitch QoS policies consist of a condition and an action. You must configure at least one condition and one action before you can create a policy.

50.94.1 Steps

1

Choose Policies→QoS→AOS QoS Policies from the NFM-P main menu. The AOS QoS Policies form opens.

2

Click Create→QoS Policy or choose an AOS QoS policy and click Properties. The AOS QoS Policy - Global Policy (Create | Edit) form opens.

3

Configure the required parameters.

4

Select a default action and a default condition.

5

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

50.95 To create an OmniSwitch QoS list

50.95.1 Purpose

A QoS list includes support of egress policy configurations to perform last minute operations on the data traffic before it egresses through the port.

See 50.92 “To configure an OmniSwitch QoS Condition policy ” (p. 1645) , 50.93 “To configure an OmniSwitch QoS policy action” (p. 1647) , and 50.94 “To create an OmniSwitch QoS policy” (p. 1647) to create AOS QoS policy actions, policy conditions, and policies.

50.95.2 Steps

1

Choose Policies→QoS→AOS QoS Policies from the NFM-P main menu. The AOS QoS Policies form opens.

2

Click Create→QoS List or choose an AOS QoS list and click Properties. The AOS QoS List - Global Policy (Create | Edit) form opens.

3

Configure the required parameters on the General tab.

4

Click on the List Policies tab and click Create. The AOS QoS Policy List, AOS QoS List, Global Policy (Create) form opens.

5

Select an AOS QoS policy list.

6

Click Properties. The AOS QoS Policy - Global Policy (Edit) form opens.

7

Configure the Precedence parameter, if required.

8

Save your changes and close the forms.

END OF STEPS

50.96 To configure a Generic QoS Profile

50.96.1 Purpose

The Generic QoS Profile (GQP) provides an abstraction layer above the specific 7x50, 7210, and Multi Vendor QoS policies in the NFM-P. This functionality allows users to create QoS profiles that are generic for both proprietary NEs and third party NEs.

Note: Considerations for binding policies to GQPs
The following considerations apply when binding SAP Access Ingress/Egress policies or 7210 SAP Access Ingress/Egress policies to the GQP:

- When applying a SAP Access Ingress/Egress policy or 7210 SAP Access Ingress/Egress policy to the GQP, you can only apply those policies that have matching queues/meters/policers with the GQPs.
- Upon GQP creation and when the relevant GQP properties are left empty, relevant values from the assigned ingress policy and/or the egress policy are used to auto-populate the relevant GQP properties. This only occurs upon GQP creation and only if a policy is added. If any of the GQP properties are edited, this will not occur. Additional policies can be added after initial creation. The relevant properties are those set in the policy's queues, meters and policers.
- During the auto-populate, if a policy has the same queue ID entry as a policer/meter entry and the same CIR, PIR, CBS, or MBS characteristics, the ingress buffers are auto-populated, displaying the type as Not Applicable in the GQP. When the entries have different CIR, PIR, CBS, or MBS characteristics, the ingress buffers are auto-populated, displaying the type as Queue in the GQP.
- When comparing queue/meter/policers entries between the two policy types: only the first 8 queue entries are used for comparison; for meter and policer entries, only the first 32 entries are used.
- When you select an additional ingress or egress policy after the first ingress or egress policy has been selected, only policies with matching relevant properties are displayed in the select NFM-P window.
- When a GQP is cloned or modified using an API, the NFM-P creates a corresponding GQP and related ingress and egress QoS policies.

50.96.2 Steps

1

Choose Policies→QoS→Generic QoS Profiles from the NFM-P main menu. The Generic QoS Profiles form opens.

2

Click Create or choose a Generic QoS Profile and click Properties. The Generic QoS Profile (Create | Edit) form opens.

3

Configure the required parameters on the General tab.

If the MultiVendor Policies parameter is enabled, and the Generic QoS Profile is being created or modified, all appropriate multi-vendor global policies are auto-generated upon applying the change. The multi-vendor policies are automatically added to the GQP, but do not replace any non-auto-generated policies which are already there.

You can view the generated policies on the QoS Policies tab of the GQP and in the policy managers from the NFM-P main menu, Policies→Multi-Vendor, after the GQP changes are applied.

In a similar way to the auto-population of GQP values, the NFM-P extracts the values set in the GQP buffer (of type Policer only), Class of Service, and Match Criteria, and auto-generates Multi-Vendor QoS policies to match these properties. The new policies are created with a fixed naming convention, ending with a number.

Upon creation of these new policies, if the NFM-P finds an existing policy with the same name and number, it checks if any local definitions of that policy (or any component policies already bound to that policy) exist. If there are no local definitions, the NFM-P updates the existing policies and ensures they are assigned to the GQP. If a local definition does exist, the NFM-P creates a new set of policies with the same names as the existing policies, but with incremental numbers. The original policies in the GQP are then replaced with new policies. This is done to ensure that policy distribution to the NEs is as accurate as possible. The set of attributes which are supported by the auto-generation are described in the *NSP NFM-P Multi-Vendor Policy Guide*.

4

Configure an Egress QoS Buffer, Class of Service, Match Criteria, and Scheduling.

1. Click on the Egress tab, then the Buffer sub-tab.
2. Click Create or select an existing buffer and click Properties. The Egress QoS Buffer form opens.
3. Configure the required parameters.

   The Buffer ID is mandatory and can represent a queue, policer, or meter.

   Note: When a generic QoS profile contains a buffer with its Buffer Type set to N/A, then based on Buffer ID matching, both the queue and policer entries are updated in the policy. However, if the Buffer Type is configured as Policer, then only the corresponding policer that matches the Buffer ID is overridden in the policy. If the Buffer Type is configured as Queue, then only the corresponding queue that matches the Buffer ID is overridden in the policy.
4. Click OK to save the changes and close the form.
5. Click on the Class of Services sub-tab.
6. Select one of the eight default Class Names and click Properties. The Egress QoS Class of Service form opens.

7. Configure the Description parameter and select a Buffer ID to associate with this Class Name.
8. Click OK to save the changes and close the form.
9. Click on the Match Criteria sub-tab.
10. Click Create or select an existing entry and click Properties. The Egress QoS Match Criteria form opens.
11. Configure the parameters on the General tab.
12. Configure the parameters on the IPv4 Match Criteria, IPv6 Match Criteria, and MAC Match Criteria tabs, as required.
13. Click OK to save the changes and close the form.
14. Click on the Scheduling sub-tab.
15. Click Create or select an existing QoS Scheduler and click Properties. The Egress QoS Scheduler form opens.
16. Configure the Name parameter and select a scheduler Type, then configure the remaining parameters.
17. Click OK to save the changes and close the form.
18. Repeat substeps 2 to 17 to configure additional egress buffers.

5

Configure an Ingress QoS Buffer, Class of Service, Match Criteria, and Scheduling.

1. Click on the Ingress tab, then the Buffer sub-tab.
2. Click Create or select an existing buffer and click Properties. The Ingress QoS Buffer form opens.
3. Configure the required parameters.

   The Buffer ID is mandatory and can represent a queue, policer, or meter.

   Note: When a generic QoS profile contains a buffer with its Buffer Type set to N/A, then based on Buffer ID matching, both the queue and policer entries are updated in the policy. However, if the Buffer Type is configured as Policer, then only the corresponding policer that matches the Buffer ID would be overridden in the policy. If the Buffer Type is configured as Queue, then only the corresponding queue that matches the Buffer ID would be overridden in the policy.
4. Click OK to save the changes and close the form.
5. Click on the Class of Services sub-tab.
6. Select one of the eight default Class Names and click Properties. The Ingress QoS Class of Service form opens.
7. Configure the Description parameter and select a Buffer ID to associate with this Class Name.
8. Click OK to save the changes and close the form.
9. Click on the Match Criteria sub-tab.

10. Click Create or select an existing entry and click Properties. The Ingress QoS Match Criteria form opens.
11. Configure the parameters on the General tab.
12. Configure the parameters on the IPv4 Match Criteria, IPv6 Match Criteria, and MAC Match Criteria tabs, as required.
13. Click OK to save the changes and close the form.
14. Click on the Scheduling sub-tab.
15. Click Create or select an existing QoS Scheduler and click Properties. The Ingress QoS Scheduler form opens.
16. Configure the Name parameter and select a scheduler Type, then configure the remaining parameters.
17. Click OK to save the changes and close the form.
18. Repeat substeps 2 to 17 to configure additional ingress buffers.

6

Assign QoS policies to the profile.

Perform one of the following:

a. For Nokia equipment:
   1. Click on the QoS Policies tab.
   2. For an SROS NE, click the SROS Ingress/Egress sub-tab and then click the appropriate Select buttons to choose the required QoS policies. The policy types include:
      - SAP Access Ingress Policy
      - SAP Access Egress Policy
      - Ingress Scheduler Policy
      - Egress Scheduler Policy
      - Ingress Policer Control Policy
      - Egress Policer Control Policy
   3. For a 7210 NE, click the 7210 Ingress/Egress sub-tab and then click the appropriate Select buttons to choose the required QoS policies. The policy types include:
      - 7210 SAP Access Ingress Policy
      - 7210 SAP Access Egress Policy

b. For a 7250 IXR NE, click the 7250 SROS VLAN QoS sub-tab and then click the Select button to choose the required 7250 SROS VLAN QoS policy.

   Note: The 7250 SROS VLAN QoS policy is only applicable for 7250 IXR nodes.

c. For multi-vendor equipment:
   1. Click on the QoS Policies tab, then the Multi Vendor Ingress/Egress Policies sub-tab.
   2. Click the appropriate sub-tab to choose the required policies. The policy types include:
      - QoS Policies
      - Policers

- Filters
- Generic Policies

3. Click Add, then choose a policy from the Select form.
4. Click OK to close the form.

7

If you are viewing or configuring an existing Generic QoS Profile, you can click on the Dynamic Policies tab to view a list of dynamic policies associated with this profile. Such a policy is a local definition automatically created by the NFM-P when it receives a QoS policy override request from NSP.

Dynamic policies are essentially cloned SAP ingress or egress QoS policies that are used to override the CIR, PIR, CBS, and/or MBS values of the queues (and additionally, set policer overrides on 7x50 NEs). These policies are then deployed to specific NEs for service application. The Generic QoS Profile functionality is used to accomplish this. Dynamic policies are not listed in the standard QoS policy forms, since they are not created from the NFM-P or through CLI or the XML API.

You can only view dynamic policies and their implicit association to service SAPs, shown on the Access interfaces tab and its sub-tabs. A dynamic policy will automatically be removed from this list under the following conditions:

- the related service is deleted
- the related service SAP is deleted
- the QoS policy is cleared on the related service SAP
- the daughter card containing the service SAP port is removed

Dynamic policies are Local Edit Only policies that do not have any global reference. In addition, all local access ingress and egress policies contain a read-only attribute named Policy Mode that indicates if a policy is Dynamic or Static. In this context, Dynamic means the values have been modified by the Generic QoS Profile. This also includes policies for 7210 SAS variants where override support is not present by default.

8

Click OK to save the profile and close the form.

END OF STEPS

50.97 To configure QoS policy overrides on an L2 or L3 access interface

50.97.1 Purpose

Perform this procedure to override settings associated with an access ingress, access egress, or scheduler policy on an L2 or L3 access interface configured for a service. It is also applicable to multi-service sites.

See the following procedures for information about overriding access ingress, access egress, or scheduler policies that are associated with residential subscribers:

- 64.5 “To configure an SLA profile” (p. 1845) for the overrides associated with SLA profiles
- 64.4 “To configure a subscriber profile” (p. 1840) for the overrides associated with subscriber profiles

50.97.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Expand Access Interface (Service Management) in the object type drop-down menu and choose one of the following:

- L2 Access Interface (Service Management)
- L3 Access Interface (Service Management)

3

Choose an L2 or L3 access interface in the list and click Properties. The L2 | L3 Access Interface (Edit) form opens.

4

Click on the Override Policy Items tab and perform one of the following:

a. Create an override for an access ingress tagged IP/IPv6 match entry. Go to Step 5 .

b. Create an override for an access ingress or access egress policy queue. Go to Step 6 .

c. Create an override for an access egress policy HSMDA queue. Go to Step 7 .

d. Create an override for an ingress or egress policy policer. Go to Step 8 .

e. Create an override for an ingress or egress policer control policy. Go to Step 9 .

f. Create an override for an ingress or egress scheduler policy. Go to Step 10 .

g. Create an override for an access egress policy HS WRR group. Go to Step 11 .

5

To create an override for an access ingress tagged IP/IPv6 match entry, click on the Ingress Criteria tab and configure the required parameters.

6

To create an override for an access ingress or access egress policy queue, click on the Access Ingress or Access Egress Queues tab.

1. Click Create.The Access Ingress | Egress Queue Override form opens.
2. Select an ingress QoS policy queue.
3. Click on the Override tab.
4. Select a slope policy on the HS WRED Queue panel, if required.
5. Configure the required parameters.

   To override parameters, you must select the associated check box. De-select the associated Default or MAX check box to enter a specific value, or to select a drop-down option.

   Overrides for the PIR and CIR are configured in kbps if the Rate Type for the queue was originally set to kbps. The PIR and CIR overrides are configured as a percentage (%) if the Rate Type for the queue was originally set to Percent Port Limit or Percent Local Limit.

   The Port Average Overhead parameter is only configurable for access egress queues.

   For egress queues, you can configure queue depth monitoring in the Stats panel. For more information, see 50.21 “Queue depth monitoring” (p. 1527).
6. Save your changes and close the forms.

7

To create an override for an access egress policy HSMDA queue, click on the Access Egress HSMDA Queues tab.

1. Click Create. The Access Egress HSMDA Queue Override form opens.
2. Select the queue you want to override.
3. Click on the Override tab.
4. Configure the required parameters.

   If you select the Override check box for a parameter, the original parameter value is displayed.

   To specific another override value for the PIR (kbps) parameter, you must first deselect the associated MAX check box. To specific another override value for the Maximum Burst Size (bytes) parameter you must first deselect the associated Default check box.

   You can only specify an override value for WRR Weight for queues 1, 2, or 3.
5. Select the HSMDA Slope policy you want to override.
6. Save your changes and close the forms.

8

To create an override for an ingress or egress policy policer, click on the Ingress|Egress Policer tab.

1. Click Create. The Policer Override form opens.
2. Click Select and choose a policy policer, then click OK.

   Policy policers must be applied to the L2 Access Interface or the L3 Access Interface in order to be selected.
3. Configure the required parameters on the General tab.
4. Click on the Override tab.
5. Select the Override check box and configure any of the required parameters.

   To override any of the parameters, you must first select the associated check box. Deselect the associated Default or MAX check box to enter a specific value or to select a drop-down parameter option.

   Overrides for the PIR and CIR are configured in kbps if the Rate Type for the policer was originally set to kbps. The PIR and CIR overrides are configured as a percentage if the Rate Type for the policer was originally set to Percent Local Limit.
6. Save your changes and close the forms.

9

To create an override for an ingress or egress policer control policy, click on the Schedulers tab.

1. On the Ingress|Egress Policer Control Override panel, click Create. The Policer Control Override form opens.

   Policer control policies must be applied to the L2 or L3 access interface in order for the policer control override panels to be displayed.
2. Configure the required override check boxes and parameters.
3. Click OK to apply the changes and close the Policer Control Override form.
4. Click Apply in the L2 | L3 Access Interface form.
5. Select the policer control override you just created and click Properties. The Policer Control Override form opens.
6. Click on the Level Override Policy Items tab.
7. Select a level override from the list and click Properties. The Policer Level Override form opens.
8. Click on the Override tab.
9. Select the Override check box and configure the Maximum Cumulative Buffer Space parameter.
10. Save your changes and close the forms.

10

To create an override for an ingress or egress scheduler policy, click on the Ingress|Egress Schedulers tab. (Ingress or egress scheduler policies must be applied to the L2 or L3 access interface in order for the Ingress or Egress Scheduler tabs to appear under the Override Policy Items tab.)

1. Click Create. The Policy Scheduler Override form opens.
2. Select a scheduler policy.
3. Click on the Override tab.
4. Select the Override check box and configure any of the required parameters.

   To override any of the parameters, you must first select the associated Override check box to select a drop-down parameter option. For PIR (kbps) you must also deselect the MAX check box if you want to enter a specific value.
5. Save your changes and close the forms.

11

To create an override for an access egress policy HS WRR group, click on the HS WRR Groups tab.

1. Click Create. The SAP Egress QoS HS WRR Group override form opens.
2. Select an HS WRR group.
3. Click on the Overrides tab.
4. Configure the PIR Percent and Class Weight parameters, if required.

   To configure the parameters, you must first select the associated check boxes.
5. Save your changes and close the forms.

END OF STEPS

50.98 To configure QoS policy overrides on access ingress meters for the 7210 SAS

50.98.1 Purpose

Perform this procedure to override the meter settings of an access ingress policy for an L2 or L3 access interface on a 7210 SAS.

You cannot override the settings for QoS policies whose scope is set to exclusive.

Policy overrides on L2 access interfaces are not supported for the following:

- Uplink SAPs
- SAPs on mirror services
- SAPs with time of day suites attached

50.98.2 Steps

1

Open the properties form for the L2 or L3 access interface for which you need to configure an override:

1. Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.
2. Choose Site (Service Management) from the object drop-down menu and click Search.
3. Choose a 7210 SAS site from the list and click Properties. The properties form for the site opens.
4. Expand the site equipment tree as required, and click on an L2 | L3 access interface. The properties form for the access interface opens.

2

Click on the Override Policy Items tab, then on the Access Ingress Meters sub-tab.

3

Click Create. The Access Ingress Meter Override (Create) form opens.

4

Click Select in the Ingress QoS Policy Meter panel and choose a policy meter, then click OK.

5

Click on the Override tab.

6

Configure the required parameters.

To override any of the parameters, you must first select the associated check box. Deselect the associated Default or MAX check box to enter a specific value, or to select a drop-down menu option.

7

Click OK. The Access Ingress Meter Override (Create) form closes.

8

Click OK to save your changes and close the form.

END OF STEPS

50.99 To configure QoS policy overrides on access ingress queues for a 7210 SAS-X

50.99.1 Purpose

Perform this procedure to override the queue settings of an access ingress policy for an L2 or L3 access interface on a 7210 SAS-X.

You cannot override the settings for QoS policies whose scope is set to exclusive.

Policy overrides on L2 access interfaces are not supported for the following:

- Uplink SAPs
- SAPs on mirror services
- SAPs with time of day suites attached

50.99.2 Steps

1

Open the properties form for the L2 or L3 access interface for which you need to configure an override.

1. Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.
2. Choose Site (Service Management) from the object drop-down menu and click Search.
3. Choose a 7210 SAS-X site from the list and click Properties. The properties form for the site opens.
4. Expand the site equipment tree as required, and click on an L2 | L3 access interface. The properties form for the access interface opens.

2

Click on the Override Policy Items tab, then on the Access Ingress Queues sub-tab.

3

Click Create. The Access Ingress Queue Override (Create) form opens.

4

Click Select in the Ingress QoS Policy Queue panel and choose a queue, then click OK.

Note: You can only configure an override on a queue that is mapped to a forwarding class.

5

Click on the Override tab and configure the required parameters.

To override any of the parameters, you must first select the associated check box. Deselect the associated Default or MAX check box to enter a specific value, or to select a drop-down menu option.

6

To override the queue management policy:

1. Select the check box for Displayed Name.
2. Click Clear, then click Select.
3. Choose a queue management policy from the list and click OK.

   Note:

   The selected queue management policy must be distributed to the NE that contains the SAP for which you are performing the policy override. Click on the Properties button to view the properties form for the queue management policy. You can use this properties form to distribute the policy to the NE, if required. See 49.2 “Policy distribution” (p. 1469) in Chapter 49, “Policies overview” .

7

Click on the OK button. The Access Ingress Queue Override (Create) form closes.

8

Click OK to save your changes and close the form.

END OF STEPS

50.100 To configure QoS policy overrides on port access egress queues for a 7210 SAS

50.100.1 Purpose

Perform this procedure to override the queue settings of a port access egress policy assigned to access ports on a 7210 SAS. When you enable overrides, you can change the settings for queues either to default settings or new values.

50.100.2 Steps

1

On the equipment tree, expand Network→NE→Shelf→Card Slot n→Daughter Card Slot n→Port n/n/n.

2

Right-click on the Port icon and choose Properties. The Physical Port (Edit) form opens.

3

Click on the Ethernet tab, then click on the Port Access Egress tab.

4

Select a queue in the list, or click Create. The Port Access Egress Queue Override (Create|Edit) form opens.

5

If you are creating an override queue, configure the ID and Displayed Name parameters.

6

Click on the Override tab and configure the required parameters.

To override a parameter, you must first select the associated Override check box. If the Default check box for a parameter is enabled, the value for that parameter is set at the default value determined by the NFM-P. If the MAX check box for a parameter is enabled, the value for that parameter is set at the MAX value. If required, deselect the associated Default or MAX check box to configure a non-default value.

7

To override the queue management policy, click Select, choose a queue management policy from the list, and click OK.

Note: The required queue management policy must be distributed to the NE that contains the port for which you are performing the policy override. Click Properties to view the properties form for the queue management policy. You can use this properties form to distribute the policy to the NE, if required. See 49.2 “Policy distribution” (p. 1469) .

8

Save your changes and close the form.

9

Configure additional queue overrides, or save your changes and close the form.

END OF STEPS

50.101 To configure a shared policer policy

50.101.1 Purpose

A shared policer policy is a VLAN group policer for rate limit traffic from many VLANs. FCs from many VLANs are policed by the shared policer. The policy allows ingress policing to support a group of VLANs instead of a single VLAN.

50.101.2 Steps

1

Choose→Policies→QoS→SROS QoS→Shared Policer from the NFM-P main menu. The Shared Policer (Create|Edit) form opens.

2

Click Create or choose a policy and click Properties. The Shared Policer (Create|Edit) form opens.

3

Configure the required parameters.

4

Configure the CIR/PIR parameters:

1. Click on the CIR/PIR tab.
2. Configure the required parameters.

5

Configure the Burst Size parameters:

1. Click on the Burst Size tab.
2. Configure the required parameters.

   The parameters are configurable when the Default check box above each is deselected.

6

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

END OF STEPS

51 Filter policies

51.1 Filter policies

51.1.1 Overview

You can use the NFM-P to configure a filter policy to define the network traffic filtering criteria used by routers and switches to allow or deny traffic on a device. You can specify a forwarding action for packets based on the matching criteria configured in the policy. For example, if you configure an ACL IPv6 filter policy, the network device analyzes the data that passes through the interface based on IPv6 matching criteria, compares it to the configuration set in the policy, and if the conditions are met, the traffic is forwarded as specified by the forwarding action. The process stops when the first complete match is found and the action defined in the entry is executed.

You can assign up to two filters to each applicable interface, circuit, or service the filter policy applies to; one in the receive direction and one in the transmit direction.

Note: When an interface, circuit, or service is not configured with a filter policy, all traffic is forwarded by the device. By default, no filters policies are applied by the NFM-P.

51.1.2 ACL IP and ACL IPv6 shared filter entries

RADIUS attributes can be used to enhance a locally configured IPv4 or IPv6 filter list with dynamic entries that can be shared between multiple subscriber hosts.

The ACL IP filter policy and ACL IPv6 filter policy include a High Watermark and Low Watermark configuration which specifies alarm thresholds for dynamically-inserted filter table counts.

51.1.3 Filter policy design considerations

Consider the following when you create NFM-P filter policies:

- The maximum number of filter entries varies depending on the NE and release. Confirm the allowable range of values for the intended device before you assign entry IDs.
- You can create up to 2000 MAC filter policies per managed NE.
- You can create up to 2000 IP filter policies per managed NE.
- The 7705 SAR has the following configuration limits for ACL filter entries:
  - For non-extended range filter entries, the match criteria cannot be defined to match more than 256 packets.
  - For extended range filter entries, there is no limit on the number of packet matches for the defined criteria; however, the total number of unique match criteria in use across all extended range filter entries within the same ACL IP filter cannot exceed eight.
- To expedite the creation of filter policies, you can copy the filter entries of one filter policy to another filter policy; see 51.19 “To copy filter policy filter entries” (p. 1700).

51.1.4 ACL MAC and ACL IP SAP and service tunnel forwarding

ACL MAC and ACL IP filters contain options for delivering packets to specific destination SAPs and service tunnels based on the match criteria. Because the forwarding action is specified separately from device configuration, the packet destination name must be entered directly in text form (for example, 1/1/2:500) and validated by the NFM-P.

Consider the following before you create a SAP or service tunnel forwarding filter:

- Although you can configure them on other service types, you should only create these filters on a VPLS. On other service types, packets are dropped.
- You can apply these filters on an ingress, but not an egress, SAP or service tunnel.
- The destination SAP or service tunnel must be on the same service as the device on which the filter is applied.
- The encapsulation type of the destination SAP and the associated port must be the same. Supported encapsulations are Ethernet Null, dot1q, QinQ, BCP, bridged Ethernet, FR, and ATM.

51.1.5 Embedded filter policy support

The NFM-P supports the use of embedded policies in ACL MAC, ACL IP, and ACL IPv6 filter policies that allow you to define a common set of filter policy rules that can then be embedded, or nested in one or more ACL filter policies.

When an exclusive or template filter policy that embeds one or more embedded filter policies is created, absolute values for all filter policy entries for both embedded and embedding filters are preserved. In the case of a conflict between entries (for instance, the same policy entry index), a higher priority filter entry is activated. The embedding filter has the highest priority, allowing its filter entries to always overwrite any embedded filter entries. This allows for customization of the common embedded filter policy rules within the embedding filter.

Any edits made to an embedded policy are automatically applied to all embedding filter policies that use the embedded filter policy.

The system ensures that system and hardware resources exist when a new embedded filter policy is created, changed or embedded by another filter policy, and either fails the configuration attempt or does not embed the embedded filter (depending on what resources are exhausted). An embedded filter is never embedded partially into another filter. If a change occurs to an already embedded filter fails due to a lack of hardware resources, the embedded filter will be removed from the embedding filter.

See 51.9 “To configure an embedding filter with embedded filter policies” (p. 1686) for information about configuring embedded filter policies.

51.1.6 ACL MAC, ACL IP, and ACL IPv6 web portal redirects

ACL MAC, ACL IP, and ACL IPv6 filter policies contain options for redirecting hosts to a URL address. The 7750 SR-7, 7750 SR-12, and 7950 XRS open a new connection to the specified web portal. The host can use the web portal to create or modify a service profile. The web portal updates the ACL policy to remove the redirection policy.

Note: The 7750 SR-1 does not support web portal redirect.

51.1.7 ACL MAC, ACL IP, and ALC IPv6 log filter configurations

You can optionally create the following policy types for ACL MAC, ACL IP, and IPv6 filter entries that can be used to specify where and how device related log information is collected and stored for a device. You can analyze the logs and extracted information on an ongoing basis to ensure your network is secure, or as required, to initiate the appropriate remediation action. See the appropriate SR node documentation for information about accessing log information on the SR device.

- Syslog policy that is used by the ACL Filter Log policy; the Syslog policy defines the destination details for log messages such as the target address and target UDP port, when the ACL Filter Log policy specifies a Syslog destination for storing log information. See 51.22 “To configure a Syslog policy” (p. 1704).
- ACL Filter Log policy that defines where log information for all actions performed on 7210 SAS, 7705 SAR, and 7x50 NEs which match ACL MAC, ACL IP, and ACL IPv6 filter entry criteria are written (memory or Syslog), how many log entries can be stored, and what action is performed when the log files meet the specified threshold. See 51.20 “To configure a ACL Filter Log policy” (p. 1702).

51.1.8 Redirect filters

A redirect filter policy allows operators to specifying multiple redirect target destinations and define health check test methods used to validate the ability for a given destination to receive redirected traffic. This destination monitoring allows a router to react to target destination failures. Operators can define IPv4 and IPv6 filter policies by specifying destinations to be IPv4 or IPv6 addresses respectively, and then referencing the redirect filter policy in the appropriate line card filter.

Reachability tests for specific destination addresses can be configured, including SNMP, URL, ping, and unicast route reachability. When a unicast route reachability test is configured, a destination becomes eligible for redirect policy destination selection only when the destination is reachable within the routing context that the policy is applied.

See 51.15 “To configure a Redirect Filter policy” (p. 1693) for information regarding configuring a redirect filter policy.

51.1.9 System filters

A system filter allows operators to configure a single set of filter policy rules that can then be activated in a system and used by other exclusive or template ingress IPv4 or IPv6 filter policies. When a system filter policy is activated (or when its configuration is changed), its entries are automatically downloaded to all line cards in the system. For packets to match system filter policy entries, an operator “chains” deployed IPv4/IPv6 ingress filter policies to the system filter. In this way, system filter entries are not duplicated into the chained filters. By employing such a chain, the active system filter policy rules are evaluated first. If a match occurs, the chained system filters are ignored. If no match occurs, only then are the rules of any chained filter policies evaluated. This allows a system filter policy to be used for implementing system blacklist rules, or security rules when multiple filter policies are required for other operational reasons (such as PBR).

Nokia recommends using a system filter policy with drop/forward actions. Other actions, for example, PBR actions or redirection to ISAs, should not be used unless the system filter policy is activated only in filters used by services that support such actions. Failure to observe this restriction

can lead to undesired behavior, since system filter actions are not verified against the services that the chaining filters are deployed for.

The system filter policy supports all IPv4/IPv6 filter policy match rules and actions, however, system policy entries cannot be LI or mirror sources. The system filter policy also does not support Radius, flowspec, or Gx inserted entries. Note that a system filter policy also requires chassis mode D to be set on an NE to which it is deployed.

See 51.18 “To configure a System Filter” (p. 1698) for information regarding configuring a system filter policy.

51.2 Supported filter policy types

51.2.1 Filter policies configurable in the NFM-P

Table 51-1 NFM-P filter policies

Filter policy type	Purpose	See
ACL Aggregate filter policy	This policy provides a container for configured filter policies. The following can be assigned to an ACL Aggregate filter policy: • ACL MAC filter policy • ACL IP filter policy • ACL IPv6 filter policy	51.3 “To configure an ACL Aggregate filter policy” (p. 1668)
ACL MAC filter policy	This policy defines the network traffic filtering criteria used to allow or deny network traffic into or out of an access interface and service tunnel based on MAC matching criteria and the forwarding action.	51.4 “To configure an ACL MAC filter policy” (p. 1668)
ACL IP filter policy	This policy defines the network traffic filtering criteria used to allow or deny network traffic into or out of a network or access IP interface or service tunnel based on IPv4 matching criteria and the forwarding action.	51.5 “To configure an ACL IP filter policy” (p. 1671)
ACL IPv6 filter policy	This policy defines the network traffic filtering criteria used to allow or deny network traffic into or out of an access interface or service tunnel based on IPv6 matching criteria and the forwarding action.	51.6 “To configure an ACL IPv6 filter policy” (p. 1677)
ACL IP Exception filter policy	This policy defines the network traffic filtering criteria used to allow or deny network traffic into or out of an access interface in an NGE or cellular domain based on protocol-specific matching criteria and source and destination information.	51.7 “To configure an ACL IP exception filter policy” (p. 1683)
ACL IPv6 Exception filter policy	This policy is an ACL IP exception filter for IPv6: it defines the network traffic filtering criteria used to allow or deny network traffic into or out of an interface based on protocol-specific matching criteria and source and destination information.	51.8 “To configure an ACL IPv6 exception filter policy” (p. 1684)
IP Prefix list filter policy	This policy defines the network traffic filtering criteria used to allow or deny network traffic into or out of an access interface based on a defined list of IP Prefix list members.	51.11 “To configure an IP Prefix List policy” (p. 1688)

Table 51-1 NFM-P filter policies (continued)

Filter policy type	Purpose	See
Port list filter policy	This policy defines the network traffic filtering criteria used to allow or deny network traffic into or out of an access interface based on a defined list of port list members.	51.12 “To configure a Port List policy” (p. 1690)
DHCP filter policy	This policy defines the network traffic filtering criteria used to allow or deny network traffic into or out of IES and VPRN group interfaces based on DHCP matching criteria.	51.13 “To configure a DHCP Filter policy” (p. 1691)
DHCPv6 filter policy	This policy defines the network traffic filtering criteria used to allow or deny network traffic into or out of IES and VPRN group interfaces based on DHCPv6 matching criteria.	51.14 “To configure a DHCPv6 filter policy” (p. 1692)
Redirect filter policy	This policy allows specifying multiple redirect target destinations and defining health check test methods used to validate the ability for a given destination to receive redirected traffic.	51.15 “To configure a Redirect Filter policy” (p. 1693)
Redirect policy binding	Redirect policy bindings allow configuration of an association between destination addresses in Rredirect policies, so that results of Ping tests can be shared.	51.16 “To configure a Redirect Policy Binding” (p. 1696)
ACL VLAN filter policy	This policy defines the network traffic filtering criteria used to allow or deny network traffic on network ports of a ring card based on a defined VLAN range.	51.17 “To configure an ACL VLAN Filter policy” (p. 1697)
System filter policy	This policy allows operators to configure a filter chain for packet matching. In this chain, an active system filter policy rules are evaluated first. If no match occurs, then rules specified by any chained filter policies are evaluated.	51.18 “To configure a System Filter” (p. 1698)
Embedded and embedding filter policies	An embedded filter policy allows users to define a common set of filter policy rules that can then be nested in one or more other filter policies. The filters that support the embedded filter policies are referred to as embedding filter policies.	51.9 “To configure an embedding filter with embedded filter policies” (p. 1686)
Syslog policy	This policy defines the destination details for log messages such as the target address and target UDP port, when the ACL Filter Log policy specifies a Syslog destination for storing log information.	51.22 “To configure a Syslog policy” (p. 1704)
ACL Filter Log policy	This policy defines where log information for all actions performed on 7210 SAS, 7705 SAR, and 7x50 NEs that match ACL MAC, ACL IP, and ACL IPv6 filter entry criteria are written (memory or Syslog), how many log entries can be stored, and what action is performed when the log files meet the specified threshold.	51.20 “To configure a ACL Filter Log policy” (p. 1702)
GRE tunnel template policy	GRE tunnel template policies specify a set of GRE encapsulation parameters to use when the primary action for ACL IP and ACL IPv6 filter policies is set to Forward (GRE Tunnel). GRE Tunnel Templates are assigned to ACL IP filter policies and ACL IPv6 filter policies.	51.21 “To configure a GRE tunnel template” (p. 1703)
Protocol List policy	This policy defines the network traffic filtering criteria used to allow or deny network traffic into or out of an access interface based on a defined list of protocols.	51.10 “To configure a protocol list policy” (p. 1687)

51.3 To configure an ACL Aggregate filter policy

51.3.1 Important information

The ACL Aggregate Filter policy provides a container for configured filter policies. The following can be assigned to an ACL Aggregate filter policy:

- ACL MAC filter policy; see 51.4 “To configure an ACL MAC filter policy” (p. 1668)
- ACL IP filter policy; see 51.5 “To configure an ACL IP filter policy” (p. 1671)
- ACL IPv6 filter policy; see 51.6 “To configure an ACL IPv6 filter policy” (p. 1677)

51.3.2 Steps

1

Choose Policies→Filter→ACL Aggregate Filter from the NFM-P main menu. The ACL Aggregate Filter Policies form opens.

2

Click Create or choose an existing policy and click Properties. The Aggregate Filter (Create|Edit) form opens.

3

Configure the parameters as required.

In the Filter References panel, select an IP, IPv6, or MAC filter policy.

For information about IP, IPv6, and MAC filter policies, see Table 51-1, “NFM-P filter policies” (p. 1666).

Each ACL Aggregate Filter policy must contain only one filter reference. If the ACL Aggregate filter policy contains more than one filter reference, distribution to the NE will fail.

4

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

51.4 To configure an ACL MAC filter policy

51.4.1 Steps

1

Choose Policies→Filter→ACL MAC Filter from the NFM-P main menu. The ACL MAC Filter Policies form opens.

2

Click Create or select an existing policy and click Properties. The ACL MAC Filter (Create|Edit) form opens.

3

Configure the parameters as required.

The Default Action parameter specifies the action to be applied to packets when no action is specified in the MAC filter entries or when the packets do not match the specified criteria.

Note: NEs that support next-generation CLI use the policy name as the key identifier for internal system reference. For policies on these NEs, you must configure a policy name (typically the service name or a numerical string). Policy IDs are also supported. You must configure a numerical range on the NE for auto-assigned policy IDs; see 12.65 “To configure an Auto-ID range for policies” (p. 395).

4

If you need to configure the parameters on the Embedded Filters tab, refer to 51.9 “To configure an embedding filter with embedded filter policies” (p. 1686) .

5

Configure a filter entry.

1. Click on the Filter Entries tab and click Create. The Entry, ACL MAC Filter (Create) form opens.
2. Configure the required parameters.
3. Click Select to assign a Log ID to the ACL MAC filter entry.
4. Click Select in the Time Range panel to assign a time range for the ACL MAC filter entry or click Create to create a new time range. The Select Time Range - MacFilterEntry list form opens.
5. Select a time range entry and click OK. The ACL MAC Filter (Create) form refreshes with the time range information.

   Note: ACL filters that include ACL filter entries to which you have assigned a time range cannot be assigned to a time of day suite policy.

   Time ranges with which you have associated a ACL filter within a time of day suite policy cannot be assigned to ACL filter entries of that ACL filter.
6. Click on the Filter Properties tab.
7. Configure the Primary Action parameter. The Entry, ACL MAC Filter (Create) form refreshes to display the parameters, panels, and tabs applicable to the option you choose. As examples, if you choose Forward (SAP), the Forwarding Destination tab appears, along with the PBR Down Action Override and the Hold Time (seconds) parameters; if you choose HTTP Redirect, the Redirect URL and Allow RADIUS Override parameters appear; if you choose Forward (ESI), then the PBR Down Action Override parameter and the Forwarding ESI Details tab appear.

Note: The Forward (ESI) option provides the ability to steer traffic using an ESI value in an EVPN data center. The required traffic flow is identified using ACL IP, ACL IPv6, or ACL MAC filters, and then the action associated with the filter steers the traffic towards the service functions hosted on the EVPN data center.

Forward (ESI) is supported only if a device is in chassis mode D (for those NEs that have chassis mode support).

8. Configure the parameters associated with each Primary Action parameter option as required.
9. Configure the remaining parameters on the Filter Properties tab as required.

   Note: Configuring a Secondary Action to specify multiple PBR/PBF targets provides redundancy and load-sharing capacities on steered traffic. Choosing a Secondary Action will also display additional sub-tabs and parameters that must be configured. You must configure a Primary Action before being able to configure a Secondary Action.

   The Source MAC, Src Mask, Destination MAC, Dst Mask, Dot1p, Dot1p Mask, Low ISID and High ISID parameter pairs are configurable when the check box for each pair is selected.

   The Low ISID and High ISID parameters are configurable when the MAC Filter Type parameter is set to ISID.

   The Inner Tag Value, Inner Tag VID Mask, Outer Tag Value, and Outer Tag VID Mask parameters are configurable when the MAC Filter Type parameter is set to VID.

   The DSAP, DSAP Mask, SSAP, and SSAP Mask parameters are configurable when the Frame Type parameter value is set to e802dot2LLC and the MAC Filter Type parameter is set to Normal.

   The SNAP OUI and SNAP PID parameters are configurable when the Frame Type parameter value is e802dot2SNAP and the MAC Filter Type parameter is set to Normal.

   The Ether Type parameter is configurable only when the Frame Type parameter value is set to Ethernet II and the MAC Filter Type parameter is set to Normal.
10. Save your changes and close the form.

6

To add an additional filter entry, repeat Step 5.

7

To define the order in which the policy tries to match filter entries with packets, perform the following steps for each filter entry.

1. Click Refresh to find an existing filter entry. The list of filter entries is displayed.
2. Select a filter entry and click Renumber ID. The Renumber Entry ID form opens.
3. Configure the New Entry ID parameter.
4. Save your changes. The Entry ID column displays the new identifier assigned to the entry.

8

Save your changes. The ACL MAC Filter Policies form reappears.

9

CAUTION

Service Disruption

Distributing a global ACL MAC filter policy with no filter entries (either because none have been created or all existing ones have been deleted) can cause a service outage. You should ensure that the policy has at least one filter entry, or you must be certain that distributing an empty policy is what you really intend to do. A global policy will be distributed to all of the policy local definitions.

If you attempt the manual distribution of an empty policy, two warning confirmations will be issued. The first warning is issued when you change the policy's Configuration Mode on the General tab from Draft to Released. You can either choose to proceed by clicking Yes, or abort the Configuration Mode change by clicking No.

The second warning is issued if you changed the Configuration Mode to Released and then try to proceed with the actual distribution in the Distribute form. You can either choose to proceed by clicking Yes, or abort the distribution by clicking No.

If you attempt to release an ACL MAC filter policy that has been initialized from an NE, you will also receive a warning confirmation, since the global policy may be partially updated from the local policy. The Discovery State indicator on the General tab displays this Initialized condition, and the Origin indicator identifies the NE. You should manually synchronize with a specific local policy before changing the Configuration Mode from Draft to Released.

Click Search, select the policy in the list and click Distribute to manually distribute the policy locally to devices. See 49.6 "To release and distribute a policy" (p. 1476) for more information. Policies are also automatically distributed to devices when they are used by resources on the device.

10

Close the ACL MAC Filter Policies form.

END OF STEPS

51.5 To configure an ACL IP filter policy

51.5.1 Steps

1

Choose Policies→Filter→ACL IP Filter from the NFM-P main menu. The ACL IP Filter Policies form opens.

2

Click Create or select an existing policy and click Properties. The ACL IP Filter (Create|Edit) form opens.

3

Configure the parameters as required.

Note: If you are creating an ACL IP filter that you will embed in another filter policy, then you must set the Scope parameter to embedded. This is referred to as an embedded filter. If you are creating an ACL IP filter that will contain an embedded filter or will enable flowspec as an embedded filter, then you must set the Scope parameter to either of the following: template, exclusive, or system. This is referred to as an embedding filter.
If you copy an embedded filter policy (Scope: embedded), the copied policy will also have a Scope of embedded. Filter entries from the embedded policy are also copied, and will have an Entry Type of Normal. See 51.19 “To copy filter policy filter entries” (p. 1700) for information on copying filter entries.

Note: If you are configuring an active system filter, then you must set the Scope parameter to system. The Chain to System Filter parameter must not be enabled. See 51.18 “To configure a System Filter” (p. 1698) for system filter information.
If you are configuring a chained system filter, then you must set the Scope parameter to either template or exclusive. The Chain to System Filter parameter must also be enabled. See 51.18 “To configure a System Filter” (p. 1698) for system filter information.
To change an existing filter policy’s Scope parameter to or from the system option, the policy must have no Filter Entries configured.

Note: To perform traffic management, you must set the Scope parameter to cpm. After the ACL IP and ACL IPv6 filter policies deploy to the 7250 IXR NEs with the Scope parameter set to cpm, then the IP Administrative Status and IPv6 Administrative Status parameters can be set to Up in the CPM filter policy; see the *NSP System Administrator Guide* for more information about configuring a CPM filter policy.

Note: NEs that support next-generation CLI use the policy name as the key identifier for internal system reference. For policies on these NEs, you must configure a policy name (typically the service name or a numerical string). Policy IDs are also supported. You must configure a numerical range on the NE for auto-assigned policy IDs; see 12.65 “To configure an Auto-ID range for policies” (p. 395).

Filtering for packet length can be configured as an action condition, or, on supporting NEs, as a match criterion. If you are configuring a policy with filter entries that use Match Criteria for packet length filtering, you must set the IP Filter Type parameter to the Packet-Length option.

4

If you need to configure the parameters on the Embedded Filters tab, including the enabling of flowspec, refer to 51.9 “To configure an embedding filter with embedded filter policies” (p. 1686).

5

Click on the Insertion Blocks tab.

6

If required, enable the check box in the Host Shared Filter Configuration panel and configure the High Watermark or Low Watermark parameters.

7

Configure the parameters as required in the Group Entry Insertion Configuration panel.

8

Configure a filter entry.

1. Click on the Filter Entries tab and click Create.The Entry, ACL IP Filter (Create) form opens.
2. Configure the required parameters.
3. Click Select to assign a Log ID to the ACL IP filter entry.
4. Click Select in the Time Range panel to assign a time range for the ACL IP filter entry or click Create to create a new time range. The Select Time Range - IP FilterEntry list form opens. Otherwise, go to Step 8 , substep 6.
5. Select a time range entry and click OK. The Entry, ACL IP Filter (Create) form refreshes with the time range information.

   Note: ACL filters that include ACL filter entries to which you have assigned a time range cannot be assigned to a time of day suite policy.

   Time ranges with which you have associated a ACL filter within a time of day suite policy cannot be assigned to ACL filter entries of that ACL filter.
6. Click on the Filter Properties tab.
7. Configure the Primary Action panel.

   Configure the Action parameter. The form refreshes to display the parameters, panels, and sub-tabs applicable to the option you choose.

   Configure the parameters (and sub-tab parameters, if applicable) associated with the chosen Action parameter option, as required.

   The Forward (ESI) option provides the ability to steer traffic using an ESI value in an EVPN data center. The required traffic flow is identified using ACL IP, ACL IPv6, or ACL MAC filters, and then the action associated with the filter steers the traffic towards the service functions hosted on the EVPN data center. Forward ESI is supported only if a device is in chassis mode D (as applicable).

   The Rate Limit option provides the ability to protect a network against DDoS attacks by specifying a TTL value (or hop-limit for IPv6), or packet length. When the specified value is exceeded, the transit traffic is dropped.

   The Forward (GRE Tunnel) option allows you to assign a GRE tunnel template that defines the encapsulation parameters; see 51.21 “To configure a GRE tunnel template” (p. 1703).

   The Forward (SAP) option requires VPLS L2 Access Interfaces. See 77.67 “To create a VPLS or MVPLS L2 access interface” (p. 2332) for information on associating an ACL IP filter to a VPLS SAP.

The Forward Next Hop (Router) option allows you to associate the filter to a VPRN L3 Access Interface. See 79.83 “To configure an L3 access interface on a VPRN site” (p. 2656) for more information.

The Forward (Pattern) option provides the ability to forward packets that contain a predefined UDP signature that conforms to the configured pattern parameters, essentially “whitelisting” authorized packets.

When the Action parameter is set to Drop, Rate Limit, or Forward (Pattern), parameters are available for pattern matching on supporting devices. Pattern matching can help identify DDoS attacks.

If you set the IP Filter Type parameter to the Packet-Length option in Step 3, do not configure packet length options and parameters in the Primary Action panel. Instead, configure packet length options in the Match Criteria panel in Step 8, substep 11.

8. For certain Primary Action options, you can set an Extended Action parameter (and associated parameters, as applicable) to enable a supplementary action to the Primary Action. Configure as required.
9. Configure a Secondary Action to specify two PBR targets as part of a single filter policy entry. This provides redundancy and load-sharing capacities on steered traffic. When primary and secondary actions are both configured, PBR uses the primary action if its target is operationally up, or the secondary action if its target is operationally up.

   If both PBR targets are down, the default behavior you configure for the primary action is used, unless you configure the PBR Down Action Override parameter otherwise. In addition, you can set a sticky destination Hold Time for a given redundant filter entry.

   Choosing a Secondary Action will also display additional sub-tabs and parameters that you must configure as required. Note that a Primary Action must be configured prior to setting a Secondary Action.

   When you configure the Secondary Action to Forward (VPRN Target), the Secondary VPRN Target tab opens.
10. For certain Secondary Action options, you can set an Extended Action parameter (and associated parameters, as applicable) to enable a supplementary action to the Secondary Action. Configure as required.
11. Configure the remaining parameters on the Filter Properties tab as required. Note the following:
    - You can assign a configured protocol list policy; see 51.10 “To configure a protocol list policy” (p. 1687) . When you assign a protocol list policy, you must set the Protocol parameter to NONE.
    - The Source Port, Destination Port, and Port related parameters are configurable when the Protocol parameter value is TCP or UDP.
    - If you select the Source and Destination option for the Configuration Type parameter, you can configure the Source and Destination ports separately, specifying either a Mask, Range, or Port List for each. If you select the Port option for the Configuration Type, then the Mask, Range, or Port List you specify will apply to both the source and destination.
    - Configuring the Src Mask and Src Net Mask parameters is mutually exclusive.
    - Configuring the Dst Mask and Dst Net Mask parameters is mutually exclusive.

- When the Protocol parameter is set to TCP, the TCP Properties panel is available for enabling TCP flags on supporting NEs. When you distribute the policy, ensure that the NE supports the required TCP flags.
- The ICMP Code and ICMP Type parameters are configurable when the Protocol parameter value is IPv6_ICMP.
- The Egress PBR parameter can only be configured when the Action parameter is set to one of the following: Forward (Redirect Filter), TCP MSS Adjust, Ignore Match, Forward (ESI), Forward Next Hop, or Forward Next Hop (Router).
- The Bonding Connection ID parameter must be configured when the Primary Action parameter is set to Forward (Bonding Connection).
- Match Criteria Packet Length options are supported only when the IP Filter Type is set to Packet-Length in Step 3. The Packet Length Option parameter is mutually exclusive with the DSCP, IP Option, IP Opt Mask, Option Present, Multiple Option, and Source Route Option match criteria.
- The Match Criteria Time-To-Live option is supported only when the IP Filter type is set to Packet-Length in Step 3. Before you change the IP Filter type, you must delete any filter entry that has the Time-To-Live option selected.
- Select a GRE tunnel template as required.

12. Click on the Cflowd tab and configure the parameters as required.

    For the Sample Profile ID parameter, enter the ID number of an existing Cflowd sample profile. For information about Cflowd sample profiles see 12.10 “To enable and configure global Cflowd sampling on an NE” (p. 347).
13. Click on the Forwarding VRPN Target tab.
14. Configure the required parameters.
15. Click on the Secondary VPRN Target tab.
16. Configure the required parameters and select a router and LSP.
17. Save your changes and close the form.

9

To create an additional filter entry, repeat Step 8.

10

To define the order in which the policy tries to match filter entries with packets, perform the following steps for each filter entry.

1. Click Refresh to find an existing filter entry. The list of filter entries is displayed.
2. Select a filter entry and click Renumber ID. The Renumber Entry ID form opens.
3. Configure the New Entry ID parameter.
4. Save your changes. The Entry ID column displays the new identifier assigned to the entry.

11

Save your changes. The ACL IP Filter Policies form reappears.

12

CAUTION

Service Disruption

Distributing a global ACL IP filter policy with no filter entries (either because none have been created or all existing ones have been deleted) can cause a service outage. You should ensure that the policy has at least one filter entry, or you must be certain that distributing an empty policy is what you really intend to do. A global policy will be distributed to all of the policy's local definitions.

If you attempt the manual distribution of an empty policy, two warning confirmations will be issued. The first warning is issued when you change the policy's Configuration Mode on the General tab from Draft to Released. You can either choose to proceed by clicking Yes, or abort the Configuration Mode change by clicking No.

The second warning is issued if you changed the policy's Configuration Mode to Released and then try to proceed with the actual distribution in the Distribute form. You can either choose to proceed by clicking Yes, or abort the distribution by clicking No.

If you attempt to release an ACL IP filter policy that has been initialized from an NE, you will also receive a warning confirmation, since the global policy may be partially updated from the local policy. The Discovery State indicator on the General tab displays this Initialized condition, and the Origin indicator identifies the NE. You should manually synchronize with a specific local policy before changing the Configuration Mode from Draft to Released.

Click Search, select the policy in the list and click Distribute to manually distribute the policy locally to devices. See 49.6 "To release and distribute a policy" (p. 1476) for more information. Policies are also automatically distributed to devices when they are used by resources on the device.

13

Select the distributed policy and click Properties. The ACL IP Filter Global Policy (Edit) form opens.

14

Click on the Local Definitions tab and select a local definition from the list and click Properties. The ACL IP Filter Local Policy (Edit) form opens.

15

Click on the Insertion Blocks tab.

16

If required, enable the check box in the Host Shared Filter Configuration panel and configure the High Watermark or Low Watermark parameters.

17

Configure the parameters as required.

Note: The Group Entries Inserted panel displays the number of entries inserted on this filter range.

18

Click Sort Group Insertions and click OK.

19

To view filter entry data.

1. Click on the Filter Entries tab, then the Credit Control Entries tab or the RADIUS Entries tab.
2. Click Search and select an entry from the list and click Properties.
3. Close the form.

20

Close all open forms.

END OF STEPS

51.6 To configure an ACL IPv6 filter policy

51.6.1 Steps

1

Choose Policies→Filter→ACL IPv6 Filter from the NFM-P main menu. The ACL IPv6 Filter Policies form opens.

2

Click Create or select an existing policy and click Properties. The ACL IPv6 Filter (Create|Edit) form opens.

3

Configure the parameters as required.

Note: If you are creating an ACL IPv6 filter that you will embed in another filter policy, then you must set the Scope parameter to embedded. This is referred to as an embedded filter. If you are creating an ACL IPv6 filter that will contain an embedded filter or will enable flowspec as an embedded filter, then you must set the Scope parameter to one of the following: template, exclusive, or system. This is referred to as an embedding filter.
If you copy an embedded filter policy (Scope: embedded), the copied policy will also have a Scope of embedded. Filter entries from the embedded policy are also copied, and will have an Entry Type of Normal. See 51.19 “To copy filter policy filter entries” (p. 1700) for information on copying filter entries.

Note: To perform traffic management, you must set the Scope parameter to cpm. After the

ACL IP and ACL IPv6 filter policies deploy to the 7250 IXR NEs with the Scope parameter set to cpm, then the IP Administrative Status and IPv6 Administrative Status parameters can be set to Up in the CPM filter policy; see section the *NSP System Administrator Guide* for more information about configuring a CPM filter policy.

Note: You can only configure the IPv6 Address Format parameter when the system resource profile settings are appropriate. See 12.50 “To configure the global system resource profile on a 7210 SAS or 7250 IXR” (p. 380) .
To configure an active system filter, set the Scope parameter to system. The Chain to System Filter parameter must not be enabled. See 51.18 “To configure a System Filter” (p. 1698) for system filter information.
To configure a chained system filter, set the Scope parameter to either template or exclusive. The Chain to System Filter parameter must also be enabled. See 51.18 “To configure a System Filter” (p. 1698) for system filter information.
To change an existing filter policy’s Scope parameter to or from the system option, the policy must have no Filter Entries configured.

Note: NEs that support next-generation CLI use the policy name as the key identifier for internal system reference. For policies on these NEs, you must configure a policy name (typically the service name or a numerical string). Policy IDs are also supported. You must configure a numerical range on the NE for auto-assigned policy IDs; see 12.65 “To configure an Auto-ID range for policies” (p. 395).

Filtering for packet length can be configured as an action condition, or, on supporting NEs, as a match criterion. If you are configuring a policy with filter entries that use Match Criteria for packet length filtering, you must set the IPv6 Filter Type parameter to the Packet-Length option.

4

If you need to configure the parameters on the Embedded Filters tab, including the enabling of flowspec, refer to 51.9 “To configure an embedding filter with embedded filter policies” (p. 1686) for detailed information.

5

Click on the Insertion Blocks tab.

6

If required, enable the check box in the Host Shared Filter Configuration panel and configure the High Watermark or Low Watermark parameters.

7

Configure the parameters in the Group Entry Insertion Configuration panel as required.

8

Configure a filter entry.

1. Click on the Filter Entries tab and click Create.The Entry, ACL IPv6 Filter, Global Policy (Create) form opens.

2. Configure the required parameters.
3. Click Select to assign a Log ID to the ACL IPv6 filter entry.
4. Click Select in the Time Range panel to assign a time range to the ACL IPv6 filter entry. The Select Time Range - Ipv6FilterEntry list form opens. Otherwise, go to Step 8 , substep 6.
5. Select a time range entry and click OK. The Entry, ACL IPv6 Filter (Create) form refreshes with the time range information.

   Note: ACL filters that include ACL filter entries to which you have assigned a time range cannot be assigned to a time of day suite policy.

   Time ranges with which you have associated a ACL filter within a time of day suite policy cannot be assigned to ACL filter entries of that ACL filter.
6. Click on the Filter Properties tab.
7. Configure the Primary Action parameter.

   The Entry, ACL IPv6 Filter (Create) form refreshes to display the parameters, panels, and sub-tabs applicable to the option you choose. For example, if you choose Forward (ESI), then the PBR Down Action Override parameter and the Forwarding ESI Details sub-tab appear.
8. Configure the parameters (and sub-tab parameters, if applicable) associated with the chosen Primary Action parameter option, as required.

   The Forward (ESI) option provides the ability to steer traffic using an ESI value in an EVPN data center. The required traffic flow is identified using ACL IP, ACL IPv6, or ACL MAC filters, and then the action associated with the filter steers the traffic towards the service functions hosted on the EVPN data center. Forward ESI is supported only if a device is in chassis mode D (if applicable to the device).

   The Rate Limit option provides the ability to protect a network against DDoS attacks by specifying a TTL value (or hop-limit for IPv6), or packet length. When the specified value is exceeded, the transit traffic is dropped.

   The Forward (GRE Tunnel) option allows you to assign a GRE tunnel template that defines the encapsulation parameters; see 51.21 “To configure a GRE tunnel template” (p. 1703).

   The Forward (SAP) option is only applicable to VPLS L2 Access Interfaces. See 77.67 “To create a VPLS or MVPLS L2 access interface” (p. 2332) for information on associating an ACL IPv6 filter to a VPLS SAP.

   The Forward Next Hop (Router) option allows you to associate the filter to a VPRN L3 Access Interface. See 79.83 “To configure an L3 access interface on a VPRN site” (p. 2656) for more information.

   The Forward (Pattern) option provide the ability to forward packets that contain a predefined UDP signature that conforms to the configured pattern parameters, essentially “whitelisting” authorized packets.

   When the Action parameter is set to Drop, Rate Limit, or Forward (Pattern), parameters are available for pattern matching on supporting devices. Pattern matching can help identify DDoS attacks.

   If you set the IPv6 Filter Type parameter to the Packet-Length option in Step 3, do not configure packet length options and parameters in the Primary Action panel. Instead, configure packet length options in the Match Criteria panel in Step 8, substep 12.

9. For certain Primary Action options, you can set an Extended Action parameter (and associated parameters, as applicable) to enable a supplementary action to the Primary Action. Configure as required.
10. Configure a Secondary Action to specify two PBR targets as part of a single filter policy entry. This provides redundancy and load-sharing capacities on steered traffic. When primary and secondary actions are both configured, PBR uses the primary action if its target is operationally up, or the secondary action if its target is operationally up.

    If both PBR targets are down, the default behavior you configure for the primary action is used, unless you configure the PBR Down Action Override parameter otherwise. In addition, you can set a sticky destination Hold Time for a given redundant filter entry.

    Choosing a Secondary Action will also display additional sub-tabs and parameters that you must configure as required. Note that a Primary Action must be configured prior to setting a Secondary Action.

    When you configure the Secondary Action to Forward (VPRN Target), the Secondary VPRN Target tab opens.
11. For certain Secondary Action options, you can set an Extended Action parameter (and associated parameters, as applicable) to enable a supplementary action to the Secondary Action. Configure as required.
12. Configure the remaining parameters on the Filter Properties tab as required. Note the following:
    - You can assign a configured protocol list policy; see 51.10 “To configure a protocol list policy” (p. 1687) . When you assign a protocol list policy, you must set the Protocol parameter to NONE.
    - The Source Port, Destination Port, and Port related parameters are configurable when the Protocol parameter value is TCP or UDP.
    - If you select the Source and Destination option for the Configuration Type parameter, you can configure the Source and Destination ports separately, specifying either a Mask, Range, or Port List for each. If you select the Port option for the Configuration Type, then the Mask, Range, or Port List you specify will apply to both the source and destination.
    - Configuring the Src Mask and Src Net Mask parameters is mutually exclusive.
    - Configuring the Dst Mask and Dst Net Mask parameters is mutually exclusive.
    - When the Protocol parameter is set to TCP, the TCP Properties panel is available for enabling TCP flags on supporting NEs. When you distribute the policy, ensure that the NE supports the required TCP flags.
    - The ICMP Code and ICMP Type parameters are configurable when the Protocol parameter value is IPv6_ICMP.
    - The Egress PBR parameter can only be configured when the Action parameter is set to one of the following: Forward (Redirect Filter), TCP MSS Adjust, Ignore Match, Forward (ESI), Forward Next Hop, or Forward Next Hop (Router).
    - The Bonding Connection ID parameter must be configured when the Primary Action parameter is set to Forward (Bonding Connection).
    - Match Criteria Packet Length options are supported only when the IPv6 Filter Type is set to Packet-Length in Step 3. Packet length configuration is mutually exclusive with Flow Label configuration.

- The Match Criteria Hop Limit option is supported only when the IPv6 Filter type is set to Packet-Length in Step 3. Before you change the IPv6 Filter type, you must delete any filter entry that has the Hop Limit option selected.

13. Configure the parameters on any additional tabs that appear as a result of the Primary Action parameter setting. The type of additional configuration depends on the primary action selected.
14. Click on the Cflowd tab and configure the parameters as required.

    For the Sample Profile ID parameter, enter the ID number of an existing Cflowd sample profile. For information about Cflowd sample profiles see 12.10 “To enable and configure global Cflowd sampling on an NE” (p. 347).
15. Click on the Next Hop Routing tab and configure the required parameters.
16. Save your changes and close the form.

9

To create an additional filter entry, repeat Step 8.

10

Click on the Forwarding VRPN Target tab.

11

Configure the required parameters.

12

Click on the Secondary VPRN Target tab.

13

Configure the required parameters and select a router and LSP.

14

To define the order in which the policy tries to match filter entries with packets, perform the following steps for each filter entry.

1. Click Refresh to find an existing filter entry. The list of filter entries is displayed.
2. Select a filter entry and click Renumber ID. The Renumber Entry ID form opens.
3. Configure the New Entry ID parameter.
4. Save your changes. The Entry ID column displays the new identifier assigned to the entry.

15

Save your changes, The ACL IPv6 Filter Policies form reappears.

16

CAUTION

Service Disruption

Distributing a global ACL IPv6 filter policy with no filter entries (either because none have been created or all existing ones have been deleted) can cause a service outage. You should ensure that the policy has at least one filter entry, or you must be certain that distributing an empty policy is what you really intend to do. A global policy will be distributed to all of the policy's local definitions.

If you attempt the manual distribution of an empty policy, two warning confirmations will be issued. The first warning is issued when you change the policy's Configuration Mode on the General tab from Draft to Released. You can either choose to proceed by clicking Yes, or abort the Configuration Mode change by clicking No.

The second warning is issued if you changed the policy's Configuration Mode to Released and then try to proceed with the actual distribution in the Distribute form. You can either choose to proceed by clicking Yes, or abort the distribution by clicking No.

If you attempt to release an ACL IPv6 filter policy that has been initialized from an NE, you will also receive a warning confirmation, since the global policy may be partially updated from the local policy. The Discovery State indicator on the General tab displays this Initialized condition, and the Origin indicator identifies the NE. You should manually synchronize with a specific local policy before changing the Configuration Mode from Draft to Released.

Click Search, select the policy in the list and click Distribute to manually distribute the policy locally to devices. See 49.6 "To release and distribute a policy" (p. 1476) for more information. Policies are also automatically distributed to devices when they are used by resources on the device.

17

Select the distributed policy in the list and click Properties The ACL IPv6 Filter Global Policy (Edit) form opens.

18

Click on the Local Definitions tab and select a local definition and click Properties. The ACL IPv6 Filter Local Policy (Edit) form opens.

19

Click on the Insertion Blocks tab.

20

If required, enable the check box in the Host Shared Filter Configuration panel and configure the High Watermark or Low Watermark parameters

21

Configure the required parameters:

Note: The Group Entries Inserted panel displays the number of entries inserted on this filter range.

22

Click Sort Group Insertions and save your changes.

23

To view filter entry data:

1. Click on the Filter Entries tab, then the Credit Control Entries tab or the RADIUS Entries tab.
2. Click Search and choose an entry and click Properties.

   Note: Some parameters may not be supported on the local definition of the policy, depending on the device. See 49.2 “Policy distribution” (p. 1469) and 49.1.5 “Policy audits” (p. 1468) in Chapter 49, “Policies overview”.
3. Close the form.

24

Close all open forms.

END OF STEPS

51.7 To configure an ACL IP exception filter policy

51.7.1 Steps

1

Choose Policies→Filter→ACL IP Exception Filter from the NFM-P main menu. The ACL IP Exception Filter Policies form opens.

2

Click Create or select an existing policy and click Properties. The ACL IP Exception Filter (Create|Edit) form opens.

3

Configure the parameters on the General tab as required.

4

Configure one or more filter entries:

1. Click on the Filter Entries tab and click Create. The Entry, ACL IP Exception Filter, Global Policy (Create) form opens.
2. Configure the required parameters on the General tab.

3. Click on the Filter Properties tab.
4. Configure the Protocol parameter.

   The form refreshes to display the parameters applicable to the option you choose. For example, if you choose ICMP, the ICMP Properties panel appears.
5. In the Match Criteria panel, configure the Source IP and Destination IP parameters.
6. Configure additional parameters as required.
7. Save your changes and close the form.

You can configure up to 256 filter entries.

5

To delete an entry, choose the entry from the list in the Filter Entries tab and click Delete.

6

To define the order in which the policy tries to match filter entries with packets, perform the following steps for each filter entry.

1. Click Search to find an existing filter entry. The list of filter entries is displayed.
2. Select a filter entry and click Renumber ID. The Renumber Entry ID form opens.
3. Configure the New Entry ID parameter.
4. Save your changes. The Entry ID column displays the new identifier assigned to the entry.

7

Save your changes. The ACL IP Exception Filter Policies form reappears.

8

Close all open forms.

END OF STEPS

51.8 To configure an ACL IPv6 exception filter policy

51.8.1 Steps

1

Choose Policies→Filter→ACL IPv6 Exception Filter from the NFM-P main menu. The ACL IPv6 Exception Filter Policies form opens.

2

Click Create or select an existing policy and click Properties. The ACL IPv6 Exception Filter (Create|Edit) form opens.

3

Configure the parameters on the General tab as required.

4

Configure one or more filter entries:

1. Click on the Filter Entries tab and click Create. The Entry, ACL IPv6 Exception Filter, Global Policy (Create) form opens.
2. Configure the required parameters on the General tab.
3. Click on the Filter Properties tab.
4. Configure the Next Header parameter.

   The form refreshes as needed to display the parameters applicable to the option you choose.
5. In the Match Criteria panel, configure the Source IP and Destination IP parameters.
6. Configure additional parameters as required.
7. Save your changes and close the form.

You can configure up to 256 filter entries.

5

To delete an entry, choose the entry from the list in the Filter Entries tab and click Delete.

6

To define the order in which the policy tries to match filter entries with packets, perform the following steps for each filter entry.

1. Click Search to find an existing filter entry. The list of filter entries is displayed.
2. Select a filter entry and click Renumber ID. The Renumber Entry ID form opens.
3. Configure the New Entry ID parameter.
4. Save your changes. The Entry ID column displays the new identifier assigned to the entry.

7

Save your changes. The ACL IPv6 Exception Filter Policies form reappears.

8

Close all open forms.

END OF STEPS

51.9 To configure an embedding filter with embedded filter policies

51.9.1 Purpose

Perform this procedure to create an embedding filter that contains one or more embedded filters. An embedded filter is used to define a common set of rules. The filter that nests embedded filters is referred to as the embedding filter.

51.9.2 Steps

Create the embedding filter policy

1

Perform one of the following:

a. Create an ACL IP filter. See 51.5 “To configure an ACL IP filter policy” (p. 1671).

b. Create an ACL IPv6 filter. See 51.6 “To configure an ACL IPv6 filter policy” (p. 1677).

Note: You must set the Scope parameter of the embedding filter to either template or exclusive.

Associate a flowspec configuration with the embedding filter policy, if required

2

Click on the Embedded Filters tab and then the Flowspec Embedded sub-tab.

3

Enable the Enable Flowspec parameter.

4

Choose the Router Instance Type, either Base or VPRN.

If you selected VPRN, then click Select to choose a VPRN service and click OK.

5

Configure the Offset and Admin State parameters.

6

To limit the BGP flowspec embedded filters to specific interfaces, configure the Group ID parameter with the same value as the group-ID configured for the flowspec-set or flowspec-set-trans community members configured in the required routing community policy; see 54.8 “To configure a community policy” (p. 1752).

7

You should also define the maximum size for an embedded flowspec on the routing instances that this policy will be applied to. See configuring the IPv4 Max Size and IPv6 Max Size parameters under the Routing tab in 27.2 “To configure a routing instance or a VRF instance” (p. 826) for base routers, or 79.26 “To configure a routing instance on a VPRN site” (p. 2564)for VPRN services, as required.

Associate an embedded IP filter policy with the embedding filter policy, if required

8

Click on the Embedded Filters tab and then the IP Embedded sub-tab.

9

Click Create. The Embedded Entry form opens.

10

Select an embedded filter and click OK.

11

Configure the Offset and Admin State parameters.

12

Click OK. The Embedded Entry form closes.

13

Click OK to save your changes. The ACL MAC/IP/IPv6 Filter properties form closes.

END OF STEPS

51.10 To configure a protocol list policy

51.10.1 Purpose

A protocol list policy defines a list of network protocols to be used as filtering criteria for filter entries in ACL IP and IPv6 filter policies.

Protocol list policies are assigned during IP or IPv6 ACL filter entry configuration; see 51.5 “To configure an ACL IP filter policy” (p. 1671) and 51.6 “To configure an ACL IPv6 filter policy” (p. 1677).

51.10.2 Steps

1

Choose Policies→Filter→Protocol List from the NFM-P main menu. The Filter - Protocol Lists form opens.

2

Click Create or select an existing policy and click Properties. The Filter - Protocol List (Create|Edit) form opens.

3

Configure the parameters as required.

4

Click on the Protocol List Members tab and click Add Protocols. The Select Protocols form opens.

5

Move the required protocols to the Selected Protocols panel, to a maximum of 32.

6

Save your changes and close the forms. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

END OF STEPS

51.11 To configure an IP Prefix List policy

51.11.1 Steps

1

Choose Policies→Filter→IP Prefix List from the NFM-P main menu. The Filter - IP Prefix Lists form opens.

2

Click Create or select an existing policy and click Properties. The Filter - IP Prefix List (Create|Edit) form opens.

3

Configure the parameters as required.

4

Configure IP prefix list member entries as required:

1. Click on the IP Prefix List Members tab and click Create, or choose an entry in the list and click Properties. The IP Prefix List Member (Create) form opens.
2. Configure the parameters.
3. Click Apply to save your entry and create another, or click OK to save your entry and close the form. The newly-defined member appears in the list on the IP Prefix List Members tab.

5

Configure IP prefix list excluded member entries as required:

Note: You cannot configure excluded members and apply path members in the same policy.

1. Click on the IP Prefix List Exclude Members tab and click Create, or choose an entry in the list and click Properties. The IP Prefix List Exclude Member (Create) form opens.
2. Configure the parameters.
3. Click Apply to save your entry and create another, or click OK to save your entry and close the form. The newly-defined excluded member appears in the list on the IP Prefix List Excluded Members tab.

6

Configure apply path member entries as required:

Note: You cannot configure apply path members and excluded members in the same policy.

1. Click on the Apply Path Members tab and click Create, or choose an entry in the list and click Properties. The Apply Path Member (Create) form opens.
2. Configure the required parameters.
3. Click Apply to save your entry and create another, or click OK to save your entry and close the form. The newly-defined apply path member appears in the list on the Apply Path Members tab.

7

Save your changes and close the Filter - IP Prefix List (Create|Edit) form.

8

To release and distribute the policy, click Search on the Filter - IP Prefix Lists form, select the newly created policy and click Properties. The Filter - IP Prefix List (Edit) form opens.

9

Perform the required steps in 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy.

10

To associate a newly-created IPv4 IP Prefix List with an ACL IP Filter policy, see 51.5 “To configure an ACL IP filter policy” (p. 1671). For ACL IPv6 filters, see 51.6 “To configure an ACL

IPv6 filter policy" (p. 1677). In either of those procedures, you can specify an IP Prefix List by configuring the Source IP Prefix and/or the Destination IP Prefix parameters for a filter entry.

11

To associate a newly-created IPv4 or IPv6 IP Prefix List with a CPM Filter policy, see the *NSP System Administrator Guide*.

12

Save your changes and close the forms.

END OF STEPS

51.12 To configure a Port List policy

51.12.1 Steps

1

Choose Policies→Filter→Port List from the NFM-P main menu. The Filter - Port Lists form opens.

2

Click Create or select an existing policy and click Properties. The Filter - Port List (Create|Edit) form opens.

3

Configure the parameters as required.

4

Click on the Port List Members tab and click Create. The Port List Member, Site (Create) form opens.

5

Configure the Port parameter. This can either be a specific port number or a range of port numbers. For a specific port number, use the EQUAL operator from the drop-down menu. For a range of port numbers, use the RANGE operator.

6

Save your changes and close the form. The newly-defined member appears on the list.

7

Repeat Step 4 to Step 6 to create additional members, as required.

8

Save your changes and close the forms. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

Note: To associate a newly-created Port List with a CPM Filter policy, see the *NSP System Administrator Guide*.

END OF STEPS

51.13 To configure a DHCP Filter policy

51.13.1 Steps

1

Choose Policies→Filter→DHCP Filter from the NFM-P main menu. The DHCP Filter Policies list form opens.

2

Click Create or select an existing policy and click Properties. The DHCP Filter (Create|Edit) form opens.

3

Configure the parameters as required.

4

Configure a filter entry.

1. Click on the Filter Entries tab and click Create. The Entry, DHCP Filter (Create) form opens.
2. Configure the required parameters.
3. Click on the Filter Properties tab.
4. Configure the required parameters:

   The Match Condition parameter is configurable only when a DHCP Option has been selected.

   The Match String Type, Match Type, and Match String parameter are configurable only when the Match Condition parameter is set to Match String
5. Save your changes and close the form.

5

Save your changes and close the forms. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

6

Repeat Step 1 and choose the distributed policy in the list and click Properties. The DHCP Filter Global Policy (Edit) form opens.

7

Click on the Group Interfaces tab to view IES or VPRN group interfaces that are bound to the DHCP filter policy. See 78.19 “To configure a group interface on an IES” (p. 2449) and 79.37 “To configure a group interface on a VPRN” (p. 2586) for more information on binding IES and VPRN group interfaces to DHCP filter policies.

8

To view DHCP filter entry data.

1. Click on the Local Definitions tab and choose a local definition from the list and click Properties. The DHCP Filter Local Policy (Edit) form opens.
2. Select an entry from the list and click Properties. An Entry, DHCP filter form opens.
3. Close the forms after viewing the filter entry data.

END OF STEPS

51.14 To configure a DHCPv6 filter policy

51.14.1 Steps

1

Choose Policies→Filter→DHCPv6 Filter from the NFM-P main menu. The DHCPv6 Filter Policies list form opens.

2

Click Create or select an existing policy and click Properties. The DHCPv6 Filter (Create|Edit) form opens.

3

Configure the parameters as required.

4

Configure a filter entry.

1. Click on the Filter Entries tab and click Create. The DHCPv6 Filter Entry (Create) form opens.
2. Configure the required parameters.
3. Click on the Filter Properties tab.
4. Configure the required parameters.

If the Action parameter is set to Bypass Host Creation, the Action Flags parameters must be configured.

After the DHCP Option parameter has been configured, the Match Condition parameter is configurable.

If the Match Condition parameter is set to Match String, the Match String Type, Match Type, and Match String parameters are configurable.

5. Save your changes and close the form.

5

Save your changes and close the forms. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

6

Repeat Step 1 and choose the distributed policy in the list and click Properties. The DHCPv6 Filter Global Policy (Edit) form opens.

7

Click on the Group Interfaces tab to view IES or VPRN group interfaces that are bound to the DHCPv6 filter policy. See 78.19 “To configure a group interface on an IES” (p. 2449) and 79.37 “To configure a group interface on a VPRN” (p. 2586) for more information on binding IES and VPRN group interfaces to DHCPv6 filter policies.

8

To view DHCP filter entry data.

1. Click on the Local Definitions tab and choose a local definition from the list and click Properties. The DHCPv6 Filter Local Policy (Edit) form opens.
2. Select an entry from the list and click Properties. An DHCPv6 filter form opens.
3. Close the forms after viewing the filter entry data.

END OF STEPS

51.15 To configure a Redirect Filter policy

51.15.1 Purpose

Redirect Filter policies allow specifying multiple redirect target destinations and defining health check test methods used to validate the ability for a given destination to receive redirected traffic. This destination monitoring allows a router to react to target destination failures.

51.15.2 Steps

1

Choose Policies→Filter→Redirect Filter from the NFM-P main menu. The Redirect Filter Policies form opens.

2

Click Create or select an existing policy and click Properties. The Redirect Filter Policy (Create|Edit) form opens.

3

Configure the parameters as required.

4

If you configured the Router Instance Type parameter to VPRN, click Select to assign a VPRN pointer to the policy.

5

Click on the Destination Addresses tab and click Create. The Destination (Create) form opens.

6

Configure the parameters as required.

If you enable the Enable Unicast Route Reachability Test parameter, no other health check test can be performed. Go to Step 8.

If you set the Address Type parameter to IPv4, go to Step 7. For IPv6, you can only perform Step 7 c.

7

Perform one or more of the following test types:

a. Configure an SNMP test:

1. Click on the SNMP Tests tab and click Create. The SNMP Test (Create) form opens.
2. Configure the required parameters.
3. Click on the SNMP Responses tab and click Create. The SNMP Response (Create) form opens.
4. Configure the required parameters.
5. Save your changes and close the form.
6. Repeat 3 to 5 to create addition SNMP responses for the SNMP test.
7. Repeat 1 to 6 to create addition SNMP tests for the redirect filter.

b. Configure a URL test:

1. Click on the URL Tests tab and click Create. The URL Test (Create) form opens.
2. Configure the required parameters.

3. Click on the URL Responses tab and click Create. The URL Response (Create) form opens.
4. Configure the required parameters.
5. Save your changes and close the form.
6. Repeat 3 to 5 to create addition URL responses for the URL test.
7. Repeat 1 to 6 to create addition URL tests for the redirect filter.

c. Configure a Ping test:

1. Enable the Enable Ping Test parameter.
2. Click on the Ping Test tab.
3. Configure the required parameters.
4. Save your changes and close the form.

For supporting NEs, the results of Ping tests can be shared among multiple destination addresses, when a redirect policy binding is configured for those addresses. See 51.16 “To configure a Redirect Policy Binding” (p. 1696).

8

Save your changes and close the form.

9

Repeat Step 2 to Step 8 to create additional IPv4 or IPv6 destination addresses as required.

10

See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

11

To associate a newly-created IPv4 redirect filter policy with an ACL IPv4 filter policy, see 51.5 “To configure an ACL IP filter policy” (p. 1671). For an IPv6 redirect filter policy, see 51.6 “To configure an ACL IPv6 filter policy” (p. 1677). You must set the Action parameter to the forward (Redirect Filter) option to enable an association. The ACL Filter Entries tab on the Redirect Filter Policy form lists all such associations for distributed policies.

12

When a Redirect Filter policy has been distributed to the required NEs, you can open local definitions from the Local Definitions tab of the global policy and examine the tests for each contained destination. A Refresh button is available on the individual test property forms to get the Last Response details.

13

Close the forms.

END OF STEPS

51.16 To configure a Redirect Policy Binding

51.16.1 Purpose

Redirect policy bindings allow configuration of an association between destination addresses in redirect filter policies, so that results of Ping tests can be shared.

The redirect filter policies and addresses configured in a redirect policy binding must already exist; see 51.15 “To configure a Redirect Filter policy” (p. 1693).

51.16.2 Steps

1

Choose Policies→Filter→Redirect Policy Binding from the NFM-P main menu. The Redirect Binding Policies form opens.

2

Click Create, or choose an existing redirect policy binding and click Properties. The Redirect Policy Binding (Create|Edit) form opens.

3

Configure the parameters on the General tab.

4

Click on the Redirect Policy Destination tab.

5

Configure redirect policy destination addresses for the binding. The required redirect policies and destination addresses must already exist.

1. Click Create, or choose an item in the list and click Properties. The Redirect Policy Binding Destination form opens.
2. Select a Redirect Policy and IP Address for the binding.
3. Save your changes and close the form.
4. Configure additional addresses as required.
5. To remove any address that is not required in the binding, choose the entry in the list and click Delete.

6

Save your changes and close the forms.

7

See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

END OF STEPS

51.17 To configure an ACL VLAN Filter policy

51.17.1 General Information

An ACL VLAN Filter policy can be configured on a 2-port ring MDA on the 7705 SAR-8 or 7705 SAR-18. Only the first two ports in network mode on the 2-port ring MDA can be configured with an ACL VLAN filter policy.

51.17.2 Steps

1

Choose Policies→Filter→ACL VLAN Filter from the NFM-P main menu. The ACL VLAN Filter Policies form opens.

2

Click Create or select an existing policy and click Properties. The ACL VLAN Filter, Global Policy (Create|Edit) form opens.

3

Configure the parameters as required.

4

Configure a filter entry.

1. Click on the Filter Entries tab and click Create.The Entry, ACL VLAN Filter, Global Policy (Create) form opens.
2. Configure the required parameters.
3. Click on the Filter Properties tab.
4. Configure the required parameters.
5. Save the changes and close the form.

5

Repeat Step 4 as required to create additional filters.

6

Save your changes and close the forms. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

7

To associate the ACL VLAN Filter Policy with an Ethernet port on a 2-port ring MDA on a 7705 SAR-8 or 7705 SAR-18, see 16.24 “To configure Ethernet ports” (p. 599).

END OF STEPS

51.18 To configure a System Filter

51.18.1 Purpose

A system filter allows operators to configure a filter chain for packet matching. In this chain, the active system filter policy rules are evaluated first. If no match occurs, only then are the rules of any chained filter policies evaluated.

The system filter policies supports all IPv4/IPv6 filter policy match rules and actions. However, system policy entries cannot be LI or mirror sources. A system filter policy also does not support Radius, flowspec, or Gx inserted entries. In addition, a system filter policy also requires chassis mode D to be set on an NE to which it is deployed.

See 51.1 “Filter policies” (p. 1663) for more information on system filters.

51.18.2 Steps

1

Perform one of the following procedures to configure and distribute an IP filter policy for use as a system filter policy on the required NEs:

a. 51.5 “To configure an ACL IP filter policy” (p. 1671) for an ACL IP filter policy

b. 51.6 “To configure an ACL IPv6 filter policy” (p. 1677) for an ACL IPv6 filter policy

Whether the policy you create will be an active system filter policy or a chained system filter policy is determined by setting the Scope and Chain to System Filter parameters.

Note: If you are configuring an active system filter policy, then you must set the Scope parameter to system when you create the new filter policy.
If you are configuring a chained system filter policy, then you must set the Scope parameter to either template or exclusive when you create the new filter policy. The Chain to System Filter parameter must also be enabled.
To change an existing filter policy’s Scope parameter to or from the system option, the policy must have no Filter Entries configured.

2

Perform one of the following:

a. To create or configure an Active System Filter, go to Step 3.

b. To view or configure a Chained Filter, go to Step 10.

Create or configure an Active System Filter

3

On the equipment tree, right-click on the NE to which you want to apply the active system filter and choose Properties. The Network Element (Edit) form opens.

4

Click on the Globals tab and then the System Filter tab.

5

Click on the Active System Filters tab and then click Create. The System Filter (Create) form opens.

6

Select either IP or IPv6 as the required System Filter Type.

7

Select the IP filter policy you created or configured in Step 1 as the System Filter.

8

Click OK to apply the configuration and close the System Filter (Create) form. The new active system filter appears in the list.

Note: You can also delete or configure the properties of an existing active system filter from this form.

9

Close the form.

View or configure a chained system filter

10

On the equipment tree, right-click on the NE to which you distributed the chained system filter and choose Properties. The Network Element (Edit) form opens

11

Click on the Globals tab and then the System Filter tab.

12

Click on the Chained Filters tab and then either the IP or IPv6 tab, as required.

All ACL IP template or exclusive filter policies that have been distributed to this NE and have an enabled Chain to System Filter parameter are displayed. No further action is required. These are the chained system filters.

13

To change the configuration of an existing chained system filter, select it from the list and click Properties.

Refer to either 51.5 “To configure an ACL IP filter policy” (p. 1671) or 51.6 “To configure an ACL IPv6 filter policy” (p. 1677) for configuration details, as required.

Note: You cannot delete a chained system filter from this form. Chained system filters can only be deleted using the ACL IP or ACL IPv6 Filter Policy selection form.

14

Close the form.

END OF STEPS

51.19 To copy filter policy filter entries

51.19.1 Purpose

Perform this procedure to copy the filter entries of one filter policy to another filter policy. The supported filter policies include:

- ACL MAC Filter
- ACL IP Filter
- ACL IPv6 Filter
- DHCP Filter

51.19.2 Steps

1

Choose Policies→Filter→*Filter type* from the NFM-P main menu, where *Filter type* is the type of filter that you want to copy a filter entry from. The appropriate policies manager form opens.

2

Select a policy, then click Properties. The filter policy properties form opens.

3

Click on the Filter Entries tab, click Search and select one or more filter entries from the list.

4

Click Copy Entries. The Copy Filter type Filter Entries form opens and the copied filter entry appears in the Copy Policy Entry Instances panel.

5

Configure the following parameters as required.

- Enable Copied Entries to Override Existing Entries with the Same ID
- Distribute the Global policy after Applying Form

6

Select the local policies that you want to copy the filter entry to from the Available Policies list. Only local policies with a distribution mode of Local Edit Only will be listed.

7

Click on the right-pointing arrow to move the selected policies to the Copy Entries to these Targeted Policies panel.

Note: If you enabled the Distribute the Global policy after Applying Form parameter and one of the Targeted Policies is a global policy, then that global policy will subsequently be distributed to all NEs with local definitions of the policy.
However, if the Distribution Mode of a local policy is set to Local Edit Only, the associated NE will not be allowed to receive the distribution of the global policy. You must set the local policy's Distribution Mode to Sync With Global if you want the NE to receive the global policy distribution.
See 49.6 "To release and distribute a policy" (p. 1476) for detailed information on policy distribution.

8

Click OK. The filter entries are copied to the targeted policies and the Copy Filter type Filter Entries form closes.

Note: If you copy a filter entry with an Entry Type of Embedded, the copies sent to the targeted policies will have an Entry Type of Normal. See 51.9 "To configure an embedding filter with embedded filter policies" (p. 1686) for information on embedded filters.
If an NE that contains one of the targeted policies is down, it cannot receive the copied filter. A deployment failure message will be issued.

9

Close the filter policy properties form.

END OF STEPS

51.20 To configure a ACL Filter Log policy

51.20.1 Purpose

You can configure a ACL Filter Log policy to define:

- where log information for all actions performed on 7210 and 7x50 NEs that match ACL MAC, ACL IP, ACL IPv6, and CPM filter entry criteria are written (memory or Syslog)
- how many log entries can be stored
- what action is performed when the log files meet the specified threshold.

51.20.2 Steps

1

Choose Policies→Log Configuration. The Manage Log Configuration Policies form opens.

2

Click Create→ACL Filter Log or select an existing ACL Filter Log (Node Log Policy) and click Properties. The ACL Filter Log, Global Policy (Create|Edit) form opens.

3

Configure the parameters as required.

The SysLog Id, Log Summary Enabled, and Log Summary Criterion parameters are configurable when you choose the SysLog option as the Log Destination.

The Maximum Number of Entries parameter is configurable when you choose the Memory option as the Log Destination.

4

Save your changes. The ACL Filter Log, Global Policy (Create|Edit) form refreshes displaying the Policy Configuration panel.

5

Click Switch Mode to release and distribute the policy to the required NEs. See 49.6 “To release and distribute a policy” (p. 1476) for more information.

6

Close all open forms.

7

Associate the Filter log with a filter entry for any of the following filter types by configuring the Log ID parameter in the associated procedure:

- CPM Filter. See the “To configure a CPM filter” procedure in the *NSP System Administrator Guide*.

- ACL MAC Filter. See 51.4 “To configure an ACL MAC filter policy” (p. 1668).
- ACL IP Filter. See 51.5 “To configure an ACL IP filter policy” (p. 1671).
- ACL IPv6 Filter. See 51.6 “To configure an ACL IPv6 filter policy” (p. 1677).

  The Log ID you specify in any of these procedures will refer to the ACL Filter Log’s ID parameter you configured in Step 3.

END OF STEPS

51.21 To configure a GRE tunnel template

51.21.1 Before you begin

A GRE tunnel template specifies a set of GRE encapsulation parameters to use when the primary action for ACL IP and ACL IPv6 filter policies is set to Forward (GRE Tunnel).

GRE tunnel templates are assigned to ACL IP filter policies and ACL IPv6 filter policies; see 51.5 “To configure an ACL IP filter policy” (p. 1671) and 51.6 “To configure an ACL IPv6 filter policy” (p. 1677).

51.21.2 Steps

1

Choose Policies→Filter→GRE Tunnel Template from the NFM-P main menu. The Filter - GRE Tunnel Template form opens.

2

Click Create, or click Search, select an existing template, and click Properties. The GRE Tunnel Template (Create|Edit) form opens.

3

If you are creating a new template, configure the Template Name and Description parameters, and click Apply.

The Template Name and Description parameters are configurable only when creating a new template.

4

Click on the IPv4 tab and configure the required parameters.

5

Click on the IPv6 tab and configure the required parameters.

6

In the IP Destination Address panel, configure one or more IP destination addresses.

When the GRE tunnel template is assigned to an ACL IP or IPv6 filter policy, traffic matching the associated IPv4 or IPv6 filter is hashed across all available destination addresses. If no

destination address is available, then matching traffic follows the configured PBR Down Action Override action, if configured; see 51.5 “To configure an ACL IP filter policy” (p. 1671) and 51.6 “To configure an ACL IPv6 filter policy” (p. 1677).

You cannot modify an existing address in the template. You must delete the existing address and create another.

1. Click Create. The IP Destination Address, Site (Create) form opens.
2. Configure the IPv4 Destination Address parameter.

   You can modify address entries before the policy is saved, but not after.
3. Save your changes and close the form. The GRE Tunnel Template (Create|Edit) form is displayed.

7

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

51.22 To configure a Syslog policy

51.22.1 Purpose

You can configure a Syslog policy that is used by the ACL Filter Log policy to define the destination details for log messages such as the target address and target UDP port.

51.22.2 Steps

1

Choose Policies→Log Configuration. The Manage Log Configuration Policies form opens.

2

Click Create→Sys Log or select an existing Sys Log Target (Node Log Policy) and click Properties. The Sys Log Target, Global Policy (Create|Edit) form opens.

3

Configure the parameters as required.

4

Click Apply. The Sys Log Target, Global Policy (Create|Edit) form refreshes displaying the Policy Configuration panel.

5

Click Switch Mode to release and distribute the policy to the required NEs. See 49.6 “To release and distribute a policy” (p. 1476) for more information.

6

Close all open forms.

7

See 51.20 “To configure a ACL Filter Log policy” (p. 1702) to associate the SysLog with a ACL Filter Log.

END OF STEPS

51.23 To configure a Log ID Profile Policy

51.23.1 Purpose

You can configure a Log ID Profile policy that is used to define various source and destination details to retrieve specific log files after the node reboot.

51.23.2 Steps

1

Choose Policies→Log Configuration. The Manage Log Configuration Policies form opens.

2

Click Create→Log ID Profile or select an existing Log ID Profile (Node Log Policy) and click Properties. The Log ID Profile, Global Policy (Create|Edit) form opens.

3

Configure the parameters as required.

- For the Destination parameter, you can assign one of the following: Console, Syslog, SNMPTraps, File, Memory, Netconf, and SubscribedCli.
- You can assign an Event Filter Log to the Log ID Profile.
- The Destination parameter can only be set once and cannot be modified. Once set, it becomes read-only and is not a part of the Audit operation. However. the associated fields and other attributes are highlighted, if different, and they can be modified during the Audit process.
- The Source and Event Filter Log can be modified.
- If Destination is set as Syslog, you can assign the Syslog and Python policy.
- If Destination is set as SNMPTraps, the Log ID should be similar as the SNMP group id. For example, if the SNMPTrap group 53 is created on the node, you can create the Log ID as 53 and set its destination as SNMPTrap.
- When the source is set as *Li*, the distribution gets successful only on the nodes that has or supports the *Li* configuration

4

Click Apply. The Log ID Profile, Global Policy (Create|Edit) form refreshes displaying the Policy Configuration panel.

5

Click Switch Mode to release and distribute the policy to the required NEs. See 49.6 “To release and distribute a policy” (p. 1476) for more information.

6

Close all open forms.

END OF STEPS

51.24 To configure an LI log ID profile

51.24.1 Purpose

You can configure an LI log ID profile to define various source and destination details to retrieve specific log files after an NE reboot. You must be an LI user in order to configure an LI log ID profile.

51.24.2 Steps

1

Choose Policies→LI Log Configuration. The Manage LI Log Configuration Policies form opens.

2

Create Create. The Li Log ID Profile, Global Policy (Create) form opens.

3

Configure the required parameters and select the event filter log.

4

Click Apply. The Li Log ID Profile, Global Policy (Create|Edit) form refreshes displaying the Policy Configuration panel.

5

Click Switch Mode to release and distribute the policy to the required NEs. See 49.6 “To release and distribute a policy” (p. 1476) for more information.

6

Close all open forms.

END OF STEPS

51.25 To configure an Event Filter Log Policy

51.25.1 Purpose

You can configure an Event Filter Log policy to define an application by adding its details as an entry to retrieve specific log files after the reboot.

51.25.2 Steps

1

Choose Policies→Log Configuration. The Manage Log Configuration Policies form opens.

2

Click Create→Event Filter Log or select an existing Event Filter Log (Node Log Policy) and click Properties. The Event Filter Log, Global Policy (Create|Edit) form opens.

3

In the General tab, configure the parameters as required.

4

Configure the Entry tab.

1. Click Create or select an existing Event Filter Log, Global Policy and click Properties. The Event Filter Log Entry (Create|Edit) form opens.
2. Configure the parameters as required.

   Note: Multiple applications ids are not allowed in one entry, but you can modify the existing application id.
3. You can also define operators and regular expressions for the following parameters: Application, Number, Severity, Subject, Router, and Message.
4. Click Apply.

5

Click Apply. The Event Filter Log, Global Policy (Create|Edit) form refreshes displaying the Policy Configuration panel.

6

Click Switch Mode to release and distribute the policy to the required NEs. See 49.6 “To release and distribute a policy” (p. 1476) for more information.

7

Close all open forms.

END OF STEPS

52 Multicast policies

52.1 Multicast policies

52.1.1 Overview

You can use the NFM-P to create multicast policies that reduce bandwidth requirements and regulate multicast traffic flow by simultaneously delivering a single stream of information to multiple receivers. Multicast traffic flow is based on the concept of a group; a multicast group is an arbitrary group of receivers that receive the same data traffic.

You can configure the following NFM-P multicast policy types:

- Multicast package
- Egress multicast group
- Multicast CAC
- Ingress multicast path management
- SSM translate
- 7210 SAS multipoint bandwidth management
- MCAC interface

52.2 Multicast package policies

52.2.1 Overview

Multicast package policies are used to assign a common set of multicast groups to NEs in an MVR VPLS. Multicast package policies ensure that the multicast groups on the devices of one or more MVR VPLS instances are consistent. See Chapter 27, “NE routing and forwarding” for information about configuring multicast groups on individual devices using a multicast routing policy.

When a multicast package policy is distributed to an NE, a multicast routing policy is configured with the appropriate multicast prefix list, which is based on the multicast groups in the multicast package policy. Multicast package policies are only used to distribute the policies to one of the two NEs. Policy discovery and synchronization are not supported.

A multicast package policy has zero or more multicast groups associated with it. The multicast groups are distributed to the NE as part of the policy. Only root catalog multicast packages can be distributed to the NE.

52.2.2 Multicast package policy design considerations

Consider the following when creating multicast package policies:

- one root multicast package policy should be created for a ring or multiple rings, which contains the multicast addresses of all BTV channels distributed in the ring
- specify this root multicast package policy for the BTV (MVR) VLAN

- create other multicast package policies from the root package by clicking on the Copy button on the configuration form, or by clicking on the More Actions button and choosing Copy, if the Copy button is not visible.
- use the child policies to differentiate the types of broadcast TV services offered, for example, basic service and premium service

52.2.3 Distributing multicast package policies

When you distribute a multicast package policy to an NE, the NFM-P maps one multicast package policy to one routing policy statement. Each multicast policy group entry is mapped to one routing policy prefix list member.

For example, the ID of a multicast package policy is 2. When the policy is distributed to an NE, the NFM-P automatically creates a routing policy statement for the device. The name created for the routing policy statement is SAM_MPP_2, where 2 is the multicast package policy ID.

When the policy is distributed to an NE, the ID of the routing policy statement entry is always 1. A name is generated by the NFM-P to identify the prefix list in the routing policy statement entry. The name is SAM_MPG_2_1, where 2 is the multicast package policy ID and 1 is the routing policy statement entry ID. The prefix list name is referenced in the routing policy statement entry as the multicast group prefix list name.

In the same example, the multicast address for the multicast group of a multicast package policy is 224.0.0.0. When the multicast package policy is distributed to an NE, the NFM-P automatically creates a routing policy prefix list member for the device. The prefix list member address is 224.0.0.0.

Since the multicast package policy is not resynchronized, you must avoid duplicate names for routing policies.

If a multicast group does not have a policy group entry, the multicast group is not distributed to the device as a prefix member.

If a multicast package policy is used by any MVR VPLS, it cannot be removed from the NFM-P.

52.3 Egress multicast group policies

52.3.1 Overview

With standard egress multicasting, the entire egress forwarding plane is used on a per destination basis to provide ACL, mirroring, QoS, and accounting for each path with the associated receivers. This process is very resource intensive. Also, when congestion occurs at the egress forwarding plane, unicast discards may be indiscriminate of the forwarding priority.

The NFM-P provides an alternative egress multicasting method that increases egress replication performance and scalability by combining multiple destinations into a single egress forwarding pass as an egress multicast group (EMG). You specify the EMG requirements using a global EMG policy

which defines the group destination SAPs in a chain. The chain receives a single multicast packet from the egress forwarding plane with only a single pass.

The EMG policy is applied to an L2 access interface that is created on an Ethernet port with null or dot1q encapsulation. SAP membership in an EMG policy has the following requirements:

- The SAP must belong to an SHG.
- The L2 access interface egress ACL filter must match that of the EMG.
- The access port and the EMG must have the same encapsulation type.

When a SAP becomes a member of an EMG, the common parameters that it shares with other EMG members cannot be changed. On the other hand, a modification to an EMG common requirement changes that parameter in all SAPs in the chain. The same common required traits apply to egress filters: individual SAP filters cannot be changed, and any change to the EMG egress filter parameters affects the egress filters in all member SAPs. In addition, if an egress filter is not defined in the EMG common parameter requirements, a new member SAP cannot have an egress filter.

The following restrictions also apply to an EMG:

- egress multicast group policies cannot be applied to SR NE variants at Release 15.0 R1 and higher.
- only IPv4 egress filters can be applied to an EMG
- up to 30 EMGs can be created on a router
- an EMG can be deleted only if it has no SAP members
- the number of members in an EMG (the chain limit) is restricted to 30, with an optimal length of 10 to 16

52.4 Multicast CAC policies

52.4.1 Overview

Multicast CAC policies control the bandwidth consumed by BTV distribution services. Bandwidth control helps manage network congestion and maintain QoS standards. The multicast CAC function is supported on IGMP, PIM, or MLD interfaces, IGMP or MLD group interfaces, and in the case of BTV distribution, on VPLS SAPs and SDPs where IGMP snooping is enabled.

A multicast CAC policy manages the bandwidth consumed by BTV services on both the access node link and specific links in the aggregation network. Routers in the path are configured to maintain certain limits on broadcast bandwidth and can limit the number of channels simultaneously sent on both the second mile link and the network link.

The total bandwidth usage of an IGMP host is calculated using the following logic:

1. Retrieve all channels (i.e. groups) from the IGMP host.
2. For each channel (i.e group), find the corresponding MCAC policy channel object defined with a matching source address.

The logic functions on the best match for the channel with the source address and prefix in the MCAC policy channel object. If the match fails, bandwidth is calculated from a matched MCAC channel object with a default (null) source address.

3. Retrieve the bandwidth assigned to each of the corresponding MCAC channels.
4. The sum of all bandwidth values is the total bandwidth usage of the host.

52.5 Ingress multicast path management policies

52.5.1 Overview

Ingress multicast path management policies are used to manage ingress multicast path bandwidth settings, path decisions, and destination server details that collect and analyze IGMP events associated with residential subscribers. You can create the following ingress multicast path management policy types:

52.5.2 Ingress multicast bandwidth policy

Ingress multicast bandwidth policies are used to manage the ingress multicast path bandwidth of the multicast forwarding paths into the switching fabric. When Multicast Path Management is disabled (the default), two paths are available:

- a high-priority path, on which packets from queues classified as “expedited” are forwarded
- a low-priority path on which packets from queues classified as “non-expedited” are forwarded

When Multicast Path Management is enabled, an ingress multicast bandwidth policy can be used to manage the flow of multicast traffic through an MDA (IOM, IOM 2, or XMA) or the forwarding plane of an 2 x XP MDA IOM 3, IMM, or XCM.

The maximum number of bandwidth policies per NE is 32, including the default policy.

MDAs can be configured to use previously defined ingress multicast bandwidth policies. However, any path limits specified in the selected policy can be overridden for each MDA, if required.

52.5.3 Ingress multicast info policy

Ingress multicast info policies are used to define how each multicast channel is handled by NEs. The policy is assigned to a VPLS/VPRN service site or default routing instance, but the policy is actually used by the Ingress Multicast Bandwidth Manager, the ECMP Path Manager, and the Egress Multicast CAC Manager to determine the path through the switch fabric and to make decisions on joins to multicast streams.

The maximum number of ingress multicast info policies per NE is limited to 32, including the default policy.

MDAs can be configured to use previously-defined ingress multicast bandwidth policies. However, any path limits specified in the selected policy can be overridden for each MDA, if required.

Ingress multicast forwarding on L2-snooped and L3-routed IP multicast traffic can be explicitly configured by applying an ingress multicast info policy to a VPLS site (all types of VPLS are supported), a VPRN site, or the default routing instance.

An ingress multicast info policy consists of one or multiple named Bundles, which in turn, contain Channel ranges with possible overrides for individual channels.

- Bundles

  A Bundle groups a set of explicit multicast channels (or channel ranges) into a common bandwidth context for CAC functions (such as join decisions) using common preferences. The channels in the bundle are managed as a defined percentage of the available bandwidth.

  Bundles also simplify provisioning, since the default characteristics of the bundle channels are specified on the bundle level. These characteristics can be overridden at the Channel range level, or explicitly per channel.

  Each ingress multicast info policy has a default bundle named “default”. It cannot be edited or removed. Any multicast channel that fails to match a channel range within an explicit operator-defined bundle is associated with this default bundle.

  Note:

  The maximum number of Bundles per Info policies is limited to 32. This limit includes the default bundle, leaving 31 operator-defined bundles per Info policy.

- Channels and channel ranges

  Channel ranges are used to define a set of multicast channels contained in a bundle and to override the default channel settings in the containing bundle.

  A channel range is defined by a start destination multicast IP address and an end destination multicast IP address (both IP v4 and IPv6 are supported, but the start and end addresses must be of the same type). A channel in this context is a channel range where the start address and end address are identical.

  Note:

  After you create a channel range, it is not possible to modify the start address or end address.

  A channel range can contain multiple channel overrides. A channel override is used to specify an explicit setting for a channel within the range. The channel override is identified by a destination multicast IP address which falls between the start and end IP addresses of the channel range.

  Note:

  The 7450 ESS does not support channel ranges and channel overrides having IPv6 addresses. Therefore, the NFM-P does not allow the creation of such channel ranges and channel overrides on local ingress multicast info policies. In addition, the NFM-P removes any such channel ranges and channel overrides when synchronizing local ingress multicast info policies with their respective global policies.

- Dual stream selection

  Dual stream selection support allows a single multicast stream to be duplicated into two different transmission paths. The two paths may have different transmission characteristics, such as latency and jitter. Rather than select one stream for retransmission to the client, the duplicate stream protection feature evaluates each stream packet-by-packet, selecting the packet that first arrives (and is valid) for retransmission.

- Video quality monitoring

VQM to provides the functionality to analyze the quality of a video stream just prior to reaching the STB of client in a IPTV network. Statistics reports and alarms can be generated for VQM, providing operators with a view of multicast video quality at the last mile of distribution.

52.5.4 Ingress multicast reporting policy

Ingress multicast reporting destination policies are used to specify the destination server for the collection of multicast reports. The policies are applied to residential subscriber IGMP policies.

52.6 SSM translate policies

52.6.1 Overview

Source-Specific Multicast policies allow the receiver of multicast packets to specify desired source addresses to the router, so that only packets originating from the specified sources are delivered. IGMP is used by the client to inform the router of the specified addresses.

The SSM translate policy allows you to create global sets of SSM translate items that can be mass-delivered to many routers at once. Every policy has one or more SSM translate items. When the policy is distributed, all of these items are deployed to the target base routers.

52.7 7210 SAS multipoint bandwidth management policies

52.7.1 Overview

A 7210 SAS Multipoint Bandwidth Management policy defines rate limits and burst sizes for multipoint queues, to balance flows with unicast traffic. The policy defines an aggregate rate for all multipoint traffic in the NE. Rates for individual queues are configured as a percentage of the aggregate rate.

In the 7210 SAS-X, SAP ingress and network ingress multipoint traffic is separated from unicast traffic and forwarded into multipoint queues before being replicated to the appropriate egress port. There are eight multipoint queues per NE, which are shared by all services. Packets are forwarded to multipoint queues based on the forwarding classes assigned during ingress. The FC-to-queue mapping is not user-configurable.

The NFM-P provides a default multipoint bandwidth management policy. The default policy is applied if no user-defined policy is explicitly assigned. The default policy specifies maximum rate and burst size settings. See the NE documentation for more information.

52.8 MCAC interface policies

52.8.1 Overview

An operator can configure one or more MCAC (Multicast CAC) interface policies under a global MCAC context to prioritize and limit the mandatory and unconstraint bandwidth values across the supported interfaces in one or more VPRN/EIS services via a Global Route Table (GRT).

When a single MCAC interface policy is used by multiple interfaces in the network, channel admittance on one interface impacts the available bandwidth on all interfaces that share the same MCAC interface policy. Changing policy values behaves the same way as if the change to

mandatory or unconstrained bandwidth was applied on an interface level.

If a MCAC interface policies is deployed together with per interface unconstrained and mandatory bandwidth constraints, a given multicast group must satisfy the MCAC conditions defined by the MCAC interface policy and by the interface to be admitted. If ESM is deployed on an interface and per-subscriber MCAC is enabled, then the per-subscriber MCAC must also be satisfied.

You can configure MCAC interface policies on 7x50 devices; this policy type can be associated with the following object/interface/policy types:

- VPLS SAP
- VPLS Spoke SDP and MVPL Spoke SDP
- IGMP Interface on base router and VPRN service
- MLD Interface on base router and VPRN service
- PIM Interface on base router and VPRN service
- IGMP Group Interface on IES and VPRN services
- MLD Group Interface on IES and VPRN services
- MSAP policy

52.9 To configure a multicast package policy

52.9.1 Purpose

You can use multicast package policies to:

- define a set of broadcast channels that are multicast across a ring group in a BTV VLAN
- assign a common set of multicast groups to all NEs in an MVR VPLS to ensure accuracy and consistency

52.9.2 Steps

1

Choose Policies→Multicast→Multicast Package from the NFM-P main menu. The Multicast Package Policies form opens.

2

Click Create or select an existing policy and click Properties. The Multicast Package Policy, Global Policy (Create|Edit) form opens.

3

Configure the parameters as required.

4

Click on the Multicast Groups tab and click Create. The Multicast Group, Multiple Package Policy (Create) form opens.

Note: Each multicast group that is specified must be preconfigured in the PIM configuration. See the PIM configuration procedures in Chapter 28, “Routing protocol configuration”.

5

Configure the parameters as required.

6

Save the form. The Multicast Package Policy, Global Policy (Create|Edit) reappears.

7

Click Apply to save the policy. Additional buttons appears on the form.

8

Click Search, select a policy in the list and click Distribute to manually release and distribute the policy locally to devices in the ring. See 49.6 “To release and distribute a policy” (p. 1476) for additional information. Policies are also automatically distributed to devices when they are used by resources on the device.

Note: When any new devices are added to the ring, the policy is automatically distributed to any new MVR VLAN service or to any new MVR VLAN service sites in the ring.

9

Close the form.

Note: You can create other multicast package policies from the root policy by clicking on the Copy button, as required. These child policies of the root policy can be used to help differentiate the types of BTV services being created, for example, basic services and premium services.

END OF STEPS

52.10 To configure an egress multicast group policy

Note: An egress multicast group policy cannot be applied to SR NE variants at Release 15.0 R1 and higher.

52.10.1 Steps

1

Choose Policies→Multicast→Egress Multicast Group from the NFM-P main menu. The Egress Multicast Group Policies form opens.

2

Click Create or select an existing policy and click Properties. The Egress Multicast Group, Global Policy (Create|Edit) form opens.

3

Configure the parameters as required.

4

Click on the SAP Common Requirements tab and configure the parameters as required.

5

Click Select in the Egress Filter panel to choose an egress ACL IP filter policy and click OK. See 51.5 “To configure an ACL IP filter policy” (p. 1671) for information about configuring an ACL IP filter policies.

Note: The egress ACL IP filter policy that you choose for this egress multicast group must be the same as the egress ACL IP filter policy specified for a member SAP.

6

Click Select in the Egress Filter IPv6 panel to choose an egress IPv6 filter policy and click OK. See 51.6 “To configure an ACL IPv6 filter policy” (p. 1677) for information about configuring IPv6 filter policies.

7

Click Apply to save the policy. Additional buttons appears on the form.

8

Click Search, select a policy in the list and click Distribute to manually release and distribute the policy locally to devices. See 49.6 “To release and distribute a policy” (p. 1476) for more information. Policies are also automatically distributed to devices when they are used by resources on the device.

Note: To associate a SAP on the device with an EMG, the access port encapsulation type on the device must be the same as the encapsulation type that you specified in Step 4.

9

Close the form.

END OF STEPS

52.11 To configure a multicast CAC policy

52.11.1 Steps

1

Choose Policies→Multicast→Multicast CAC from the NFM-P main menu. The Multicast CAC Policies form opens.

Note: Multicast CAC policies are not supported on VSR or 7705 SAR-Hm chassis types.

2

Click Create or select an existing policy and click Properties. The Multicast CAC, Global Policy (Create|Edit) form opens.

3

Configure the parameters as required.

4

Click on the Bundles tab and click Create to associate a multicast bundle with the multicast CAC policy.The Multicast CAC Bundle (Create) form opens.

5

Configure the parameters as required.

6

Click on the Channels tab and click Create. The Multicast CAC Channel, Multicast CAC Bundle (Create) form opens.

7

Configure the parameters as required.

8

Save your changes. The Multicast CAC Bundle (Create) form reappear and lists the newly configured channel.

9

Click Search, select a policy in the list and click Distribute to manually release and distribute the policy locally to devices. See 49.6 “To release and distribute a policy” (p. 1476) for more information. Policies are also automatically distributed to devices when they are used by resources on the device.

10

Close the form.

End of steps

52.12 To configure an ingress multicast bandwidth policy

52.12.1 Steps

1

Choose Policies→Multicast→Ingress Multicast Path Management from the NFM-P main menu. The Ingress Path Management Policies form opens.

2

Click Create→Multicast Bandwidth Policy or select an existing policy and click Properties. The Multicast Bandwidth Policy (Create|Edit) form opens.

3

Configure the parameters as required.

4

Click on the T1 Paths tab and choose one of the primary, secondary, and ancillary paths and click Properties. The Bandwidth Policy Path (Create) form opens.

5

Configure the parameters as required.

6

Save your changes.

7

Click on the T2 Paths tab and choose the primary or secondary path and click Properties.The Bandwidth Policy Path (Create) form opens.

8

Configure the parameters as required.

9

Save your changes.

10

Click Apply to save the policy. Additional buttons appears on the form.

11

Click Search, select a policy in the list and click Distribute to manually release and distribute the policy locally to devices. See 49.6 “To release and distribute a policy” (p. 1476) for more information. Policies are also automatically distributed to devices when they are used by resources on the device.

12

Close the form.

END OF STEPS

52.13 To configure an ingress multicast information policy

52.13.1 Steps

1

Choose Policies→Multicast→Ingress Multicast Path Management from the NFM-P main menu. The Ingress Path Management Policies form opens.

2

Click Create→Multicast Info Policy or select an existing policy and click Properties. The Multicast Info Policy (Create|Edit) form opens.

3

Configure the parameters as required.

4

Click on the Bundles tab and click Create. The Info Policy Bundle, Multicast Info Policy (Create) form opens.

5

Configure the parameters as required.

6

Click on the Video Defaults tab.

7

Configure the parameters as required.

8

Configure the stream selection parameters, if enabled for the video group.

Note: Stream selection parameters are only available if you are performing the configuration on a local policy definition. After the changes are applied to the local policy, the policy can be switched back to Sync With Global mode and the local changes made to the policy are retained. See Chapter 49, “Policies overview” for information on policy distribution modes.

Proceed as follows:

1. Enter a unicast IPv4 address for the Source Address parameter.
2. Click Select to choose a primary access interface and click OK.
3. Click Select to choose a secondary access interface and click OK.

   The primary Interface and secondary Interface must be different.

9

Configure VQM if the Analyzer parameter in the VQM panel is enabled for the video group.

1. Configure the Description parameter.
2. Click on the VQM Config tab.
3. Configure the parameters as required.

10

Click on the Tunnel Interfaces tab.

11

Click Select to choose a Multicast Path Management Bundle and click OK.

12

Click Select to choose an LDP Tunnel Interface and click OK.

13

Configure the Ingress LER parameter.

You can configure either the P2MP LSP Name parameter or the P2MP ID for LDP parameter.

The Ingress LER parameter is automatically configured when the P2MP ID for LDP parameter is configured.

14

Click on the Channels tab and click Create.The Info Policy Channel Range, Info Policy Bundle (Create) form opens.

15

Configure the parameters as required.

The 7450 ESS does not support channel ranges and channel overrides having IPv6 addresses. Therefore, the NFM-P does not allow the creation of such channel ranges and channel overrides on local Ingress Multicast Info policies. In addition, the NFM-P removes any such

channel ranges and channel overrides when synchronizing local Info policies with their respective global policies.

16

Click on the Video tab.

17

Configure the parameters as required.

Note: If the Stream Selection parameter is enabled for the video group, repeat Step 8 . If the Analyzer parameter in the VQM panel is enabled for the video group, repeat Step 9 .

18

Click on the Tunnel Interfaces tab and repeat Step 11 to Step 13 if required.

19

Click on the Channel Override tab and click Create to specify overrides for explicit channels within the Channel Range. The Info Policy Channel Override (Create) form opens.

20

Configure the parameters as required.

21

Save the changes.

22

Click on the Video tab.

23

Configure the parameters as required.

Note: If the Stream Selection parameter is enabled for the video group, repeat Step 8 . If the Analyzer parameter in the VQM panel is enabled for the video group, repeat Step 9 .

24

Click on the Tunnel Interfaces tab and repeat Step 11 to Step 13 if required.

25

Click on the Video Interfaces tab and click Create if you need to configure a video interface. The Multicast Video Interface (Create) form opens.

Note: If you are configuring a video interface you must perform the configuration in the local policy definition. After the changes are applied to the local policy, the policy can be switched back to Sync With Global mode and the local changes made to the video

interface are retained. See Chapter 49, “Policies overview” for information on policy distribution modes. See Chapter 35, “ISA-Video” for more information about IPTV video features and configuration.

26

Configure the Address parameter.

27

Click on the Channel Config tab and select a channel and click Properties. The Multicast Video Interface Channel Config (Create) form opens.

28

Configure the parameters as required.

29

Save the changes. The configured channels are displayed.

30

Repeat Step 27 to Step 29 to configure additional channels, if required.

31

Save your changes. The Multicast Info Policy (Create|Edit) form reappears.

32

Click Distribute to manually release and distribute the policy locally to devices in the ring. See 49.6 “To release and distribute a policy” (p. 1476) for additional information. Policies are also automatically distributed to devices when they are used by resources on the device.

33

You can view information on VPLS sites (regular sites and I-Sites), VPRN sites, and Default Routing Instances affected by the Multicast Info Policy by clicking the appropriate tab. Run a search and view the properties for the desired item.

34

Click Search to display the newly created policy or policies in the bottom panel of the form.

END OF STEPS

52.14 To configure an ingress multicast reporting destination policy

52.14.1 Steps

1

Choose Policies→Multicast→Ingress Multicast Path Management from the NFM-P main menu. The Ingress Path Management Policies form opens.

2

Click Create→Multicast Reporting Destination or select an existing policy and click Properties. The Multicast Reporting Destination, Global Policy (Create|Edit) form opens.

3

Configure the parameters as required.

4

Click Apply to save the changes. The form refreshes to display additional tabs and buttons.

5

Click Distribute to manually release and distribute the policy locally to devices. See 49.6 “To release and distribute a policy” (p. 1476) for additional information. Policies are also automatically distributed to devices when they are used by resources on the device.

6

Close the forms.

END OF STEPS

52.15 To configure an SSM translate policy

Note: IGMP must be enabled on the routers to which you intend to distribute the SSM translate policy.

52.15.1 Steps

1

Choose Policies→Multicast→SSM Translate from the NFM-P main menu. The SSM Translate Policies form opens.

2

Click Create or select an existing policy and click Properties. The SSM Translate Policy (Create|Edit) form opens.

3

Configure the parameters as required.

4

Click on the SSM Translate Items tab and click Create. The SSM Translate Policy Item (Create) form opens.

5

Configure the parameters as required and save your changes. The SSM Translate Policy (Create|Edit) form reappears.

Note: The SSM Translate Items added to a policy should not have overlapping IPv4 address ranges, otherwise a configuration error message will be issued.

6

Click Apply to save your changes. The form refreshes to display additional tabs and buttons.

7

Click Distribute to manually release and distribute the policy locally to devices. See 49.6 “To release and distribute a policy” (p. 1476) for additional information. Policies are also automatically distributed to devices when they are used by resources on the device.

Note: When you distribute an SSM Translate policy to a router, it replaces any SSM Translate policy that may exist on that router. All existing SSM Translate Items on the router will be overwritten.

8

Close the SSM Translate Policy (Create|Edit) form. The SSM Translate Policies form reappears.

9

Click Search to display the newly created policy or policies in the bottom panel of the form.

END OF STEPS

52.16 To configure a 7210 multipoint bandwidth management policy

52.16.1 Steps

1

Choose Policies→Multicast→7210 Multipoint Bandwidth Management Policies from the NFM-P main menu. The 7210 Multipoint Bandwidth Management Policies form opens.

2

Click Create or choose a policy and click Properties. The 7210 Multipoint Bandwidth Management, Global Policy (Create|Edit) form opens.

3

Configure the required parameters.

4

Configure the multipoint queues.

1. Click on the Queues tab. Eight default queues are displayed.
2. Choose a queue and click Properties. The Multipoint Bandwidth Queue (Create) form opens.
3. Configure the required parameters.
4. Save your changes and close the form.

5

Save the policy and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

6

Assign the policy to a 7210 SAS-X.

1. On the network navigation tree, right-click on a 7210 SAS-X and choose Properties.
2. Click on the Globals tab, then the Multipoint Management tab.
3. Click Select to assign the multipoint bandwidth management policy to the 7210 SAS-X. The Select Bandwidth Policy, Network Element Form opens.
4. Select a policy and click OK.
5. Save your changes and close the form.

END OF STEPS

52.17 To configure a Multicast CAC interface policy for IPv4/IPv6

52.17.1 Steps

1

Choose Policies→Multicast→Multicast CAC Interface from the NFM-P main menu. The Multicast CAC Interface Policies form opens.

Note: Multicast CAC Interface policies are not supported on VSR or 7705 SAR-Hm chassis types.

2

Click Create or choose a policy and click Properties. The Multicast CAC Interface, Global Policy (Create|Edit) form opens.

3

Configure the required parameters.

4

Save the policy and close the form.

5

Click Distribute to manually release and distribute the policy locally to devices. See 49.6 “To release and distribute a policy” (p. 1476) for additional information. Policies are also automatically distributed to devices when they are used by resources on the device.

6

As required, create the supported object type for this policy type and associate the policy to the object by clicking the Select button. Save your changes and close the form.

Supported object type	Base configuration procedure to create the supported object	Policy location on each object type
VPLS SAP	77.67 “To create a VPLS or MVPLS L2 access interface” (p. 2332)	Click on the IGMP Snooping tab, then the General sub-tab.
VPLS Spoke SDP MVPL Spoke SDP	77.92 “To create a VPLS or MVPLS spoke SDP binding” (p. 2386)	Click on the IGMP Snooping tab, then the General sub-tab.
IGMP Interface on a base router and VPRN service	78.8 “To add an IGMP interface to an IES” (p. 2433)	Click on the Multicast CAC tab, then the General sub-tab.
MLD Interface on a base router and VPRN service	28.123 “To configure an MLD interface on a base routing instance or VPRN routing instance” (p. 1035)	Click on the Multicast CAC tab, then the General sub-tab.
PIM Interface on a base router and VPRN service	28.101 “To create a PIM interface on a base routing instance or VPRN routing instance” (p. 1013)	Click on the Multicast CAC tab, then the General sub-tab.

IGMP Group Interface on IES and VPRN services	79.42 “To add an IGMP group interface to a VPRN” (p. 2601)	For VPRNs, click on the Multicast CAC tab, then the General sub-tab. For IES service sites, click on the Multicast tab, then the IGMP Group Interfaces sub-tab or MLD Group Interface sub-tab.
MLD Group Interface on IES and VPRN services	28.125 “To configure an MLD group interface on a base routing instance or VPRN routing instance” (p. 1039)	Click on the Multicast CAC tab, then the General sub-tab.
MSAP policy	64.10 “To configure an MSAP policy” (p. 1852)	Click on the VPLS Configuration tab, then on the ICMP Snooping sub-tab.

END OF STEPS

52.18 To view NE multicast reporting destination statistics

52.18.1 Purpose

Perform this procedure to view multicast reporting destination statistics for an NE including frames and records lost and sent.

52.18.2 Steps

1

Choose Policies→Multicast→Ingress Multicast Path Management from the NFM-P main menu. The Ingress Path Management Policies form opens.

2

Choose Local from the Policy scope drop-down menu.

3

Click Select to choose an NE. The Select a Network Element form opens.

4

Choose an NE and click OK. The NE IP address is displayed in the Local Node IP Address field.

5

Choose Multicast Reporting Destination (Multicast) from the object drop-down menu and click Search.

6

Choose a policy and click Properties. The Multicast Reporting Destination, Local Policy (Edit) form opens.

7

Click on the Statistics tab and click Collect to collect on-demand statistics.

8

Choose a statistics record and click Properties to view the record. The Statistics Record - Multicast Reporting Destination Stats form opens.

9

View the statistics information.

10

Close the forms.

END OF STEPS

52.19 To view multicast CAC channel statistics

52.19.1 Purpose

You can view multicast CAC channel statistics to determine:

- the status of BTV channels on a managed NE
  - which channels are blocked
  - the channel location
  - the channel bandwidth availability
- the number of times channel requests are dropped on an interface
- the cause of the action based on the multicast CAC policy

52.19.2 Steps

1

Choose Tools→BTV Channel Monitor from the NFM-P main menu. The Select Site form opens.

2

Select a site and click OK. The BTV Channel Monitor form opens.

3

Choose one of the following from the object drop-down menu and click Search.

a. To list network protocol statistics, choose Multicast CAC Channel Statistics (multicast).

b. To list service statistics, choose Multicast CAC Channel Statistics on Services (multicast).

A list of multicast CAC channel statistics is displayed at the bottom of the form.

Note: To get the most recent channel information on a managed NE, click Resync before clicking Search.

4

Close the form.

END OF STEPS

53 Time-of-day policies

53.1 Time-of-day policies

53.1.1 Overview

The NFM-P supports time-of-day policies that define the times when policies, filters and schedulers are in effect. You can specify a time range and apply that range to QoS policies, ACL filters, and schedulers that are applied to aggregation schedulers and L2 and L3 access interfaces. For example, a time-of-day policy allows you to manage peer-to-peer traffic by limiting access during peak hours, such as evenings and weekends.

A time range policy consists of one or more schedules that specify a start and end day and time. You can configure ongoing time ranges that recur at a specified frequency.

The default time range policy is the NO-TIME-RANGE policy, which specifies that no time and day restrictions apply. There can be only one NO-TIME-RANGE entry in each type of time-of-day suite policy entry.

A time-of-day suite policy is a collection of ingress and egress policies, filter policies, and schedulers, to which time range policies have been assigned. You can apply time-of-day suite policies to aggregation schedulers and L2 and L3 access interfaces.

You can create a time-of-day suite policy by assigning time range policies to the following objects to apply time and day restrictions to their deployment and access:

- ACL MAC filters and filter entries
- ACL IP filters and filter entries
- ACL IPv6 filters and filter entries
- access ingress and egress QoS policies
- scheduler policies

Time-of-day policies are first created globally and then distributed to NEs.

53.2 Time range assignment analysis tool

53.2.1 General Information

The time range assignment analysis tool allows you to view the time range policies that have been assigned over a specific time period to the following objects:

- L2 access interfaces
- L3 access interfaces
- aggregation schedulers
- time-of-day suite policies

You can use the time range assignment analysis tool to verify the configuration of multiple schedules and the adequacy of a time-of-day suite policy on a specific NE. For example, you can use this tool to verify that multiple time ranges that are assigned to IP filters in a time-of-day suite policy cover an entire month.

See 53.5 “To perform a time range entry assignment analysis” (p. 1735) for information about configuring time range assignment analysis.

53.3 To configure a time range policy

53.3.1 Steps

1

Choose Policies→Time of Day→Time Range from the NFM-P main menu. The Time Range Policies form opens.

2

Click Create, or choose a policy in the list. The Time Range (Create|Edit) form opens.

3

Configure the required general parameters.

4

Configure one or more time ranges.

1. Click on the Time Range Entries tab.
2. Click Create, or choose an entry in the list and click Properties. The Time Range Entries (Create) form opens.
3. Configure the Time Settings parameters.

   When the Ongoing parameter is enabled, the Frequency parameter is available.

   When the Frequency parameter is set to Weekly, the Start Run Day and End Run Day parameters are available.
4. Save your changes and close the form.

5

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

53.4 To configure a time-of-day suite policy

53.4.1 General Information

Consider the following when you create a time-of-day suite policy:

- when there are overlapping time range policy entries within a time-of-day suite policy, the time range policy entry with the highest priority is applied first
- only one time-of-day suite policy entry without a time range (default NO-TIME-RANGE) is allowed for each type of policy
- you cannot modify a time-of-day suite policy entry after you create the entry
- you cannot assign the same priority of a global policy within the same policy type
- you cannot assign the same priority of a local policy within the same policy type
- you cannot assign the same time range of a global policy within the same policy type
- you cannot assign the same time range a local policy within the same policy type
- you cannot distribute a time-of-day suite policy entry to a local policy if the local policy already has been assigned the same time range as the global policy
- you cannot distribute a time-of-day suite policy entry to a local policy if the local policy already has been assigned the same priority as the global policy
- all time-of-day suite policy entries of a local policy are replaced by the time-of-day suite policy entries of a global policy if none of the entries from the local policy have the same priority or time ranges as the global policy

53.4.2 Steps

1

Choose Policies→Time of Day→Time Of Day Suite from the NFM-P main menu. The Time Of Day Suite Policies form opens.

2

Click Create, or choose a policy and click Properties. The Time of Day Suite (Create) form opens.

3

Configure the required general parameters.

4

Click on the TOD Suite Entries tab.

5

Configure time-of-day suite entries for ingress traffic. Click on the Ingress tab and perform any of the following:

a. Associate time ranges with ingress filter policies.
   1. Click on the IP Filter, IPV6 Filter or MAC Filter tab. A list of available time range policies is displayed.
   2. Click Create, or choose an entry in the list and click Properties. The Ingress *type_of_filter* (Create) form opens.
   3. Configure the Priority parameter.
   4. Click Select in the Time range panel and choose a time range policy.
   5. Click Select in the Policy ID panel and choose a filter policy.
   6. Save your changes and close the form.

b. Associate time ranges with ingress QoS policies.
   1. Click on the QoS tab. A list of available time range policies is displayed.
   2. Click Create, or choose an entry in the list and click Properties. The Ingress QoS (Create) form opens.
   3. Configure the Priority parameter.
   4. Click Select in the Time range panel and choose a time range policy.
   5. Click Select in the Policy panel, or 7210 Policy panel, and choose a QoS policy.
   6. Save your changes and close the form.

c. Associate time ranges with ingress scheduler policies.
   1. Click on the Schedulers tab. A list of available time range policies is displayed.
   2. Click Create, or choose an entry in the list and click Properties. The Ingress Scheduler (Create) form opens.
   3. Configure the Priority parameter.
   4. Click Select in the Time range panel and choose a time range policy.
   5. Click Select in the Policy Name panel and choose a scheduler policy.
   6. Save your changes and close the form.

6

Configure time-of-day suite entries for egress traffic. Click on the Egress tab and perform any of the following:

a. Associate time ranges with egress filter policies.
   1. Click on the IP Filter, IPV6 Filter or MAC Filter tab. A list of available time range policies is displayed.
   2. Click Create, or choose an entry in the list and click Properties. The Egress *type_of_filter* (Create) form opens.
   3. Configure the Priority parameter.
   4. Click Select in the Time range panel and choose a time range policy.
   5. Click Select in the Policy ID panel and choose a filter policy.
   6. Save your changes and close the form.

b. Associate time ranges with egress QoS policies.
   1. Click on the QoS tab. A list of available time range policies is displayed.
   2. Click Create, or choose an entry in the list and click Properties. The Egress QoS (Create) form opens.
   3. Configure the Priority parameter.
   4. Click Select in the Time range panel and choose a time range policy.
   5. Click Select in the Policy ID panel and choose a QoS policy.
   6. Save your changes and close the form.

c. Associate time ranges with egress scheduler policies.
   1. Click on the Schedulers tab. A list of available time range policies is displayed.
   2. Click Create, or choose an entry in the list and click Properties. The Egress Scheduler (Create) form opens.
   3. Configure the Priority parameter.
   4. Click Select in the Time range panel and choose a time range policy.
   5. Click Select in the Policy Name panel and choose a scheduler policy.
   6. Save your changes and close the form.

7

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

53.5 To perform a time range entry assignment analysis

53.5.1 Steps

1

Choose Tools→Time Range Entry Assignments from the NFM-P main menu. The Time Range Entry Assignments form opens.

2

Click Select and choose a site for the analysis.

3

Configure the Time Range Entry Container Type parameter, then click Select to choose a specific object of the configured container type.

4

If required, configure the Search by Time Of Day Entry Type and Time Of Day Entry Policy Type parameters.

5

Configure the Start Date and End Date parameters.

6

Click Search. A list of time range entries that meet the defined criteria is displayed.

7

Double-click on an entry to view information about the time range policy and time-of-day suite policy. The Time Range Entry Assignment: *Start Date End Date* form opens.

8

Close the forms.

END OF STEPS

54 Routing policies

54.1 Routing policies

54.1.1 Overview

Routing policies, also known as route redistribution policies, are used to make routing decisions based on policies that override the default routing protocol decisions. Normally, when a router receives a packet, where it is forwarded to is based on the destination address in the packet, which is then used to look up an entry in a routing table.

You may have a requirement to forward a packet based on other criteria to reach a destination. For example, you can selectively apply routing policies based on prefix and community access lists, packet size, advertised routes, the size and contents of the routing table, and other user-defined criteria. Additional user actions can also be applied to define user-defined routes, and to set the precedence, the type of service bits, and the damping method for the routes.

There are no default routing policies on the NFM-P. Each policy must be created and applied to an object, a routing protocol, or the forwarding table. Each set of rules that is associated with controlling routes are called routing policy statement entries on the client GUI. For example, use routing policies to:

- control routing protocols, such as BGP, to allow routes from another protocol, such as OSPF, into the routing table, which allows the routing table to redistribute packets into other protocols
- control the import and export of learned active routes of a protocol
- modify the characteristics of a route, for example, to change the community values of BGP AS path attributes
- prevent the routes for specific customers from being added to routing tables
- control BGP route flapping

54.2 Supported NE routing policies

54.2.1 General Information

The following table describes the NE routing policies you can configure using the NFM-P. The table below describes the additional functions you can perform with routing policies.

Table 54-1 NFM-P supported NE routing policies

Routing policy type	Purpose	See
Statement	This policy defines the flow control actions taken if a route matches all the conditions specified by the policy. Flow control actions determine whether to accept or reject the route or whether to evaluate the next term or routing policy. In addition, you can configure a multicast redirection interface as part of the routing policy statement to ensure that multicast IGMP traffic coming from the access network is only passed onto downstream devices once.	54.5 “To configure a routing policy statement” (p. 1745) 54.6 “To configure a multicast redirect interface on a local routing policy statement” (p. 1750)
Prefix List	This policy defines a list of IP prefixes members used by the Routing policy statement that specifies the matching criteria used for incoming routes. A prefix list is a named list of IP addresses. You can specify an exact match with incoming routes and apply a common action to all matching prefixes in the list.	54.7 “To configure a prefix list policy” (p. 1752)
Community	This policy defines the community members used for routing policy entries and provide a means of grouping destinations to which routing decisions can be applied, for example, to change the community values of BGP AS path attributes.	54.8 “To configure a community policy” (p. 1752)
Damping	This policy defines the damping mechanism used to control BGP route flapping which reduces the number of update messages sent between BGP peers, thereby reducing the load on these peers, without adversely affecting the route convergence time for stable routes.	54.9 “To configure a damping policy” (p. 1755)
AS Path	This policy defines the AS path to a destination and is used for both route selection and to prevent routing loops. An AS path consists of the AS numbers of the networks that a packet traverses if it takes the associated route to a destination.	54.10 “To configure an AS Path policy” (p. 1756)
AS Path group	This policy defines the match conditions based on an AS path group which consists of multiple AS paths to which a single routing policy can be applied.	54.11 “To configure an AS Path Group policy” (p. 1756)
Accounting Template Policy	This policy defines if accounting statistics are collected on IP interfaces for received packets and bytes that are sourced from or destined for routes marked with the class indexes contained in the policy. An accounting template policy can be associated with the following interfaces on base routers, IES services, and VPRN services: • network interfaces • L3 access interfaces • tunnel interfaces • subscriber group interfaces	54.12 “To configure an accounting template policy” (p. 1757)
Administrative Group	This policy defines the administrative groups that can be assigned to MPLS interfaces, LSPs, LSP paths, L3 interfaces for VPRN and IES services, or flexible algorithm definitions. You can also assign Administrative groups to network interfaces at the base routing instance. See 54.2.2 “Administrative Group policies” (p. 1740) for more information.	54.13 “To configure an administrative group policy” (p. 1758)

Table 54-1 NFM-P supported NE routing policies (continued)

Routing policy type	Purpose	See
Shared Risk Link Group	This policy defines which links in a network share a common fiber which, in the event one link fails, other links in the group may fail therefore they have a shared risk. See 54.2.3 “Shared Risk Link Group policies” (p. 1741) for more information. In addition, you can create a static configuration for a SRLG Policy to manually enter the SRLG membership for links in the entire network into the SRLG database.	54.14 “To configure a Shared Risk Link Group policy” (p. 1759) 54.15 “To create a static configuration for a SRLG Policy” (p. 1761)
Route Next Hop Template	This policy defines the policy control for the Loop-Free Alternate Shortest Path First (LSA SPF) feature which is used to reduce the routing transition time in case of link/router failures. A Route Next Hop Template policy can be applied to OSPFv2, OSPFv3 and IS-IS interfaces on base routing instances and VPRN services.	54.16 “To configure a route next hop template policy” (p. 1762)
Re-Assembly Profile	This policy defines the timers that assure all expected fragments of a packet are received within an expected time frame, on a per forwarding class basis. When the specified timer expires, all of the fragments of an incomplete frame are dropped. The system visits the reassembly queues every 64 ms in a constant loop, which causes up to a 63 ms variation between the user configured value and the actual detection time. For example, with the default configuration of 2000 ms, the system visits the reassembly queue timer at 1999 ms in which case there will not be a timeout. The timeout will occur during the next visitation at 2063 ms.	54.17 “To configure a re-assembly profile policy” (p. 1764)
Maintenance Policy	This policy provides BFD template information to support segment routing seamless BFD sessions. The maintenance policy must be associated with a segment routing static policy for a seamless BFD session to be created; see 28.77 “To create a segment routing policy” (p. 976).	54.18 “To configure a maintenance policy” (p. 1764)
Route Distinguisher	This policy defines the route distinguisher (RD). A route distinguisher is an 8-byte value that is prepended to an IPv4 or IPv6 prefix to ensure that the resulting BGP NLRI is unique within the routing domain that propagates BGP routes for this prefix. An RD set is a list of one or more route-distinguisher entries. Each route-distinguisher entry matches one or more route-distinguisher values depending on the use of wildcards.	54.25 “To configure a route distinguisher policy” (p. 1771)

Table 54-2 Additional routing policy functions

Policy function	Purpose	See
View policy variable usage in a routing policy statement	Allows you to view policy variable usage in a routing policy statement. Policy variables are defined in a (main) routing policy statement and are essentially pointers to certain other routing policy types. They are subsequently called by a subordinate routing policy statement that is specified in the main policy.	54.20 “To view policy variable usage in a routing policy statement” (p. 1766)
View routing policy usage	Allows you to display which NEs are currently using a global or local version of certain routing policy type.	54.21 “To view routing policy usage” (p. 1767)

Table 54-2 Additional routing policy functions (continued)

Policy function	Purpose	See
Shows the routing policy CLI configuration in the client GUI	Allows you to display the output of the **show router policy** *policy_type* CLI command on the NFM-P GUI.	54.22 “To show a routing policy CLI configuration in the client GUI” (p. 1768)
Verify BGP routes against a routing policy statement	Allows you to verify BGP routes against a routing policy statement to identify the prefixes that are matched or not matched by the policy, before attaching the prefix to a routing neighbor or instance.	54.23 “To verify BGP routes against a routing policy statement” (p. 1769)
Verify a BGP prefix list against a routing policy statement	Allows you to verify a BGP prefix list against a routing policy statement to identify the accepted and rejected route entries.	54.24 “To verify a BGP prefix list against a routing policy statement” (p. 1770)
Configure a global policy variable	Global variables function similarly to policy variables, but allow for more efficient configuration, because they can be configured once, then selected in multiple routing policy statements. This eliminates having to manually configure a policy variable in every routing statement. Support for global variables depends on the NE and release; see the NE documentation for information.	54.19 “To configure global variables” (p. 1765)

54.2.2 Administrative Group policies

Administrative group policies define administrative groups that can be assigned to MPLS interfaces, LSPs, LSP paths, and L3 interfaces in VPRN and IES services. You can also assign Administrative groups to network interfaces at the base routing instance, and to flexible algorithm definitions in NE global properties. After you configure the administrative groups, they can be assigned to interfaces and paths on their respective properties forms. Multiple administrative groups can be assigned to each of these objects.

When establishing LSP and LSP paths, devices only consider MPLS interfaces which are associated with the same administrative group as the LSP or LSP path. MPLS interfaces advertise administrative group associations using CSPF. This is done using the 32 bit mask which you configure using the Value parameter on the administrative group policy form.

An administrative group can also be assigned to be explicitly excluded from LSPs and LSP paths. The device cannot use MPLS interfaces in the administrative group to establish LSPs or LSP paths. Administrative group exclusion takes priority over administrative group inclusion.

CSPF must be enabled on LSPs for administrative groups to be relevant. You can enable and configure CSPF on the LSP properties form. When CSPF is enabled on an LSP, it is automatically enabled on associated LSP paths. LSP paths can be configured on the LSP path properties form to inherit additional CSPF, administrative group, and other parameters from LSPs.

The following table describes where to find information about assigning administrative groups.

Table 54-3 Administrative group assignments

To assign groups to	See Procedure
MPLS interfaces	31.7 “To create an MPLS interface” (p. 1120) in Chapter 31, “MPLS”
LSPs	31.10 “To create a static LSP” (p. 1124) in Chapter 31, “MPLS”
LSP paths	31.22 “To configure an LSP path” (p. 1144) in Chapter 31, “MPLS”
L3 interfaces	27.17 “To create an L3 network interface on a routing instance” (p. 856) in Chapter 27, “NE routing and forwarding”
Flexible algorithm definitions	12.5 “To modify NE properties” (p. 343) in Chapter 12, “Device object configuration”

54.2.3 Shared Risk Link Group policies

SRLG policies defines which links in a network share a common fiber which, in the event one link fails, other links in the group may fail therefore they have a shared risk. SRLGs are constructs which allow you to perform two operations that enhance overall system reliability.

SRLGs policies are associated with MPLS interfaces; an MPLS interface can belong to multiple SRLGs. SRLGs can also assigned to network interface at base routing instance and to L3 access interface of VPRN & IES service.

You can use SRLGs to establish a FRR LSP path and you also use SRLGs to establish a secondary LSP path which is disjointed from the primary LSP path. SRLG avoids the need to define MPLS path hops for secondary LSPs and creation of static bypass tunnels and management of these LSPs to achieve the same result dynamically.

Links that are members of the same SRLG represent resources which share the same risk. For example, fiber links sharing the same conduit, or multiple wavelengths sharing the same fiber.

An SRLG is modeled as a policy object. It therefore follows the normal policy behavior for creation, listing, updating, deletion, distribution, and re synchronization.

The SRLGs are used by the CSPF when computing a FRR detour/bypass path, or a secondary LSP path. SRLGs indicate to the CSPF which interfaces to avoid in the path’s computation. CSPF can include the SRLG penalty weight in the computation of a FRR detour or bypass for the protection of the primary LSP path at a PLR NE. Configured SRLGs can be associated with MPLS interfaces, and network, tunnel, and L3 access interfaces on base routers, VPRN services, and IES services.

The following table describes where to find information about related MPLS and LSP procedures.

Table 54-4 Related MPLS and LSP procedures

To:	See Procedure:
Configure an MPLS instance	31.6 “To configure an MPLS instance” (p. 1116) in Chapter 31, “MPLS”
Create an MPLS interface	31.7 “To create an MPLS interface” (p. 1120) in Chapter 31, “MPLS”
Configure LSP paths	31.22 “To configure an LSP path” (p. 1144) in Chapter 31, “MPLS”
Configure L3 interfaces	27.17 “To create an L3 network interface on a routing instance” (p. 856) in Chapter 27, “NE routing and forwarding”

54.3 Routing policy design considerations

54.3.1 General information

Careful planning is essential to implementing routing policies that affect the flow of routing information or packets traversing managed devices. Before configuring and applying a routing policy, consider the following:

- Develop an overall plan and strategy to accomplish your intended routing actions.
- Analyze the effect of what happens to a packet that meets the specified criteria in a routing policy statement entry to ensure the proper action is executed and that no routing loops are created.
- Ensure that routing policy statement entries are properly numbered, so they will be compared to packets in the correct order. Entries are compared in the numerical sequence of the Entry IDs, from lowest to highest. Nokia recommends staggering the numerical Entry ID values (for example, using 10, 20, 30… instead of 1, 2, 3…), to allow insertion of additional entries. The NFM-P supports renumbering existing entries on supporting NEs.
- When possible, redistribute from a lower-level routing protocol to a higher-level routing protocol; for example, from RIP to OSPF.
- Redistribute exported routes at a single device, when possible.
- To ensure routing configuration flexibility, the following routing policies can be configured as separate policies or can be cross-referenced to form a framework of policies depending on the network requirements:
  - Policy Statement
  - Prefix List
  - Community
  - Damping
  - AS Path
- Policies that are cross-referenced are distributed together. For example, a Policy Statement can reference the Prefix List policy by matching the From Criteria and the To Criteria for each policy type. In addition, policy variables can be defined in an upper-level routing Policy Statement, and then called by a specified subordinate routing Policy Statement. The variables are pointers to certain types of routing policies, including Community Lists, AS Paths, AS Path Groups, and Prefix Lists. To improve configuration efficiency, you can create global policy variables (for supporting NEs) and assign them to multiple routing policy statements. This routing policy parameterization allows operators a powerful and flexible approach to the configuration of routing policies.
- When IGMP join requests originate from subscriber host sessions, the NE can use a multicast redirection policy to redirect the requests to a plain (non-ESM) L3 access interface. Additionally, individual local routing policy statements can be configured with a multicast redirect action to redirect specific IGMP join requests for processing at the subscriber level.
- Imported BGF, OSPF, and RIP learned routes can be altered using import and export route policies. For example, for devices learning about routes from BGP or OSPF, you can create an import route policy that can limit the number and types of routes accepted and added to the routing tables. For exporting routes, some default behaviors exist:
  - internally learned routes are redistributed using the same protocol

  - externally learned routes are not automatically advertised to all neighbors or peers
- In the case of externally learned routes, you can create an export policy to determine how the routes are advertised; for example, configuring something learned by BGP to be redistributed using OSPF. This is useful in cases:
  - where legacy equipment does not support a specific protocol
  - when companies merge and they use different routing protocols on the devices

54.4 Routing policy decision sequence

54.4.1 General information

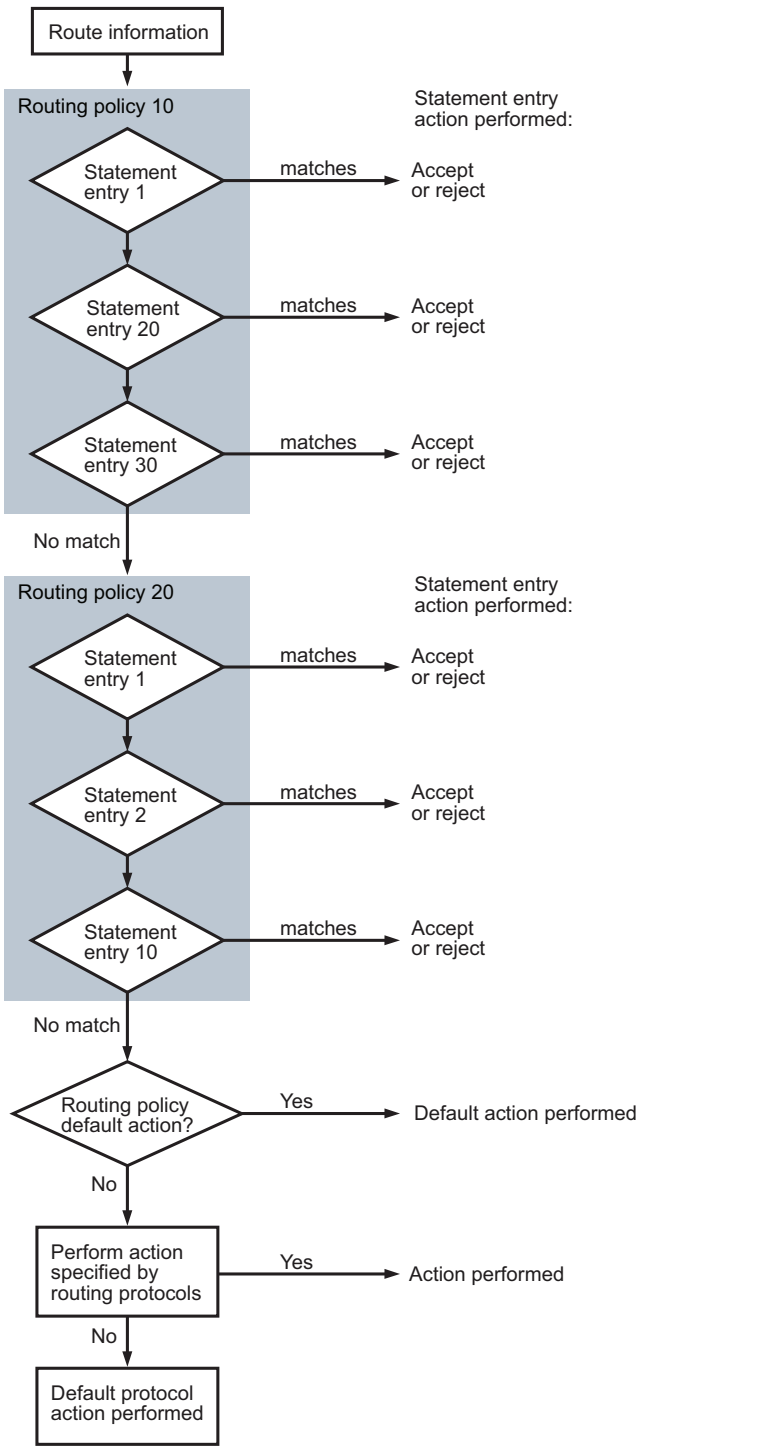
Routing policy statements and routing policy statement entries are compared against incoming packets in the following sequence.

1. The routing packets arrive.
2. The first routing policy is analyzed.
3. The first entry in the routing policy statement is analyzed. Entries are compared in sequence based on the Entry ID, from lowest to highest.

   If a match is found based on the first routing policy statement entry, the specified action is performed. You can use the Action parameter to specify the continued evaluation of route policy entries, or additional policy statements.
4. If no match is found, the packet is compared against the second routing policy statement entry. If a match is found based on the second routing policy statement entry, the specified action is performed.
5. If no match is found, the packet is compared sequentially against all remaining routing policy statements and routing policy statement entries. If a match is found, the specified action is performed.
6. If the packet does not match any routing policy statements or entries, the default action is performed.

   The following figure shows how routes are analyzed using routing policies.

Figure 54-1 Routing policy analysis workflow



54.4.2 No action/default action routing policy decision sequence

When no action or default action in a routing policy is matched on a packet, then the routing protocols determine the default action for the packet. The action can be specified for the protocol. If the action is not specified, there are default routing protocol import and export actions performed, as described in the following table.

Table 54-5 Default routing protocol actions

Protocol	Default import route action	Default export route options
BGP	All routes from BGP peers are accepted and forwarded to the BGP route selection process.	All active internal BGP routes are advertised to BGP peers. All non-BGP learned routes are not advertised to BGP peers.
IS-IS	IS-IS route acceptance cannot be configured. All IS-IS routes are accepted from IS-IS neighbors.	All internal IS-IS routes are advertised to all IS-IS neighbors. All non-IS-IS learned routes are not advertised to IS-IS neighbors.
OSPF	OSPF route acceptance cannot be configured. All OSPF routes are accepted from OSPF neighbors.	All OSPF routes are advertised to all OSPF neighbors. All non-OSPF learned routes are not advertised to OSPF neighbors.
RIP	All RIP-learned routes are accepted from RIP peers.	All non-RIP learned routes are not advertised to RIP peers.

54.5 To configure a routing policy statement

54.5.1 Steps

1

Choose Policies→Routing→Statement from the NFM-P main menu. The Routing Policy - Statements form opens.

2

Click Create or choose a policy and click Properties. The Routing Policy - Statement, Global Policy form opens.

3

Configure the required parameters on the General tab.

Note: Do not create a new routing policy statement with the following terms as the Policy Statement Name: N/A, n/a, or @. Creating a routing policy statement with @ in the Policy Statement Name results in Template Inconsistent/Configuration Mismatch alarms, which

do not clear after a synchronization with the global policy. Also, updating the policy statement name using node CLI as N/A is not valid.

If you set the Default Action parameter to Accept, Next Entry, Next Policy, or Reject/Drop, the Default Action tab is selectable. Go to Step 4.

If you set the Default Action parameter to None, go to Step 6.

4

Configure a default action for the routing policy statement. Click on the Default Action tab and perform the following on the General tab:

1. Configure the parameters, policy variables, and global variables on the General sub-tab, as required.

   Note:

   If you want to specify a policy variable for an action item on this tab, select the policy statement entry that defines the required policy variable.

   If you want to specify a policy variable for an action item on this tab, then you cannot configure a corresponding parameter Value for the same item. They are mutually exclusive.

   If you want to specify a global variable for an action item on this tab, select the global variable entry that defines the required global variable. Global variables are configured in 54.19 “To configure global variables” (p. 1765).

2. Click on the Path sub-tab and configure the BGP AS path parameters and variables, as required.

   Note:

   A BGP AS Path Name must be selected if the BGP AS Path Action is set to Add or Replace.

   You cannot specify both a BGP AS Prepend Number and a BGP AS Prepend Policy Variable. They are mutually exclusive.

   If you are specifying a BGP AS Prepend Policy Variable, this is done by selecting the policy statement entry that defines the required variable.

   If you want to specify a global variable for an action item on this tab, select the global variable entry that defines the required global variable. Global variables are configured in 54.19 “To configure global variables” (p. 1765).

5

Configure the default community actions for the routing policy statement.

1. Click on the Default Community Actions tab and click on the Add, Remove, or Replace sub-tabs as required to perform the specific action that you want to configure.
2. Click Select to add, remove, or replace a Community Name Action. Review the usage notes provided below the Community Name Action field and implement, as required.

Note: You can specify mid-string expansions such as "peer-@asname@" or "comm-@peeras@-add" for example, for the Community Name Action field. However, there is no validation on the parameterized mid-strings entered for communities.

6

Configure policy statement entries for the routing policy statement.

Note: Routing policy entries are compared against incoming packets. Entries are compared in the numerical sequence of the Entry IDs, from lowest to highest. When a match is found, the action specified using the Action parameter occurs. If no action is specified, the action specified using the Default Action parameter occurs. If no default action is specified, the default action for the protocol or the route configuration occurs. For this reason, Nokia recommends that you sequence the routing policy entries to ensure the first entry is the most explicit and the last entry is the least explicit.
Nokia recommends staggering the numerical Entry ID values (for example, using 10, 20, 30… instead of 1, 2, 3…), to allow insertion of additional entries without renumbering the entire set. The NFM-P supports renumbering existing entries on supporting NEs.

1. Click on the Policy Statement Entries tab.
2. To renumber an entry on an existing policy statement, choose the entry in the list and click Renumber ID. Repeat for each additional entry that requires renumbering.

   When the routing policy statement is redistributed to NEs that support entry renumbering, the new Entry ID values are used.
3. Click Create, or choose a policy in the list and click Properties. The Policy Statement Entry, Site form opens.
4. Configure the required parameters on the General tab.

   Select a policy variable for the SRv6 Sid Prefix Address parameter, configure the SRv6 Sid Prefix Length parameter, and select a global variable for the Policy/Global Variable parameter.

   You can choose to enable or disable either or both the To Criteria and From Criteria here, whether they are configured or not.

   If you set the Action parameter to Accept, Next Entry, or Next Policy, the Action tab is selectable. Go to Step 7 .

   If you set the Action parameter to None or Reject/Drop, go to Step 8 .

7

Click on the Action tab to configure actions for the policy statement entry.

1. Configure the parameters and select policy variables on the General sub-tab, as required.

   Notes:

   You must configure the SR Maintenance Policy parameter in order to select the policy variables in the SRv6 Return Path BFD and SR Return Path BFD Label panels.

   If you want to specify a policy variable for a subordinate policy action item on this tab, this is done by selecting the policy statement entry that defines the required variable. Such a policy statement entry is typically part of another existing (higher level) routing policy statement.
2. Click on the Path sub-tab and configure the BGP AS path parameters, as required.

   Note:

A BGP AS Path Name must be selected if the BGP AS Path Action is set to Add or Replace.

You cannot specify both a BGP AS Prepend Number and a BGP AS Prepend Policy Variable. They are mutually exclusive.

If you are specifying a BGP AS Prepend Policy Variable, this is done by selecting the policy statement entry that defines the required variable. Such a policy statement entry is typically part of another existing (higher level) routing policy statement.

3. Click on the Community Actions tab to configure a community action for the policy statement entry.
4. Click on the Add, Remove, or Replace sub-tabs as required to perform the specific action that you want to configure.
5. Click Select to add, remove, or replace a Community Name Action. Review the usage notes provided below the Community Name Action field and implement as required.

   Note:

   You can specify mid-string expansions such as "peer-@asname@" or "comm-@peeras@-add" for example, for the Community Name Action field. However, there is no validation on the parameterized mid-strings entered for communities.

8

Configure the From criteria for the policy statement entry.

1. Click on the From Criteria tab, select a route distinguisher policy, and configure the parameters on the General sub-tab, as required.

   Note:

   If you are performing this procedure to create a subordinate (lower level) routing policy that needs to specify an AS Path Name, AS Path Group Name, or Community List Name as a policy variable (defined in a higher level routing policy), then these policy variables are selected at this step.

   If you are performing this procedure to create a main (higher level) routing policy that contains policy variables that will be called by a subordinate routing policy, then that subordinate routing policy name must be specified at this step using the Policy Statement Name parameter. The policy variables for this higher level routing policy are defined in Step 10 .

   You cannot add policies that have nested sub-policies.

   Configuring a Community List Name in this step, either by selection or as a policy variable, is mutually exclusive with creating a Community List Expression in Step 9 .
2. Click on the Prefix Lists sub-tab to assign a prefix list to the policy statement entry.

   The Prefix Lists sub-tab displays if you did not assign a prefix list on the Prefix List Override sub-tab.
3. Configure the Prefix List Members as required.

   Note:

   You can specify mid-string expansions such as "prefixA-@prefixB@" or "prefixA-@prefixB@-add" for example, in the Prefix List field. However, there is no validation on the parameterized mid-strings entered for prefix lists.

4. Click on the Prefix List Override sub-tab.

   The Prefix List Override sub-tab displays if you did not assign a prefix list on the Prefix Lists sub-tab.

5. Select the prefix list and configure the required parameter.

   Depending on the option that you selected for the Type parameter, additional parameters may display.

9

Create a community expression list for the policy statement entry.

1. Click on the Community Expression tab and click Create. The Community Expression, Site form opens.
2. Select or enter a Community Name.
3. Click the Add button to add an entry into the Community List Expression field. The following conditions apply to this parameter:
   - The entire Community List Expression is limited to 900 characters. Use Boolean operators (AND, OR, and NOT) to form expressions, and use parentheses to form more complex expressions. For example:

     `[comlist1] AND ([comlist3] OR [comlist4])`
   - If you make an error in the construction of the string, use the Clear All button to start again, or place your cursor in the field and manually edit the text.
4. Save your changes and close the form.

10

Create a policy variable for the policy statement entry.

This step is required if you are creating a main (higher level) routing policy that will be called by a subordinate (lower level) routing policy. A policy variable in this context may be an integer, an IPv4/IPv6 address, or a string (that is, a pointer to another routing policy type). If you want to select the Type as a String, then you must create the other routing policy type (for example, Prefix List or Community policy) before you start this step. You can create up to ten policy variables for each policy statement entry.

1. Click on the Policy Variables tab and click Create. The Policy Variable, Site form opens.
2. Configure the Name parameter for the policy variable. The name must begin and end with an “@” sign; for example: @variable-name_1@.
3. Configure the Type and Value parameters. If you configure Type as String, then click Select to choose and assign a routing policy to the policy variable.
4. Click OK. The Policy Variable, Site form reappears.
5. Click OK to save your changes and close the form.

Note: You can configure global policy variables (for supporting NEs) that you can assign to multiple routing policy statements to improve configuration efficiency; see 54.19 “To configure global variables” (p. 1765).

11

Configure the To criteria for the policy statement entry.

1. Click on the To Criteria tab and configure the parameters on the General tab, as required.
2. Click on the Prefix Lists sub-tab and configure the Prefix List Members as required.

12

Configure a conditional expression for the policy statement entry.

1. Click on the Conditional Expression tab and click Create. The Conditional Expression, Site form opens.
2. Specify a conditional expression for the Route Exists String parameter, or click on the Select button to select an existing prefix list policy.
3. Save your changes and close the form.

13

To create an additional policy statement entry, go to Step 6 otherwise go to Step 14 .

14

Save your changes and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

Note: A routing policy is discovered as local edit only. To synchronize a routing policy with all NEs, you must change the distribution mode of the routing policy to sync with global. To configure the distribution mode, see 49.6 “To release and distribute a policy” (p. 1476) .

15

See 54.20 “To view policy variable usage in a routing policy statement” (p. 1766) to view policy variable usage in a distributed routing policy statement.

END OF STEPS

54.6 To configure a multicast redirect interface on a local routing policy statement

54.6.1 General Information

To perform this procedure, you must use a global routing policy statement that has been released and distributed to one or more NEs. See 54.5 “To configure a routing policy statement” (p. 1745) for more information.

54.6.2 Steps

1

Choose Policies→Routing→Statement from the NFM-P main menu. The Routing Policy - Statements form opens.

2

Choose a policy and click Properties. The Routing Policy - Statement form opens.

3

Click on the Local Definitions tab. The sites the Routing policy statement is distributed to are listed.

4

Choose a site and click Properties. The Routing Policy - Statement, Site Local Policy form opens.

5

Click on the Policy Statement Entries tab.

6

Choose a policy statement and click Properties. The Policy Statement Entry, Routing Policy, Site form opens.

7

Click on the Action tab.

The Action tab is only available if the Action parameter on the Policy Statement was set to Accept, Next Entry, or Next Policy.

8

Click Select to choose an interface in the Multicast Redirection panel. The Select Interface - Policy Statement Action - Site form opens.

9

Select an interface and save your changes. The Policy Statement Entry, Routing Policy, Site form reappears.

10

Save your changes and close the form. The Policy Statement Entry, Routing Policy, Site form reappears. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

END OF STEPS

54.7 To configure a prefix list policy

54.7.1 Steps

1

Choose Policies→Routing→Prefix List from the NFM-P main menu. The Routing Policy - Prefix Lists form opens.

2

Click Create or choose a policy and click Properties. The Routing Policy Prefix List, Global Policy form opens.

3

Configure the required parameters on the General tab.

4

Click on the Prefix List Members tab and click Create. The Prefix List Member, Site form opens.

5

Configure the required parameters.

Note: The Begin Length and Through Length parameters are configurable when the Type parameter value is set to Range or Through.
A prefix list policy can be created without creating prefix list members. These can be added to the policy at a later date.

6

Save your changes and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

Note: A routing policy is discovered as local edit only. To synchronize a routing policy with all NEs, you must change the distribution mode of the routing policy to sync with the global policy. See 49.9 “To change the distribution mode of a policy” (p. 1482) to change the distribution mode of a routing policy.

End of steps

54.8 To configure a community policy

54.8.1 Steps

1

Choose Policies→Routing→Community from the NFM-P main menu. The Routing Policy - Communities form opens.

2

Click Create or choose a policy and click Properties. The Routing Policy - Community, Global Policy form opens.

3

Configure the required parameters on the General tab.

4

Perform one of the following:

Note: You must create at least one Community Expression or Community Member for this policy type.

a. To create a Community Expression, go to Step 5 .

b. To create a Community Member, go to Step 6 .

5

Click on the Community Expression tab and click Create. The Community Expression, Site (Create) form opens.

1. Configure the Exact Match parameter as required.
2. Enter a string in the Community Expression text field. Use Boolean operators to define the policy actions between different values. Valid expression operators include: AND, OR, and NOT. For example, if you enter the following string:

   `target:5:1000 OR target:9:10`

   then the policy matches a route that has either target. Or if you enter:

   `2:2 AND 200:200`

   then the policy only matches a route that has both targets.

   The Boolean operators can also be used with parentheses and combined into a more complex expression, such as:

   `(8:8 AND NOT 9:9) OR (7:7)`

   In this case, the policy matches a route which contains the regular expression for target 8:8 with the exception of target 9:9, or just target 7:7 alone.

Any community, extended community, large community, or well-known community can be part of the Community Expression. Valid values for the Community Expression's components include:

- Community Values, such as 100:100
- Extended Community Values, such as target:1:1, origin 1:1, target:1.1.1.1:1, or origin 1.1.1.1:1. On supporting NEs, flowspec-set:<ext-asnum>:<group-id>, and flowspec-set-trans:<ext-asnum>:<group-id> are configurable; see the NE documentation.
- Regular expressions for origins, such as origin:.*&.*
- Regular expressions for communities, such as 100|200:100|200

- Regular expressions for extended community values, for example, Extended Community Bandwidth:<as-number>:<value in Mbps> to specify link bandwidth
- Large Community Values (on supporting NEs; see the NE documentation)
- Well-known Community values

Note:

When constructing a Community Expression, Community IDs must be limited to 75 characters maximum, and regular expressions must be limited to 72 characters maximum. The entire Community Expression must be limited to 900 characters maximum.

Community Expressions are supported on the 7750 SR, 7750 SR-c12, 7750 SR-12E, and 7450 ESS. IOM3 is required, in chassis mode B, C, or D.

3. Save your changes. The Routing Policy - Communities form reappears. Go to Step 7 .

Note: 7x50 NEs support non-matching lists for regular expressions.

6

Click on the Community Members tab and click Create. The Community Member, Site (Create) form opens.

1. Configure the Community Member parameter.

For extended communities, use the generic format of ext:<value1>:<value2> or ext:<regex1>&<regex2>, where:

- ext is a keyword similar to target and origin
- <value1> if 4 hex digits, then <value2> can have 1-12 hex digits
- <value1> if 2 hex digits, then <value2> can have 1-14 hex digits
- <regex1> is a regular expression that can match a pattern of 4 hex digits representing the first 2 bytes of the extended community
- <regex2> is a regular expression that can match a pattern of 1-12 hex digits representing the last 6 bytes of the extended community

Use of the <regex> attributes can provide flexibility for removing multiple extended communities from a BGP route.

Note:

If you are configuring an origin validation state extended community for BGP SIDR, configure ext:xx[yy]:value, where ext indicates an extended community and value indicates the new origin validation state, from 0 to 299.

The ext format has following restrictions:

- <value1> must have the value 4300, specifying a non-transitive opaque extended community
- <value2> can have values 0, 1, or 2, corresponding to the three possible origin valid states

If you are configuring a link bandwidth extended community, then configure the Community Member as: bandwidth:<as-number>:<value in Mbps>

If you are creating a flowspec-set or flowspec-set-trans community member that will be used in an embedded filter, set the group-ID value to the same value configured for the

Group ID parameter in 51.9 “To configure an embedding filter with embedded filter policies” (p. 1686). The format for flowspec-set and flowspec-set-trans values is <AS-number>:<group-ID>.

2. Save your changes. The Routing Policy - Communities form reappears. Go to Step 7 .

7

Save your changes and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

Note: A routing policy is discovered as local edit only. To synchronize a routing policy with all NEs, you must change the distribution mode of the routing policy to sync with the global policy. See 49.9 “To change the distribution mode of a policy” (p. 1482) to change the distribution mode of a routing policy.

End of steps

54.9 To configure a damping policy

54.9.1 Steps

1

Choose Policies→Routing→Damping from the NFM-P main menu. A Routing Policy - Dampings form opens.

2

Click Create or choose a policy and click Properties. A Routing Policy - Damping, Global Policy form opens.

3

Configure the required parameters on the General tab.

4

Save your changes and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

Note: A routing policy is discovered as local edit only. To synchronize a routing policy with all NEs, you must change the distribution mode of the routing policy to sync with the global policy. See 49.9 “To change the distribution mode of a policy” (p. 1482) to change the distribution mode of a routing policy.

End of steps

54.10 To configure an AS Path policy

54.10.1 Steps

1

Choose Policies→Routing→AS Path from the NFM-P main menu. A Routing Policy - AS Paths form opens.

2

Click Create or choose a policy and click Properties. A Routing Policy - AS Path, Global Policy form opens.

3

Configure the required parameters on the General tab.

4

Save your changes and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

Note: A routing policy is discovered as local edit only. To synchronize a routing policy with all NEs, you must change the distribution mode of the routing policy to sync with the global policy. See 49.9 “To change the distribution mode of a policy” (p. 1482) to change the distribution mode of a routing policy.

END OF STEPS

54.11 To configure an AS Path Group policy

54.11.1 Steps

1

Choose Policies→Routing→AS Path Group from the NFM-P main menu. The Routing Policy - AS Path Groups form opens.

2

Click Create or choose a policy and click Properties. The Routing Policy - AS Path Group, Global Policy form opens.

3

Configure the required parameters on the General tab.

Note: You must create at least one AS Path Group Entry for this policy type.

4

Click on the AS Path Group Entries tab and click Create. The AS Path Group Entry, Site form opens.

1. Configure the required parameters. If the Regular Expression you enter is invalid, then the OK and Apply buttons are disabled.
2. Save you changes and close the form. The Routing Policy - AS Path Group, Global Policy form reappears.

5

Save your changes and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

Note: A routing policy is discovered as local edit only. To synchronize a routing policy with all NEs, you must change the distribution mode of the routing policy to sync with the global policy. See 49.9 “To change the distribution mode of a policy” (p. 1482) to change the distribution mode of a routing policy.

End of steps

54.12 To configure an accounting template policy

54.12.1 Steps

1

Choose Policies→Routing→Accounting Template Policy from the NFM-P main menu. The Routing Policy - Accounting Template Policy form opens.

2

Click Create or choose a policy and click Properties. The Routing Policy - Accounting Template, Global Policy form opens.

3

Configure the required parameters on the General tab.

4

Configure a destination class index for the policy.

1. Click on the Destination Class Indexes tab and click Create. The Destination Index form opens.
2. Configure the required parameter.
3. Save your changes close the form.

5

Configure a source class index for the policy.

1. Click on the Source Class Indexes tab and click Create. The Source Index form opens.
2. Configure the required parameter.
3. Save your changes close the form.

6

Save your changes and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

Note: A routing policy is discovered as local edit only. To synchronize a routing policy with all NEs, you must change the distribution mode of the routing policy to sync with the global policy. See 49.9 “To change the distribution mode of a policy” (p. 1482) to change the distribution mode of a routing policy.

END OF STEPS

54.13 To configure an administrative group policy

54.13.1 General Information

See 54.2.2 “Administrative Group policies” (p. 1740) in this chapter for more information.

54.13.2 Steps

1

Choose Policies→Routing→Administrative Group from the NFM-P main menu. The Routing Policy - Administration Group Policy form opens.

2

Click Create or choose a policy and click Properties. The Administrative Group Policy, Global Policy form opens.

3

Configure the required parameters on the General tab.

4

Click Apply to save the policy and to access the additional tabs on the form.

5

Configure the parameters or view the information associated with each tab as required. Table 54-6, “Description of Administrative group form tabs” (p. 1759) describes the tabs you can configure/view.

Table 54-6 Description of Administrative group form tabs

Tab	Description
Local Definitions	Lists Administrative group policies and allows you to manage administrative group policy distribution.
LSPs	Lists and allows you to manage LSPs to which the administrative group has been assigned.
LSP-Path Bindings	Lists and allows you to manage LSP paths to which the administrative group has been assigned.
Interfaces	Lists and allows you to manage interfaces to which the administrative group has been assigned. You can access the following interface types on the sub-tabs: • MPLS • L3 access • network • tunnel
P2MP LSPs	Lists and allows you to manage P2MP LSPs to which the administrative group has been assigned.
Route Next-Hop	Lists and allows you to manage the next-hop to which the administrative group has been assigned.
Flexible Algorithm Definition	Lists and allows you to manage flexible algorithm definitions to which the administrative group has been assigned.
Faults	List and manage alarms related to the administrative group.

6

Save your changes and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

Note: A routing policy is discovered as local edit only. To synchronize a routing policy with all NEs, you must change the distribution mode of the routing policy to sync with the global policy. See 49.9 “To change the distribution mode of a policy” (p. 1482) to change the distribution mode of a routing policy.

END OF STEPS

54.14 To configure a Shared Risk Link Group policy

54.14.1 General Information

See 54.2.3 “Shared Risk Link Group policies” (p. 1741) in this chapter for more information.

54.14.2 Steps

1

Choose Policies→Routing→Shared Risk Link Group from the NFM-P main menu. The Routing Policy - Shared Risk Link Group Policy form opens.

2

Click Create or choose a policy and click Properties. The Shared Risk Link Group, Global Policy (Create|Edit) form opens.

3

Configure the required parameters on the General tab.

4

Click Apply to save the policy. The form refreshes with additional tabs.

5

Configure the parameters or view the information associated with each tab as required. Table 54-7, “Description of Shared Risk Link Group Policy form tabs” (p. 1759) describes the tabs you can configure/view.

6

Configure the parameters or view the information associated with each tab as required. Table 54-7, “Description of Shared Risk Link Group Policy form tabs” (p. 1759) describes the tabs you can configure/view.

Table 54-7 Description of Shared Risk Link Group Policy form tabs

Tab	Description
Local Definitions	Lists Shared Risk Link Group policies and allows you to manage policy distribution.
Interfaces	Lists and allows you to manage MPLS interfaces to which the SRLG policy has been assigned. You can access the following interface types on the sub-tabs: • MPLS • L3 access • network • tunnel
Faults	List and manage alarms related to the SRLG.

7

Save your changes and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

Note: A routing policy is discovered as local edit only. To synchronize a routing policy with all NEs, you must change the distribution mode of the routing policy to sync with the global policy. See 49.9 “To change the distribution mode of a policy” (p. 1482) to change the distribution mode of a routing policy.

END OF STEPS

54.15 To create a static configuration for a SRLG Policy

54.15.1 General Information

This procedure differs from the standard SRLG policy configuration described in 54.14 “To configure a Shared Risk Link Group policy” (p. 1759) by allowing you to manually enter the SRLG membership into the SRLG database for links in the entire network.

54.15.2 Steps

1

Choose Policies→MPLS→Shared Risk Link Group Static Configuration from the NFM-P main menu. The Shared Risk Link Group Static Configuration Policies form opens.

2

Click Create or choose a policy and click Properties. The Static Configuration for SRLGs Policy form opens.

3

Configure the required parameters on the General tab.

4

Click Apply to save the policy.

The Static Configuration for SRLGs Policy form is refreshed and the tabs become selectable. The following table describes the tabs that you can choose to configure parameters or view fault information.

Table 54-8 Description of Static Configuration for SRLG Policy form tabs

Tab	Description
Local Definitions	Lists Static Configuration for SRLG policies and allows you to manage policy distribution.
Routers	Lists and allows you to manage existing static configuration entries or add new ones.
Faults	List and manage alarms related to the static configuration for SRLGs.

5

Click on the Routers tab and click Create. The Router for Static Config for SRLG policy form opens.

6

Configure the required parameters.

7

Save your changes and close the form. The router(s) you added appears in the list on the Routers tab.

8

Repeat Step 5 to Step 7 if you need to add other routers, otherwise, go to Step 9 .

9

Select one of the routers and click Properties. The Router for Static Config for SRLG policy form opens.

10

Configure the Admin State parameter if required.

11

Click on the Interfaces tab and click Create. The Static Configuration for SRLGs Policy, Global Policies form opens.

12

Configure the required parameters.

Note: You can associate the same Interface Ip Address parameter with more than one SRLG.

13

Click Apply and repeat Step 9 to Step 12 to add other entries or save your changes and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

Note: A routing policy is discovered as local edit only. To synchronize a routing policy with all NEs, you must change the distribution mode of the routing policy to sync with the global policy. See 49.9 “To change the distribution mode of a policy” (p. 1482) to change the distribution mode of a routing policy.

END OF STEPS

54.16 To configure a route next hop template policy

54.16.1 Steps

1

Choose Policies→Routing→Route Next Hop Template Policy from the NFM-P main menu. The Routing Policy - Route Next-Hop Template Policy form opens.

2

Click Create or choose a policy and click Properties. The Routing Policy - Route Next-Hop Template, Global Policy form opens.

3

Configure the required parameters on the General tab.

4

Configure included groups for the policy.

1. Click on the Include Group tab and click Create. The Route Next-Hop Admin Group Include Entry, Create Admin Group Entry form opens.
2. Click Select to choose an Admin Group Policy. The Select Admin Group Name - Route Next-Hop Admin Group Include Entry form opens.
3. Click Create or choose a group. The Administrative Group Policy, Global Policy form opens.
4. Configure the required parameters.
5. Click OK. The Select Admin Group Name - Route Next-Hop Admin Group Include Entry form reappears.
6. Select an entry and click OK. The Route Next-Hop Admin Group Include Entry form reappears.
7. Click OK. The Routing Policy - Route Next-Hop Template, Global Policy form reappears.

5

Configure excluded groups for the policy.

1. Click on the Exclude Group tab and click Create. The Route Next-Hop Admin Group Exclude Entry, Create Admin Group Entry form opens.
2. Click Select to choose an Admin Group Policy. The Select Admin Group Name - Route Next-Hop Admin Group Exclude Entry form opens.
3. Click Create or choose a group. The Administrative Group Policy, Global Policy form opens.
4. Configure the required parameters.
5. Click OK. The Select Admin Group Name - Route Next-Hop Admin Group Exclude Entry form reappears.
6. Select an entry and click OK. The Route Next-Hop Admin Group Exclude Entry form reappears.
7. Click OK. The Routing Policy - Route Next-Hop Template, Global Policy form reappears.

6

Save your changes and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

Note: A routing policy is discovered as local edit only. To synchronize a routing policy with all NEs, you must change the distribution mode of the routing policy to sync with the global policy. See 49.9 “To change the distribution mode of a policy” (p. 1482) to change the distribution mode of a routing policy.

END OF STEPS

54.17 To configure a re-assembly profile policy

54.17.1 Steps

1

Choose Policies→Routing→Re-Assembly Profile Policy from the NFM-P main menu. The Re-Assembly Profile Policies form opens.

2

Click Create or choose a policy and click Properties. The Re-Assembly Profile, Global Policy form opens.

3

Configure the required parameters on the General tab.

4

Configure a forwarding class.

1. Click on the Forwarding Class tab.
2. Click Create. The Forwarding Class Reassembly Profile form opens.
3. Configure the parameters and click OK.

5

Save your changes and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

Note: A routing policy is discovered as local edit only. To synchronize a routing policy with all NEs, you must change the distribution mode of the routing policy to sync with the global policy. See 49.9 “To change the distribution mode of a policy” (p. 1482) to change the distribution mode of a routing policy.

END OF STEPS

54.18 To configure a maintenance policy

54.18.1 Steps

1

Choose Policies→Routing→ Maintenance Policy from the NFM-P main menu. The Manage Maintenance Policies form opens.

2

Click Create or choose a policy and click Properties. The Maintenance Policy, Global Policy form opens.

3

Configure the required parameters on the General tab.

4

Configure a BFD template

1. Click Select in the BFD Template panel. The Select BFD Template form opens.
2. Click Search to populate the list of available BFD templates.
3. Select a template or click Create. See 28.25 “To configure a BFD template policy” (p. 911) to create a BFD template.
4. Click OK to close the Select BFD Template form.

5

Save your changes and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

Note: A routing policy is discovered as local edit only. To synchronize a routing policy with all NEs, you must change the distribution mode of the routing policy to sync with the global policy. See 49.9 “To change the distribution mode of a policy” (p. 1482) to change the distribution mode of a routing policy.

END OF STEPS

54.19 To configure global variables

54.19.1 Before you begin

For supporting NEs, you can create global variables and assign them to routing policy statements. Global variables are similar to policy variables, but allow for more efficient configuration, because they can be configured once, then selected in multiple routing policy statements; see 54.5 “To configure a routing policy statement” (p. 1745).

54.19.2 Steps

1

Choose Policies→Routing→Global Variables from the NFM-P main menu. The Routing Policy - Global Variables form opens.

2

Click Create or choose a variable and click Properties. The Routing Policy - Global Variables (Create|Edit) form opens.

3

Configure the Name parameter for the global variable. The name must begin and end with an “@” sign; for example: @variable-name@.

4

Configure the required parameters.

When you configure the Type parameter to Prefix, you must configure the Value parameter to an IP or IPv6 address and also configure the Prefix parameter.

A global variable may be an integer, an IPv4/IPv6 address, or a string. A string is a pointer to another routing policy type (for example, a Prefix List or Community policy). If you choose STRING for the Type parameter, you must create the required routing policy first, and click Select to choose and assign the policy to the global variable.

5

Save your changes and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

6

Close the Routing Policy - Global Variables form.

END OF STEPS

54.20 To view policy variable usage in a routing policy statement

54.20.1 General Information

To perform this procedure, you must use a global routing policy statement that has been released and distributed to one or more NEs; see 54.5 “To configure a routing policy statement” (p. 1745) .

54.20.2 Steps

1

Choose Policies→Routing→Statement from the NFM-P main menu. The Routing Policy - Statements form opens.

2

Click Search and choose the required policy, then click Properties. The Routing Policy - Statement form opens.

3

Click on the Local Definitions tab. A list of NEs is displayed to which the policy was distributed.

4

Choose a site and click Properties. The Routing Policy - Statement form for the local definition opens.

5

Click on the Policy Statement Entries tab. A list of policies statement entries appears.

6

Choose an entry and click Properties. The Policy Statement Entry, Site form opens.

7

Click on the From Criteria tab.

8

Click Expand Policy adjacent to the Policy Statement Name field. A window opens and displays the show command from the NE. The policy variable names defined in the main routing policy statement are seen to be replaced by the actual routing policy names they represent, provided that those routing policies exist. If a particular routing policy does not exist, the name of the policy variable calling it is shown instead.

Note: Policy mediation must contain the username and/or password for the selected NE to allow the Expand Policy function to execute.
The Policy Statement Name field displays the name of the subordinate routing policy statement that calls the policy variables defined in this main routing policy statement.

9

Close all open forms as required.

End of steps

54.21 To view routing policy usage

54.21.1 Purpose

You can use the NFM-P to display which NEs are currently using a global or local version of certain routing policy type. For some policy types, for example, a route next hop template policy, you can view the OSPF/ISIS interfaces on which the policy was applied.

Note: To perform this procedure, you must use a routing policy that has been released and distributed to one or more NEs; see 49.6 “To release and distribute a policy” (p. 1476) .
Not all NFM-P routing policies support this functionality. If you can select the Policy Usage tab associated with a distributed routing policy, then the policy is supported.

54.21.2 Steps

1

Choose Policies→Routing→*Policy type* in the NFM-P main menu where *Policy Type* is the type of policy that you want to view the routing policy usage of. The appropriate policy manager form opens.

2

Click Search and choose the required policy, then click Properties. The appropriate Routing Policy form opens.

3

Click the Policy Usage tab and click Search.

The location of Policy Usage details varies for some routing policies. For example, for Routing Policy Statements, click on the required protocol sub-tab such as LDP, BGP, or OSPF for policy usage information.

4

Choose an entry and click Properties. The properties form opens and provides

5

Close all open forms as required.

END OF STEPS

54.22 To show a routing policy CLI configuration in the client GUI

54.22.1 General Information

To perform this procedure, you must use a routing policy that has been released and distributed to one or more NEs; see 49.6 “To release and distribute a policy” (p. 1476) . You must also ensure that the mediation security policy associated with the NE is configured to allow CLI access; see 9.17 “To configure device mediation” (p. 301) .

54.22.2 Steps

1

Choose Policies→Routing→*Policy type* in the NFM-P main menu where *Policy Type* is the type of policy that you want to view. The appropriate policy manager form opens.

2

Click Search and choose the required policy, then click Properties. The appropriate Routing Policy form opens.

3

Click on the Local Definitions tab. A list of NEs is displayed to which the policy was distributed.

4

Choose a site and click Properties. The Routing *Policy_type*, Local Policy form opens.

5

Click Show Policy. A Routing Policy Show Policy window opens and the NFM-P executes a “show router policy *type*” command on the NE. The Routing Policy Show Policy window displays the command output.

6

View the policy.

7

Close all open forms as required.

END OF STEPS

54.23 To verify BGP routes against a routing policy statement

54.23.1 Purpose

Perform the following procedure to verify BGP routes against a routing policy statement. The output of the test returns the prefixes that are accepted and rejected by the policy. This test allows you to evaluate an existing routing policy against the RIB to identify the prefixes that are matched or not matched by the policy, before attaching the prefix to a routing neighbor or instance.

54.23.2 Steps

1

Perform one of the following:

a. Perform a routing policy test on a base router instance BGP site.

1. In the navigation tree Routing view, expand Network→*NE*→Routing Instance→BGP.
2. Right-click on the BGP icon and choose Routing Policy Test. The rtr BGP Routing Policy Test form opens.

b. Perform a routing policy test on a VPRN instance BGP site.

1. Choose Manage→Service→Services from the NFM-P main menu.
2. Choose a VPRN service and click Properties.
3. Navigate to the BGP Site icon in the service navigation tree. The path is Sites→Routing Instance - NE System ID→Routing Instance→Protocols→BGP Site.
4. Right-click on the BGP Site icon and choose Routing Policy Test.

2

Configure the required parameters.

You must enter the name of an existing and distributed routing policy for the Policy Name parameter.

3

Click Execute.

4

Click Close.

End of steps

54.24 To verify a BGP prefix list against a routing policy statement

54.24.1 Purpose

Perform the following procedure to verify BGP route attributes against the routing policy statement. This test allows a routing policy statement to be checked against a local definition on a user-specified NE. The supported matching criteria include community lists and BGP prefix lists (BGP NLRI).

The test results lists the accepted and rejected route entries. Associated actions for accepted entries are performed. Actioned attributes include Communities, MED, Local Preference, and Next Hop.

54.24.2 Steps

1

Choose Tools→BGP Prefix Routing Policy Test from the NFM-P main menu.

2

Click Create.

3

Configure the general parameters and select a policy statement.

4

Click on the BGP Prefix Input tab and click Create.

5

Configure the input address and BGP neighbor peer parameters. IPv4 and IPv6 addresses are supported.

6

Configure the attributes to action in the Attributes panel.

7

Click OK.

8

Repeat Step 4 to Step 7 to create another BGP Prefix Input, if required.

9

Click Execute or Execute All. Execute is used to evaluate the policy on selected BGP Prefix Inputs.

10

Click on the BGP Prefix Output tab to list the results.

11

Close the forms.

END OF STEPS

54.25 To configure a route distinguisher policy

54.25.1 Steps

1

Choose Policies→Routing→Route Distinguisher from the NFM-P main menu. The Route Distinguisher, Global Policy (Edit) form opens.

2

Configure the required parameters on the General tab.

3

Click on the Route Distinguisher Entries tab.

4

Click Create. The Route Distinguisher Entry (Create) form opens.

5

Configure the Route Distinguisher Entry parameter and click OK.

6

Save your changes and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

Note: A routing policy is discovered as local edit only. To synchronize a routing policy with all NEs, you must change the distribution mode of the routing policy to sync with global. To configure the distribution mode, see 49.6 “To release and distribute a policy” (p. 1476) .

END OF STEPS

55 VRRP policies

55.1 Overview

55.1.1 General Information

VRRP priority control-policies manage VR backup router priorities. The policies override the base priority value, depending on NE events or conditions. You can configure a VRRP policy only for the non-owner VRRP instance; the same policy can be applied to IPv4 and IPv6 VRRP instances.

The main function of a VRRP priority-control policy is to define the conditions or events that affect the VR ability to communicate with outside hosts or portions of the network. When at least one of these events is true, the base priority for the VR instance is affected in one of two ways:

- an explicit value is overridden
- a value is subtracted from the sum of delta priorities

The result is the actual in-use priority for the VR instance. Any priority event may be configured as an explicit event or a delta event. The following table describes the policy events that you can configure using the NFM-P.

Table 55-1 VRRP policy events

Policy Event	Description
Host unreachable	Configures a host unreachable priority-control event that monitors the ability of a host to receive an ICMP echo reply packet from a specific IP host address. A host unreachable priority-control event creates a continuous ICMP echo request (ping) probe to the specified IP address. During ping failure, the event is considered to be set. During ping success, the event is considered to be cleared.
IPv6 Host unreachable	Configures an IPv6 host unreachable priority-control event that monitors the ability of a host to receive an ICMP echo reply packet from a specific IPv6 host address. An IPv6 host unreachable priority-control event creates a continuous ICMP echo request (ping) probe to the specified IPv6 address. During ping failure, the event is considered to be set. During ping success, the event is considered to be cleared.
LAG port down	Configures a LAG priority-control event that monitors the operational state of the links and each port in the LAG. When one or more of the ports enters the operational down state, the event is considered to be set. When all ports enter an operational up state, the event is considered to be clear.
Route unknown	Configures a route unknown priority-control event that monitors the existence of a specific active IP route prefix in the routing table. Route unknown defines a link between the VRRP priority-control policy and the RTM. The RTM registers the specified route prefix as monitored by the policy. If any change (add, delete, new next hop) occurs relative to the prefix, the policy is notified and takes action according to the priority event definition.

Table 55-1 VRRP policy events (continued)

Policy Event	Description
Port Down Events	Configures an override or adjustment to the base priority value of a VRRP VR instance depending on the operational state of the event. Port Down events can only be configured on the local definitions of VRRP policies.
Multi Chassis IPsec Non Forwarding Events	Configures an MC IPsec priority-control event that monitors the MEP state of a device. When the MEP state is down, the event is considered to be set. When the MEP state is up, the event is considered to be clear. For more information about MC IPsec, see Chapter 41, “MC IPsec” .

As priority events clear in the policy, the in-use priority can eventually be restored to the base priority value.

55.2 To configure a VRRP priority-control policy

55.2.1 Steps

1

Choose Policies→VRRP from the NFM-P main menu. The Manage VRRP Policies form opens.

2

Perform one of the following:

a. Specify a filter to search for and edit an existing policy. Use the filters to search for and open an existing policy by choosing a policy in the filtered list and clicking on the Properties button.

b. Click Create button. The VRRP Policy (Create) form opens.

3

Configure the required parameters.

4

Click Apply.

5

Perform one of the following steps:

a. For IPv4 hosts, click on the Host Unreachable tab.

1. Click Create. The Host Unreachable Event (Create) form opens.
2. Configure the required parameters.
3. Click OK and save your changes. The Host Unreachable Event form reappears with the newly created filter entries displayed.

b. For IPv6 hosts, click on the IPv6 Host Unreachable tab.
   1. Click Create. The IPv6 Host Unreachable Event (Create) form opens.
   2. Configure the required parameters.

      The Interface Name parameter can be configured only when the host IP Address parameter is a Link Local Address.
   3. Click OK and save your changes. The IPv6 Host Unreachable Event form reappears with the newly-created filter entries displayed.

6

Perform the following to create a Lag Port Down event.

1. Click on the Lag Port Down tab.
2. Click Create. The Lag Port Down Event (Create) form opens.
3. Configure the required parameters.
4. Click on the Number Down tab.
5. Click Create. The Number Down (Create) form opens.
6. Configure the required parameters.
7. Close the Number Down (Create) form. A dialog box appears.
8. Click OK and save your changes. The Lag Port Down Event form reappears with the newly created filter entries displayed.

7

Perform the following to create a Route Unknown event.

1. Click on the Route Unknown tab.
2. Click Create. The Route Unknown (Create) form opens.
3. Configure the required parameters.
4. Click on the Next Hop tab.
5. Click Create.

   If the IP Address parameter you specify on the General tab is an IPv4 address, the NextHop (Create) form opens; if it is an IPv6 address, the NextHopV6 (Create) form opens.
6. Configure the Interface Name parameter if the IPv6 Next Hop Address is a Link Local Address.
7. Configure the Hop Address parameter.
8. Click OK and save your changes.

8

Perform the following to create a Multi Chassis IPsec Non Forwarding event.

1. Click on the Multi Chassis IPsec Non Forwarding tab.
2. Click Create. The MC IPsec Non Forwarding Event form appears.

3. Configure the required parameters.
4. Click OK and save your changes.

9

Click OK. The Manage VRRP Policies form reappears.

10

Click Search to display the newly-created policy or policies.

11

Save your changes and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

12

Close the Manage VRRP Policies form.

END OF STEPS

56 Auto tunnel policies

56.1 Auto tunnel policies

56.1.1 Overview

The NFM-P supports the automatic creation of service tunnels for groups of NEs, using mesh, hub-and-spoke, or ring topology rules. These rules, or auto tunnel policies, define the conditions for the service tunnel creation. An auto tunnel policy has the following components:

- a least one tunnel template
- a rules-based group to define which NEs are part of the tunnel group
- the topology rules, for example mesh or ring, that specify the service-tunnel characteristics, such as the type of tunnel and the underlying transport.

56.1.2 Tunnel templates

To create a tunnel template, you can create a new XML API template for service tunnel use or you can modify a provided LSP or SDP tunnel template. Use an example as a starting point to create service or tunnel templates with or without format and range policies. When a template with format and range policies is associated with an auto tunnel rule, the format and range policies defined in the template override the name defined in the auto tunnel rule.

Depending on the tunnel type selected for an auto tunnel, an SDP or LSP tunnel template can be selected. For an RSVP LSP tunnel type, one LSP template must be selected. For an RSVP SDP tunnel type, 16 LSP templates can be selected. When an LSP parent template with more than one LSP path child templates is specified, more than one LSP path is created.

A template should be configured to be deployed to a majority of the NE types. The user must validate the template and enter appropriate changes to the script before the template can be deployed in an auto tunnel policy. The parameters that can be modified depend on the template type.

56.1.3 Tunnel groups

A tunnel group is defined as collection of network resources, such as NEs, that perform the same role in the network; for example, the way that the designation of a port as an access or network port defines the role of the port in the network.

By grouping resources by role, a common policy-based management framework can be used to ensure the appropriate configuration of resources, for example, create service tunnels for different topologies.

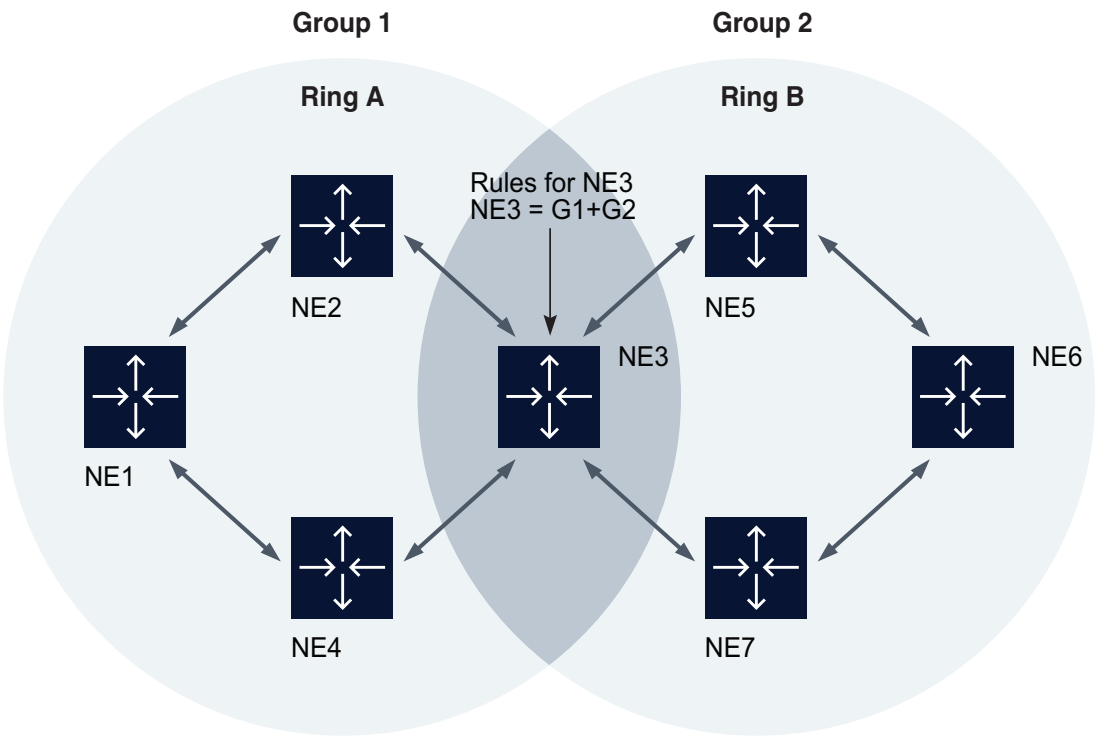
The following conditions apply to tunnel groups.

- An NE can belong to multiple groups.
- A group is ordered or unordered depending on the requirements. The members in a group must

be ordered when you create some topologies; for example, a ring topology. Topologies such as mesh or hub-and-spoke, in which NEs are not linearly arranged, do not need an ordered group.

- A non-NFM-P-managed NE can belong to the tunnel group to which it was added, however, it is not active as a destination NE during rule execution.
- When two or more tunnel groups share an NE, the shared NE performs the roles defined for each group. In Figure 56-1, “NE shared by two tunnel groups” (p. 1777), Group 1 contains routers NE1, NE2, NE3, and NE4, and Group 2 contains routers NE3, NE5, NE6, and NE7. NE3 is the intersection set of Groups 1 and 2, therefore NE3 assumes the roles defined for Groups 1 and 2.

Figure 56-1 NE shared by two tunnel groups



18983

56.2 Auto tunnel design considerations

56.2.1 General Information

The following applies to the configuration of auto tunnels:

- An NFM-P operator requires topology-management privileges to create or modify an auto tunnel.
- When an NE in a rule-based group is unmanaged or deleted, it is identified as unmanaged in the

rule-based group. Auto tunnels to the NE are not removed; however auto tunnels from the NE are removed from the NFM-P.

- When an auto tunnel rule is created for a group that contains non-NFM-P-managed NEs, auto tunnels cannot be created to and from the NE using that rule.
- When you add NEs to a tunnel group that is in use, new auto tunnels are created according to the rule definition.
- A group condition must contain at least one group of NEs.
- Auto tunnel elements are not updated dynamically.
- An unmanaged NE is removed from the tunnel groups to which the NE belongs. The associated service tunnels are also removed if they originate from a managed NE. A service tunnel that originates on an unmanaged NE is retained, but is not included in the tunnel group after reconfiguration.
- When a service tunnel created by a tunnel policy is removed, the policy does not attempt to recreate the tunnel.
- You can modify the tunnel definition in a tunnel policy when the tunnel policy has not yet created a service tunnel.

Not all NEs that are assigned to a topology rule share the same functionality. The topology rule runs capability checks on the source NEs to determine whether specific tunnels or tunnel configurations can be applied. The following table lists the auto tunnel rules that are supported by each NE.

Table 56-1 Auto tunnel rules and NE support

Auto tunnel rule	7450 ESS, 7750 SR, and 7950 XRS	7705 SAR
SDP LDP	X	X
SDP GRE	X	X
SDP LSP	X	X
Dynamic LSP	X	X
CoS-based SDP	X	—
LDP-over-RSVP	X	—

56.3 Workflow to configure auto tunnels

56.3.1 Stages

1

Configure a tunnel template from one of the following:

a. Choose Tools→Scripts from the NFM-P main menu to create a new XML API template.

b. Choose Manage→Templates from the NFM-P main menu to modify a provided LSP or SDP tunnel template.

2

Configure rule-based groups to define which NEs are part of the tunnel group; see 56.4 “To configure rule-based groups” (p. 1780).

3

Configure the required topology rules to allow for service-tunnel creation:

- for mesh or ring topology rules; see 56.5 “To create a mesh or ring topology rule” (p. 1782).
- for hub and spoke topology rules; see 56.6 “To create a hub-and-spoke topology rule” (p. 1783).

4

Configure a service and select the Automatic Mesh SDP Binding Creation parameter with the service to bind it to the previously created service tunnels. See the appropriate service chapter for more information.

Incidental tasks

5

Perform the following tasks, as required to manage auto tunnels:

- import tunnels not managed by topology rules; see 56.7 “To import tunnels not managed by topology rules” (p. 1785).
- display and delete tunnel elements; see 56.8 “To display and delete tunnel elements” (p. 1786).
- manually execute or reapply an auto tunnel topology rule; see 56.9 “To manually execute or reapply an auto tunnel topology rule” (p. 1786).
- display missing tunnel elements; see 56.10 “To view missing tunnel elements” (p. 1787).

56.4 To configure rule-based groups

56.4.1 Purpose

Perform this procedure to create or modify a rule-based group that defines which NEs are part of the tunnel group.

56.4.2 Steps

1

Choose Policies→Auto Tunnels→Rule-Based Groups from the NFM-P main menu. The Rule-Based Groups form opens.

2

Click Create and choose Rule-Based NE Group, or choose an entry and click Properties. The Rule-Based NE Group (Create|Edit) form opens.

3

Configure the required general parameters.

The Order parameter is configurable only during group creation.

4

If you are creating a new group, click Apply to save the configuration and create the group. The Group Members tab becomes available.

5

Click on the Group Members tab.

6

If you are configuring member NEs for an unordered group, perform the following. Otherwise, go to Step 7.

1. To delete existing member NEs, select the required NEs and click Delete.
2. To add member NEs, click Create. The Select Network Elements form opens.
3. Select the required NEs and click OK.
4. Go to Step 8.

7

To configure member NEs for an ordered group, perform any of the following:

a. To delete existing member NEs, select the required NEs and click Delete.

b. Add NEs in sequence.

   1. Click Create. The Select Network Elements form opens.
   2. Choose an NE and click OK.
   Add the NEs one at a time, in the required order.

   The order of NEs is shown in the Position in Group column on the Group Members tab. Position in Group is based on the sequence in which you add the NEs.

c. Insert an NE at a selected position in the group.

   1. Select a Position in Group in the list on the Group Members tab.
   2. Click Insert. The Select Network Elements form opens.
   3. Choose an NE and click OK. The NE is inserted in the list on the Group Members tab, at the position selected. From that position, existing members are displaced by one position.

8

Save your changes and close the form.

END OF STEPS

56.5 To create a mesh or ring topology rule

56.5.1 Purpose

Perform this procedure to create a mesh or ring topology rule for service tunnel creation. A template must be applied to an auto-tunnel policy. You must configure an LSP or SDP tunnel template before you can deploy a template to an LSP or SDP tunnel. .

56.5.2 Steps

1

Choose Policies→Auto Tunnels→Auto Tunnel Rules from the NFM-P main menu. The Auto Tunnel Rules form opens.

2

Click Create and choose one of the following:

a. Mesh Topology Rule. The Mesh Topology Rule (Create) form opens.

b. Ring Topology Rule. The Ring Topology Rule (Create) form opens.

3

Configure the required general parameters.

4

Add one or more rule-based groups.

1. Click on the LERs Definition tab.
2. Click Add and choose one or more tunnel groups.

5

Click on the Tunnel Definition tab and configure the Tunnel Type parameter.

6

Perform one of the following:

a. If you chose SDP as the tunnel type:

   1. Click on the SDP tab.
   2. Click Select and choose an SDP Template.
   3. Configure the required parameters.

4. If you chose RSVP-LSP or Mixed LSP Mode as the underlying transport type, configure the additional parameters. Otherwise, go to Step 7 .
5. Click on the LSPs tab, then click Add and choose an LSP template.

b. If you chose RSVP-LSP as the tunnel type:

1. Click on the LSP tab.
2. Click Select and choose an LSP Template.
3. Configure the required parameters.

7

Save your changes and close the form.

END OF STEPS

56.6 To create a hub-and-spoke topology rule

56.6.1 Purpose

Perform this procedure to create a hub-and-spoke topology rule for service tunnel creation. A template must be applied to an auto-tunnel policy. You must configure an LSP or SDP tunnel template before you can deploy a template to an LSP or SDP tunnel.

56.6.2 Steps

1

Choose Policies→Auto Tunnels→Auto Tunnel Rules from the NFM-P main menu. The Auto Tunnel Rules form opens.

2

Click Create and choose Hub and Spoke Topology Rule. The Hub and Spoke Topology Rule (Create) form opens.

3

Configure the required general parameters.

4

Add rule-based groups.

1. Click on the Hub LERs Definition tab.
2. Click Add and choose one or more tunnel groups.
3. Click on the Spoke LERs Definition tab.
4. Click Add and choose one or more tunnel groups.

5

Click on the Hub Tunnel Definition tab and configure the Tunnel Type parameter.

6

Perform one of the following:

a. If you chose SDP as the tunnel type:
   1. Click on the SDP tab.
   2. Click Select and choose an SDP Template.
   3. Configure the required parameters.
   4. If you chose RSVP-LSP or Mixed LSP Mode as the underlying transport type, configure the additional parameters. Otherwise, go to Step 7.
   5. Click on the LSPs tab, then click Add and choose an LSP template.
   6. If the Class Forwarding Capability parameter in 4 is enabled, the buttons in the Class Forwarding panel are available. If the buttons are not available, go to Step 7.
   7. Click Set as Default LSP to specify the LSP as the default, if required.
   8. Click Set as Multicast LSP to specify that the LSP is a multicast LSP, if required.
   9. Click Choose a Forwarding Class and choose a forwarding class from the contextual menu, if required.

b. If you chose RSVP-LSP as the tunnel type:
   1. Click on the LSP tab.
   2. Click Select and choose an LSP Template.
   3. Configure the required parameters.

7

Click on the Spoke Tunnel Definition tab and configure the Tunnel Type parameter.

8

Perform one of the following:

a. If you chose SDP as the tunnel type:
   1. Click on the SDP tab.
   2. Click Select and choose an SDP Template.
   3. Configure the required parameters.
   4. If you chose RSVP-LSP or Mixed LSP Mode as the underlying transport type, configure the additional parameters. Otherwise, go to Step 9.
   5. Click on the LSPs tab, then click Add and choose an LSP template.

b. If you chose RSVP-LSP as the tunnel type:
   1. Click on the LSP tab.
   2. Click Select and choose an LSP Template.

3. Configure the required parameters.

9

Save your changes and close the form.

END OF STEPS

56.7 To import tunnels not managed by topology rules

56.7.1 Purpose

Perform this procedure to import a tunnel that is not managed by a topology rule. After you import the tunnel, the tunnel is managed by the rule. However, the rule does not enforce the source and destination IDs to match the rule group. If the imported tunnel is not part of the group, the execute button or change notifications by the group members do not apply, even though the imported tunnel is part of the rule.

56.7.2 Steps

1

Choose Policies→Auto Tunnels→Auto Tunnel Rules from the NFM-P main menu. The Auto Tunnel Rules form opens.

2

Select a topology rule type from the object drop-down menu.

3

Choose a rule and click Properties. The properties form for the rule opens.

4

Click on the Created/Imported Tunnel Elements tab, then click Import Tunnels. The Import Tunnels form opens.

5

Click Add SDPs or Add LSPs and choose the required tunnels.

6

For topology rules where the tunnel definition is SDP and the underlying transport is RSVP-LSP, you can associate the imported LSP with an LSP template to avoid unnecessary LSP creation by the rule.

1. Choose an LSP from the list of imported LSPs.
2. Click Associate Template With Imported LSP and choose an LSP template from the list of LSP templates that are associated with the rule.

The Associate Template With Imported LSP button is available only for SDP-LSP rules that support the creation of multiple LSPs.

7

Click on the Import button. The Import Tunnels form closes.

8

Close the forms.

END OF STEPS

56.8 To display and delete tunnel elements

56.8.1 Steps

1

Choose Policies→Auto Tunnels→Auto Tunnel Rules from the NFM-P main menu. The Auto Tunnel Rules form opens.

2

Select a topology rule type from the object drop-down menu.

3

Choose a rule and click Properties. The properties form for the rule opens.

4

Click on the Created/Imported Tunnel Elements tab.

5

Click Search and perform one of the following to delete tunnel elements as required:

a. Click Delete Unused to delete tunnels that are no longer applied to a group.

b. Click Delete All to delete all tunnels that are not associated with a service.

6

Confirm your changes and close the forms.

END OF STEPS

56.9 To manually execute or reapply an auto tunnel topology rule

56.9.1 Purpose

Executing a topology rule causes an evaluation and reapplication of the rule.

Note: The NFM-P supports the reapply function, except in reference to hop-less path changes. If a hop-less path changes, it may not be corrected by a reapply operation.

You do not need to perform this procedure if the Auto-Rule Execution parameter was set to enabled when the rule was created. When the parameter is enabled, the rule is automatically applied to any objects that are added to the rule-based group.

56.9.2 Steps

1

Choose Policies→Auto Tunnels→Auto Tunnel Rules from the NFM-P main menu. The Auto Tunnel Rules form opens.

2

Select a topology rule type from the object drop-down menu.

3

Choose a rule and click Properties. The properties form for the rule opens.

4

Click Execute.

5

Close the form.

END OF STEPS

56.10 To view missing tunnel elements

56.10.1 Purpose

A missing tunnel element is one that the NFM-P is unable to create based on the specified tunnel rules, or a tunnel element that is deleted. Use this procedure to view such elements.

56.10.2 Steps

1

Choose Policies→Auto Tunnels→Auto Tunnel Rules from the NFM-P main menu. The Auto Tunnel Rules form opens.

2

Select a topology rule type from the object drop-down menu.

3

Choose a rule and click Properties. The properties form for the rule opens.

4

Click on the Missing Tunnel Elements tab.

5

Choose a missing tunnel element and click Properties. The properties form for the element opens.

6

View the element properties.

7

Close the forms.

END OF STEPS

57 AAA policies

57.1 AAA policy types

57.1.1 Overview

AAA policies provide security for network traffic on one or more NEs. You can use the NFM-P to create AAA policies that provide authentication, authorization, and accounting functionality. The NFM-P supports the following AAA policies:

57.1.2 Accounting on/off groups

An accounting on/off group defines a group of RADIUS server policies for the purpose of synchronizing accounting on/off messages across all policies in the group. It establishes which policy in the group acts as the controller policy, and which policies act as monitors. The accounting on/off state of the monitor policies is set by the controller policy.

The controller/monitor designation is configured on each RADIUS server policy in the group. Only one policy in a group can be designated as the controller.

57.1.3 ISA RADIUS policies

An ISA RADIUS policy defines the network security requirements used when an ISA server is configured to use a RADIUS server for AAA client requests.

The policy can also be configured to limit the sending rate of periodic logging messages to the RADIUS server, thereby reducing the chance of a backlog of pending messages accumulating at the RADIUS server.

57.1.4 L2TP RADIUS accounting policies

An L2TP RADIUS accounting policy defines the usage data collected for subscribers based on either an L2TP tunnel or an L2TP session and sends this data to a RADIUS server.

57.1.5 NAT RADIUS accounting policies

To increase logging performance (messages-per-second) and provide a reliable logging facility, a RADIUS accounting option is provided for Large Scale NAT. The configuration of a NAT RADIUS policy and its assignment to a NAT ISA group (NAT or WLAN GW) will cause the node to instruct the RADIUS user to start logging when a port-range-block is assigned to a user, or to stop logging when this block is released back into the pool.

57.1.6 RADIUS-based accounting policies

A RADIUS-based accounting policy is used to send accounting information to a RADIUS server.

When an NE uses a RADIUS-based accounting policy and the creation of a subscriber host invokes the policy, the NE generates an accounting-start packet that includes the policy parameters, and forwards the packet to a RADIUS server. Depending on the policy specifications, the NE also sends

interim update messages that contain usage statistics. When a policy is no longer used by any subscriber host, the NE sends an accounting-stop packet that contains the final usage statistics.

A RADIUS-based accounting policy specifies the type of accounting information that is forwarded to a RADIUS server. The information is one of the following:

- per-SLA profile—forwards start, stop, and interim update messages regarding SLA profile usage
- per-host and per-SLA profile—forwards the following:
  - start, stop, and interim update messages regarding SLA profile usage
  - start and stop messages for individual host sessions
- per-host only—forwards start, stop, and interim update messages for each subscriber host session

When a subscriber host disconnects, the NE sends an accounting-stop packet that contains the final usage statistics. An accounting-stop packet is also sent when a subscriber or subscriber host is deleted, or when an SLA profile instance (non-HSMDA) or subscriber instance (HSMDA) is changed.

You can reduce the volume of data that is generated by the accounting policy and sent to the RADIUS server by defining custom records. Custom records include specific counters in RADIUS accounting messages. Custom records eliminate queues or selected counters within these queues, that are not relevant for billing.

You can further decrease the number of accounting messaging by including only objects which have experienced a significant change in the specified counters. When this significant change is met, the record is generated.

57.1.7 RADIUS script policies

The RADIUS script policy references python scripts for RADIUS AAA packet manipulation in a subscriber management application. See 64.23 “To configure a RADIUS script policy” (p. 1865).

Operational states of primary and secondary RADIUS scripts

When the Up state is selected for primary or secondary scripts, the NE downloads the Python script from the specified path and copies it to the memory. If the path is invalid or the script is too long or contains syntax errors, the operational state of the script will change to the Down state. If the Python script installs correctly, the operational state of the script will remain in the Up state.

Script modifications are only applied by the NE after the script admin state has been changed to Down and then Up again.

57.1.8 RADIUS server policies

A RADIUS server policy is used to configure access to a group of RADIUS servers.

A maximum of five RADIUS server entries can be created under each RADIUS server policy. These RADIUS server entries must be created under the specified routing instance. For the global policy, the RADIUS server entries can be created within all base routing instances if Base routing instance is specified, or within the sites of the specified VPRN service if VPRN routing instance is specified. A RADIUS server entry cannot be created if Management routing instance is specified.

You can associate RADIUS server policies to Ethernet ports under 802.1x. See 57.8 “To associate a RADIUS Server policy to an Ethernet port for dot1x authentication” (p. 1799) for information.

57.1.9 Route download policies

A route download policy provides a mechanism for an NE to download (in advance) customer-assigned subnets from a RADIUS server, so that they can be re-advertised to the corresponding routing protocols. In this manner, subscriber connections can potentially be established faster because the routes are already in place. Routing protocol churn is reduced as subscribers connect and disconnect.

57.1.10 Subscriber authentication policies

A subscriber authentication policy uses RADIUS authentication to grant network access to a dynamic host. These DHCP-based policies define the parameters for dynamically-created subscriber host sessions and authenticate the sessions. They can be applied to a VPLS or IES SAP, or to a VPRN or IES group interface.

You can configure a subscriber authentication policy for LLID pre-authentication. The policy is specified as a pre-authentication policy on a local user database, as described in 74.9 “To configure a local user database for subscriber host authentication” (p. 2025).

57.1.11 Diameter peer policies

Diameter peer policies are used in a subscriber management context to provide a credit control mechanism. The diameter peer policy establishes a server/peer configuration. The NE functions as the credit control client, while the peer acts as the credit control server. The diameter peer policy is used to specify common diameter protocol parameters, while the diameter peer defines the relationship with an external diameter server. The diameter peer policy can be configured with a python policy, allowing the diameter policy to be modified by python scripts and diameter python messages.

A diameter peer policy can be configured to function as part of a redundancy configuration, based on a Gx proxy model. Two NEs run instances of Gx proxy, with one Gx proxy instance active and the other inactive. The active instance has a peering connection to DRA. The purpose of the redundancy is predictable operations recovery after an NE failure. A diameter peer policy with proxy configuration is associated with a diameter application policy which, in turn, is applied to a group interface. The diameter proxy monitors the group interface.

Peers

The diameter peer policy defines a set of peers with which to establish diameter sessions. Peers share the configuration of the policy with which they are associated, but can override individual timer parameters inherited from the policy. In addition, each peer defines transport and connection-specific parameters, values for destination-specific AVPs, and a preference value.

57.2 Workflow to configure AAA policies

57.2.1 Stages

1

As required, configure a RADIUS-based accounting policy. See 57.3 “To configure a RADIUS-based accounting policy” (p. 1793).

2

As required, configure a NAT RADIUS accounting policy. See 57.4 “To configure a NAT RADIUS accounting policy” (p. 1795).

3

As required, configure an L2TP RADIUS accounting policy. See 57.5 “To configure an L2TP RADIUS accounting policy” (p. 1796).

4

As required, configure a RADIUS server policy. See 57.6 “To configure a RADIUS server policy” (p. 1797).

5

As required, initiate an accounting on/off message from a RADIUS server policy. See 57.7 “To initiate an accounting on/off message from a RADIUS server policy” (p. 1798).

6

As required, configure an accounting on/off group. See 57.9 “To configure an accounting on/off group” (p. 1800).

7

As required, configure a route download policy. See 57.10 “To configure a route download policy” (p. 1801).

8

As required, force a route download. See 57.15 “To force a route download on an NE” (p. 1806).

9

As required, configure a subscriber authentication policy. See 57.11 “To configure a subscriber authentication policy” (p. 1802).

10

As required, configure an ISA RADIUS policy. See 57.12 “To configure an ISA RADIUS policy” (p. 1803).

11

As required, configure a diameter peer policy. See 57.13 “To configure a diameter peer policy” (p. 1804).

57.3 To configure a RADIUS-based accounting policy

57.3.1 Steps

1

Choose Policies→AAA Policies→RADIUS Based Accounting from the NFM-P main menu. The RADIUS Based Accounting Policies form opens.

2

Click Create or choose a policy and click Properties. The RADIUS Accounting Policy (Create|Edit) form opens.

3

Configure the general policy and RADIUS Attributes parameters.

If you enable the NAS Port ID checkbox, you must configure the Port Prefix Type, Port Prefix String, and Port Suffix Type parameters.

If you enable the NAS Port Type checkbox, you must configure the Port Type parameter.

If you enable the NAS Port Type checkbox and you set the Port Type parameter to Config, you must configure the Port Type Value parameter.

If you enable the Calling Station ID checkbox, you must configure the Calling Station ID Type parameter.

If you enable the NAS Port checkbox, you must configure the Port Binary Specification parameter.

4

Configure the required parameters in the Accounting and Interval panels.

Only two accounting modes can be applied in combination. The accounting modes are host accounting, queue instance accounting, and PPPoE session accounting. A subscriber host can have up to two simultaneously active accounting modes. You can configure Host Accounting Message, Queue Instance Accounting, and Session Accounting parameters to non-default values provided that SLA Only is chosen for one parameter, and not more than two accounting modes are combined.

If you configure the Delay Start Time parameter to reduce accounting messages in a dual stack PPP session configuration, you must also configure the Optimize for Session Accounting parameter on the subscriber profile to which the RADIUS accounting policy is applied; see 64.4 “To configure a subscriber profile” (p. 1840).

5

Select an accounting request script in the RADIUS Script Policy panel.

6

Select a RADIUS server policy in the RADIUS Server Policy panel.

7

Configure one or more RADIUS servers for accounting information forwarding:

1. Click on the RADIUS Servers tab and configure the required parameters.

   If you set the Router Instance parameter to VPRN, you must configure a VPRN service as a virtual router instance by selecting a VPRN service in the Service Type panel.
2. Click Create in the Servers panel.
3. Configure the required parameters.
4. Save your changes and close the form.

8

To create one or more custom queue counter configuration for a custom statistics record:

1. Click on the Custom Record tab, then on the Queue Counter Config tab.
2. Click Create or select a queue and click Properties. The Custom Queue Config (Create|Edit) form opens.
3. Configure the required parameters.

   You must select one or more ingress or egress counters in order to apply them to reference counters to the significant change delta]
4. Save your changes and close the form.

9

To create one or more custom override counter configurations you must select one or more ingress/egress counters in order to apply them to reference counters to the significant change delta.

1. On the Custom Record tab, click on the Override Counter Config tab.
2. Click Create or select an override and click Properties. The Custom Override Config (Create|Edit) form opens.
3. Configure the required parameters.
4. Save your changes and close the form.

10

Configure record criteria that define the RADIUS statistics that the NFM-P collects per queue or for all queues:

1. Click on the Significant Change Criteria tab.
2. Configure the Significant Change Delta parameter.
3. Select a queue ID to monitor for the significant change or enable the All Queues parameter in the Reference Queue panel.
4. Configure the ingress and egress counters.

5. Select an override ID or enable the All Overrides parameter in the Reference Override panel.
6. Configure the ingress and egress counters.

11

Save the policy and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

57.4 To configure a NAT RADIUS accounting policy

57.4.1 Steps

1

Choose Policies→AAA Policies→NAT RADIUS Accounting from the NFM-P main menu. The NAT RADIUS Accounting Policies form opens.

2

Click Create or select an existing NAT RADIUS accounting policy and click Properties. The NAT RADIUS Accounting Policy (Create|Edit) form opens.

3

Configure the required parameters.

4

Configure the Router Instance parameter. If you set the Router Instance parameter to VPRN, perform Step 5. Otherwise, go to Step 6.

The Router Instance parameter is configurable on the 7450 ESS and 7750 SR.

5

To configure a VPRN service as a virtual router instance for the NAT RADIUS accounting policy, select a VPRN site in the VPRN ID panel.

6

Configure RADIUS servers for the policy:

1. Click on the RADIUS Servers tab.
2. Click Create or select an existing RADIUS server and click Properties. The RADIUS Server (Create|Edit) form opens.
3. Configure the required parameters.

7

Save your changes and close the forms. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

57.5 To configure an L2TP RADIUS accounting policy

57.5.1 Purpose

Perform the following procedure to create an L2TP RADIUS accounting policy to collect usage data based on either an L2TP tunnel or an L2TP session and send this data to a RADIUS server. See 28.89 “To configure L2TP on a routing instance” (p. 989) for information on configuring an L2TP RADIUS accounting policy on a routing instance.

57.5.2 Steps

1

Choose Policies→AAA Policies→L2TP RADIUS Accounting from the NFM-P main menu. The L2TP RADIUS Accounting Policies form opens.

2

Click Create or select an existing L2TP RADIUS accounting policy and click Properties. The L2TP RADIUS Accounting Policy (Create|Edit) form opens.

3

Select a RADIUS Script policy.

4

Select a RADIUS server policy.

5

Configure the required parameters.

The Definition and Value parameters are only configurable when the NAS Port Type option is enabled.

The Bit Specification parameter is only configurable when the NAS Port option is enabled.

The Prefix Type, Prefix, and Suffix Type parameters are only configurable when the NAS Port ID option is enabled.

6

Click on the RADIUS Servers tab.

7

Configure the required parameters.

The Source Address parameter only appears when you are editing an existing local version of an L2TP RADIUS accounting policy.

8

Configure the Router Instance parameter. If you set the Router Instance parameter to VPRN, perform Step 9. Otherwise, go to Step 10.

The Router Instance parameter is configurable on the 7450 ESS and 7750 SR.

9

To configure a VPRN service as a virtual router instance for the L2TP RADIUS-based accounting policy, select a VPRN service in the VPRN ID panel.

10

Click Create or select an existing L2TP RADIUS server and click Properties. The L2TP RADIUS Server (Create|Edit) form opens.

11

Configure the required parameters.

12

Save your changes and close the forms. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

57.6 To configure a RADIUS server policy

57.6.1 Steps

1

Choose Policies→AAA Policies→RADIUS Server from the NFM-P main menu. The Radius Server Policies form opens.

2

Click Create or select an existing RADIUS server policy and click Properties. The Radius Server Policy (Create|Edit) form opens.

3

Configure the required parameters.

4

Configure the Router Instance parameter. If you set the Router Instance parameter to VPRN, select a VPRN service in the VPRN ID panel.

5

Select a Python policy.

6

Configure RADIUS scripts for the policy:

1. Select a RADIUS Accept script.
2. Select a RADIUS authentication request script.
3. Select a RADIUS accounting request script.

7

Click on the Accounting On/Off tab to configure an accounting on/off group for the policy.

1. Configure the Admin State parameter. perform 2.
2. If you set the Admin State parameter to Enabled With State Change or Enabled With Monitoring, select an accounting on/off group.

   Only one RADIUS server policy in an accounting on/off group can be configured with an Admin State parameter of Enabled With State Change.

8

Click on the RADIUS Servers tab to configure RADIUS servers for the policy.

1. Click Create or select an existing RADIUS server and click Properties. The Server Entry (Create|Edit) form opens.
2. Configure the required parameters.

9

Save your changes and close the forms. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

57.7 To initiate an accounting on/off message from a RADIUS server policy

57.7.1 Purpose

Perform the following procedure to manually send an Accounting On or Accounting Off message from a RADIUS server policy. The command is enabled only on a RADIUS sever policy that is configured as the controller in an accounting on/off group. In order to perform this procedure, the RADIUS server policy must be distributed to an NE (see Chapter 49, “Policies overview”).

57.7.2 Steps

1

Choose Policies→AAA Policies→RADIUS Server Policies from the NFM-P main menu. The Manage Radius Server Policies form opens.

2

Select a RADIUS server policy and click on the Properties button. The RADIUS Server Policy (Edit) form opens.

3

Click on the Send Accounting On/Off Message button and confirm the action.

4

In the Accounting On/Off Operation form, configure the Action parameter.

5

Click OK to send the Accounting On or Accounting Off message.

6

Close the forms.

END OF STEPS

57.8 To associate a RADIUS Server policy to an Ethernet port for dot1x authentication

57.8.1 Purpose

The RADIUS Server Authentication Policy and RADIUS Server Accounting Policy support IPv6 connectivity for dot1x. Perform this procedure to associate these Radius server policies to Ethernet ports under the 802.1x Port Authenticator tab on the Ethernet Physical Port configuration form.

57.8.2 Steps

1

Create one or more RADIUS servers.

2

On the equipment tree, expand Network→*NE*→Shelf→Card Slot *n*→Daughter Card Slot *n*→Port *n/n/n*.

3

Associate the RADIUS servers under AAA→Radius Server Policy and distribute to the NE

4

Right-click on the Port icon and choose Properties. The Physical Port (Edit) form opens.

5

Click on the 802.1x Port Authenticator tab and then click Select beside the RADIUS Server Policy Authentication and RADIUS Server Policy Accounting parameters, as required. A list of the AAA RADIUS server policies displays.

6

Select and apply the policies, as required.

7

Save your changes and close the form.

END OF STEPS

57.9 To configure an accounting on/off group

57.9.1 Steps

1

Choose Policies→AAA Policies→Accounting On/Off Group from the NFM-P main menu. The Accounting On/Off Groups form opens.

2

Click Create or select an existing accounting on/off group and click Properties. The Accounting On/Off Group (Create|Edit) form opens.

3

Configure the Displayed Name and Description parameters.

4

To manage the RADIUS server policies assigned to the accounting on/off group, click on the RADIUS Server Policies tab.

The controller policy name is displayed in the Controller panel. The monitor policies are listed in the Monitors panel.

To change a controller policy to a monitor, open its Properties form and change its accounting on/off Admin State to Enabled With Monitoring (see 57.6 “To configure a RADIUS server policy” (p. 1797)).

To change a monitor policy to a controller, open its Properties form and change its accounting on/off Admin State to Enabled With State Change (see 57.6 “To configure a RADIUS server policy” (p. 1797)).

5

Save your changes and close the forms. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

57.10 To configure a route download policy

57.10.1 Purpose

In order to configure a route download policy, you must have a RADIUS server configured on each NE that is to be associated with the route download policy (see 27.8 “To configure a RADIUS server on a routing instance” (p. 846)), and you must have a RADIUS server policy configured (see 57.6 “To configure a RADIUS server policy” (p. 1797)).

57.10.2 Steps

1

Choose Policies→AAA Policies→Route Download from the NFM-P main menu. The Route Download Policies form opens.

2

Click Create or select an existing route download policy and click Properties. The Route Download Policy (Create|Edit) form opens.

3

Configure the required parameters.

4

Click Apply. The Route Download Policy form refreshes with additional tabs.

5

Select a RADIUS server policy.

6

Save your changes and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

57.11 To configure a subscriber authentication policy

57.11.1 Purpose

Perform this procedure to create a DHCP-based subscriber authentication policy that defines the parameters for dynamically created subscriber host sessions and authenticates the sessions. The NFM-P supports up to 32 subscriber authentication policies.

57.11.2 Steps

1

From the NFM-P main menu, choose Policies→AAA Policies→Subscriber Authentication. The Subscriber Authentication form opens.

2

Click Create or select an existing subscriber authentication policy and click Properties. The Subscriber Authentication Policy (Create|Edit) form opens.

3

Configure the required parameters.

The NAS Port Bit Specification parameter is configurable when the NAS Port option is enabled for the RADIUS Attributes parameter.

The Calling Station ID Type parameter is configurable when the Calling Station ID option is enabled for the RADIUS Attributes parameter.

The Port Type parameter is configurable when the NAS Port Type option is enabled for the RADIUS Attributes parameter.

The Port Type Value parameter is configurable when the NAS Port Type option is enabled for the RADIUS Attributes parameter, and the Port Type parameter is set to Config.

The Port Prefix Type, Port Prefix String, and Port Suffix Type parameters are configurable when the NAS Port ID option is enabled for the RADIUS Attributes parameter.

4

If you need to configure PAP/CHAP user name re-writing, configure the required parameters in the User Name panel.

The Domain Name parameter is configurable when the User Name Operation parameter is set to Append, Replace, or Use As Default.

5

In the RADIUS Fallback panel, configure the required parameters.

The Local User DB Name parameter is configurable when the Fallback Action parameter is set to User DB.

6

In PPP User Name panel, configure the required parameters.

The Domain Name parameter is configurable when the User Name Operation parameter is set to Append, Replace, or Use As Default.

7

Configure RADIUS script policies.

1. Select an accept script.
2. Select a CoA script.
3. Select a request script.

8

Select a RADIUS server policy.

9

Click on the RADIUS Servers tab to configure the RADIUS servers for the policy.

1. Configure the required parameters:

   If you set the Router Instance parameter to VPRN, select a VPRN site on the VPRN ID panel.
2. Click Create. The RADIUS Entry form opens.
3. Configure the required parameters.
4. Save your changes and close the form.

10

Save your changes and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

57.12 To configure an ISA RADIUS policy

57.12.1 Steps

1

Choose Policies→AAA Policies→ISA RADIUS from the NFM-P main menu. The ISA RADIUS Policies form opens.

2

Click Create or select an existing ISA RADIUS policy and click Properties. The ISA RADIUS Policy (Create|Edit) form opens.

3

Configure the required parameters.

4

Select a Python policy.

5

Save your changes and close the form. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

57.13 To configure a diameter peer policy

57.13.1 Steps

1

Choose Policies→AAA Policies→Diameter Peer from the NFM-P main menu. The Diameter Peer Policies form opens.

2

Click Create or select an existing diameter peer policy and click Properties. The Diameter Peer Policy (Create|Edit) form opens.

3

Configure the required parameters.

On the Connection Origin panel, set the Role parameter to Proxy if you intend to configure proxy entries on local definitions of the policy after it is distributed to NEs.

4

Select a Python policy.

5

Click Apply. The Diameter Peer Policy form refreshes with additional tabs.

6

Click on The Peers tab to configure diameter peers.

1. Click Create or select an existing diameter peer object and click Properties. The Diameter Peer (Create|Edit) form opens.
2. Configure the required parameters.
3. If you want to specify local override settings for any of the timer settings for the peer, deselect the Inherit Value check box and then specify a value for the corresponding timer parameter.

   When the Inherit Value check box is selected for a timer parameter on a peer object, the timer value is inherited from the parent diameter policy.

4. Save your changes and close the form.

7

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

End of steps

57.14 To configure a proxy site on a local diameter peer policy

57.14.1 Purpose

The proxy configuration is only available on local definitions of the diameter peer policy if the parent (global) policy is configured with the connection origin role set to the Proxy option. See 57.13 “To configure a diameter peer policy” (p. 1804).

57.14.2 Steps

1

Choose Policies→AAA Policies→Diameter Peer from the NFM-P main menu. The Diameter Peer Policies form opens.

2

Select a diameter peer policy and click Properties. The Diameter Peer Policy (Edit) form opens.

3

Click on the Local Definitions tab.

4

Select a local definition item and click Properties. The Diameter Peer Policy, Local Policy (Edit) form opens.

5

Click on the Proxy tab.

6

Configure the Administrative State parameter and select a routing instance.

7

Click on the MC Peer tab to configure MC peer entries.

1. Click Create or select an existing peer entry and click Properties. The Multi Chassis Diameter Proxy Entry (Create|Edit) form opens.
2. Select an MC peer.

3. Configure the Peer Sync Tag parameter.
4. Save your changes and close the form.

8

Save your changes and close the forms.

END OF STEPS

57.15 To force a route download on an NE

57.15.1 Purpose

Use this procedure to force an immediate route download on an individual NE. In order to complete this procedure, you must have a route download policy configured (see 57.10 “To configure a route download policy” (p. 1801).

57.15.2 Steps

1

Choose Policies→AAA Policies→Route Download from the NFM-P main menu. The Route Download Policies form opens.

2

Select the route download policy that is configured on the NE for which you want to force a route download and click Properties. The Route Download Policy (Edit) form opens.

3

Click on the Local Definitions tab and click Search. A list of NEs associated with the route download policy is displayed.

4

Select an NE and click Properties. The Route Download Policy - Local Policy (Edit) form opens.

5

Click Force Download. The NE sends a route request to the RADIUS server.

6

Close the form.

END OF STEPS

58 Python policies

58.1 Python policies and Python script policies

58.1.1 Overview

A Python policy references one or more Python script policies in the NFM-P, and associates each with a message (RADIUS or other). Each message entry is configured to act on either ingress or egress traffic.

A Python script policy is configured on a Python policy. A Python script policy is used to specify the location of a Python script. The Python script policy specifies three possible URL locations for the script (for example, a local CF card or a remote FTP server). The system picks the first URL that establishes a valid connection. The Python script policy also specifies the method used to ensure the integrity and/or the confidentiality of the content of a Python script, and the action taken when the defined RADIUS message type fails.

A Python script policy can be configured with a script protection key that is shared with the script protection configuration on an NE. If Python script protection is configured, the NE is configured with the same protection key, along with the source URL of the Python script, and the destination URL where the protected script is stored.

A Python policy message entry can be used, for example, to modify RADIUS messages of a RADIUS proxy server, change the RADIUS attributes of the different RADIUS messages, or to process DHCP messages for an interface. A Python policy message entry of the type Syslog can be used to customize the formatting of syslog messages carrying NAT information. Python policies can be configured on the following object types:

- RADIUS server or RADIUS proxy server on a base routing instance (27.8 “To configure a RADIUS server on a routing instance” (p. 846) and 27.9 “To configure a RADIUS proxy server on a routing instance” (p. 847))
- RADIUS server policy (57.6 “To configure a RADIUS server policy” (p. 1797))
- IES group interface (78.19 “To configure a group interface on an IES” (p. 2449))
- VPRN group interface (79.37 “To configure a group interface on a VPRN” (p. 2586))

A Python policy can be configured with a cache in which script message strings are saved. Other scripts can be configured to retrieve the strings. This functionality is not limited to a particular service type. For example, a RADIUS Python script could save an SLA profile name provided in RADIUS Access-Accept message to the cache, and a DHCP Discovery script could retrieve it. The Python cache is configured with a maximum number of entries, and a maximum size for each entry. The lifespan of cache entries is also configurable.

Each local definition of a distributed (global) Python policy can be configured with a Python cache peer object, which specifies the IP address of an MC redundancy synchronization peer and its associated synchronization tag.

A Python policy can be associated with an ISA-WLAN GW group or and ISA-NAT group, in which case the policy acts as an ISA Python policy. This means that all Python scripts associated with the Python policy are loaded into ISA memory, depending on the state of the Python script (shutdown or

not shutdown), and its association with a Python policy.

58.2 To configure a Python script policy

58.2.1 Steps

1

Choose Policies→Python→Python Script from the NFM-P main menu. The Python Scripts form opens.

2

CAUTION

Service Disruption

Modifying an active Python script is potentially service-affecting.

Ensure that you consider the implications of reconfiguring the Python script before you proceed.

Click Create or select an existing entry and click Properties. The Python Script form opens.

3

Configure the required parameters.

If the Protection parameter is set to HMAC-SHA-256, you must specify a protection key. The protection key value must match the protection key value specified on the NE to which the Python script policy is applied. The two values are not validated against each other until script protection is enabled on the NE.

4

Save your changes and close the form.

END OF STEPS

58.3 To configure a Python policy

58.3.1 Steps

1

Choose Policies→Python→Python Policy from the NFM-P main menu. The Python Policies form opens.

2

CAUTION

Service Disruption

Modifying an active Python script is potentially service-affecting.

Ensure that you consider the implications of reconfiguring the Python policy before you proceed.

Click Create or select an existing entry and click Properties. The Python Policy form opens.

3

Configure the required parameters.

The ISA -WLAN GW group and ISA-NAT group parameters can only be configured at the time of policy creation. You can configure an ISA -WLAN GW group OR an ISA-NAT group on the policy, but not both. If the policy is configured with an ISA -WLAN GW group or an ISA-NAT group, you cannot configure a Python cache or message entries. Save your changes and close the form.

4

Click on the Cache tab to configure a Python cache.

1. Click Create or select the existing entry and click Properties. The Python Policy Cache form opens.
2. Configure the required parameters.
3. Save your changes and close the form.

5

Click on the Message Entries tab to configure message entries.

1. Click Create or select an existing entry and click Properties. The Python Policy Message form opens.
2. Configure the required parameters.
3. Select a Python script policy.

6

Click OK to confirm and close the forms, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

58.4 To configure a Python policy cache peer

58.4.1 Purpose

A cache peer can only be configured on a local definition of a global Python policy that has been distributed to NEs.

58.4.2 Steps

1

Choose Policies→Python→Python Policy from the NFM-P main menu. The Python Policies form opens.

2

CAUTION

Service Disruption

Modifying an active Python script is potentially service-affecting.

Ensure that you consider the implications of reconfiguring the Python policy before you proceed.

Select an entry and click Properties. The Python Policy form opens.

3

Click on the Local Definitions tab.

4

Select an entry and click Properties. The Python Policy, Local Policy (Edit) form opens.

5

Click on the Peer tab.

1. Click Create or select an existing entry and click Properties. The Python Policy Cache Peer form opens.
2. Select a peer address.
3. Configure the Sync Tag parameter.

6

Save your changes and close the forms.

END OF STEPS

59 802.1x policies

59.1 802.1x policies function

59.1.1 Overview

The NFM-P implementation of the 802.1X protocol provides 802.1X authentication on an individual port basis.

In an 802.1X environment, a user, called the supplicant, requests access to an access point, called the authenticator. The authenticator forces the supplicant into an unauthorized state, forcing them to send an EAP start message.

The authenticator returns an EAP message to request the user identity. The user returns the identity, which is forwarded by the authenticator to the authentication server. The server authenticates the user and returns an accept or reject message to the authenticator.

If an accept message is received, the authenticator changes the user state to authorized and user traffic is processed.

59.2 To configure an 802.1x policy

Note: Before you can assign an 802.1x policy to a port, 802.1x must be enabled on the device. See 12.17 “To enable or disable 802.1X” (p. 353) for information about enabling 802.1x.

59.2.1 Steps

1

Choose Policies→Ethernet→802_1x from the NFM-P main menu. The Manage 802_1x Policies form opens.

2

Click Create. The 802_1x Policy (Create) form opens with the General tab displayed.

3

Configure the required parameters.

4

Click the RADIUS Servers tab, if required. Otherwise, go to Step 8.

5

Click Create. The RADIUS Server (Create) form opens.

6

Configure the required parameters.

7

Click OK to save your changes and close the form.

8

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

9

Close the form.

END OF STEPS

60 PBB MRP policies

60.1 PBB MRP policies

60.1.1 Overview

PBB MRP policies limit the scope of MMRP advertisements to a specific network domain using ISID-based filters for both the MMRP control plane and the B-VPLS data plane. A PBB MRP policy contains a configurable option to instantiate an MMRP tree and related entry only when both an MMRP declaration and registration are received on a port.

A PBB MRP policy specifies either a forward or a drop action for the Group B-MAC attributes associated with the ISIDs that are specified in the match criteria. If the scope of the policy is set to template, you can apply the PBB MRP policy to multiple B-VPLS services.

See 77.2.4 “Provider Backbone Bridging in VPLS” (p. 2215) and “MRP and MMRP support” (p. 2218) in Chapter 77, “VPLS management ” for more information.

60.1.2 Workflow to manage PBB MRP policies

1

Create a PBB MRP policy. See 60.2 “To configure a PBB MRP policy” (p. 1813) .

2

Release and distribute the PBB MRP policy to NEs. See 60.2 “To configure a PBB MRP policy” (p. 1813) .

3

Configure MRP forwarding control on a B-site. See 77.24 “To create a B-site for VPLS or MVPLS” (p. 2283) .

4

Configure MRP forwarding control and apply the PBB MRP policy to a B-VPLS L2 access interface, or spoke or mesh SDP binding. See 77.105 “To configure learning protection parameters on a VPLS SDP binding” (p. 2403) and 77.87 “To create a VPLS or MVPLS B-L2 access interface” (p. 2366) .

60.2 To configure a PBB MRP policy

60.2.1 Steps

1

Choose Policies→Ethernet→PBB MRP from the NFM-P main menu. The PBB MRP Policies form opens.

2

Click Create. The PBB MRP Policy (Create) form opens with the General tab displayed.

3

Configure the required parameters.

4

Click the Entries tab.

5

Click Create. The PBB MRP Policy Entry (Create) form opens with the General tab displayed.

6

Configure the required parameters.

7

Click the ISID Match Criteria tab.

8

Click Create to specify ISID matching criteria for an entry. Multiple ISID matching criteria can be specified for each entry. The ISID Match Criteria (Create) form opens.

9

Configure the required parameters and click OK.

10

Repeat Step 8 and Step 9 to add another set of criteria. Otherwise, go to Step 11 .

11

Click OK. The PBB MRP Policy Entry (Create) form closes.

12

Repeat Step 5 to Step 11 to add another entry. Otherwise, go to Step 13 .

13

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

14

Close the form.

END OF STEPS

61 AOS Ethernet Service policies

61.1 AOS Ethernet Service policy types

61.1.1 Overview

This chapter describes how to configure the UNI, SAP, UNP, and custom L2 profiles associated with OmniSwitch Ethernet services.

A UNI profile is associated with a UNI port and configures how a variety of protocol control packets are processed on the UNI port. Processing actions include Tunnel, Drop, Peer, and MAC Tunnel.

A SAP is associated with a stacked VLAN service. A SAP profile defines values for ingress bandwidth sharing, rate limiting, customer VLAN tag processing (translate or preserve), and priority mapping (inner to outer tag or fixed value).

A custom L2 profile is associated with a UNI profile for specific packet control and can be applied to specific actions, such as tunnel, MAC-tunnel, and discard.

61.2 To configure an OmniSwitch Ethernet service UNI profile

61.2.1 Steps

1

Choose Policies→Ethernet→AOS Ethernet Service from the NFM-P main menu. The Ethernet Service Policies form opens.

2

Click Create and choose Create UNI Profile. The Ethernet Service UNI Profile (Create) form opens with the General tab displayed.

3

Configure the required parameters.

4

As required, bind the UNI profile to a custom L2 profile.

1. Click on the Custom L2 Profile Binding tab.
2. Select a custom L2 profile from the list and click OK.

   Note:

   If no custom L2 profiles exist, click Create. See 61.4 “To configure an OmniSwitch Ethernet service custom L2 profile” (p. 1816) for more information.

5

Click OK. The Ethernet Service UNI Profile (Create) form closes.

6

Close the Ethernet Service Policies form.

END OF STEPS

61.3 To configure an OmniSwitch Ethernet SAP profile

61.3.1 Steps

1

Choose Policies→Ethernet→AOS Ethernet Service from the NFM-P main menu. The Ethernet Service Policies form opens.

2

Click Create and choose Create SAP Profile. The Ethernet Service SAP Profile (Create) form opens with the General tab displayed.

3

Configure the required parameters.

4

Click OK. The Ethernet Service SAP Profile (Create) form closes.

5

Close the Ethernet Service Policies form.

END OF STEPS

61.4 To configure an OmniSwitch Ethernet service custom L2 profile

61.4.1 Before you begin

Support for OmniSwitch custom L2 profiles varies depending on the NE family, variant, release, and license; see the NE documentation for more information.

61.4.2 Steps

1

Choose Policies→Ethernet→AOS Ethernet Service from the NFM-P main menu. The Ethernet Service Policies form opens.

2

Click Create and choose Create Custom L2 Profile. The Custom L2 Profile (Create) form opens with the General tab displayed.

3

Configure the required parameters.

The Protocol Mac parameter must be a multicast MAC address.

4

If you set the Protocol Entry Type parameter to a value other than Mac Type (the default value), then addition parameters are displayed. Configure the required parameters.

5

Click OK. The Custom L2 Profile (Create) form closes.

6

Close the Ethernet Service Policies form.

END OF STEPS

61.5 To clear custom L2 profile statistics

61.5.1 Steps

1

Right-click on the required OmniSwitch NE in the navigation tree and choose Properties from the contextual menu. The properties form for the NE opens with the General tab displayed.

2

Click on the Globals tab.

3

Click on the L2PT Clear Stats tab.

4

Configure the required parameters.

5

Click OK. The properties form for the NE closes.

END OF STEPS

61.6 To configure an OmniSwitch Ethernet UNP profile

61.6.1 Steps

1

Choose Policies→Ethernet→AOS UNP Profile from the NFM-P main menu. The AOS UNP Profile Policy form opens.

2

Click Create. The AOS UNP Profile (Create) form opens with the General tab displayed.

3

Configure the required parameters.

4

Save your changes and close the form.

END OF STEPS

62 VLAN Connection Profile policies

62.1 Overview

62.1.1 NE support

The VLAN Connection Profile policy is supported on 7450 ESS, 7750 SR and 7950 XRS NEs.

62.1.2 Description

The Ethernet policy VLAN Connection Profile and TPS Connection Profile enable you to configure SAPs to be part of multiple VLANs in a single command. You can specify all the VLANs that the SAPs needs to be part of by providing a range of VLAN IDs or separate, individual, VLAN IDs. When this policy is used under a SAP, the NFM-P distributes the connection profile to the NE first and then references the connection profile.

After creating a policy, you can use it in Epipe (terminating sites only) and VPLS (regular sites only) services. The VLAN Connection Profile policies are not supported in the following services: Etree, M-VPLS, B-VPLS, R-VPLS, I-VPLS and PBB-Epipe.

The NFM-P performs the validation of VLAN ID ranges to ensure that different connections profiles do not overlap.

62.1.3 SAP encapsulation

Only access and hybrid ports with the encapsulation type of Dot1 Q and Q-in-Q support VLAN Connection Profile and TPS Connection Profile policies. You need to be aware of the SAP encapsulation requirements and dependencies for the policy when using the policy in an Epipe or VPLS service.

The VLAN Connection Profile policy supports the following new SAP types:

- Dot1 Q encapsulation port
  - sap 1/1/1:cp-1

    A connection profile policy is required for the creation of this SAP type.
- Q-in-Q encapsulation port
  - sap 1/1/2:cp-2.*

    A connection profile policy is required for the creation of this SAP type, the VLAN Connection Profile tag needs to be Outer, and the inner encapsulation value needs to be set to 0, 4095, or * (asterisk).
  - sap 1/1/3:1234.cp-3

    A connection profile policy is required for the creation of this SAP type, the VLAN Connection Profile tag needs to be Inner, and the outer encapsulation value needs to be set to a value from 1 through 4094.

The assignment of SAPs with overlapping encapsulation types causes operation failure.

62.1.4 Constraints

This section describes the constraints that must be considered when configuring SAPs for VLAN connection profiles.

Services

VLAN connection profiles are not supported in the following types of services:

- Etree
- M-VPLS
- B-VPLS
- R-VPLS
- I-VPLS
- PBB-Epipe

Features

The following features are not supported in combination with VLAN connection profile services:

- Proxy ARP and Proxy ND
- Capture SAPs
- Ethernet tunnel SAPs
- Ethernet ring SAPs

  The VLAN connection profile SAPs can be used as Ethernet ring data SAPs, but do not support control G.8032 traffic.
- VLAN translation
- Xstp

  The VLAN connection profile SAPs can be managed by an M-VPLS, but services with CP SAPs do not support Xstp.
- L2PT
- BPDU translation
- Subscriber management features
- IGMP/MLD/PIM (v4 or v6)
- VLAN VC Tag under an SDP-binding sharing service with a VLAN connection profile SAP

62.2 To configure a VLAN Connection Profile policy

62.2.1 Steps

1

Choose Policies→Ethernet→VLAN Connection Profile or TPS Connection Profile from the NFM-P main menu. The Manage VLAN Connection Profile form opens.

2

Click Create. The Connection Profile (Create) form opens.

3

Configure the required parameters on the General tab..

4

Configure a VLAN Connection Profile range.

1. Click on the VLAN Connection Profile Range tab, and click Create. The VLAN Connection Profile Range, VLAN Connection Profile (Create) form opens.
2. Configure the required parameters.
3. Save your changes and close the form.

5

Save your changes and close the VLAN Connection Profile (Create) form.

6

Close the Manage VLAN Connection Profile form.

END OF STEPS

62.3 To view SAPs associated with a specific VLAN connection profile

62.3.1 Steps

1

Choose Policies→Ethernet→VLAN Connection Profile or TPS Connection Profile from the NFM-P main menu. The Manage Connection Profile form opens.

2

Perform a search to find the configured connection profile. You can search for all the configured VLAN connection profiles or search using the ID of a specific VLAN connection profile.

3

Select the VLAN connection profile and click Properties. The VLAN Connection Profile form opens.

4

Click on the L2AccessInterface tab and then on the VLL L2Access Interface or VPLS L2Access Interface tab.

5

Click Search. The SAPs associated with the VLAN connection profile are displayed.

END OF STEPS

63 Connection profile policies

63.1 Connection profile policies

63.1.1 Overview

You can configure an ATM-cell Apipe service with an ATM SAP type. The SAP type is an ATM connection profile name. The NFM-P ATM connection profile configures a list of VPI/VCI pairs.

You can apply a connection profile only to a SAP that is part of an Apipe VLL with a VC Type parameter that is set to ATM-cell. The ATM SAP can be on a regular port or APS port. You can apply a connection profile to any number of ATM SAPs.

Consider the following when you configure a connection profile:

- A SAP-to-SAP VLL service is not supported using ATM SAP to which a connection profile is assigned. You must configure each VPI/VCI pair into a separate SAP and create as many Apipe VLL services with the VC type ATM-vcc as required.
- You cannot configured an ATM SAP to which a connection profile is assigned on a port which is part of a MC-APS protection group.
- You cannot add an ATM SAP to which a connection profile to an Apipe VLL endpoint. The SAP cannot be configured on a MC-LAG or MC-APS port. However, this ATM SAP can be part of a VLL service which has an endpoint on a spoke SDP.

You can configure connection profile policies on the 4-port OC-3/STM-1:OC-12/STM-4 ATM MDA and on the 16-port OC-3/STM-1 ATM MDA, on the IOM3/IMM on the 7750 SR-1, 7750 SR-7, 7750 SR-12, 7750 SR-c4, and the 7750 SR-c4.

63.1.2 7210 SAS VLAN ranges

7210 SAS VLAN ranges allow you to group a range of VLAN IDs as a single entity. This allows you to provide a VPLS or VLL Epipe service configuration—such as forwarding, ACL, QoS, and accounting—to the group of VLAN IDs.

You can use a connection profile to specify either a range of VLAN IDs or individual VLANs to be grouped together in a single SAP. You can configure only one VLAN range SAP in a VPLS or Epipe service. In an Epipe service, the other endpoint must be a Q.* SAP or a spoke SDP binding. Access SAPs that use VLAN range values are allowed only for a Dot1Q-encapsulated port or LAG. You can configure multiple connection profiles for each port or LAG, as long as the VLAN values that are specified in each profile do not overlap.

For VPLS VLAN range SAPs, the following restrictions apply:

- BPDU translation, IGMP snooping, and MVR are not supported
- IPv4 and Ipv6 egress ACL filters are not supported
- You cannot configure the Maximum Entries parameter for the FIB

- The Learning Enabled parameter for the SAP cannot be set to false

VLAN ranges for VLL Epipe services are supported on the following 7210 SAS NEs:

- 7210 SAS-D
- 7210 SAS-K
- 7210 SAS-M
- 7210 SAS-Mxp
- 7210 SAS-R
- 7210 SAS-S
- 7210 SAS-Sx
- 7210 SAS-T
- 7210 SAS-X

VLAN ranges for VPLS are supported on the following 7210 SAS NEs:

- 7210 SAS-D
- 7210 SAS-K
- 7210 SAS-M
- 7210 SAS-T

63.2 Workflow to manage connection profiles

63.2.1 Purpose

The following workflow lists the high-level steps required to manage ATM connection profiles.

63.2.2 Stages

1

Create an ATM connection profile. See 63.3 “To configure a connection profile policy” (p. 1825).

2

Release and distribute the ATM connection profile to NEs. See 63.3 “To configure a connection profile policy” (p. 1825).

3

Apply the connection profile to an Apipe VLL L2 access interface. See 76.40 “To create a VLL L2 access interface on a terminating site” (p. 2174).

63.3 To configure a connection profile policy

63.3.1 Steps

1

Choose Policies→ATM→Connection Profile from the NFM-P main menu. The Manage Connection Profile form opens.

2

Click Create. The Connection Profile (Create) form opens with the General tab displayed.

3

Configure the required parameters.

4

Perform the following to add ATM members to the connection profile:

1. Click on the ATM Member tab.
2. Click Create. The ATM Member (Create) form opens.
3. Configure the required parameters and click OK. The Connection Profile (Edit) form refreshes with the VPI and VCI information displayed.
4. Repeat 2 and 3 to add additional members. You can add up to 16 members.

5

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

6

Close the forms.

End of steps

63.4 To configure a VLAN range for a 7210 SAS VPLS or VLL Epipe service

63.4.1 Purpose

Perform this procedure to create a connection profile to configure a range of VLAN values that you can assign to an Dot1q SAP in a VPLS or VLL Epipe service.

Note: You cannot modify an existing connection profile that is associated with a SAP. If you need to modify the connection profile, you must first remove the profile from all SAPs with which it is associated.

63.4.2 Steps

1

Choose Policies→ATM→Connection Profile from the NFM-P main menu. The Manage Connection Profile form opens.

2

Click Create. The Connection Profile (Create) form opens with the General tab displayed.

3

Configure the required parameters.

4

Specify the list of VLAN ranges or individual VLAN IDs to be used for mapping the VLANs to the VPLS or VLL Epipe SAP.

1. Click on the VLAN Ranges tab.
2. Click Create. The VLAN Range form opens.
3. Configure the Range parameter and click OK. The VLAN Range form closes.
4. Repeat 2 and 3 to create additional ranges.

5

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

6

Close the forms.

END OF STEPS

64 Residential subscriber policies

64.1 Primary residential subscriber policy components

64.1.1 Overview

This section describes the major policy components that are essential components in a residential subscriber configuration.

These required policies include:

- Subscriber identification policies
- Subscriber profiles
- SLA profiles
- Subscriber explicit maps

See Chapter 74, “Residential subscriber management” for information about configuring and managing residential subscribers.

64.1.2 Subscriber identification policies

Subscriber identification policies apply to SAPs and associate dynamic residential subscriber hosts with NE subscriber instances. Hosts that use the same subscriber identifier, called a subscriber identification string, belong to the same subscriber and receive common general HQoS and accounting treatment as defined by the customer SLA specifications in a subscriber profile. Hosts from multiple SAPs can belong to the same subscriber, but for HQoS scheduling purposes, all hosts of a subscriber must be active on the same IOM.

A subscriber identification policy includes:

- URLs for subscriber identification scripts
- subscriber profile map
- SLA profile map

Entries in the subscriber and SLA profile maps are optional and are used for the direct assignment of profiles to hosts when hosts include profile ID strings in the DHCP Option 82 field.

Default subscriber identification policy

Although the NFM-P is installed with no default subscriber identification policy, the user can create a subscriber identification policy and designate it as the default policy by giving it the case-sensitive name “default”.

Subscriber identification scripts

A URL in a subscriber identification policy points to the location of a subscriber identification script that an NE uses to parse DHCP option information. During initialization, an NE downloads scripts

from the URLs that are specified in the applied subscriber identification policies. An NE can store a maximum of four subscriber identification policies; each policy can contain up to three scripts.

A subscriber identification script derives the mandatory subscriber ID string, as well as a DSLAM identifier and optional profile ID strings, from the DHCP option information.

The user assigns a priority to each script in a subscriber identification policy. Only the operationally enabled script with the highest priority is active. If an NE encounters an error in a script or cannot find a script at the specified location, the NE marks the URL as operationally down, raises an alarm, and attempts to use the script that is next in priority.

The script-related alarms that the NFM-P raises against the local instance of a subscriber identification policy are:

- warning alarm when the primary URL is operationally up but a lower-priority URL is operationally down
- major alarm when the primary script is operationally down but one of the other scripts is operationally up
- critical alarm when all scripts are operationally down

A modification to a subscriber identification script or URL takes effect only after the URL is administratively disabled and then re-enabled, which causes an NE to reload the script. Replacing or modifying a subscriber identification script or a URL can be service-affecting if not done properly. To avoid a service disruption when you modify a subscriber identification script or URL, perform 74.19 “To modify the primary subscriber identification script or URL” (p. 2040) .

64.1.3 Subscriber profiles

A subscriber profile defines the aggregate HQoS and accounting characteristics for the hosts of a specific subscriber. During the creation of a subscriber profile, the user chooses ingress and egress scheduler policies that apply to all host queues of the subscriber. A subscriber profile permits the optional selection of SLA profiles to override the SLA profiles that are named in the subscriber identification policy.

A subscriber profile can be specified in the following components, which an NE searches in the order shown when it attempts to assign a subscriber profile to a host:

- subscriber explicit map
- subscriber identification policy

A subscriber requires an association with one and only one subscriber profile. If no subscriber profile is associated with a subscriber ID string or explicitly specified by a host, and there is no available default subscriber profile on an NE or on a SAP, the NE rejects the host.

When an accounting policy is associated with the subscriber profile, the user can configure the type of subscriber host accounting data that is reported in the RADIUS accounting message, and in the XML accounting records.

The user can define a default subscriber profile for an NE or a SAP by giving it the case-sensitive name “default” during profile creation. NE and SAP default subscriber profiles apply to hosts for which a subscriber profile is unspecified in the subscriber explicit map and subscriber identification policy.

64.1.4 SLA profiles

An SLA profile defines the resources that an NE assigns to a particular subset of subscriber hosts, such as VoIP telephones or BTV set-top boxes. These resources include network-access and ACL policies. An SLA profile also optionally defines the maximum number of hosts that use the profile and the action taken when the number of hosts reaches the maximum.

An SLA profile can be specified in the following components, which an NE searches in the order shown when it attempts to assign an SLA profile to a host:

- subscriber explicit map
- subscriber profile
- subscriber identification policy

An SLA profile includes:

- access ingress policy association
- access egress policy association
- local scheduler policy association for access egress policy
- ingress IP ACL filter policy association
- egress IP ACL filter policy association
- host limit that specifies the maximum number of hosts that use the SLA profile
- access ingress and access egress policy parameter override values
- access ingress and access egress policer override values
- egress scheduler override values

The queues in the access ingress and egress policies of an SLA profile must use a scheduler from the scheduler policy in the subscriber profile as their parent scheduler. Additionally, a local scheduler can be specified under the access egress policy configuration. The local scheduler policy QoS settings override the QoS settings of the parent scheduler specified in the subscriber profile.

All hosts that use the SLA profile must be active on the same IOM. When an SLA profile does not name an access ingress or access egress policy, an NE uses the SAP default policy.

The user can define a default SLA profile for a SAP. A default SAP SLA profile applies only to hosts for which an SLA profile is unspecified in the subscriber explicit map, subscriber profile, and subscriber identification policy.

64.1.5 Subscriber explicit maps

A subscriber explicit map is a table that directly associates dynamic subscriber hosts with subscriber profiles and SLA profiles. The entries in a subscriber explicit map override the default profile definitions. A subscriber ID string is the unique key for a subscriber explicit map entry.

A subscriber explicit map includes:

- subscriber ID string
- subscriber profile name
- SLA profile name

- AA group policy name
- subscriber ID alias

A subscriber explicit map does not allow the association of a subscriber ID string with the subscriber profile called “default”. However, if the explicit mapping omits a subscriber profile, the subscriber ID string is associated with the SAP or NE default subscriber profile. An attempt to delete a subscriber profile that is named in a subscriber explicit map fails. The user can remove explicit map entries at any time.

If the user creates a subscriber explicit map entry without using the NFM-P, for example, using CLI, the NFM-P creates a subscriber instance in the global subscriber explicit map. If the NFM-P subsequently discovers another NE with the same subscriber entry that has a mapping to different profile, the NFM-P treats the second mapping as a local mismatch to the global entry for the subscriber.

64.2 Secondary residential subscriber policy components

64.2.1 Overview

This section describes additional and optional policy components that can be applied to a residential subscriber configuration, depending on the specific application and service delivery model:

- ANCP policies
- PPPoE policies
- PPP policies
- MSAP policies
- Host tracking policies
- Category map policies
- Credit control policies
- IGMP policies
- IPoE session policies
- BGP peering policies
- Diameter policies
- Subscriber multicast CAC policies
- Mobile gateway/peer profiles
- Host lockout policies
- RADIUS script policies
- HTTP redirect policies
- MLD policies
- Diameter application policies
- Distributed subscriber management traffic policers
- Distributed subscriber management IP filter policies
- PIM policies
- SHCV policies
- RIP policies
- BRG profiles
- UPnP policies
- APN policies
- MAP-T domain policies

64.2.2 ANCP policies

An ANCP policy defines the behavior of the residential subscriber host with which the policy is associated.

An ANCP policy includes one of the following:

- static ANCP association
- static ANCP MSS association

- dynamic subscriber-profile association on VPLS, IES, VPRN and VLL services

An ANCP policy conveys status and control information based on port-up/port-down messages and changes to the current access line rate between the edge device and the access node. This allows supporting NEs to adjust the HQoS subscriber scheduler with the correct rate or raises an alarm when the rate goes below a set threshold. The policy can be changed if the rate drops below a minimal threshold value. The ANCP actual upstream synchronization rate is configured in the ingress panel while the ANCP actual downstream synchronization rate is configured in the egress panel.

64.2.3 PPPoE policies

PPPoE is used in subscriber networks to encapsulate PPP frames inside Ethernet frames. PPPoE combines the point-to-point protocol used with DSL sessions with the Ethernet protocol used to support multiple subscribers in a local area network. PPPoE takes advantage of the speed of a packet-based Ethernet network with the security and accounting functions of a PPP network. PPPoE allows service providers to use existing RADIUS authentication.

Since more than one subscriber is sharing the same connection to a service provider, PPPoE organizes subscribers during two stages:

- PPPoE discovery stage
- PPPoE session stage

During the discovery stage, the subscriber and service provider identify each other's MAC address and establish a PPPoE session ID.

The PPPoE discovery stage consists of the following steps:

1. PPPoE Active Discovery Initiation (PADI). The client initiates a session by broadcasting a PADI packet to the LAN to request a service.
2. PPPoE Active Discovery Offer (PADO). Any access device that can deliver the service requested by PADI packet, replies with a PADO packet that contains its name, unicast address and service requested.
3. PPPoE Active Discovery Request (PADR).The client selects one of the PADOs that it receives and sends a PADR packet to indicate the services required.
4. PPPoE Active Discovery Session Confirmation (PADS). When the selected device receives the PADR packet, it can accept or reject the PPPoE session. To accept the session the device sends the client a PADS packet with a unique ID and a service name. If the device rejects the session, it sends a PADS packet with a service name error and resets the session ID to zero.

During the session stage, PPPoE behaves as a peer-to-peer protocol. Each PPPoE session is identified by the MAC address of the peer and the session ID. Once a session is established, both end points build a point to point connection over the Ethernet and exchange packets. Once the connect is established, the RADIUS accounting policy can begin. LCP negotiates authentication parameters. After a session is authenticated IPCP sends an IP address to the PPPoE client. IP Addresses can be stored in the DHCP local user database, if configured.

After a session is established both end points monitor the session and can terminate a session after a configured number of keep alive intervals are exceeded. An alarm is raised by the NFM-P when a PPPoE session fails. Either peer can send a PPPoE Active Discovery Termination (PADT) packet.

See 74.2.4 “Local DHCP server” (p. 1996) in this chapter for more information on associating PPPoE with a local DHCP server.

PPPoA sessions

PPPoA is used in subscriber networks to encapsulate PPP frames inside ATM Adaption Layer 5 packets. Each PPP session is carried over a single ATM VC to the BNG. Two types of encapsulation are supported:

- AAL5_nlpid_PPP
- AAL5_Mux_PPP

PPPoEoA sessions

PPPoEoA is used in subscriber networks to encapsulate PPPoE messaging within ATM Adaption Layer 5 packets. Each PPP session can be directly terminated on any host within the customer Ethernet network and then transported over an ATM network to the BNG. Two types of encapsulation are supported:

- AAL5_muxed_bridged_EHT_no_FCS
- AAL5_snap_bridged

64.2.4 PPP policies

A PPP policy defines PPP parameters for an access interface. A PPP policy is applied to an access interface.

64.2.5 MSAP policies

An MSAP policy defines how parameters are applied in the creation of an MSAP. An MSAP policy is applied to capture SAP L2 access interfaces and MSAP L2 and L3 access interfaces. An MSAP policy can be configured to create sticky MSAPs, which are not automatically cleared by the system when they become idle. Sticky MSAPs must be cleared manually; see 64.11 “To clear idle sticky MSAPs” (p. 1854).

64.2.6 Host tracking policies

A host tracking policy is used to allow a subscriber's video traffic (multicast) to be included in the egress rate control for the subscriber. When a host tracking policy is specified in a subscriber profile, the egress traffic rate for the subscriber takes into account the unicast and multicast traffic in the aggregate egress rate or in the egress scheduler rate specified in the ANCP policy. There is no default host tracking policy.

When a host tracking policy is applied to a subscriber profile, all subscribers associated with the subscriber profile are tracked using that host tracking policy. You can view the tracked subscribers on the associated local host tracking policy property form.

You can also configure IGMP host tracking parameters on VPLS, IES, and VPRN service sites and SAPs.

The following on-demand host tracking information is available:

- on the Residential Subscriber Instance form, Host Tracking Info tab, which hosts are being

tracked for this particular subscriber

- on the Residential Subscriber Instance form, Host Tracking Status tab, the egress traffic rate reduction for this particular subscriber
- on the VPLS L2 access interface property form, Host Tracking Info tab, which hosts are being tracked
- on the IES and VPRN service access point property form, Host Tracking Info tab, which hosts are being tracked

On-demand historical and real-time host tracking statistics are supported for SAPs and residential subscribers. Only historical statistical plotting is supported. The statistics and read-only host tracking information can be cleared by the NFM-P.

64.2.7 Category map policies

A category map policy combines up to sixteen credit category mappings for association with SLA profiles and credit control policies. Each category specifies a group of queues and policers, as well as credit exhausting IP filter entries.

64.2.8 Credit control policies

A credit control policy is used to associate additional policy objects with a credit control server. If the credit control server is a RADIUS server, a category map policy is specified. If the credit control server is a diameter server, a diameter policy, diameter application policy, and category map policy are specified. A credit control policy also specifies out-of-credit and error handling actions. The credit control policy is configured on SLA profiles.

64.2.9 IGMP policies

An IGMP policy specifies IGMP group parameters and a list of static multicast group addresses and static source addresses. The IGMP policy is associated with subscriber profiles.

64.2.10 IPoE session policies

The IPoE session policy allows dual-stack IPoE subscriber sessions to function simlarly to dual-stack PPoE sessions. The policy specifies which session key information in the trigger packet is used to instantiate the IPoE session, and session timeout information. The IPoE session policy is bound to a VPLS capture SAP, and to a VPRN or IES group interface.

64.2.11 Diameter policies

The NFM-P supports diameter policies and associated diameter peers. Diameter policies are used in a subscriber management context to provide a credit control mechanism. The diameter policy establishes a server/peer configuration, as well as Diameter Credit-Control Application (DCCA) support. The NE functions as the credit control client, while the peer acts as the credit control server.

DCCA represents an alternative to RADIUS for providing a mechanism to support pre-paid service model in access networks. Under a DCCA configuration, the credit control server is used to grant service to a subscriber for pre-defined duration. Before a subscriber host is created, the BNG queries the credit control server about the credit for the given subscriber. If credit is granted, the

subscriber host is installed with the appropriate SLA level. If the subscriber has no credit, the credit control server denies access and no subscriber host is created.

The diameter policy is used to specify common diameter protocol parameters, while the diameter peer defines the relationship with an external diameter server. The diameter protocol parameters defined on the diameter policy describe connection and session characteristics, and indicate which AVPs to use in messages.

The diameter policy is configured on the credit control policy.

Peers

The diameter policy defines a set of peers with which to establish diameter sessions. Peers share the configuration of the policy with which they are associated, but can override individual timer parameters inherited from the policy. In addition, each peer defines transport and connection-specific parameters, values for destination-specific AVPs, and a preference value.

The 7750 SR and 7450 ESS provide read-only operational values and statistics for the peer definition of local diameter policies. The NFM-P can provide a snapshot view of operational values and statistics. Operational values include the peer's timer values, the current state of the peer's state machine, and the peer's order among the other peers within the policy.

DCCA

The 7750 SR supporst a DCCA, which can be customized through a set of parameters on the diameter policy in the NFM-P. The parameters allow customization of DCCA error handling, DCCA timer(s), and AVP value definitions.

64.2.12 Subscriber multicast CAC policies

The subscriber multicast CAC policy defines bandwidth constraints for multicast CAC. The subscriber multicast CAC policy is applied to a subscriber profile.

64.2.13 Mobile gateway/peer profiles

The mobile gateway/peer profile configures a signalling interface between the WLAN gateway and the mobile gateway. The mobile gateway/peer profile is applied to a PGW or a GGSN.

64.2.14 Host lockout policies

A host lockout policy implements the ability to hold off a misconfigured or malicious subscriber that is continuously retrying to connect. This conserves resources on the NE and on the RADIUS server.

A host lockout policy can be associated with the following objects:

- VPLS or MVPLS L2 access interface
- IES or VPRN L3 access interface
- IES or VPRN group interface

Host lockouts can be cleared at the policy level, at the NE level, or from the SAP to which they are applied.

64.2.15 RADIUS script policies

See 57.1.7 “RADIUS script policies” (p. 1790).

64.2.16 HTTP redirect policies

The HTTP redirect policy specifies a redirect URL and destination port, as well as a list of forwarding address/port pairs. An HTTP redirect policy is associated with a WLAN GW configuration on an IES or VPRN group interface.

64.2.17 MLD policies

The MLD policy specifies MLD group-related parameters, as well as a list of static multicast group/source address pairs. An MLD policy is configured on a subscriber profile.

64.2.18 Diameter application policies

The NFM-P supports diameter application policies and associated diameter peer policies. The diameter application policy is used to specify common diameter protocol parameters. The diameter protocol parameters defined on the diameter application policy describe connection and session characteristics, and indicate which AVPs to use in messages.

The protocols and AVP types vary, depending on the policy’s application type:

- Gx
- Gy
- NASREQ

The diameter application policy can be configured on local user database IPoE and PPP hosts, and on VPRN and IES group interfaces.

Diameter NASREQ

In network configurations where a Diameter infrastructure is available, Diameter NASREQ can be used an alternative to a local user database and RADIUS for ESM host authentication. If the diameter application policy is configured for NASREQ, it can be configured as a Diameter Authentication Policy on IES and VPRN group interfaces, on local user database IPoE and PPP hosts, and on VPLS capture SAPs.

64.2.19 Distributed subscriber management traffic policers

The distributed subscriber management traffic policer object specifies per-subscriber bandwidth policing on the anchor ISA. Distributed subscriber management traffic policers can be configured in two ways:

- Single-bucket policers monitor bandwidth using a single traffic flow rate (PIR) and burst parameter (MBS)
- Dual-bucket policers monitor bandwidth using dual traffic flow rates (PIR/CIR) and dual burst parameters (MBS/CBS).

Distributed subscriber management traffic policers are available to all the ISAs in a WLAN-GW group. A default policer template for the WLAN-GW group is always created on the ISA when a

WLAN-GW IOM is added to a WLAN-GW group. When a UE is authenticated, RADIUS returns a policer template in a VSA. On an anchor ISA, the ingress and egress policer is instantiated for the subscriber, based on the policer template and overrides for rates/bursts returned from RADIUS.

64.2.20 Distributed subscriber management IP filter policies

The distributed subscriber management IP filter policy installs shared per-SAP filters on SAPs between the anchor ISA and the IOM. The filters map the DSCP on ingress and egress traffic to per-SAP queues.

You can create a redirect filter with a drop action and configure RADIUS to perform a COA to associate this drop action filter with a given UE. The policy filter name is included in the RADIUS VSA.

64.2.21 PIM policies

The PIM policy is configured on a subscriber profile to enable PIM on residential subscriber hosts. For more information, see 78.1.11 “PIM on IES group interfaces” (p. 2425).

64.2.22 SHCV policies

See “SHCV policies” (p. 2000). To create an SHCV policy, see 64.31 “To configure an SHCV policy” (p. 1872).

64.2.23 RIP policies

The RIP policy is used to authenticate an associated host object on a RIP listener interface. A RIP policy can be configured on the following host objects:

- local user database PPP host
- local user database IPoE host
- IES SAP static host
- VPRN SAP static host

To create a RIP policy, see 64.32 “To configure a RIP policy” (p. 1872).

64.2.24 BRG profiles

The Bridged Residential Gateway (BRG) profile is used to apply default attributes to a virtual CPE, including SLA and subscriber profile strings, SHCV timers and hold times, RADIUS server policy, RADIUS proxy servers, and DHCPv4 configuration. A BRG profile can be configured on IES and VPRN group interfaces.

To create a BRG profile, see 64.35 “To configure a BRG profile” (p. 1875).

64.2.25 Trace profiles

The Trace profile allows debug information for IPoE sessions to be collected as a trace. It correlates debug information across multiple applications into a single trace, allowing you to easily find the root cause of an issue.

Use a trace profile to gather debug information for the following applications:

- Local user database
- RADIUS accounting
- RADIUS authentication
- Connectivity Management
- Python
- MSAP

To create a trace profile, see .

Workflow to configure call trace debugging

Complete the following procedures to deploy call trace debugging in a network.

1. Configure a trace profile; see 64.36 “To configure a trace profile” (p. 1876).

   Specify the applications for which you want to gather debug information, and specify the type of output for gathered information. Deploy the profile to NEs you want to trace.
2. Specify trace log file storage information on traced NEs; see 12.35 “To configure call-trace debug storage on an NE” (p. 369).

64.2.26 UPnP policies

The universal plug and play (UPnP) policy is configured on a subscriber profile to add UPnP port mapping functionality on residential subscriber hosts. UPnP provides user-friendly, automatic creation/deletion of port mappings for non-technical users.

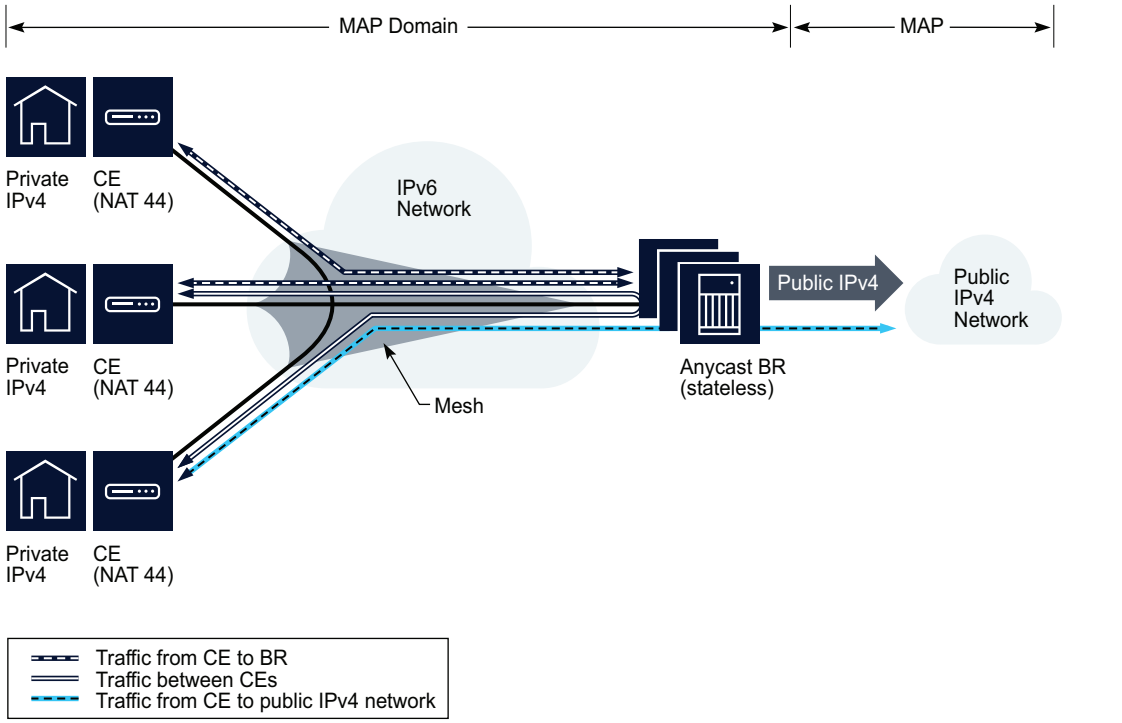
UPnP performs NAT port mapping management by application (P2P, gaming, etc.). In a typical routed home, a CPE router (with NAT) acts as a UPnP IGD, accepting UPnP requests from home devices and applications to add or remove NAT port mappings as required.

64.2.27 MAP-T domain policies

The MAP-T domain policy defines a series of MAP rules to associate with a MAP domain. The MAP domain is configured as part of a NAT configuration on a VPRN service site.

Mapping Address and Port with Translation (MAP-T) functionality is used to connect a private IPv4 network and associated customer equipment (CE), over an IPv6 network, to a public IPv4 network connected to a centralized border router. MAP-T can also be used for direct communication between CEs.

Figure 64-1 MAP-T domain



64.2.28 APN policies

See 74.2.15 “HSQ” (p. 2006).

64.2.29 Service chaining policies

For information on service chaining, see 74.2.18 “ISA service chaining” (p. 2007).

For information on configuring service chaining policies, see 64.33 “To configure a service chaining EVPN policy” (p. 1873) and 64.34 “To configure a service chaining VAS filter policy” (p. 1874).

64.3 To configure a subscriber identification policy

64.3.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

CAUTION

Service Disruption

Modifying an active subscriber identification policy is potentially service-affecting.

Ensure that you consider the implications of reconfiguring the subscriber identification policy before you proceed.

Click Create→Subscriber Identification Policy or choose an existing subscriber identification policy and click Properties. The Subscriber Identification Policy (Create|Edit) form opens.

3

Configure the required parameters.

You can designate a subscriber identification policy as the default policy by specifying the case-sensitive name “default” for the Displayed Name parameter. The Displayed Name parameter is configurable only during subscriber identification policy creation.

4

Click on the Supported Service Models tab and specify the intended service model(s) for the subscriber identification policy.

5

Click on the SLA Profiles tab to configure SLA profiles for the subscriber identification policy.

1. On the General tab, configure the Use Direct Map as Default parameter.
2. Click on the Profiles tab.
3. Click Create or choose an SLA profile entry and click Properties. The SLA Profile Entry (Create|Edit) form opens.
4. Configure the SLA Profile String parameter.
5. Select an SLA profile to associate with the subscriber identification policy.
6. Save your changes and close the form.

6

Click on the Subscriber Profiles tab to configure subscriber profiles for the subscriber identification policy.

1. On the General tab, configure the Use Direct Map as Default parameter.
2. Click on the Profiles tab.
3. Click Create or choose a subscriber profile entry and click Properties. The Subscriber Profile Entry (Create|Edit) form opens.
4. Configure the Subscriber Profile String parameter.
5. Select a subscriber profile to associate with the subscriber identification policy.

6. Save your changes and close the form.

7

Click on the Application Profiles tab to configure application profiles for the subscriber identification policy.

1. On the General tab, configure the Use Direct Map as Default parameter.
2. Click on the Profiles tab.
3. Click Create or choose an application profile entry and click Properties. The App Profile Entry (Create|Edit) form opens.
4. Configure the required parameters.
5. Select an application profile to associate with the subscriber identification policy.

   Note:

   If the subscriber identification policy is a global policy, global AA group policies are listed. If the subscriber identification policy is a local policy, local AA group policies are listed.

   Global AA group policies must be manually distributed to the NE before a global subscriber identification policy using the application profiles can be distributed.

   When a new subscriber identification or subscriber explicit map is discovered from the NE, the AA group policy is not automatically resynchronized to the global subscriber identification policy.
6. Save your changes and close the form.

8

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs

END OF STEPS

64.4 To configure a subscriber profile

64.4.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

CAUTION

Service Disruption

Modifying an active subscriber profile is potentially service-affecting.

Ensure that you consider the implications of reconfiguring the subscriber profile before you proceed.

Click Create→Subscriber Profile or choose an existing Subscriber Profile and click Properties. The Subscriber Profile (Create|Edit) form opens.

3

Configure the required parameters.

You can designate a subscriber profile as the default profile by specifying the case-sensitive name “default” for the Displayed Name parameter. The Displayed Name parameter is configurable only during subscriber profile creation.

The Egress Aggregate Rate Limit and Frame Base Accounting parameters are configurable only when a scheduler is not specified in the Egress Scheduler panel.

The Virtual Port Hashing parameter applies only to standard LAG ports. The Secondary Shaper Hashing parameter applies only to HSMDA and HSQ ports. Both of these parameters can also be configured on a local definition of an existing subscriber profile, accessed on the Local Definitions tab.

4

Configure policies to associate with the subscriber profile.

1. Select an accounting policy in the Accounting Policy panel and configure the Volume Stats Type parameter.
2. Configure the required policy objects on the subscriber profile:
   - ANCP policy
   - host tracking policy
   - NAT policy
   - IGMP policy
   - MLD policy
   - subscriber multicast CAC policy
   - PIM policy
   - UPnP policy
   - NAT prefix list (NAT policy must also be configured)
   - Firewall policy

5

Click on the Scheduling tab and configure the required parameters.

An additional parameter, Encapsulation Offset Mode, can be configured using the XML API.

6

Configure LAG per-link hashing parameters, if required.

7

Select an ingress or egress scheduler in the Ingress or Egress panel.

You cannot specify an egress scheduler in a subscriber profile when the Egress Aggregate Rate Limit parameter is set to a value greater than zero.

8

Configure HS Egress Aggregate Rate Limit parameters, as required.

9

Click on the RADIUS Accounting tab and select first, second, and third RADIUS accounting policies. Depending on the NE version, the third RADIUS accounting policy option may not be displayed.

If you configure the Optimize for Session Accounting parameter to reduce accounting messages in a dual stack PPP session configuration, you must also configure the Delay Start Time parameter on the RADIUS accounting policies; see 57.3 “To configure a RADIUS-based accounting policy” (p. 1793).

10

Click on the SLA Profiles tab to configure SLA profiles for the subscriber profile.

1. On the General tab, configure the Use Direct Map as Default and HS SLA Profile Handling Mode parameters.
2. Click on the Profiles tab.
3. Click Create or choose an SLA profile entry and click Properties. The SLA Profile Entry (Create|Edit) form opens.
4. Configure the SLA Profile String parameter.
5. Select an SLA profile to associate with the subscriber profile.
6. Save your changes and close the form.

11

Click on the HSMDA QoS tab and perform one of the following:

a. Select an ingress policy in the Ingress panel.

b. Select an egress policy in the Egress panel and configure the Aggregate Rate Limit parameter.

12

Select a WRR policy in the Egress HSMDA Override panel and configure the Packet Byte Offset parameter, if required.

13

Click on the Policer Control tab to configure ingress and egress policer control policies.

1. Select a policer control policy in the Ingress Policer Control Policy panel.
2. Configure local override parameters for the selected ingress policer control policy, if required.
3. Select a policer control policy in the Egress Policer Control Policy panel.
4. Configure local override parameters for the selected egress policer control policy, if required.

14

Click on the Override Policy Items tab to specify local overrides for schedulers, queues, or policers assigned to the subscriber profile.

15

On the Ingress Schedulers tab, click Create or choose an ingress scheduler entry and click Properties. The Ingress Scheduler Entry Override (Create|Edit) form opens.

1. Select a scheduler policy.
2. Click on the Override tab and configure the required parameters.

   The CIR parameter can only be configured when Summed CIR is set to false.
3. Save your changes and close the form.

16

On the Egress Schedulers tab, click Create or choose an egress scheduler entry and click Properties. The Egress Scheduler Entry Override (Create|Edit) form opens.

1. Select a scheduler policy.
2. Click on the Override tab and configure the required parameters.

   The CIR parameter can only be configured when Summed CIR is set to false.
3. Save your changes and close the form.

17

On the Ingress Policer Level tab, click Create or choose an ingress policer level override entry and click Properties. The Ingress Policer Level Override (Create|Edit) form opens.

1. Select a policer level.

   The current maximum cumulative buffer space value for the policer level is displayed.

2. Click on the Override tab and then enable and configure the Maximum Cumulative Buffer Space (bytes) parameter.
3. Save your changes and close the form.

18

On the Egress Policer Level tab, click Create or choose an egress policer level override entry and click Properties. The Egress Policer Level Override (Create|Edit) form opens.

1. Select a policer level.

   The current maximum cumulative buffer space value for the policer level is displayed.
2. Click on the Override tab and then enable and configure the Maximum Cumulative Buffer Space (bytes) parameter.
3. Save your changes and close the form.

19

On the HSMDA Ingress Queues tab, click Create or choose an access ingress HSMDA queue override entry and click Properties. The Access Ingress HSMDA Queue Override (Create|Edit) form opens.

1. Select an access ingress policy queue.
2. To configure separate IPv4 and IPv6 statistics counters for the queue override, click on the Override tab and configure the Stat Mode parameter.
3. Save your changes and close the form.

20

On the HSMDA Ingress Policers tab, click Create or choose an access ingress HSMDA policer override entry and click Properties. The Access Ingress HSMDA Policer Override (Create|Edit) form opens.

1. Select an access ingress policy policer.
2. To configure separate IPv4 and IPv6 statistics counters for the policer override, click on the Override tab and configure the Stat Mode parameter.
3. Save your changes and close the form.

21

On the Access Egress HSMDA Queues tab, click Create or choose an access egress HSMDA queue override entry and click Properties. The Access Egress HSMDA Queue Override (Create|Edit) form opens.

1. Select an access egress policy queue.
2. To specify override values for the queue, click on the Override tab and configure the required parameters.

If you enable the Override check box for any of these parameters, then the original value of the parameter that was configured for the Access Egress HSMDA Queue will appear in that parameter's value field. You can then configure the override value for that parameter.

You can only specify an override value for WRR Weight for queues 1, 2, or 3.

3. Select an HSMDA slope policy.
4. Save your changes and close the form.

22

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 "To release and distribute a policy" (p. 1476) to distribute the policy to NEs.

END OF STEPS

64.5 To configure an SLA profile

64.5.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

CAUTION

Service Disruption

Modifying an active SLA profile is potentially service-affecting.

Ensure that you consider the implications of reconfiguring the SLA profile before you proceed.

Click Create→SLA Profile or choose an existing SLA Profile entry and click Properties. The SLA Profile (Create|Edit) form opens.

3

Configure the required parameters.

The Displayed Name parameter is configurable only during SLA profile creation.

4

Select a credit control policy to associate with the SLA profile.

5

Click on the QoS tab to associate ingress and egress QoS policies with the SLA profile.

1. Select an access ingress policy to associate with the SLA profile.

2. Configure the required ingress parameters.
3. Select an access egress policy to associate with the SLA profile.
4. Select a scheduler policy to associate with the SLA profile.
5. Configure the required egress parameters.

6

Click on the ACL tab to associate ingress or egress IP filters with the SLA profile. Select any of the following filters:

- ingress IP filter
- egress IP filter
- ingress IPv6 filter
- egress IPv6 filter
- one-time HTTP redirect filter

7

Click on the Supported Service Models tab to specify the intended service model(s) for the SLA profile.

8

Click on the Category Map tab.

1. Select a category map to associate with the SLA profile.

   If you selected a credit control policy in Step 4, you will not be able to select a category map.
2. Click Create or choose a category entry and click Properties. The Category (Create|Edit) form opens.
3. Select a category name and configure the Idle Timeout parameter.

   Note:

   The session will be disconnected if the value of the Activity Threshold parameter is not met during the period specified by the Idle Timeout parameter. See 64.13 “To configure a category map policy” (p. 1855) for information about configuring the Activity Threshold parameter.
4. Save your changes and close the form.

9

Click on the Bonding Selection tab to configure the SLA profile for use in a connection bonding configuration.

Configure the required selection bonding parameters.

10

Click on the Host Limits tab to specify a maximum host count for the SLA profile.

You can set an overall limit, or configure host limits at a more granular level for each of the IPv4, IPv6, and L2TP host type categories, and their respective subcategories.

Although the NFM-P specifies a Host Limit parameter range of 1-131071, the maximum host limit varies for different NE types and chassis types.

11

Click on the Override Policy Items tab to specify local overrides for queue parameters of the QoS policies assigned to the SLA profile.

12

On the Access Ingress Queues tab, click Create or choose an ingress queue override item and click Properties. The Access Ingress Queue Override (Create|Edit) form opens.

1. Select an access ingress policy queue.
2. Click on the Override tab and configure the required parameters.
3. Save your changes and close the form.

13

On the Access Egress Queues tab, click Create or choose an egress queue override item and click Properties. The Access Egress Queue Override (Create|Edit) form opens.

1. Select an access egress policy queue.
2. Click on the Override tab and configure the required parameters.
3. Configure overridden HS queue parameters and select an override slope policy in the HS WRED Queue, if required.
4. Save your changes and close the form.

14

On the Access Ingress Policer tab, click Create or choose an ingress policer override item and click Properties. The Ingress Policer Override (Create|Edit) form opens.

1. Select an access ingress policy policer.
2. Click on the Override tab and configure the required parameters.
3. Save your changes and close the form.

15

On the Access Egress Policer tab, click Create or choose an egress policer override item and click Properties. The Egress Policer Override (Create|Edit) form opens.

1. Select an access egress policy policer.
2. Click on the Override tab and configure the required parameters.
3. Save your changes and close the form.

16

On the Egress Scheduler tab, specify local overrides for traffic flow rate parameters of the egress schedulers assigned to the SLA profile.

1. Click Create or choose an egress scheduler override item and click Properties. The Egress Scheduler Override (Create|Edit) form opens.
2. Select the scheduler policy you want to override.
3. Click on the Override tab and configure the required parameters.

   The CIR parameter is available only when the Summed CIR parameter is set to False.
4. Save your changes and close the form.

17

On the HS WRR Groups tab, specify local overrides for traffic flow rate parameters of the egress schedulers assigned to the SLA profile.

1. Click Create or choose an HS WRR group override item and click Properties. The HS WRR Group Override (Create|Edit) form opens.
2. Select an HS WRR group.
3. Click on the Override tab and configure the required parameters.
4. Save your changes and close the form.

18

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

64.6 To configure a subscriber explicit map entry

64.6.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

CAUTION

Service Disruption

Modifying an active subscriber explicit map entry is potentially service-affecting.

Ensure that you consider the implications of reconfiguring the subscriber explicit map entry before you proceed.

Click Create→Subscriber Explicit Map Entry or choose an existing subscriber explicit map entry and click Properties. The Subscriber Explicit Map Entry (Create|Edit) form opens.

3

Configure the required parameters.

The Subscriber Identification parameter is configurable only during subscriber explicit map creation.

4

Select a subscriber profile to associate with the subscriber explicit map.

5

Select an SLA profile to associate with the subscriber explicit map.

6

Select an application profile to associate with the subscriber explicit map.

Note: The global AA group policy must be manually distributed to the NE before a global subscriber identification policy using the application profiles can be distributed.
When a new subscriber identification or subscriber explicit map is discovered from the NE, the AA group policy is not automatically resynchronized to the global subscriber identification policy.

7

Save your changes and close the form.

END OF STEPS

64.7 To configure an ANCP policy

64.7.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

Click Create ANCP or choose an existing ANCP policy and click Properties. The ANCP Policy (Create|Edit) form opens.

3

Configure the required parameters.

You can select an ingress or egress rate modification scheduler when the Rate Modification parameter is set to Scheduler.

4

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

64.8 To configure an ANCP MSS static map

Note: You can configure an ANCP MSS static map when you have created an ANCP policy and an Aggregation Scheduler. See 64.7 “To configure an ANCP policy” (p. 1849) and 50.56 “To create an Aggregation Scheduler” (p. 1597) for more information.

64.8.1 Steps

1

Choose Manage→Service→Customers from the NFM-P main menu. The Manage Customers form opens.

2

Select a customer in the list and click Properties. The Customer (Edit) form opens.

3

Click on the Aggregation tab.

4

Select a site in the list and click Properties. The Aggregation Scheduler (Edit) form opens.

5

Click ANCP Static Map.

6

Select an ANCP policy in the list and click Create. The ANCP MSS Static Map (Create) form opens.

7

Configure the required parameters and click OK.

The ANCP Policy is listed in the ANCP Static Map tab of the Aggregation Scheduler (Edit) form.

8

Save your changes and close the forms.

END OF STEPS

64.9 To configure a PPP policy

64.9.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

Click Create→PPP Policy or choose an existing PPP policy and click Properties. The PPP Policy (Create|Edit) form opens.

3

Configure the required parameters.

4

Click on the Apply button. The PPP Policy form refreshes.

5

Click on the Options tab to configure PPP options on the PPP policy.

1. Click Create or choose an existing PPP option entry and click Properties. The PPP Option (Create|Edit) form opens.
2. Configure the required parameters.
3. Save your changes and close the form.

6

Click on the MLPPP tab to configure MLPPP on the PPP policy.

7

Configure the required parameters.

8

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

64.10 To configure an MSAP policy

64.10.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form appears.

2

Click Create→MSAP Policy or choose an existing MSAP policy and click Properties. The MSAP Policy (Create|Edit) form opens.

3

Configure the required parameters.

4

Click on the Security tab to configure security policies on the MSAP Policy.

1. Select an NE DoS protection policy to associate with the MSAP policy.
2. Configure the MAC Monitoring and IP Src Monitoring parameters.
3. Select an NE DDoS protection policy to associate with the MSAP policy.

5

Click on the Subscriber Management tab to configure subscriber management parameters on the MSAP policy.

1. Configure the required parameters.
2. On the Policies panel, select the following policy objects:
   - default subscriber profile
   - default SLA profile
   - subscriber identification policy
3. On the Default Application Profile panel, select a default application profile.
4. On the Single Subscriber Configuration panel, select the following policy objects:
   - Non-Subscriber Traffic Subscriber Profile
   - Non-Subscriber Traffic SLA Profile
5. On the Non-Subscriber Traffic Application Profile panel, select a non-subscriber traffic application profile.

6

Click on the ATM tab.

1. Configure the ATM OAM Alarm Cell Handling and Periodic ATM OAM Loopback parameters.
2. Select an ingress ATM policy.
3. Select an egress ATM policy.

7

Perform the following, as required:

a. If the MSAP policy is for an MSAP on a VPLS, click on the VPLS Only Configuration tab.
   1. On the General tab, configure the required parameters.

      An egress multicast group policy cannot be applied to SR NE variants at Release 15.0 R1 and higher.
   2. Select an egress multicast group policy.
   3. Select an access Ingress policy.
   4. Select an access Egress policy.
   5. Click on the DHCP tab and configure the required parameters.
   6. Click on the IGMP Snooping tab and configure the required parameters.
   7. Select a multicast CAC policy.

b. If the MSAP policy is for an MSAP on an IES or VPRN, click on the IES VPRN Only Configuration tab.
   1. Set the Anti-Spoofing parameter to be Source IP and MAC Address.
   2. Configure the Ingress Queuing Type parameter.
   3. Select an access Ingress policy.
   4. Select an access Egress policy.

c. Click on the VPLS Multicast CAC Constraints tab.
   1. On the LAG Port Down tab, click Create or select an existing multicast CAC Lag entry and click Properties. The Multicast CAC Lag Entry (Create|Edit) form opens.

      Up to eight Multicast CAC LAG entries can be created for an MSAP policy
   2. Configure the Number of Ports Down and Level ID parameters:
   3. Save your changes and close the form.
   4. Click on the Levels tab.

      Up to eight Multicast CAC Level entries can be created for an MSAP policy.
   5. Click Create or select an existing muliticast CAC level entry and click Properties. The Multicast CAC Level (Create|Edit) form opens.
   6. Configure the Level ID and Bandwidth parameters:

      The Bandwidth range is 1 to 4 294 967 952 for an MSAP policy.
   7. Save your changes and close the form.

d. Click on the IGMP Host Tracking tab and configure the required parameters.

8

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

64.11 To clear idle sticky MSAPs

64.11.1 Purpose

Perform this procedure to clear idle sticky MSAPs created by a local MSAP policy.

64.11.2 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

Select the MSAP policy for which you want to clear idle sticky MSAPs and click Properties. The MSAP Policy (Edit) form opens.

3

Click on the Local Definitions tab.

4

Select a policy definition and click Properties. The Policy Definition Properties form opens.

5

Click Clear Idle MSAPs.

6

Click OK. The MSAPs are cleared.

7

Close the forms.

END OF STEPS

64.12 To configure a host tracking policy

64.12.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

Click Create→Host Tracking Policy or choose an existing host tracking policy and click Properties. The Host Tracking Policy (Create|Edit) form opens.

3

Configure the required parameters.

4

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

64.13 To configure a category map policy

64.13.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form appears.

2

Click Create→Category Map Policy or choose an existing category map policy and click Properties. The Category Map Policy (Create|Edit) form opens.

3

Configure the required parameters.

4

Click on the Category tab to configure a category entry for the category map policy.

A maximum of 16 categories can be configured for each category map policy. If you must delete categories from the global policy in order to create space for new categories, you must also apply your changes to the policy after the deletions, and then distribute the policy as described in 49.6 “To release and distribute a policy” (p. 1476). This will clear out the deleted categories from all local instances of the policy, leaving room for the new categories when the global policy is re-distributed.

1. Click Create or select an existing category entry and click Properties. The Category (Create|Edit) form opens.
2. Configure the required parameters.

   The Rating Group parameter is only configurable when the Use Rating Group check box is enabled.

   The PIR (kbps) parameter is configured to its maximum value when the MAX check box is enabled.

5

Click on the Queues tab.

Select the required ingress and egress queues to be defined in the category.

6

Click on the Policers tab.

Select the required ingress and egress policers to be defined in the category.

7

Click on the Credit Exhausting Service Levels tab and perform one of the following:

a. To define credit exhausting service levels for IP filter entries, go to Step 8.

b. To define credit exhausting service levels for IPv6 filter entries, go to Step 9.

8

Click on the IP Filter Entries tab.

1. Click Create or select an existing filter entry and click Properties. The Exhausted IP Filter (Create|Edit) form opens.
2. Configure the required parameters on the General and Filter Properties tabs.

   If you are configuring the filter entry for an HTTP redirect override function, set the Action parameter to HTTP Redirect. The Web Redirect tab appears.
3. Click on the Web Redirect tab. Enable the Allow Override parameter and specify a redirect URL.
4. Save your changes and close the form.

9

Click on the IPv6 Filter Entries tab.

1. Click Create or select an existing filter entry and click Properties. The Exhausted IPv6 Filter (Create|Edit) form opens.
2. Configure the required parameters on the General and Filter Properties tabs.
3. Save your changes and close the form.

10

Save your changes and close the Category form.

11

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

64.14 To configure a credit control policy

64.14.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form appears.

2

Click Create→Credit Control Policy or choose an existing credit control policy and click Properties. The Credit Control Policy (Create|Edit) form opens.

3

Configure the required parameters.

4

If you set the Credit Control Server parameter to Diameter, select a diameter policy and a diameter application policy.

5

Select a category map in the Category Map panel.

6

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

64.15 To configure an IGMP policy

64.15.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

Click Create→IGMP Policy or choose an existing IGMP policy and click Properties. The IGMP Policy (Create|Edit) form opens.

3

Configure the required parameters.

If any (or all) of the three query interval parameters are configured, the Query Interval parameter value must be greater than the Last Listener Query Interval and Response Query Interval parameter values.

4

Select a multicast reporting destination in the multicast reporting panel.

5

Click on the Static Group/Source tab. A list of multicast static group/static source address pairs appears.

6

Click Create or choose an existing address pair and click Properties. The IGMP Policy (Create|Edit) form opens.

7

Configure the Static Multicast Group and Static Source parameters.

8

Save your changes and close the form.

9

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

64.16 To configure an IPoE session policy

64.16.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

Click Create→IPoE Session Policy or choose an existing IPoE Session policy and click Properties. The IPoE Session Policy (Create|Edit) form opens.

3

Configure the required parameters.

The Circuit ID or Remote ID option should only be selected for the Session Key parameter if all hosts in the IPoE session have one of these fields in their trigger packets. Do not enable both of these options.

4

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

64.17 To configure a BGP Peering policy

Note: Most of the parameters in a BGP peering policy can be configured directly on the policy object, or the parameter value can be inherited from the parent BGP object by enabling the Inherit Value check box next to each parameter.

64.17.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

Click Create→BGP Peering Policy or choose an existing BGP peering policy and click Properties. The BGP Peering Policy (Create|Edit) form opens.

3

Configure the required parameters.

4

Click on the Behavior tab and configure the required parameters.

5

Click on the AS Properties tab and configure the required parameters.

6

Click on the Import Policies tab and select import routing policy statements for the BGP peering policy.

7

Click on the Export Policies tab and select export routing policy statements for the BGP peering policy.

8

Click on the Authentication tab and configure the MD5 Authentication and Authentication Key parameters.

9

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

64.18 To configure a diameter policy

64.18.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

Click Create→Diameter Policy or choose an existing diameter policy and click Properties. The Diameter Policy (Create|Edit) form opens.

Modifying an active diameter policy is potentially service-affecting. Ensure that you consider the implications of reconfiguring the diameter policy before you proceed.

3

Configure the required parameters.

If you set the Virtual Router Type parameter to VPRN Service, you must also specify a VPRN service.

4

Click on the DCAA Parameters tab and configure the required parameters.

5

Click on the Peers tab to configure diameter peers.

1. Click Create or choose an existing diameter peer entry and click Properties. The Diameter Peer (Create|Edit) form opens.
2. Configure the required parameters.

   If you want to specify local override settings for any of the timer settings for the peer, disable the Inherit Value check box and then specify a value for any of the timer parameters:
   - Watchdog Timer (seconds)
   - Connection Timer (seconds)
   - Transaction Timer (seconds)

   When the Inherit Value check box is selected for a timer parameter on a peer object, the timer value is inherited from the parent diameter policy.
3. Save your changes and close the form.

6

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

64.19 To configure a subscriber multicast CAC policy

64.19.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

Click Create→Subscriber Multicast CAC Policy or choose an existing subscriber multicast CAC policy and click Properties. The Subscriber Multicast CAC Policy (Create|Edit) form opens.

3

Configure the required parameters.

4

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

64.20 To configure a mobile gateway/peer profile

64.20.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

Click Create→Mobile Gateway/Peer Profile or choose an existing mobile gateway/peer profile and click Properties. The Mobile Gateway/Peer Profile (Create|Edit) form opens.

3

Configure the required parameters.

4

Select a python policy, if required.

5

If you want to specify non-default message-retransmit parameters, disable the Message-Retransmit - Default parameter and configure the Message-Retransmit - Timeout (seconds) and Message-Retransmit - Retries parameters.

6

If you want to specify non-default keep-alive parameters, disable the Keep-Alive - Default parameter and configure the Keep-Alive - Interval (seconds), Keep-Alive - Timeout (seconds), and Keep-Alive - Retries parameters.

7

On the Charging Characteristics panel, configure the rquired home charging characteristics and roaming charging characteristics.

8

Click on the PGW tab to configure packet data network gateway QoS parameters.

Configure the required parameters.

You must disable the Default check box for each parameter in order to configure the parameter.

9

Click on the GGSN tab to configure gateway GPRS support node QoS parameters.

Configure the required parameters.

You must disable the Default check box for each parameter in order to configure the parameter.

10

Click on the MME tab to configure gateway MME node parameters.

Configure QoS, Dowlink, Uplink, and AMBR parameters as required.

11

Click OK to save the profile and close the form, or click Apply to save the profile. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the profile to NEs.

END OF STEPS

64.21 To configure a host lockout policy

64.21.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

Click Create→Host Lockout Policy or choose an existing host lockout policy and click Properties. The Host Lockout Policy (Create|Edit) form opens.

3

Configure any applicable parameters:

4

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

64.22 To clear host lockouts

64.22.1 Purpose

Perform this procedure to clear host lockouts enforced by a specific host lockout policy. Lockouts can be cleared at the policy level, or they can be cleared from an NE with which the policy is associated. Host lockouts can also be cleared from IES or VPRN SAPs.

64.22.2 Steps

1

To clear host lockouts, do one of the following:

a. To clear host lockouts at the host lockout policy level or NE level, complete the sub-steps within Step 2.

b. To clear host lockouts from a SAP on an IES or VPRN, complete the sub-steps within Step 3.

2

To clear host lockouts at the host lockout policy level or NE level, do the following:

1. Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.
2. Select the host lockout policy for which you want to clear lockouts and click Properties. The Host Lockout Policy (Edit) form opens.
3. Click on the Local Definitions tab.
4. Select a policy definition and click Properties. The Policy Definition Properties form opens.
5. Click Clear Host Lockout Policy.
6. Choose one of the following options:
   - Network Element: all host lockouts are cleared from the associated NE.
   - Policy: all host lockouts are cleared for the selected policy.
7. Click OK. The lockouts are cleared.
8. Close the forms.

3

To clear host lockouts from IES or VPRN service SAPs, do the following:

1. Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.
2. Select a service that has SAPs from which you want to clear host lockouts and click Properties. The <*service*> (Edit) form appears.
3. On the navigation tree, expand Sites→<*site_n*>→Subscriber Interfaces→<*subscriber_interface_n*>→<*group_interface_n*>→Service Access Points.object, and then expand a group interface object to navigate to the SAP .

4. Right-click on the SAP object from which you want to clear host lockouts and choose Properties from the menu. The Service Access Point (Edit) form opens.
5. Click on the Subscriber Management tab, and then click on the Locked Out Hosts tab.
6. Click on the Search button to display a list of locked out hosts.
7. Click Clear Locked Out Hosts. You can either clear all host lockouts on the SAP, or you can clear lockouts selectively by specifying ID criteria.
8. Click OK. The lockouts are cleared.
9. Close the forms.

End of steps

64.23 To configure a RADIUS script policy

64.23.1 Purpose

A RADIUS script policy references python scripts for RADIUS AAA packet manipulation in a subscriber management application.

64.23.2 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

Click Create→RADIUS Script Policy or choose an existing RADIUS script policy and click Properties. The RADIUS Script Policy (Create|Edit) form opens.

3

Configure the required parameters.

4

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

End of steps

64.24 To configure an HTTP redirect policy

64.24.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

Click Create→HTTP Redirect Policy or select an existing HTTP redirect policy and click Properties. The HTTP Redirect Policy (Create|Edit) form opens.

3

Configure the required parameters.

4

Click on the Forward Entries tab to configure forward entries.

1. Click Create or select an existing forward entry and click Properties. The HTTP Redirect Forward Entry form appears.
2. Configure the required parameters.
3. Save your changes and close the form.

5

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

64.25 To configure an MLD policy

64.25.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

Click Create→MLD Policy or select an existing MLD policy and click Properties. The MLD Policy (Create|Edit) form opens.

3

Configure the required parameters.

If any (or all) of the three query interval parameters are configured, the Query Interval parameter value must be greater than the Last Listener Query Interval and Response Query Interval parameter values.

4

Select an import policy.

5

Select a redirection policy.

6

If you set the Rate Modification parameter to Scheduler, select a rate modification scheduler.

7

Click on the Static Groups/Sources tab.

1. Click Create or select an existing static multicast group and click Properties. The MLD Policy Static (Create|Edit) form opens.
2. Configure the required parameters.
3. Save your changes and close the form.

8

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

64.26 To configure a diameter application policy

64.26.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

Click Create→Diameter Application Policy or select an existing diameter application policy and click Properties. The Diameter Application Policy (Create|Edit) form opens.

Modifying an active diameter application policy is potentially service-affecting. Ensure that you consider the implications of reconfiguring the policy before you proceed.

3

Configure the required parameters.

4

Select a diameter peer policy.

5

If you set the Application parameter to Gx in Step 3, click on the Gx tab.

1. Select applicable diameter attributes.

   Selecting certain diameter attributes requires additional configuration:
   - NAS Port Type - Port Type Value
   - NAS Port - NAS Port Bit Specification
   - Calling Station ID - Calling Station ID Type
   - User Equipment Info - User Equipment Info Type
   - NAS Port ID - Port Prefix Type, Port Prefix String, Port Suffix Type
2. Configure the remaining parameters, as required.

   Enable the Show Format Examples check box to display a series of MAC address syntax examples for the MAC Format parameter.

6

If you set the Application parameter to Gy in Step 3, click on the Gy tab and configure the required parameters.

7

If you set the Application parameter to NASREQ in Step 3, click on the NASREQ tab.

1. Select applicable diameter attributes.

   Selecting certain diameter attributes requires additional configuration:
   - NAS Port Type - Port Type Value
   - NAS Port - NAS Port Bit Specification
   - Calling Station ID - Calling Station ID Type
   - NAS Port ID - Port Prefix Type, Port Prefix String, Port Suffix Type
2. Configure the Name Format parameter.

   If the Name Format parameter is set to DHCP Client Vendor Options, configure the MAC Format parameter. Enable the Show Format Examples check box to display a series of MAC address syntax examples for the MAC Format parameter.
3. Configure the Domain parameter (if required) and the Password parameter.

8

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

64.27 To configure a distributed subscriber management traffic policer

64.27.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

Click Create→Distributed Subscriber Management Traffic Policer or select an existing policer item and click Properties. The Distributed Subscriber Management Traffic Policer (Create|Edit) form opens.

Modifying an active distributed subscriber management traffic policer is potentially service-affecting. Ensure that you consider the implications of reconfiguring the policer before you proceed.

3

Configure the required parameters.

The Action parameter is configurable only if the Type parameter is set to Single Bucket Bandwidth.

The CBS parameter is configurable only if the Type parameter is set to Dual Bucket Bandwidth.

4

On the Rates and Adaptation Rules panels, configure the required parameters.

The CIR parameter is configurable only if the Type parameter is set to Dual Bucket Bandwidth.

5

Click OK to save the policer and close the form, or click Apply to save the policer. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policer to NEs.

END OF STEPS

64.28 To configure a distributed subscriber management IP filter policy

64.28.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

Click Create→Distributed Subscriber Management IP Filter Policy or select an existing policy item and click Properties. TheDistributed Subscriber Management IP Filter Policy (Create|Edit) form opens.

Modifying an active distributed subscriber management IP filter policy is potentially service-affecting. Ensure that you consider the implications of reconfiguring the policy before you proceed.

3

Configure the required parameters.

4

Click on the IPv4 Filter Entries tab to configure IPv4 filter entries.

5

Click Create to create a new filter entry or select an existing filter entry and click Properties. The DSM IPv4 Filter Entry (Create|Edit) form appears.

1. Configure the required parameters.

   The Port parameter is configurable if the Protocol parameter is set to TCP or UDP.
2. Save your changes and close the form.

6

Click on the IPv6 Filter Entries tab to configure IPv6 filter entries.

7

Click Create to create a new filter entry or select an existing filter entry and click Properties. The DSM IPv6 Filter Entry (Create|Edit) form appears.

1. Configure the required parameters.

   The Port parameter is configurable if the Protocol parameter is set to TCP or UDP.
2. Save your changes and close the form.

8

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policer to NEs.

END OF STEPS

64.29 To configure a UPnP policy

64.29.1 Steps

1

Choose Policies→ISA Policies→UPnP Policies from the NFM-P main menu. The UPnP Policies form opens.

2

Click Create or select an existing UPnP policy and click Properties. The UPnP Policy (Create|Edit) form opens.

Modifying an active UPnP policy is potentially service-affecting. Ensure that you consider the implications of reconfiguring the policy before you proceed.

3

Configure the required parameters.

4

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

64.30 To configure a PIM policy

64.30.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

Click Create→PIM Policy or select an existing PIM policy and click Properties. The PIM Policy (Create|Edit) form opens.

Modifying an active PIM policy is potentially service-affecting. Ensure that you consider the implications of reconfiguring the policy before you proceed.

3

Configure the Displayed Name and Description parameters.

4

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

64.31 To configure an SHCV policy

64.31.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

Click Create→SHCV Policy or select an existing SHCV policy and click Properties. The SHCV Policy (Create|Edit) form opens.

Modifying an active SHCV policy is potentially service-affecting. Ensure that you consider the implications of reconfiguring the policy before you proceed.

3

Configure the required parameters.

4

Click on the Triggers tab to configure SHCV triggers.

1. Select a trigger entry in the list and click Properties. The SHCV Trigger Entry form appears.
2. Configure the required parameters and close the form.

5

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

64.32 To configure a RIP policy

64.32.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

Click Create→RIP Policy or select an existing RIP policy and click Properties. The RIP Policy (Create|Edit) form opens.

Modifying an active RIP policy is potentially service-affecting. Ensure that you consider the implications of reconfiguring the policy before you proceed.

3

Configure the required parameters.

4

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

64.33 To configure a service chaining EVPN policy

64.33.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

Click Create→Service Chaining EVPN Policy or select an existing EVPN policy and click Properties. The Service Chaining EVPN Policy (Create|Edit) form opens.

Modifying an active EVPN policy is potentially service-affecting. Ensure that you consider the implications of reconfiguring the policy before you proceed.

3

Configure the EVPN Service ID, Import Mode, and Prefix Route Resolution parameters.

These parameters cannot be changed after policy creation.

If Import Mode is set to Bridged, the Prefix Route Resolution parameter is not displayed on the policy form, but is set to Recursive by default.

The EVPN Service ID parameter value must be unique among other EVPN policies, and among services that have a service ID.

4

Depending on the setting of the Import Mode parameter, do one of the following:

- If the Import Mode parameter is set to Bridged, configure the parameters on the Route Distinguisher, Route Target, and VXLAN panels, or accept default values.
- If the Import Mode parameter is set to None or Routed, configure the parameters on the

Route Distinguisher, Route Target, GW Address Range, VXLAN, and IP Advertise Routes panels or accept default values.

The Route Distinguisher and Route Target parameters have a unique mandatory syntax which is described in the tooltips for the fields.

In order for an EVPN policy to be set to Admin State: In Service, the Route Distinguisher, Route Target, and VXLAN parameters must be configured with non-default values.

In order for the IP Advertise Routes - Admin State parameter to be set to Enabled, the GW Address Range - Start and End parameters must be configured.

5

If the Import Mode parameter is set to None or Routed, configure NAT pools for the EVPN policy. Associated NAT pools must be of type L2-aware, and must be configured on the base routing instance or VPRN routing instance.

1. On the NAT Pools panel, click Create or select an existing NAT pool entry and click Properties. The NAT Pool (Create|Edit) form opens.
2. Do one of the following:
   - Set the Router Type parameter to Base and select a pool.
   - Set the Router Type parameter to VPRN, select a VPRN service, and then select a pool.
3. Save your changes and close the form.

6

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

64.34 To configure a service chaining VAS filter policy

64.34.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

Click Create→Service Chaining VAS Filter Policy or select an existing VAS filter policy and click Properties. The Service Chaining VAS Filter Policy (Create|Edit) form opens.

Modifying an active VAS filter policy is potentially service-affecting. Ensure that you consider the implications of reconfiguring the policy before you proceed.

3

On the General tab, configure the Displayed Name and Description parameters.

4

Click on the VAS Filter Entries tab to configure filter entries for the policy.

1. Click Create or select an existing filter entry and click Properties. The VAS Filter Entry (Create|Edit) form opens.
2. Configure the required parameters.

   You must configure at least one of the Protocol, Foreign IP Address, or Foreign IP Address Prefix (with Mask and Port) parameters.
3. Click on the Actions tab to configure filter actions.

   In order to configure filter actions, the filter entry Admin State must Out of Service.
4. Click Create or select an existing action entry and click Properties. The VAS Filter Action (Create|Edit) form opens.
5. Configure the required parameters.

   Only one Downstream action and one Upstream filter action can be created per filter entry.
6. Save your changes and close the forms.

5

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

64.35 To configure a BRG profile

64.35.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

Click Create→BRG Profile or select an existing BRG profile and click Properties. The BRG Profile (Create|Edit) form opens.

Modifying an active BRG Profile is potentially service-affecting. Ensure that you consider the implications of reconfiguring the profile before you proceed.

3

Configure the required parameters.

4

Select a RADIUS server policy and specify a RADIUS authentication password.

5

Click on the DHCP Pool tab to configure a DHCP pool for the BRG profile.

Configure the required parameters.

6

Click on the Custom Options tab to configure DHCP options for the BRG profile. The options are included in DHCP reply messages.

1. Click Create or select an existing custom option entry and click Properties. The DHCP Pool Custom Option (Create|Edit) form opens.
2. Configure the Number and Type parameters.
3. Depending on the value of the Type parameter, configure the following:
   - IP addresses (for IP address custom option type)
   - String value (for ASCII or Hex string custom option type)
4. Save your changes and close the form.

7

Click on the RADIUS Proxy Servers tab to associate proxy servers with the BRG profile.

1. Click Create or select an existing RADIUS proxy server entry and click Properties. The RADIUS Proxy (Create|Edit) form opens.
2. Configure the Router Instance parameter.
3. Depending on the value of the Router Instance parameter (Base or VPRN), select a VPRN service (where required) and a RADIUS proxy server.
4. Save your changes and close the form.

8

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

64.36 To configure a trace profile

64.36.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

Click Create or select an existing trace profile and click Properties. The Trace Profile (Create|Edit) form opens.

3

Configure the required parameters and select the applications you want to trace.

4

Click OK to save the profile and close the form, or click Apply to save the profile. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the profile to NEs.

END OF STEPS

64.37 To configure a MAP-T domain policy

64.37.1 Steps

1

Choose Policies→ISA Policies→MAP-T Domains from the NFM-P main menu. The MAP-T Domains form opens.

2

Click Create or select an existing MAP-T domain policy and click Properties. The MAP-T Domain (Create|Edit) form opens.

Modifying an active MAP-T domain policy is potentially service-affecting. Ensure that you consider the implications of reconfiguring the policy before you proceed.

3

Configure the required parameters.

4

Click on the Mapping Rules tab to configure a mapping rules for the MAP-T domain policy.

1. Click Create or select an existing mapping rule and click Properties. The Mapping Rule (Create|Edit) form opens.
2. Configure the required parameters.
3. Save your changes and close the form.

5

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

64.38 To configure an APN policy

64.38.1 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form opens.

2

Click Create→APN Policy or select an existing APN policy and click Properties. The APN Policy (Create|Edit) form opens.

Modifying an active APN policy is potentially service-affecting. Ensure that you consider the implications of reconfiguring the policy before you proceed.

3

On the General tab, configure the Displayed Name parameter.

4

Click on the APN tab to configure APN entries for the APN policy.

1. Click Create or select an existing APN entry and click Properties. The APN (Create|Edit) form opens.
2. Configure the Displayed Name parameter.
3. Configure the APN entry in ONE of the following ways:
   - For RADIUS authentication; select a RADIUS authentication policy
   - For Diameter authentication; select a Diameter authentication policy
   - For LUDB authentication; select a Local user database
   - For default service; select a service ID and interface ID

   Configure AMBR QoS mapping downlink and uplink information, if required.
4. Save your changes and close the form.

5

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to distribute the policy to NEs.

END OF STEPS

65 Remote network monitoring policies

65.1 Remote network monitoring policies

65.1.1 Overview

You can create remote network monitoring (RMON) policies that allow you to perform the following tasks.

- Use the policy framework to configure RMON that allows NFM-P users to deploy configurations to multiple devices.
- Map RMON events to information alarms in the NFM-P GUI.

Remote network monitoring allows you to monitor the behavior of functions that are not typically supported by the NFM-P. For example, you can configure events on GNEs to monitor system temperature or CPU usage. The NFM-P can raise informational alarms for the exceeded thresholds. You can also configure custom values to supersede the hard-coded threshold values associated with an NE function.

The NFM-P maps RMON SNMP traps to alarms in the GUI.

Policy distribution and event mapping are supported for the following NE types:

- 7210 SAS
- 7450 ESS
- 7705 SAR
- 7750 SR
- 7950 XRS

Support for 7210 SAS NEs varies depending on the chassis type and release; see the NE documentation for support information.

65.2 To configure a remote network monitoring policy

65.2.1 Steps

1

Choose Tools→Remote Network Monitoring (RMON) from the NFM-P main menu. The Remote Network Monitoring (RMON) form opens.

2

Click Create. The RMON (Create) form opens with the General tab displayed.

3

Configure the required parameters.

4

Create events to associate with the rising and falling thresholds on the remote NE.

1. Click on the Events tab.
2. Click Create. The Event RMON (Create) form opens.
3. Configure the required parameters.
4. Click OK. The Event RMON (Create) form closes and the RMON (Create) form reappears.
5. Repeat 2 to 4 to create another event, if required.

5

Configure the alarm information to associate with an event you created in Step 4 .

1. Click on the Alarms tab.
2. Click Create. The Alarm RMON (Create) form opens.
3. Configure the required parameters.

6

Configure the properties for the rising threshold crossing alarm.

1. Click Select in the Rising TCA Properties panel. The Select Rising Event - Alarm form opens.
2. Select an event and click OK. The Select Rising Event - Alarm form closes and the Alarm RMON form reappears.
3. Click Enable and configure the Rising Threshold parameter for the event.

7

Configure the properties for the falling threshold crossing alarm.

1. Click Select in the Falling TCA Properties panel. The Select Falling Event - Alarm form opens.
2. Select an event and click OK. The Select Falling Event - Alarm form closes and the Alarm RMON form reappears.
3. Click Enable and configure the Falling Threshold parameter for the event.

8

Click OK. The Alarm RMON form closes and the RMON (Create) form reappears.

9

Repeat Step 5 to Step 8 to create another alarm, if required.

10

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

11

Close the form.

END OF STEPS

66 NAT policies

66.1 NAT policies

66.1.1 Overview

A Network Address Translation (NAT) policy, defines general NAT properties and associates a NAT address pool with an ISA-NAT group on the same NE. A NAT policy is associated with a subscriber profile for L2-aware NAT in an IES or VPRN service, or for large-scale NAT in a VPRN service. You can add an IPFIX export policy to a NAT policy. An IPFIX export policy defines how IP traffic flow information is formatted and transferred from an exporter to a collector to facilitate services such as measurement, accounting and billing. You can specify the router instance type, IPFIX Collector address, MTU, and refresh timeouts.

66.1.2 Procedural reference

See Chapter 30, “NAT” for information about configuring and deploying NAT in a network.

67 PCP policies

67.1 PCP policies

67.1.1 Overview

PCP operates between subscribers and NAT directly. This protocol provides the subscriber with limited but direct control over the NAT function. PCP configuration is supported on the 7750 SR.

PCP allows a customer to configure static port forwards, obtain information about existing port forwards and to obtain the outside IP address from software that runs on the home network or the CPE.

A PCP policy allows you to configure PCP parameters that affect the function of a NAT PCP server. The policy is applied to multiple NAT PCP servers so that they behave consistently.

67.2 Workflow to configure and apply PCP policies

67.2.1 Stages

1

Create a PCP policy. See 67.3 “To configure a PCP policy” (p. 1885).

2

Create a NAT PCP server. See 67.4 “To configure a NAT PCP server on a base routing instance” (p. 1886) for information on creating a NAT PCP server on a base routing instance. See 67.5 “To create a NAT PCP server on a VPRN routing instance” (p. 1887) for information on creating a NAT PCP server on a VPRN routing instance.

3

Associate an interface with the NAT PCP server. See 67.6 “To associate an interface with a NAT PCP server” (p. 1887).

67.3 To configure a PCP policy

67.3.1 Steps

1

Choose Policies→ISA Policies→NAT from the NFM-P main menu. The NAT Policies form opens.

2

Choose Port Control Protocol Policy (Network Address Translation) in the object drop-down.

3

Click Create or select an existing PCP policy and click Properties. The PCP Policy (Create|Edit) form opens.

4

Configure the required parameters.

5

Save your changes and close the forms.

End of steps

67.4 To configure a NAT PCP server on a base routing instance

67.4.1 Steps

1

Choose Routing from the navigation tree view selector.

2

Expand *NE→routing_instance*. Right-click on the routing instance and choose Properties. The Routing Instance (Edit) form opens.

3

Click on the PCP Servers tab.

4

Click Create or select an existing PCP server and click Properties. The Port Control Protocol Server (Create|Edit) form opens.

5

Configure the required parameters.

6

Select a PCP policy.

7

Select a routing instance to act as the forwarding inside virtual router.

8

Save your changes and close the forms.

End of steps

67.5 To create a NAT PCP server on a VPRN routing instance

67.5.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

In the navigation tree, expand the Sites icon, right-click on the Routing Instance icon, and choose Properties. The Routing Instance (Edit) form opens.

4

Click on the PCP Servers tab.

5

Click Create or select an existing PCP server and click Properties. The Port Control Protocol Server (Create|Edit) form opens.

6

Configure the required parameters.

7

Select a PCP policy.

8

Select a routing instance to act as the forwarding inside virtual router.

9

Save your changes and close the forms.

END OF STEPS

67.6 To associate an interface with a NAT PCP server

67.6.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

In the navigation tree, expand the Sites icon, right-click on the Routing Instance icon, and choose Properties. The Routing Instance (Edit) form opens.

4

Click on the PCP Servers tab.

5

Choose a server from the list and click Properties. The Port Control Protocol Server (Create) form opens.

6

Click on the Interfaces tab.

7

Click Create. The Port Control Protocol Server Interface form opens.

8

Select an interface for the PCP server.

9

Save your changes and close the forms.

END OF STEPS

68 7705 SAR Security policies

68.1 Security policies

68.1.1 Overview

You can configure the following security policies on the 7705 SAR and 7705 SAR-H:

Release 6.1 R1 or later:

- security profile policy
- security policy
- security zone policy

Release 7.0 R2 or later:

- security log profile policy
- security log policy

Release 7.0 R4 or later:

- security host group policy
- security application group policy
- security policer group policy

Release 20.0 R3 or later:

- security bypass policy

You can view the security policies associated with a 7705 SAR device on the Security tab on the Network Element (Edit) form.

68.2 Zone creation

68.2.1 General Information

On a 7705 SAR, NAT configuration is based on zones. A zone is a group of L2 or L3 interfaces with common criteria that can be bundled together. The same action can be applied to the bundle. For example, in an MC application, all of the SAPs on the access interface used to aggregate the MC can be placed in a single zone and the uplink public interface can be placed in a second zone. All traffic routed between the two zones have NAT applied, based on the security policies created on the first zone. This simplifies the configuration and management of NAT functionality.

You can configure 7705 SAR security policies based on traffic direction entering or leaving the zone.

A zone can be configured on L2 access interfaces, L3 access interfaces, and SDPs on a base routing instance or an EPIPE, IES, MVPLS, VPLS, or VPRN service. Zone configuration is only allowed per service. There is a one-to-one mapping between a service and a zone.

68.3 Security policies and NAT pools

68.3.1 General Information

A 7705 SAR security policy defines how NAT is applied and can vary from subscriber to subscriber. A security policy is applied to zones at creation. Security policies are all type NAPT, denoting a network address and port translation mechanism. Within a security policy, a specific set of matching criteria are configured. If there is a match on a packet, an action is applied. If the action is NAT, the packet has NAT applied to the configured NAT pool IP address and port range.

68.4 Dynamic source NAT

68.4.1 General Information

Source NAT is used to create connections from a private network to a public network. If an arriving IP packet on a 7705 SAR matches the security policy rules, an internal mapping is created between the private source IP address and source port to a public source IP address and source port. The public IP address and port can be configured in the NAT Pool on the security policy.

NAT automatically creates a reverse mapping for incoming traffic from a public domain to a private domain for the same connection. The reverse mapping is based on an outside destination IP address and destination port to an inside destination IP address and destination port.

The configurable outside NAT pool for the source IP address and source port can either be a range of addresses and ports or a unique IP address and port.

The 7705 SAR supports a single public IP address - all inside source IP addresses can be mapped to a single outside IP address and a range of ports by assigning the interface name to the NAT pool configuration. All local interfaces on a 7705 SAR can be assigned to the NAT pool - local L3 interfaces, loopback interfaces, and system interfaces.

68.5 Static destination NAT

68.5.1 General Information

Static destination NAT or static port forwarding is a one-to-one mapping of an outside destination IP address and destination port to an inside destination IP address and port. Static port forwarding can be used when certain applications are hidden behind a single IP address. Each application can be accessed through the public IP address and the destination port for that application.

68.6 Security pairing

68.6.1 General information

A security pair is a minimum configuration requirement on the 7705 SAR to enable Firewall/NAT functionality.

There are 2 steps to creating a security pair:

- Configuring security policies from Policies>Security in the NFM-P main menu.

- Assigning a security zone policy to a network interface. You can also assign a security zone policy to an L3 access interface on an IES or VPRN service site; an L2 access interface or a spoke or mesh SDP on an EPIPE, VPLS, or MVPLS service; and a tunnel interface on a VPRN service.

To enable Firewall or NAT, these two configuration areas must exist and pair together on a 7705 SAR device. The final result is a security policy that is applied to the Zone to enable Firewall/NAT functionality.

68.6.2 Security bypass

When you create a zone for an EPIPE, VPLS, or MVPLS service, you can assign a security bypass policy to L2 services at the site level. The security bypass policy defines protocols and traffic that is permitted to cross the zone at that site, regardless of other firewall configurations. The bypass policy does not affect traffic moving within the security zone, and each bypass policy counts as a global filter entry.

68.7 To configure a security profile policy for a 7705 SAR

68.7.1 Purpose

A security profile policy is used to configure fragmentation, application assurance, and UDP/TCP timers. A security profile policy dictates if fragmented packets are allowed in the network or if the fragmented packets should be discarded. You can configure the timers for different states of a UDP/TCP connection. For example, in a TCP three way hand shake, each state can have its own timer. If the connection does not change state within the allowed time, the connection is closed. Idle timers time out when there are no packets on the session for the period of the configured idle timer. Strict timers time out after the session's last transition state, i.e. the timer starts and counts down from the time that the session was created. The strict timer never renews if a packet arrives on the session.

68.7.2 Steps

1

Choose Policies→Security from the NFM-P main menu. The Security Policies form opens.

2

Click Create and choose Security Profile, or choose an existing security profile policy and click Properties. The Security Profile, Global Policy (Create|Edit) form opens with the General tab displayed.

3

Configure the required general parameters.

4

Configure the Allow Fragments parameter.

5

Configure the Application Layer Gateway parameter.

6

Enable the Application Assurance Inspection checkbox, if required.

The Application Assurance parameters appear in the Application Assurance panel when you enable the Application Assurance Inspection checkbox.

7

Configure the ICMP parameters in the ICMP Timeouts panel.

8

Configure the required parameters in the TCP Timeouts, UDP Timeouts, and Other Timeouts panels.

9

Select a policer group policy in the Fwd Policer Group panel and the Rev Policer Group panel, if required.

10

Configure the required parameters in the Application Assurance panel.

You must enable the IP Options Inspection checkbox in the Application Assurance panel in order for the IP Options parameter to appear.

11

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

END OF STEPS

68.8 To configure a security policy for a 7705 SAR

68.8.1 Purpose

A security policy is set of rules that a packet must match in order for an action to be performed on the packet.

You cannot delete a security policy if it is associated with a security profile policy or a security zone policy.

68.8.2 Steps

1

Choose Policies→Security from the NFM-P main menu. The Security Policies form opens.

2

Click Create and choose Security Policy, or choose an existing security policy and click Properties. The Security Policy, Global Policy (Create|Edit) form opens with the General tab displayed.

3

Configure the required general parameters and click Apply. Additional tabs are enabled.

4

Assign a security policy entry to the security policy.

1. Click on the Security Policy Entry tab and click Create.
2. Configure the required general parameters.
3. Configure the required parameters in the Limit panel.
4. Select a security profile policy in the Profile panel.

   To create a security profile policy, see 68.7 “To configure a security profile policy for a 7705 SAR” (p. 1891) .
5. Configure the Logging parameter in the Logging panel.
6. If you configure the Logging parameter as To Log, select a Security Log policy. To create a security log policy, see 68.11 “To configure a security log policy for a 7705 SAR” (p. 1897) .

5

Configure the match criteria.

1. Click on the Match Criteria tab.
2. Configure the Flow Direction parameter.
3. Configure the required parameters in the Criteria panel.

   If you specified ICMP (1) as the Protocol, configure the parameters in the ICMP Properties panel.

   If you specified UDPTCP (*), TCP, or UDP as the Protocol, configure the parameters in the Port panel.

   If you enabled the Local parameter, the NAT panel appears. Configure the Destination IP Address and Destination Port parameters.
4. Select an Application Group.
5. Configure the Source IP Operator and Destination IP Operator parameters in the IP Address panel.
6. Select a Source Host Group.
7. Select a Destination Host Group.

6

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

END OF STEPS

68.9 To configure a security zone policy for a 7705 SAR

68.9.1 Purpose

Perform this procedure to configure a security zone policy for a 7705 SAR, Release 6.1 R1 or later. You can assign a security zone policy to a network interface. You can also assign a security zone policy to an L3 access interface on an IES or VPRN service site; an L2 access interface or spoke SDP on an EPIPE, VPLS, or MVPLS service; and a tunnel interface on a VPRN service.

68.9.2 Steps

1

Choose Policies→Security from the NFM-P main menu. The Security Policies form opens.

2

Click Create and choose Security Zone, or choose an existing security zone policy and click Properties. The Security Zone, Global Policy (Create|Edit) form opens with the General tab displayed.

3

Configure the required general parameters.

4

Configure the Zone Type parameter in the Zone Instance panel.

a. If you specified a Zone Type of BASE, go to Step 5 .

b. If you specified a Zone Type that is a service type, select a service in the appropriate service panel (for example, an IES service in the IES panel).

5

Configure the required parameters in the Inbound Concurrent Sessions panel and Outbound Concurrent Sessions panel.

6

If you chose VPRN in Step 4 , configure the Auto-bind parameter in the MP-BGP Auto-Bind panel.

7

Select a security log policy in the Logging panel. You can click Create to create a security log policy; see 68.11 “To configure a security log policy for a 7705 SAR” (p. 1897) .

8

Select a security policy in the Security Policy panel.

Only one security policy can be assigned to each security zone. The same security policy can be assigned to multiple security zones. See 68.8 “To configure a security policy for a 7705 SAR” (p. 1892) for more information about configuring a security policy.

9

Save your changes. If you specified a Zone Type of VPLS, MVPLS, or EPIPE, go to Step 16.

10

Assign a NAT pool to the security zone.

1. Click on the NAT Pool tab and click Create. The NAT Pool, Global Policy, (Create) form opens with the General tab displayed.
2. Configure the required parameters.

11

To assign a NAT pool entry to the NAT pool, click on the NAT Pool Entry tab and click Create. The Nat Pool Entry, Global Policy (Create) form opens.

12

Configure the required parameters.

13

Perform one of the following:

a. If you specified a Zone Type of BASE in Step 4 , select a Source Network Interface.

b. If you specified a Zone Type of IES in Step 4 , select a Source IES L3 Access Interface.

c. If you specified a Zone Type of VPRN in Step 4 , select a Source VPRN L3 Access Interface.

14

Configure the IP Operator parameter in the IP Address panel.

Note: The configuration of the network interface and IP address are mutually exclusive.

15

Configure the Port Operator parameter in the Port panel.

16

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

END OF STEPS

68.10 To configure a security log profile policy for a 7705 SAR

68.10.1 Steps

1

Choose Policies→Log Configuration from the NFM-P main menu. The Manage Log Configuration Policies form opens.

2

Click Create and choose Log Profile or choose an existing log profile policy and click Properties. The Log Profile, Global Policy (Create|Edit) form opens with the General tab displayed.

3

Configure the required general parameters.

4

Configure the parameters in the Throttle Events panel, and click Apply.

5

Click on the Log Event tab.

6

Choose an event type and click Properties.

7

Configure the Event Control parameter and click OK. Repeat Step 6 and Step 7 to configure more event types.

8

Save your changes. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

END OF STEPS

68.11 To configure a security log policy for a 7705 SAR

68.11.1 Steps

1

Choose Policies→Log Configuration from the NFM-P main menu. The Manage Log Configuration Policies form opens.

2

Click Create or choose an existing security log policy and click Properties. The Security Log, Global Policy (Create|Edit) form opens with the General tab displayed.

3

Configure the required general parameters.

4

If you configure the Log Destination as SysLog, select a Syslog ID.

5

Select a security log profile policy in the Log Profile panel. See 68.10 “To configure a security log profile policy for a 7705 SAR” (p. 1896) to configure a Security Log Profile policy.

6

Save your changes. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

END OF STEPS

68.12 To configure a security host group policy for a 7705 SAR

68.12.1 Purpose

A host group policy is configured with single source/destination IP addresses or a range of IP addresses. For a single pre-assigned set of IP addresses that are allowed in a network, a list can be created once and assigned to every edge router. The host group policy can be assigned to a security policy.

68.12.2 Steps

1

Choose Policies→Security from the NFM-P main menu. The Security Policies form opens.

2

Click Create and choose Security Host Group, or choose an existing security host group policy and click Properties. The Host Group, Global Policy (Create|Edit) form opens with the General tab displayed.

3

Configure the required general parameters and click Apply.

4

Click on the Host Group Entries tab and click Create. The Host Group Entry, Global Policy form opens.

5

Configure the required general parameters and the parameters in the IP Address panel.

6

Save your changes. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

END OF STEPS

68.13 To configure a security application group policy for a 7705 SAR

68.13.1 Purpose

An application group policy maintains a group configuration based on common criteria. For example, an application group policy can contain UDP/TCP ports for a specific application or the ICMP type and code which must be matched in the policy. An application group policy can be assigned to a security policy.

68.13.2 Steps

1

Choose Policies→Security from the NFM-P main menu. The Security Policies form opens.

2

Click Create and choose Security Application Group, or choose an existing security application group policy and click Properties. The Application Group, Global Policy (Create|Edit) form opens with the General tab displayed.

3

Configure the required general parameters and click Apply.

4

Click on the Application Group Entries tab and click Create. The Application Group Entry, Global Policy form opens.

5

Configure the required general parameters and the Protocol parameter.

If you choose ICMP for the Protocol parameter, configure the parameters in the ICMP Properties panel. If you choose TCP or UDP for the Protocol parameter, configure the parameters in the Port Properties panel.

6

Save your changes. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

END OF STEPS

68.14 To configure a security policer group policy for a 7705 SAR

68.14.1 Purpose

A policer group policy ensures that each connection does not use more than the assigned bandwidth allocation. Any packet above the policed rate is dropped and discarded with a log event. A policer group policy can be assigned to a security profile policy.

68.14.2 Steps

1

Choose Policies→Security from the NFM-P main menu. The Security Policies form opens.

2

Click Create and choose Security Policer Group, or choose an existing security policer group policy and click Properties. The Policer Group, Global Policy (Create|Edit) form opens with the General tab displayed.

3

Configure the required general parameters.

4

Configure the Maximum Ingress Bandwidth (Mbps) and Committed Burst Size (bytes) parameters in the Burst Size panel and click Apply.

5

Save your changes. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

END OF STEPS

68.15 To configure a security bypass policy for a 7705 SAR

68.15.1 Purpose

A security bypass policy is a set of match criteria that define what traffic is allowed to pass across a security zone at the L2 service where the policy is applied. If a security bypass policy is not applied, then traffic is filtered based on the security zone configuration; if the policy is applied, then traffic that matches the criteria is allowed to pass regardless of other security zone configurations.

68.15.2 Steps

1

Choose Policies→Security from the NFM-P main menu. The Security Policies form opens.

2

Click Create and choose Security Bypass Policy, or choose an existing policy and click Properties. The Security Bypass, Global Policy (Create|Edit) form opens with the General tab displayed.

3

Configure the required general parameters.

4

Click on the Security Bypass Entry tab and create security bypass entries as required. Traffic matching the criteria defined in the entries is allowed to pass through the site where the policy is applied. Perform the following to create a security bypass entry:

1. Click Create. The Security Bypass Entry form opens.
2. Configure the required general parameters.
3. Click on the Match Criteria tab and configure the match criteria for the entry.
4. Save your changes.

5

Save your changes. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

END OF STEPS

69 PDN profile policies

69.1 PDN profile policies

69.1.1 Overview

You can create a PDN (Packet Data Network) profile policy to define the cellular interface used to connect mobile data users to the network from 7705 SAR-Hm nodes.

The PDN profile policy defines the APN (Access Point Name) used to define the type of network connection used, the Authorization Type (either PAP (Password Authentication Protocol) or CHAP (Challenge Handshake Authentication Protocol), the user name, and password.

69.2 To configure a PDN Profile policy for a 7705 SAR-Hm

69.2.1 Steps

1

Choose Policies→PDN Profile from the NFM-P main menu. The PDN Profile Policy form opens.

2

Click Create or select an existing PDN Profile policy and click Properties. The PDN Profile Policy, Global Policy (Create|Edit) form opens.

3

Configure the required parameters.

4

As required, click on the appropriate tabs and click Search to determine to which network objects the PDN Profile Policy is applied.

5

Click OK to save the policy and close the form, or click Apply to save the policy. See 49.6 “To release and distribute a policy” (p. 1476) to release and distribute the policy to NEs.

END OF STEPS

Part VI: Service management

Overview

Purpose

This part provides information about service management using the NFM-P.

Contents

70 Service management and QoS

70.1 Service management and QoS

70.1.1 Overview

The NFM-P supports the configuration of the following network services:

- virtual leased line (VLL) service
- virtual private LAN service (VPLS) / management virtual private LAN service (MVPLS) / hierarchical virtual private LAN service (HVPLS)
- internet enhanced service (IES)
- virtual private routed network (VPRN) service
- virtual LAN (VLAN) service
- composite service
- mirror service

An NFM-P operator can create, configure and delete services on sites and routers that are within their span of control.

An administrator can configure NFM-P system preferences related to service creation and deletion; see the procedure to configure NFM-P system preferences in the *NSP System Administrator Guide*.

The benefits of the NFM-P service model include:

- service creation using configuration forms
- service management using configuration forms and a navigation tree
- service priority setting to manage service deletion: low priority services can be deleted by simply ticking a box in the confirmation dialog. Medium priority services can be deleted by confirming the priority. High priority services can only be deleted by a user with administrator rights.
- linking of services to create composite services that support complex customer applications
- policies that specify the NE traffic classification, policing, shaping, time of day restrictions, and marking
- traffic management capabilities to customize the delivery of different services according to SLAs
- integrated alarm management functions

Customer traffic enters a service through one or more access interfaces. In a local service, all access interfaces are on one NE. In a distributed service, multiple NEs are deployed at the PE. Customer traffic is transported across an IP/MPLS core network in unidirectional service tunnels that use GRE or MPLS LSPs. Many services can use the same tunnel.

Figure 70-1 Distributed VLL service

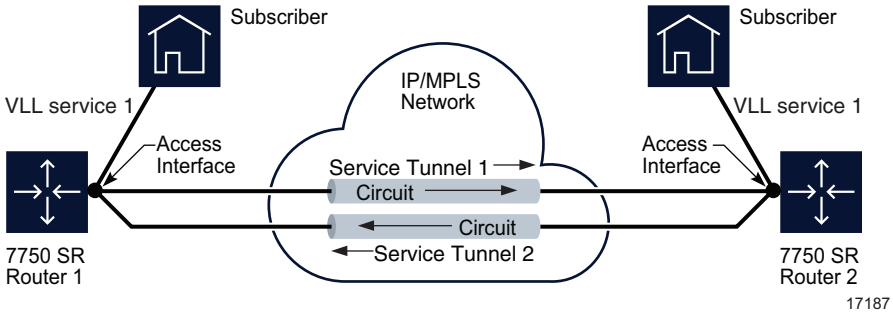


Figure 70-2 Distributed VPLS

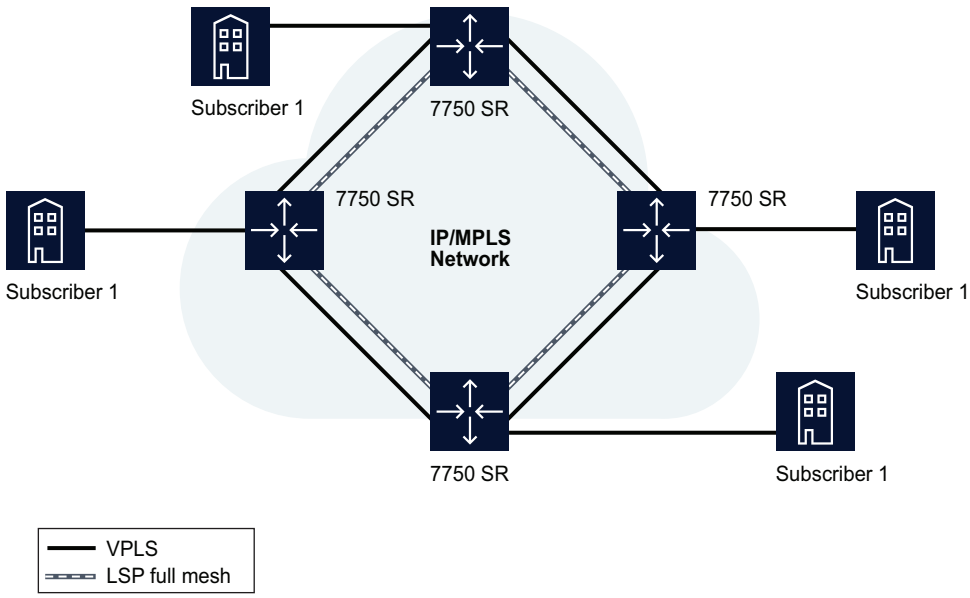
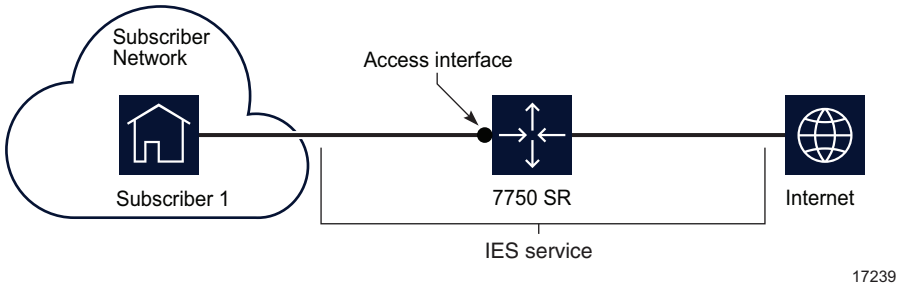


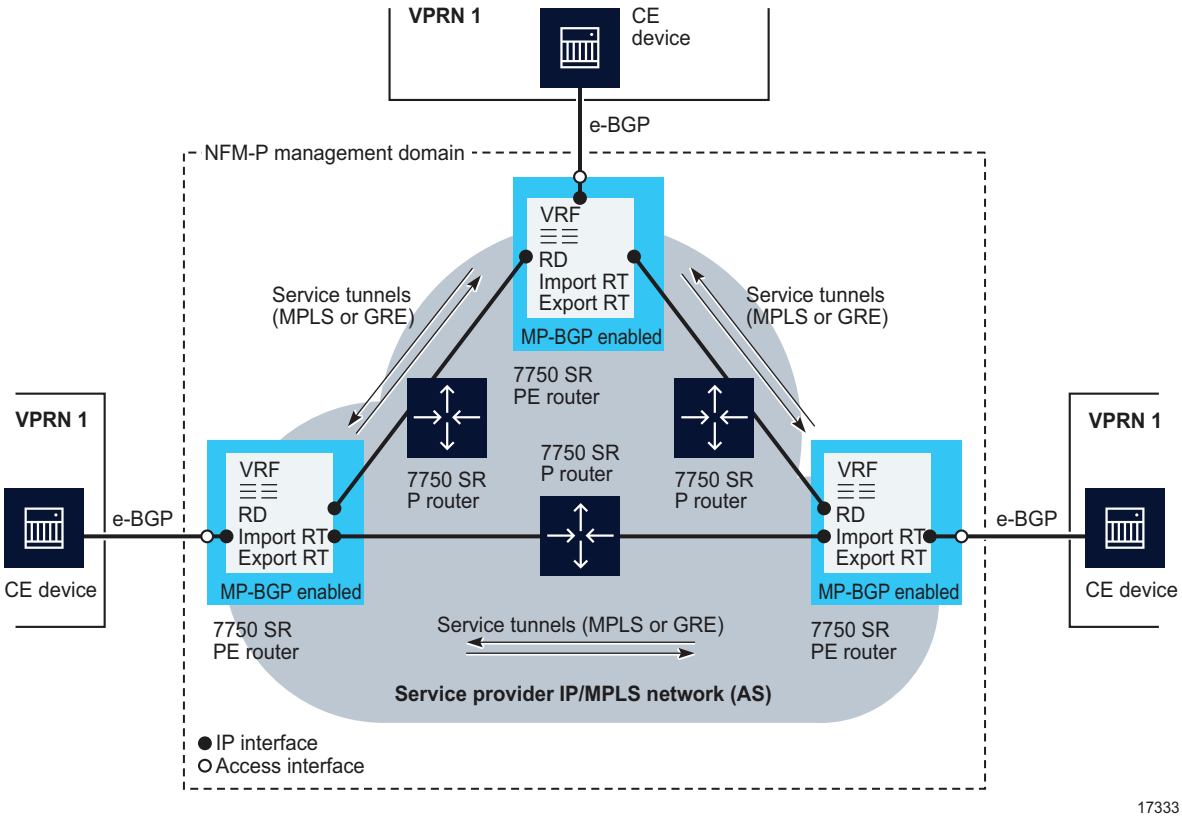
For IES, the managed devices are deployed at the provider edge and customer traffic enters the service using access interfaces. IES is a routed connectivity service where the customer communicates with an IP router interface to send and receive Internet traffic.

Figure 70-3 Sample IES



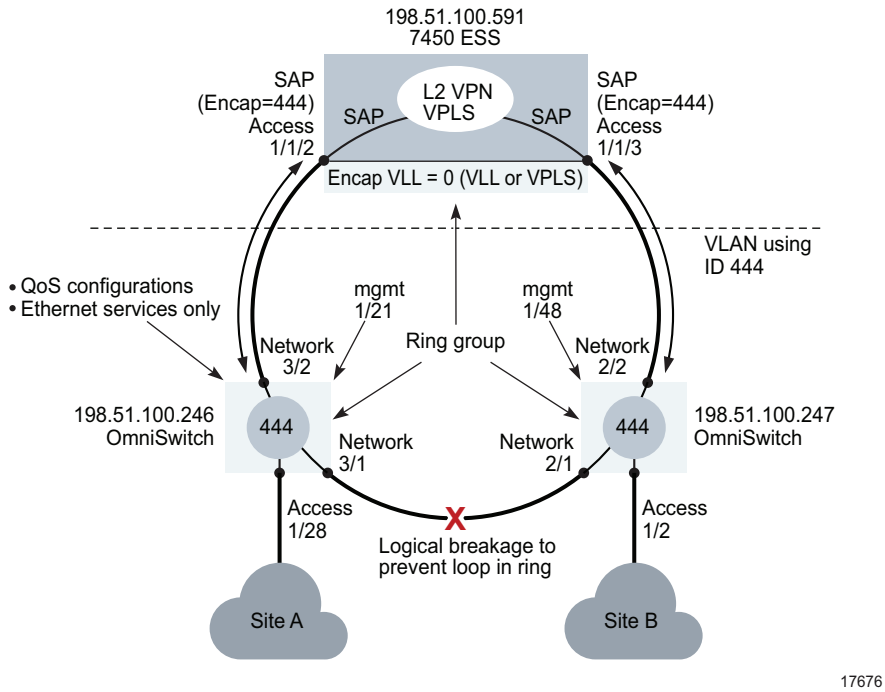
For VPRN services, the managed devices can be deployed as PE or provider core routers. Data and routing information are forwarded across an IP/MPLS service provider core network.

Figure 70-4 Sample VPRN service



VLAN ring groups are used to send traffic across an Ethernet ring using copper or fiber optic connections from the source traffic device, for example, a 7450 ESS, to all devices in the ring. Any breaks in the physical links between devices are rerouted.

Figure 70-5 Sample VLAN configuration for L2 VPNs



A composite service allows the interconnection of different service types to form a service delivery network that is tailored to a specific application. For example, VPRN, VPLS, and VLAN services can be joined to create a routed multicast TV distribution mechanism that spans a wide geographical area.

A mirror service is a unidirectional service function that duplicates a specified traffic stream and sends the duplicate stream to a monitoring device for troubleshooting or surveillance purposes. With pseudo-wire redundancy support, an ICB can be enabled in a mirror service spoke and a remote source, which can provide bidirectional service that enables support for active and standby PE redundancy.

QoS provides the ability to rate limit across multiple queues from one or more access interfaces for a customer, and to differentiate service levels for different types of traffic. For higher priority traffic such as VoIP or video, you can specify reserved bandwidth. Lower priority applications, such as data traffic, may not have reserved bandwidth but can burst to use all the available bandwidth.

The main elements of QoS are:

- QoS markings

Customer traffic may be marked with QoS markings, such as DSCP, EXP, and dot1p, that are mapped to forwarding classes.

All forwarding classes support profile marking of packets as in-profile or out-of-profile. In-profile packets have a high enqueuing priority. Out-of-profile packets have a low enqueuing priority. Profile marking of packets can occur at two points: when packets are classified into forwarding classes at access ingress and when packets are classified at service egress. Profile marking is only done on the internal header and not in an actual encapsulation.

- forwarding classes

  Provide network elements with a method to weigh the relative importance of packets, only in relation to other forwarding classes. A forwarding class is also referred to as a Class of Service.

- queues

  Location for buffering packets that are to be forwarded before they are scheduled.

- schedulers

  Hardware scheduling (or single-tier scheduling) exists by default on a device and consists of a high-priority and a low-priority scheduler.

  Scheduler policies (or multi-tier scheduling) provide a more complex, hierarchical structure of virtual schedulers that override the default hardware behavior for more flexible scheduling capabilities.

- slope policies

  Define the WRED slope characteristics of hardware buffer space that is used by the ingress and egress queues

See Chapter 49, “Policies overview” for more information about policies on the NFM-P. See the *7750 SR OS Services Guide* for more detailed information about QoS.

70.2 Access interfaces

70.2.1 Overview

Each customer service is configured with at least one access interface point called a SAP. The access interface identifies the point of customer interface for a service on the managed device.

A Layer 2 or Layer 3 access interface is uniquely identified using these parameters:

- physical Ethernet port or POS port and channel
- encapsulation type (if applicable)
- encapsulation id (if applicable)

Depending on the encapsulation type, a physical port or channel can have more than one access interface associated with it. Using encapsulation or a SONET/SDH channel, devices can support multiple services for a customer or for multiple customers.

Access interfaces can only be created on ports or channels that are designated as access in the physical port configuration. Access interfaces cannot be created on ports designated as core-facing network ports because these ports have a different set of features enabled in software.

Access interfaces can participate in policies. Time of day suites can also be associated with access interfaces to apply a set of time-based policies, filters, and schedulers. Configuration of access interfaces can be performed during service configuration or modification.

When you configure an access interface, consider the following:

- An access interface is owned by and associated with the service in which it is created.
- An access interface is a local entity and is locally unique to a specific device. The same access interface ID value can be used on another device.
- There are no default access interfaces. All access interfaces must be created.
- The default administrative state for an access interface at creation time is administratively enabled.
- If a port or channel is shut down (administratively or operationally), access interfaces on that port/channel are operationally out of service.

70.3 Automatic SDP (service tunnel) binding for services

70.3.1 Overview

You configure automatic service tunnel (SDP) binding for services when you configure a service using configuration forms.

The NFM-P defines its own internal rules on how automatic mesh SDP bindings are performed.

1. The NFM-P tries to find the least-used SDP (service tunnel) with the lowest load factor (the lower the number of bindings, the lower the load factor) from the source to destination NE when the service tunnel meets the following conditions:
   - the service tunnel operational state is up
   - the operational MTU is greater than or equal to the MTU value of the service site
   - T-LDP is set for SDP bindings of VPLS, IES, or VLL services
   - the selected transport method, either GRE, LDP, or RSVP
2. When no service tunnel operational state is up, NFM-P tries to find the least-used service tunnel with the lowest load factor in an operationally down state.
3. For mirror services, binding are created from the source sites to the destination sites.
4. When a service tunnel cannot be found for a service site, a change in the site leads to another search. For example, if the service MTU is 1500 and the highest path MTU in all SDPs from that site is 1472, no SDP binding can be successful. If the service MTU is lowered to 1472 or less, a successful SDP binding results.
5. When a service tunnel is not found, and the transport method selected is GRE, NFM-P attempts to create a GRE service tunnel with a path MTU equal to the service site service MTU with T-LDP signaling turned on.

See 16.5.9 “MTU size and port configuration” (p. 573) in 16.1.2 “Working with port and channel objects” (p. 565) for more information on MTU size considerations.

70.4 Multi-segment tunnel selection

70.4.1 Overview

Multi-segment tunnel selection functionality enhances tunnel selection functionality to allow the system to select intermediate NEs in a path, as well as the service tunnels from a selected intermediate NE to its next hop. Multi-segment tunnel selection functionality is used to select existing SDPs. It cannot create new SDPs.

Tunnels are selected based on the following criteria:

- If a metric value is specified for any of the SDPs along the path, the path with the lowest sum of the metric property for all SDPs along the path is selected.
- If no metric is specified for any of the SDPs along the path, the path with the fewest number of SDPs (hops) is selected.
- If two paths or SDPs are equal based on the selection criteria mentioned above, the SDP/path with the lowest load factor (number of services using that SDP) is selected.

Multi-segment tunnel selection functionality must be enabled on the Services tab on the NFM-P System Preferences form, as well as at the tunnel selection profile level. The table below describes the objects to which a tunnel selection profile with multi-segment tunnel selection can be assigned, and the service tunnel configurations that result.

Table 70-1 Multi-segment tunnel selection scenarios

Tunnel selection profile applied to...	Resulting tunnel configuration
Spoke SDP binding on a VLL service	This scenario applies to a VLL service with two terminating sites. One of the sites has a spoke SDP binding configured with Auto-Select Transport Tunnel enabled, and a tunnel selection profile with Multi-segment Tunnel Selection enabled. If a valid path is found between the two terminating sites, the spoke SDP bindings and switching sites are created.
VLL service	This scenario applies to a VLL service with two terminating sites. The service is configured with Automatic SDP Binding/PBB Tunnel Creation enabled, and a tunnel selection profile with Multi-segment Tunnel Selection enabled. If a valid path is found between the two terminating sites, the spoke SDP bindings and switching sites are created.

Table 70-1 Multi-segment tunnel selection scenarios (continued)

Tunnel selection profile applied to...	Resulting tunnel configuration
Spoke termination point	This scenario applies to a spoke SDP binding between any two supporting objects. These include (M-)VPLS sites, (M-)VPLS I-sites, (M-)VPLS B-sites, VLL sites, IES L3 access interfaces, VPRN L3 access interfaces, VLL endpoints, and VPLS endpoints. The spoke SDP binding is configured with Auto-Select Transport Tunnel enabled, and a tunnel selection profile with Multi-segment Tunnel Selection enabled. If a termination point is specified, the spoke SDP bindings and return spoke SDP bindings are created. Switching sites are created as follows: • If the spoke SDP binding is created on a VLL service, the switching sites are created on the VLL service. • If the specified termination point is on a VLL service, the switching sites are created on the VLL service. • If neither end of the tunnel is on a VLL service, a new EPIPE service is created. The service component ID is auto-selected by the system. The subscriber ID is the same as the service on which the spoke is created. All other parameters are default values.

70.4.2 Redundant path selection

If Redundant Path Selection is enabled on a tunnel selection profile, a redundant path is created. Redundant Path Selection can only be enabled if Multi-Segment Tunnel Selection is also enabled. The selected redundant path does not use any of the same switching sites as the primary path. Redundant path selection is not supported when a termination point is selected on a spoke SDP binding. The table below describes the objects to which a tunnel selection profile with redundant path selection can be assigned, and the service tunnel configurations that result.

Table 70-2 Redundant path selection scenarios

Tunnel selection profile applied to...	Resulting redundant path configuration
Spoke SDP binding on a VLL service	This scenario applies to a VLL service with two terminating sites. One of the sites has a spoke SDP binding configured with Auto-Select Transport Tunnel enabled, and a tunnel selection profile with Multi-segment Tunnel Selection and Redundant Path Selection enabled. If a valid path is found between the two terminating sites, the spoke SDP bindings and switching sites for the redundant path are created. In this case, an endpoint and a return endpoint must be specified.

Table 70-2 Redundant path selection scenarios (continued)

Tunnel selection profile applied to...	Resulting redundant path configuration
VLL service	This scenario applies to a VLL service with two terminating sites. The service is configured with Automatic SDP Binding/PBB Tunnel Creation enabled, and a tunnel selection profile with Multi-segment Tunnel Selection and Redundant Path Selection enabled. If a valid path is found between the two terminating sites, the spoke SDP bindings and switching sites for the redundant path are created. From a VLL Service, endpoints on the terminating sites that do not have SAPs or spokes are used for the auto-created spokes. If multiple endpoints exist on a terminating site, the endpoint without any SAPs is used. If multiple viable endpoints are available, an error is raised by the NFM-P and the operation fails. If there are no endpoints available, an endpoint is automatically created with default parameter values, with the following exceptions: • The Name parameter value is the endpoint Service ID. • The Description parameter value is auto-generated by the system.

70.4.3 Service tunnel required bandwidth

Service tunnel bandwidth requirement can be specified as an additional constraint in the path search process. When required bandwidth is specified at the service or service site level, the selection of service tunnels is based on bandwidth availability. If all other tunnel selection criteria are equal, the tunnel with higher available bandwidth is selected.

Note: Service tunnel required bandwidth functionality requires that the CPAM feature set is correctly configured. See the *NSP NFM-P Control Plane Assurance Manager User Guide* for information about the CPAM feature set. Additionally, the Multi-Segment Tunnel Selection and Service Bandwidth Management system options must be enabled.

All physical links between service sites must be configured (either manually or through LLDP) before bandwidth can be allocated to service tunnels.

This functionality applies to RSVP tunnels on VLL, VPLS, and MVPLS services, and G.8032 Ethernet rings on VPLS services. Bandwidth requirement criteria are specified at the service level, and are inherited by all associated service sites by default. Optionally, bandwidth requirement criteria can be specified on individual service sites. Bandwidth requirements are specified on the service or site configuration form, Bandwidth tab - Required Bandwidth sub-tab.

Bandwidth can be user-specified on a per-CoS basis, or it can be calculated automatically. When bandwidth values are calculated automatically, the calculation is based on the ingress CIR configurations, taking the sum of the bandwidths for the endpoints (SAPs) connected to each site. In the event that two sites with different bandwidth sums are connected by a service path, the lower of the two bandwidth sums is booked for the service path.

There are two options that determine how service bandwidth is booked in the network:

- For Epipe services only, the user has the option to enable bandwidth booking on both the active and redundant service paths (if a redundant path is available). Otherwise, only the active path is booked.

- For all VLL, VPLS, and MVPLS services, the user has the option to enable bandwidth booking on all operationally up LSP paths in use by the service. Otherwise, only the active path is booked.

70.5 Automatic PBB tunnel binding

70.5.1 Overview

This feature is applicable only to VLL Epipes and I-VPLS services using a PBB tunnel.

The configuration of the service CAC functionality allows you to manage bandwidth at the service level and at the link level, which in turn enables the NFM-P to automatically select the best tunnel based on the number of active links and on the amount of available bandwidth on the service. The NFM-P also considers the shortest available path when it allocates bandwidth.

Although the NFM-P can select tunnels automatically—see 70.3 “Automatic SDP (service tunnel) binding for services” (p. 1910) —if service CAC is not configured, bandwidth will not be considered by the NFM-P when selecting the tunnel.

Bandwidth availability for the tunnel is calculated at the service admission request time and is based on the links currently used by the tunnel forwarding path. The booking of reserved bandwidth by the service is done directly on the link and directly on the tunnel, for a bandwidth-reserved tunnel.

The link monitors the bandwidth used by all of the services using that link. Since the bandwidth reserved on each tunnel that is used by a service can be different, the link monitors bandwidth usage through the tunnels rather than through a service.

You can perform a system-wide audit to ensure that the bandwidth on each link is properly calculated. The audit visits all tunnels in the network and adjusts the available bandwidth in all links currently being used by the forwarding tunnel path. The adjustments are made based on total bandwidth requests per CoS for all EVPLs currently using the tunnels.

You can perform this audit by clicking on the CAC Audit button on the Manage Services form, or by choosing CAC Audit on the More Actions button. The audit also occurs automatically on system startup and when service CAC is switched from disabled to enabled.

70.6 Lightweight SAPs

70.6.1 Overview

SAPs that are associated with residential split horizon groups on VPLS sites are called lightweight SAPs. An RSHG uses dual-pass queue optimization and does not support downstream broadcast or multicast traffic. Lightweight SAPs have fewer internal configuration settings than regular SAPs. Therefore, you can create more lightweight SAPs on a NE. The SAP Lightweight property is automatically set at creation time, when the SAP is associated with an RSHG, and cannot be modified later.

Users can:

- assign SAPs to residential split horizon groups
- list lightweight SAPs using the Lightweight filter property

Note: To get the most recent state of a lightweight SAP, it is recommended that users perform a resynchronization by clicking on the Resync button in the SAP configuration form. If this button is not visible, click on the More Actions button and choose Resync.

70.7 QoS policies

70.7.1 Overview

Policies group and manage the various QoS elements used to determine how traffic is routed.

- access ingress policies

  Specify how QoS marking is interpreted, how customer traffic is mapped into queues, and how queues are classified.
- access egress policies

  Specify how customer traffic is mapped into queues, specify queue classification, queue parameters, and QoS marking.
- network policies

  Specify QoS marking to forwarding class mapping on ingress and QoS marking to forwarding class mapping on egress.
- network queue policies

  Specify CIR, PIR, and burst sizes for each queue. Forwarding class to queue mapping is not configurable.
- scheduler policies

  Specify custom settings and a hierarchical structure of virtual schedulers to replace the default hardware schedulers on the device.
- port scheduler policies

  Specify bandwidth allocation at the egress port level.
- HSMDA scheduler policies

  Specify schedulers to define egress port and ingress scheduler behavior on an HSMDA.
- slope policies

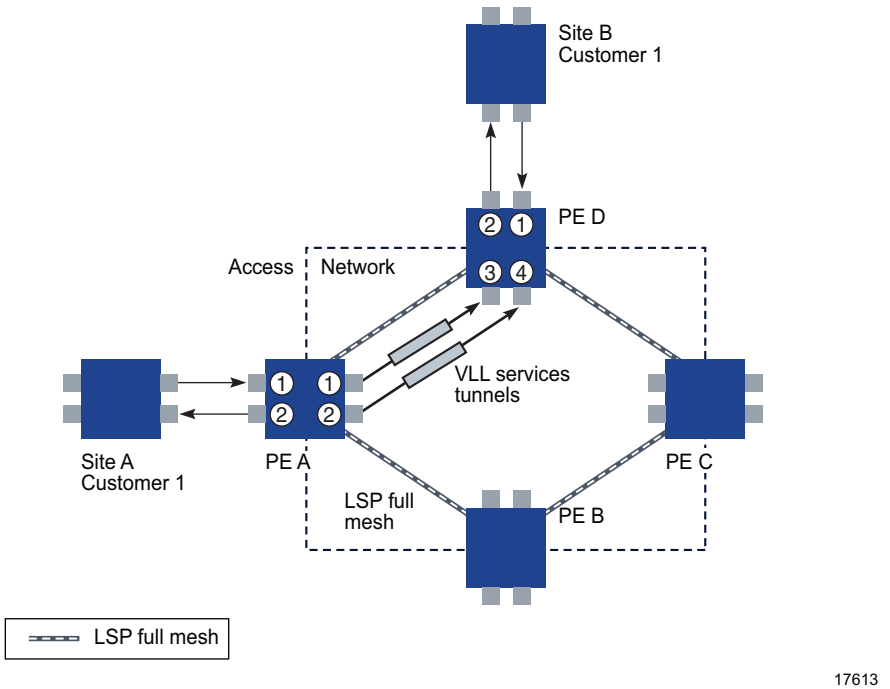
  Specify WRED settings to customize how in-profile and out-of-profile traffic is processed in hardware buffers, applied to daughter cards or ports.
- HSMDA slope policies

  Specify settings for controlling how the depth of HSMDA queues is managed.
- ATM QoS policies

  Specify ATM QoS settings to customize ATM traffic parameters including service category and shaping.

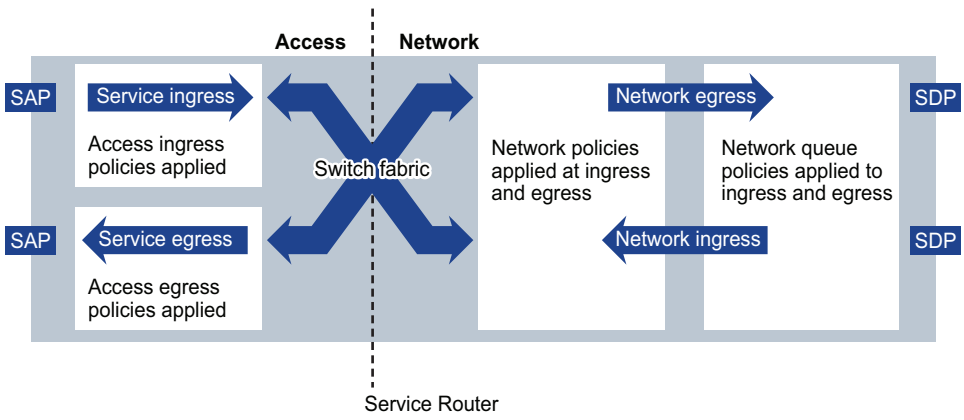
The figure below shows where QoS policies are applied at the service level.

Figure 70-6 Service-level view of policies



The figure below shows where policies are applied on a device with respect to access and network ingress and egress traffic.

Figure 70-7 Types of traffic on a device and applied policies



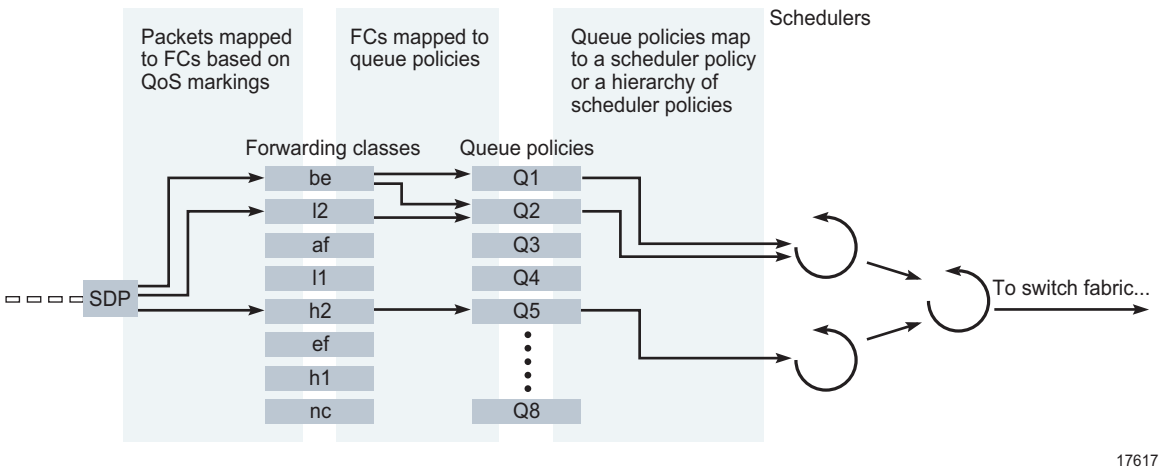
70.7.2 SAP access ingress policies

Access ingress policies are applied to access interfaces and specify QoS characteristics on ingress. Participation in access ingress policies is defined when access interfaces are configured or modified.

Access ingress policies include:

- mapping of QoS marking, such as dot1p, DSCP, and precedence, and IP/MAC address information to forwarding classes
- forwarding class definitions and mapping to queues
- queue definitions and mapping to schedulers

Figure 70-8 Access ingress policy elements



See 50.2 “SAP access ingress policies” (p. 1507) in “QoS policy types” (p. 1507) for more information about access ingress policies.

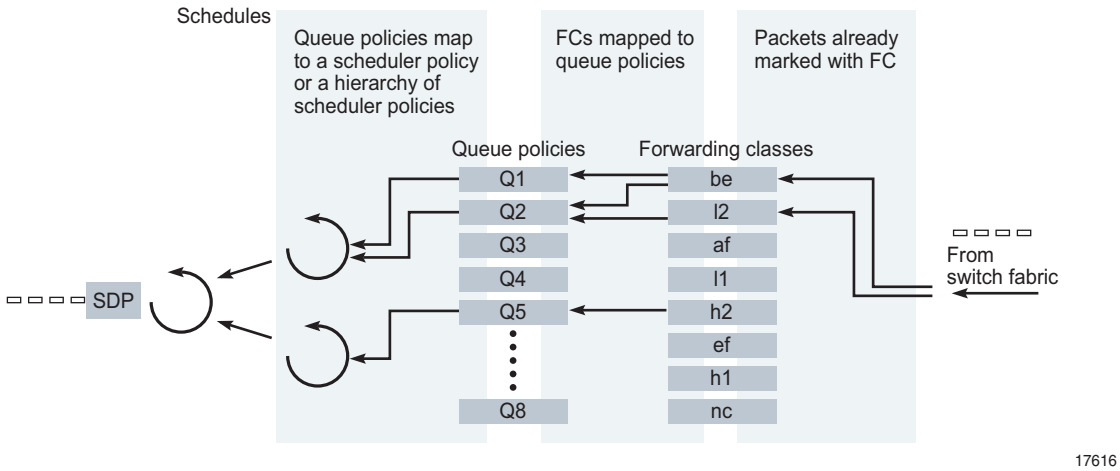
70.7.3 SAP access egress policies

Access egress policies are applied to access egress interfaces and specify QoS characteristics on egress. Participation in access egress policies is defined when access interfaces are configured or modified.

Access egress policies include:

- forwarding class definitions and mapping to queues
- queue definitions and mapping to schedulers

Figure 70-9 Access egress policy elements



In Figure 70-9, “Access egress policy elements” (p. 1918) , packets are marked with an FC, either by:

- ingress policy if the packet was received on the same device
- in the tunnel transport encapsulation if received using a service tunnel

See 50.3 “SAP access egress policies” (p. 1513) in “QoS policy types” (p. 1507) for more information.

70.7.4 Network policies

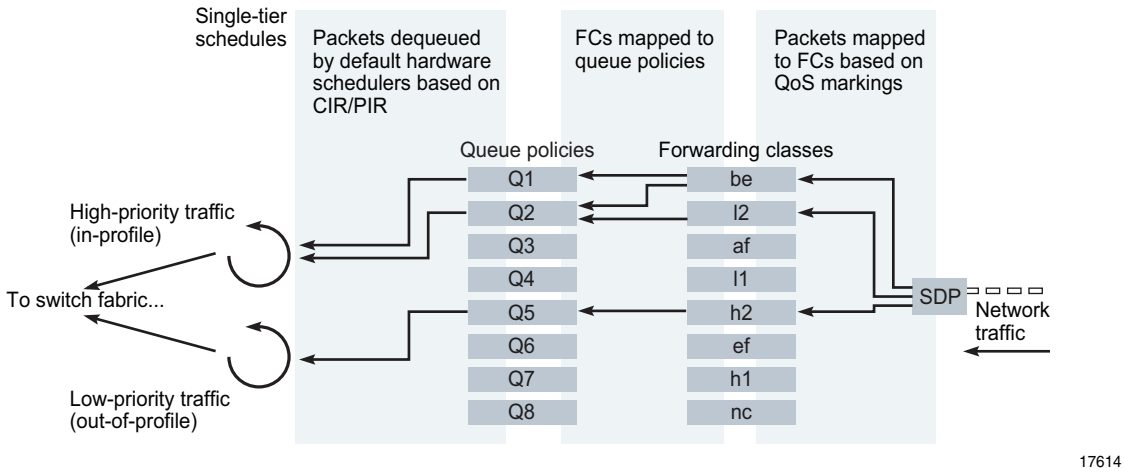
Network policies define egress QoS markings and ingress QoS interpretation for traffic on core network IP interfaces.

A network policy defines:

- DSCP name mapping to forwarding classes
- LSP EXP value mappings to forwarding classes
- whether QoS remarking is enabled

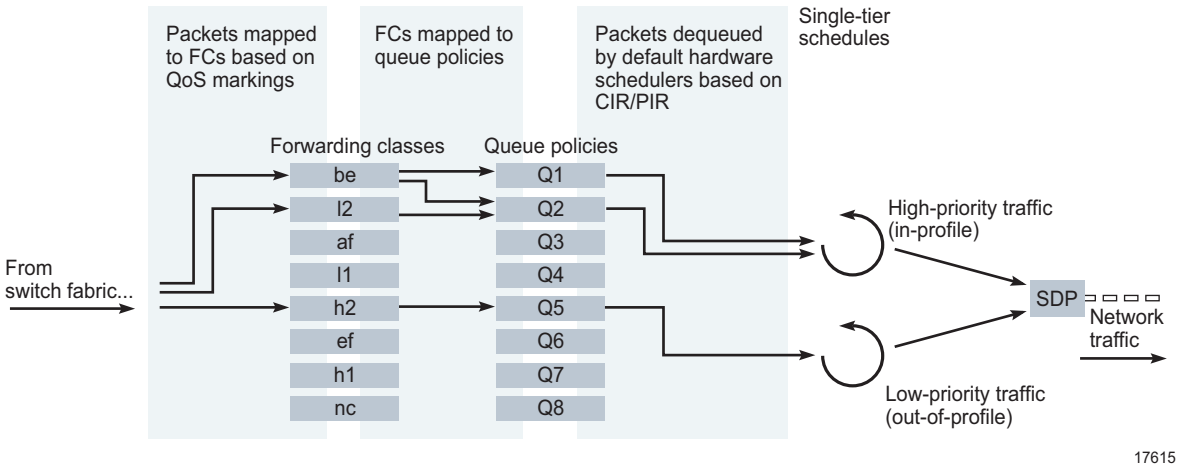
The figure below shows the sequence of how the elements of network and network queue policies are applied at ingress.

Figure 70-10 Network and network queue policy elements on ingress



The figure below shows the sequence of how the elements of network and network queue policies are applied at egress.

Figure 70-11 Network and network queue policy elements on egress



See 50.8 “Network policies” (p. 1516) in “QoS policy types” (p. 1507) for more information.

70.7.5 Network queue policies

Network queue policies define the network forwarding class queue characteristics for core egress network ports and for ingress on MDAs.

See Figure 70-10, “Network and network queue policy elements on ingress” (p. 1919) and Figure 70-11, “Network and network queue policy elements on egress” (p. 1919) for the sequence of how the different elements of network and network queue policies are applied on ingress in and on egress.

The queued packets are serviced by single-tier schedulers on the device and are forwarded to a single destination switch fabric port or a network interface.

See 50.9 “Network queue policies” (p. 1516) in “QoS policy types” (p. 1507) for more information about network queue policies.

70.7.6 Scheduling

Scheduling defines the order and method for how packets which are enqueued in different queues, are dequeued. Ingress schedulers control the data transfer between the queues and the switch fabric. Egress schedulers control the data transfer between the egress queues and the switch fabric. Packets are not actually forwarded to schedulers, but are forwarded from the queues directly to ingress and egress interfaces. Participation in scheduler policies is defined when access interfaces are configured or modified.

There are two types of scheduling:

- Single-tier scheduling is the hardware-based default method for scheduling queues on the device. There are no configurable parameters for single-tier schedulers. When a scheduler policy is not specified for an access interface, rate limiting is specified by the values specified in the queue and scheduling is performed by the default hardware scheduler on the device. Single-tier scheduling consists of a pair of scheduling priority loops in the 7750 SR and bases scheduling on the CIR and the PIR set in the queue policy. One loop is for scheduling high-priority (in-profile) traffic, and the other loop is for low-priority (out-of-profile) traffic.
- Virtual hierarchical (multi-tier) scheduling can provide more flexible scheduling for access ingress and egress interfaces, and determine how queues are scheduled. They are defined using a Scheduler policy, and can be configured to override default hardware scheduling. You can create up to three tiers of virtual schedulers.

  Aggregation schedulers are used to share a scheduler policy across a number of ports or daughter cards. This can be useful when a number of ports or cards are dedicated to the same customer. See 50.13 “Scheduler policies” (p. 1521) in “QoS policy types” (p. 1507) for more information about configuring aggregation schedulers.

70.7.7 Port scheduler policies

Port scheduler policies define the bandwidth allocation based on the available bandwidth at the egress port level. A port scheduler policy manages a bandwidth allocation algorithm that represents a virtual multi-tier scheduling hierarchy.

The port scheduler allocates bandwidth to each service or subscriber that is associated with an egress port. Egress queues on the service may have a child association with a scheduler policy on the SAP or multi-service site. All queues must compete for bandwidth from an egress port.

There are two methods of bandwidth allocation on the egress access port:

- **direct association of port scheduler on a SAP or multi-service site with service or subscriber queue**

A service or subscriber queue is associated with a scheduler on the L2 access interface or multi-service site, and the service-level scheduler policy is associated with a port level scheduler.

- **direct association of port scheduler with service or subscriber queue**
  A service or subscriber queue is associated with a port scheduler. The port scheduler hierarchy allocates bandwidth at each priority level to each service or subscriber queue.

See 50.14 “Port scheduler policies” (p. 1523) in “QoS policy types” (p. 1507) for more information about configuring port scheduler policies.

70.7.8 HSMDA scheduler policies

The port-based scheduler manages forwarding for each egress port on the HSMDA. Each port-based scheduler maintains up to eight forwarding levels. Eight scheduling classes contain each of the queues that are assigned to the port scheduler. Membership in a scheduler is defined by the queue identifier.

The port-based scheduler supports a port-based shaper that is used to create a sub-rate condition on the port. Each scheduling level can be configured with a shaping rate to limit the amount of bandwidth allowed for that level.

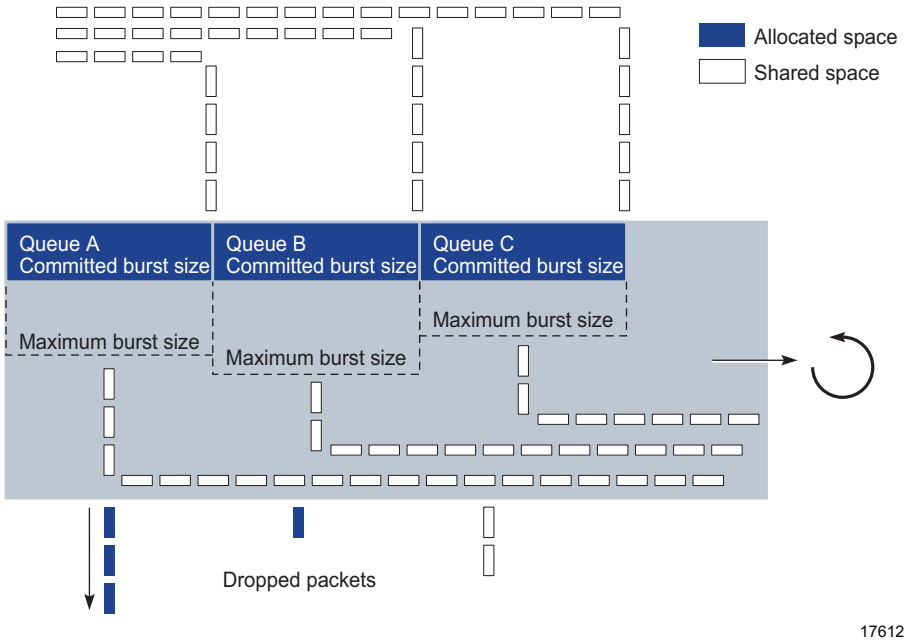
The port-based scheduler allows two weighted groups (group 1 and group 2) to be created. Each group can be populated with three consecutive scheduling classes.

See 50.15 “HSMDA scheduler policies” (p. 1523) in “QoS policy types” (p. 1507) for more information about configuring slope policies.

70.7.9 Slope policies

Slope policies manage how shared buffers are utilized on the SR. When traffic is queued, the WRED slope parameters in the slope policy determine how the traffic is buffered for de-queuing, as shown in the figure below.

Figure 70-12 Slope policy characteristics



All queues are in contention for shared buffer space when they exceed their CBS, and can use their MBS, when space is available in the shared buffer space. The WRED parameters determine whether a packet is discarded or not, and, as a result, determine whether the packet is dequeued. When the shared buffer space exceeds or approaches the maximum percentage defined by the WRED configuration, packets are discarded.

By using two independent slope policy configurations, one for in-profile traffic and one for out-of-profile traffic, you can configure in-profile traffic to receive preferential treatment over out-of-profile traffic.

See 50.11 “Slope policies” (p. 1519) in “QoS policy types” (p. 1507) for more information about configuring slope policies.

70.7.10 HSMDA slope policies

HSMDA slope policies control the HSMDA queues. Each queue supports an index for an HSMDA slope policy table. Each policy in the table consists of two RED slopes (one high priority and another for low priority) to manage queue congestion. HSMDA RED slopes operate on the instantaneous depth of the queue.

A packet that attempts to enter a queue triggers a check to see whether the packet is allowed based on queue congestion conditions. The packet contains a congestion-priority flag that indicates whether the HSMDA is to use the high or low slope. The slope policy containing the slope is derived from the policy index in the queue configuration parameters on the HSMDA.

The RED slope discards are based on the current queue depth before a packet is allowed into the queue. Therefore, a queue may consume buffers that are greater than the configured MBS value

based on the size of the packet. After the packet maximum is reached, packets that are associated with the queue are discarded. When the schedule removes packets from the queue, the queue depth decreases, which eventually lowers the depth of the threshold.

See 50.12 “HSMDA WRED slope policies” (p. 1520) in “QoS policy types” (p. 1507) for more information about configuring HSMDA slope policies.

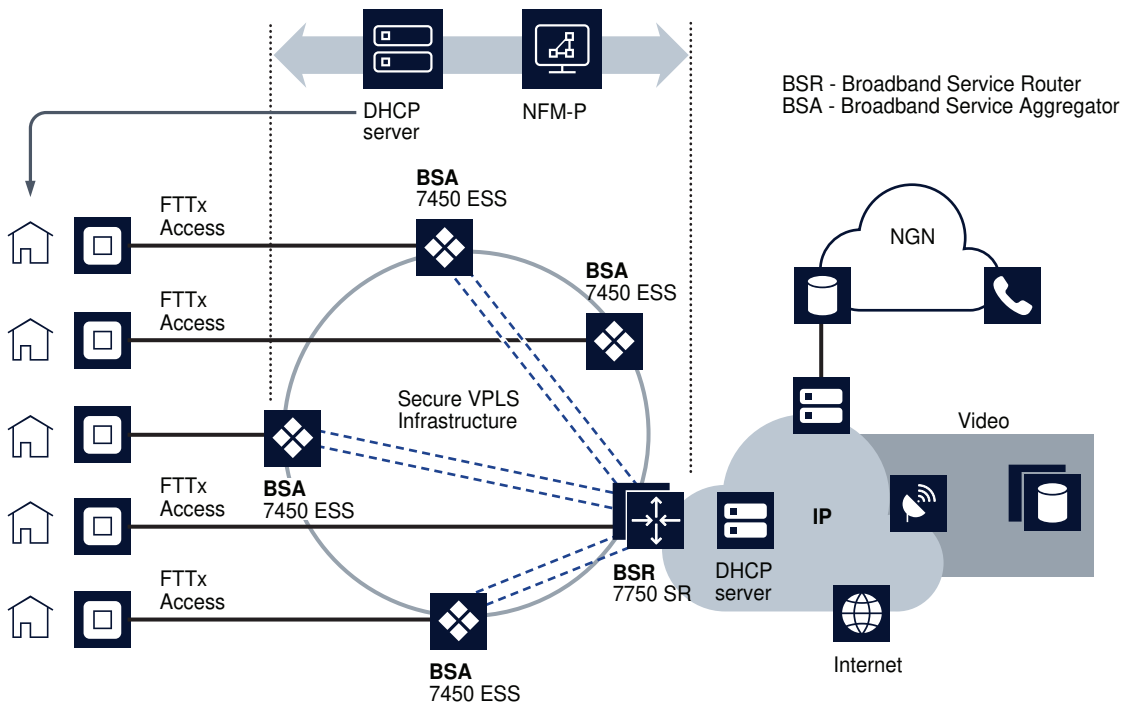
70.8 The triple play service delivery architecture

70.8.1 Overview

The triple play service delivery architecture (TPSDA) is based on three major components, as shown in the figure below:

- broadband service aggregator
- broadband service router
- service and policy activation

Figure 70-13 TPSDA components



The table below lists the Nokia TPSDA product components.

Table 70-3 Product components of the TPSDA

Product	Role	Notes
NFM-P	Provides network, service, and policy management across the TPSDA architecture, including a unified interface for element management and simple service activation and monitoring.	—
7750 SR	BSR	Support per-service and per-content type differentiation of QoS levels and supports distribution of multicast traffic.
7450 ESS	BSA	Aggregate traffic from DSLAMs and other FTTx access devices that are connected to end-user residential gateways.

DSLAMs or other access NEs are connected to Ethernet access ports on the broadband service aggregator. Typically, a single VLAN for each customer is set up between the access NE and the BSA. This a configuration enables the application of consistent per-customer policies, such as QoS, filtering, and accounting, to be applied on the BSA.

Scaling of traffic and services is done by dividing L2 and L3 functions between the BSA and the BSR. The BSA aggregates traffic over Gigabit Ethernet ports and performs per-customer service queuing, scheduling, accounting and filtering, as described later in this chapter. The BSR terminates L2 access and routes over IP/MPLS with support for all protocols, including multicasting. Time of day QoS policies can be applied using NFM-P policy management.

Interconnectivity between BSAs and BSRs is provided by VPLS. VPLS instances can be automatically established using hub-and-spoke or ring topologies. Both can be configured and sites added to the VPLS using the NFM-P. Regardless of the fiber plant layout, VPLS enables a full mesh between all sites that are receiving and distributing customer traffic in the TPSDA, ensuring efficient transport and protection from NE or fiber failures.

VPLS also provides mechanisms for traffic security, including residential split horizon groups in which direct user bridging is prohibited; ARP and broadcast suppression; DHCP-populated MAC and IP address filtering to prevent denial or service and theft of service using DHCP snooping, and RADIUS or TACACS+ authentication.

70.9 Service differentiation and QoS

70.9.1 Overview

This TPSDA approach provides a model based on call admission for video and VoIP, with the need to guarantee delay, jitter, and loss characteristics after the service connection is accepted. The architecture also meets the different QoS needs of HSI, namely per-user bandwidth controls, including shaping and policing functions that have little or no value for video and VoIP service delivery.

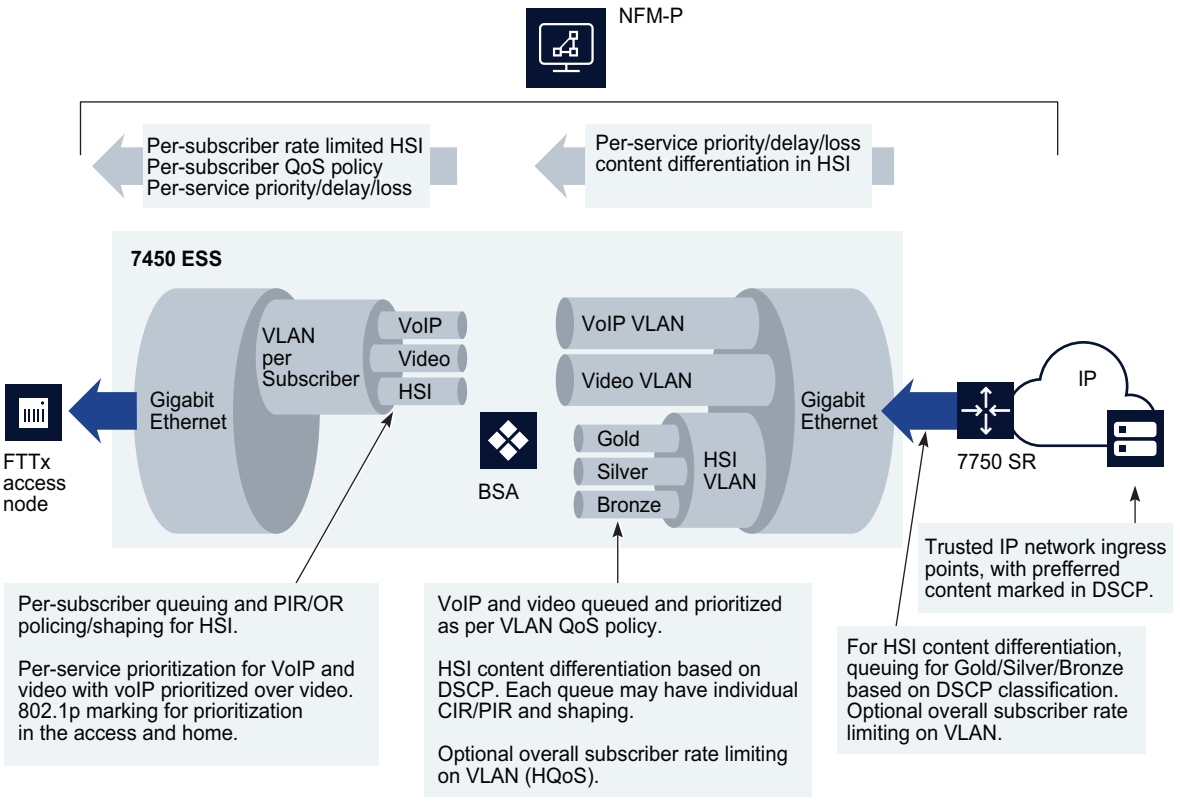
In conjunction with the architecture's support for content differentiation, this approach enables differentiated service pricing within high-priority data packages, also known as HSI. The distribution of QoS policy and enforcement across BSA and BSR allows the service provider to implement

meaningful per-user service level controls. Sophisticated and granular QoS in the BSA allows the service provider to deliver truly differentiated IP services differentiation based on the user as well as on the content.

In the BSR to BSA downstream direction, IP services rely on IP layer classification of traffic from the network to queue traffic appropriately towards the BSA. Under extreme loading (only expected to occur under network fault conditions), lower priority data services and/or HSI traffic are compromised to protect video and voice traffic. Classification of HSI traffic based on source network address or IEEE 802.1p marking allows the QoS information to be propagated to upstream or downstream devices.

The BSR performs service distribution routing based on guarantees required to deliver the service and associated content, rather than on individual end users. The BSR only needs to classify content based on its forwarding class for a specific BSA to ensure that traffic for each service receives the appropriate treatment towards the BSA.

Figure 70-14 TPSDA downstream QoS configurations

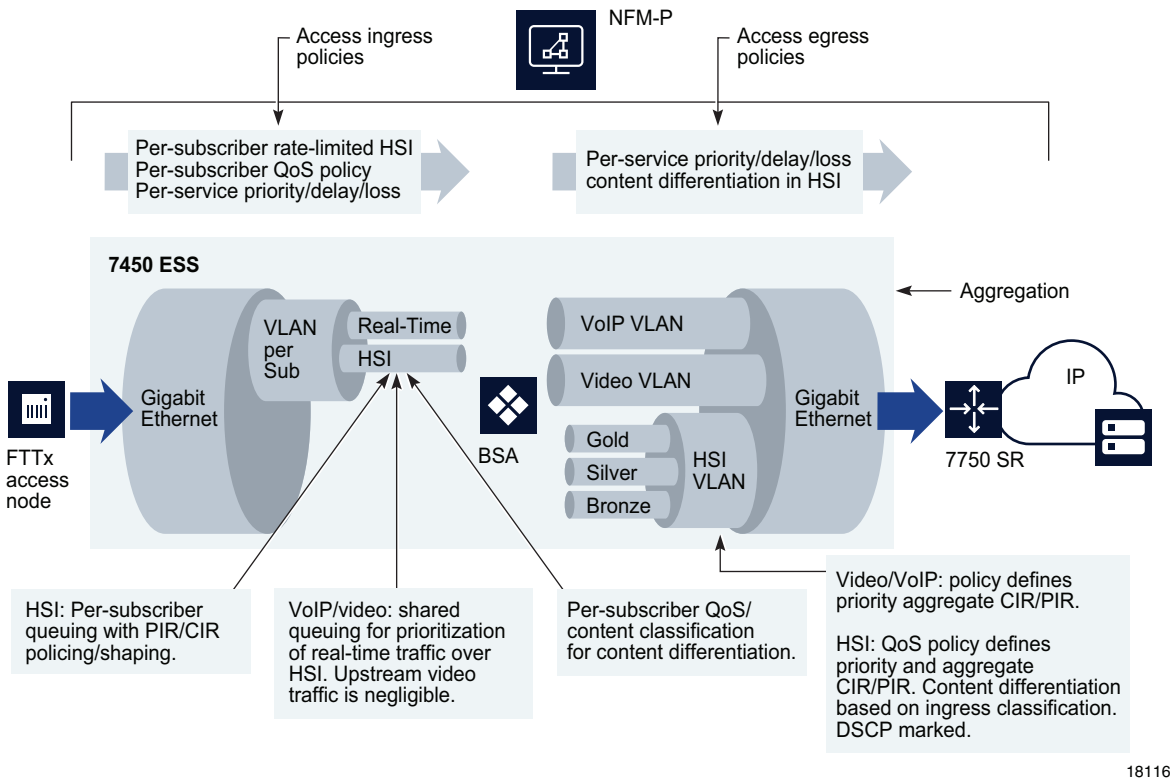


In the BSA-to-BSR upstream direction, traffic levels are substantially lower. Class-based queuing is used on the BSA network interface to ensure that video traffic is forwarded with minimal delay and that preferred data or HSI high-priority data traffic services receive better treatment than for best-

effort Internet traffic. The IP edge device (BSR) therefore does not need to enforce per-user policies for hundreds of thousands of users. This function is distributed to the BSAs, and the per-user policies can be implemented on the interfaces directly facing the access NEs.

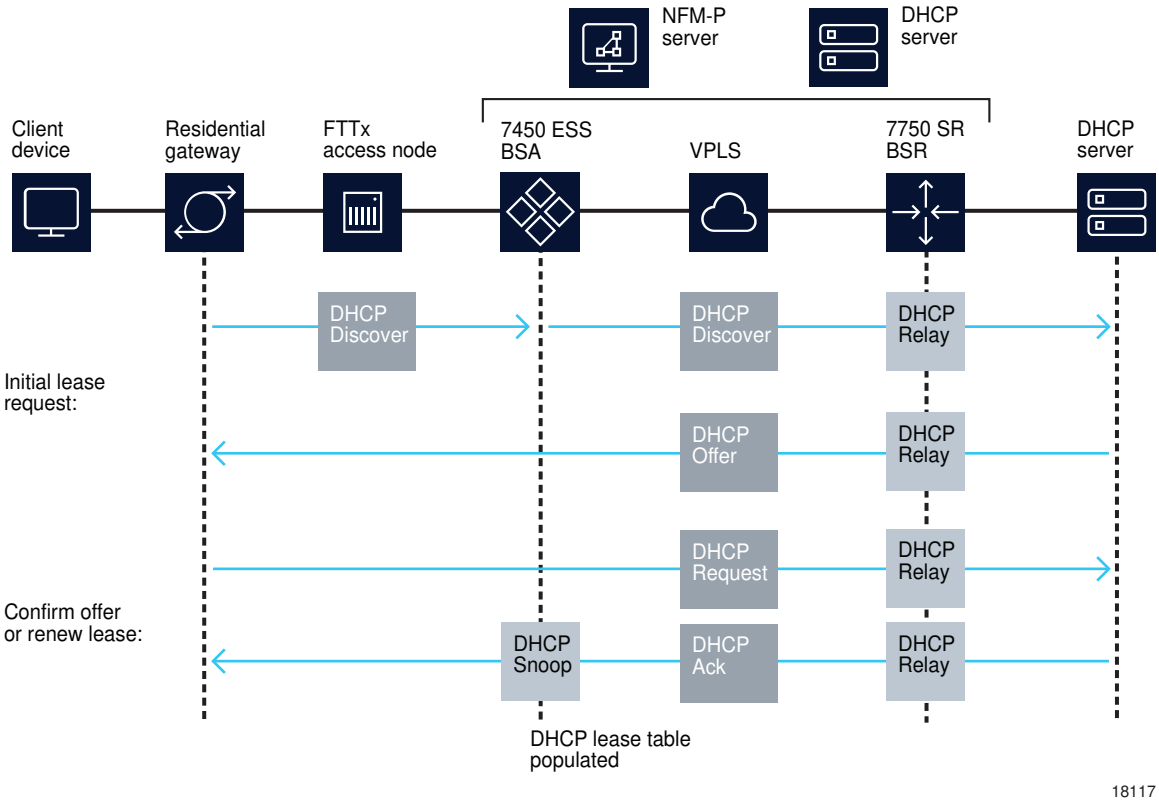
The BSA is capable of scheduling and queuing functions on a per-service, per-user basis, in addition to performing wire-speed packet classification and filtering based on both L2 and L3 interfaces. In addition to per-service rate limiting for Internet services, service traffic for each user can be rate-limited as an aggregate using a bundled service policy created using the NFM-P. These functions allow different users to receive different service levels independently and simultaneously.

Figure 70-15 TPSDA upstream QoS configurations



When a residential host device such as a residential gateway or a set-top box in the customer's home starts up, it requests network information, including the required IP address from a DHCP server. The figure below shows IP address assignment. See Table 70-4, “TPSDA features” (p. 1927) for information about DHCP configuration options in the TPSDA.

Figure 70-16 DHCP IP address assignment in the TPSDA



The table below lists the TPSDA features that you can configure using the NFM-P.

Table 70-4 TPSDA features

Feature and use	Notes	Reference
Split horizon groups		
For the TPSDA, there can be no user-to-user communication in the BSA; instead, all communication is done through the BSR. This residential bridging is done using split horizon groups, which ensures that traffic from different SAPs in the same service are not forwarded to other SAPs or spokes.	Traffic arriving on a spoke service tunnel or SAP within the split horizon group is not copied to other SAPs or spoke service tunnels. Traffic is copied to SAPs and spokes in other split horizon groups existing within the same service, such as a VPLS.	See Chapter 77, "VPLS management" for configuration of split horizon groups.
DHCP		

Table 70-4 TPSDA features (continued)

Feature and use	Notes	Reference
For the TPSDA, host devices, such as a residential gateway, SIP phone, or set-top box, use DHCP to obtain IP address and other network configuration information. The client device sends a DHCP discover message to request an IP address. The sequence of events is shown in Figure 70-16, "DHCP IP address assignment in the TPSDA" (p. 1927) .	Information added to the DHCP discover requests may include information added by the FTTx access NE or the BSA, for example, the shelf, slot, port, VPI, VCI, or other identifier of the host. You can use the NFM-P to configure DHCP relay on the first IP interface in the upstream direction. The BSA or BSR relays the message to a DHCP server. The gateway (residential gateway) IP address indicates to the DHCP server the subnet an IP address should be allocated to for the host.	See the appropriate service configuration chapter, as DHCP, option 82, and DHCP relay are configured at the service level.
DHCP relay DHCP discover messages are broadcast packets that typically do not leave the IP subnet. DHCP relay agents intercept the requests and forward them as unicast messages to a DHCP server. DHCP request messages from subscriber hosts are usually sent from the FTTx access NE, with information appended to uniquely identify the residential gateway, either by MAC address of the residential gateway or by an option 82 string identifier that indicates the device, port type, rack, shelf, slot, port, and VLAN ID or VPI/VCI of the circuit connected to the residential gateway.	The DHCP relay agent sets the GIADDR in the packet to the IP address of the ingress interface (SAP). You must configure the BSA and BSR devices as DHCP relay agents when the DHCP requests are going to be forwarded to a DHCP server. The maximum DHCP relay packet size is 1500 bytes.	See the appropriate L3 service (IES and VPRN) or L2 service (VPLS) configuration chapter.
DHCP lease state table The BSA maintains the identities of hosts that are allowed network access for each SAP on each service.	The lease state information is collected by snooping DHCP acknowledge messages on the SAP, using DHCP snooping. Entries in the DHCP lease state table remain valid for the duration of the IP address lease.	See Chapter 16, "Port and channel object configuration" .
DHCP snooping The BSA can copy DHCP packets and inspect them to help secure the system. For example, if malicious user A sends an IP packet requesting a video stream intended for user B, return packets sent to user B could jam B's connection.	Use the NFM-P to configure DHCP snooping for the following purposes: • To insert Option 82 information when the system is not configured for DHCP relay by enabling DHCP snooping on the SAP closest to the host. • To build a DHCP lease state table by enabling DHCP snooping on the service tunnel nearest the network egress and on the SAP closest to the host. • To efficiently associate dynamic hosts with subscriber instances and associated network resources in a triple play service configuration	See the appropriate service chapters for configuration of the lease populate and snooping parameters. See Chapter 74, "Residential subscriber management" for information about using DHCP snooping for subscriber identification purposes.

Table 70-4 TPSDA features (continued)

Feature and use	Notes	Reference
Option 82 The DHCP relay option allows managed devices to append information to the DHCP request that identifies where the DHCP request originated. You can also independently insert Option 82 information when DHCP snooping is enabled on a VPLS SAP. The Option 82 information can be: • The DHCP Option 82 string circuit ID value associated with the 7330 ISAM FTTN, or other ISAM family of NEs. The *device port_type rack/shelf/slot/port: VPI:VCI* identifier on the 7330 ISAM FTTN indicates that this is the connection to the residential gateway. • The DHCP Option 82 string remote ID value associated with the 7330 ISAM FTTN, or other ISAM family of NEs.	Using Option 82, you can identify: • the circuit ID (service tunnel binding) that is unique to the device relaying the circuit • the remote ID (MAC address) of the host at the far end of the circuit • the subscriber to which a host belongs for the purpose of assigning network resources The maximum DHCP relay packet size is 1500 bytes. If adding Option 82 information to the packet causes the packet to exceed 1500 bytes, the DHCP relay request is forwarded without including the Option 82 information.	See the appropriate service configuration chapter. For DHCP option 82 information inserted to identify subscribers, see Chapter 74, “Residential subscriber management” .

70.10 BTV multicast

70.10.1 Overview

This section describes how the NFM-P can be used to configure and manage the delivery of BTV multicast traffic streams. See 70.11 “BTV multicast configuration examples” (p. 1931) for examples.

Optimizing for broadcast TV means implementing multicast packet replication throughout the network. Multicasting improves the efficiency of the network by reducing the bandwidth and fiber needed to deliver broadcast channels to the end user. A multicasting device can receive a single copy of a broadcast channel and replicate it to any downstream devices that require it, thus substantially reducing the required network resources. This efficiency becomes increasingly important closer to the end user.

70.10.2 Multicast routing overview

Multicast routers direct traffic to several receivers without incurring any additional overhead for the source router or the receivers. In contrast, unicast networks can suffer from increased bandwidth requirements as the number of receivers increases.

In multicast routing, receivers query the source router to request a specific data stream. The multicast group is not restricted by physical location, so long as the hosts can be reached through the Internet. Routers in the network must use IGMP to send and receive multicast data streams.

A multicast-enabled device, such as a switch or router, distributes a data stream to multiple receivers. Multicast packets are replicated in the network by routers that are enabled with PIM, which results in the efficient delivery of data to multiple receivers using less bandwidth.

1. A switch or router distributes a data stream to multiple receivers, such as multicast-enabled PE switches or routers.

2. The multicast-enabled switch or router replicates the data stream, when required, and transmits a copy to each downstream switch or router in the multicast tree.
3. Each client receives the data stream it has subscribed to from the downstream switch or router.

The NEs involved in delivering BTV multicast streams are first preconfigured through CLI for discovery and management by NFM-P. After discovery, routing protocols are applied to the NEs using NFM-P. Routing, QoS, and network queue policies are then created. On some devices, multicast package and ACL filter policies are created. These policies are applied to NEs during service creation through NFM-P.

70.10.3 Content delivery

BTV source traffic consists of one IP multicast stream per broadcast channel. As a multicast stream enters the core network, it is directed by PIM to the RP, which replicates the multicast traffic to all DRs that have requested the specific multicast stream. DRs distribute the multicast stream directly to set-top receivers or through an M-VPLS to BTV VLAN rings to which customer set-top receivers are connected. Multicast streams are forwarded only to those set-top receivers that have requested them through IGMP and are entitled to them as subscriber hosts.

70.10.4 Content management

Multicast package policies on some devices define the available multicast addresses (BTV channels) for end users in a BTV network. Typically, a root package policy which includes all BTV channels associated with an NFM-P customer service is created. Subsets of the root policy are then created as BTV content packages to which end customers can subscribe. ACL filter policies on CE devices ensure that only the channels to which an end customer has subscribed are delivered to the customer set-top receiver.

70.10.5 PIM

PIM uses RPF to correctly forward multicast packets down a distribution tree, using the independent multicast and unicast routing tables created by the 7450 ESS in mixed mode or the 7750 SR. The unicast routing table is populated by the unicast routing protocols, such as OSPF, BGP, IS-IS, or static routes, which can also be configured to submit routes to the multicast routing table.

Depending on the configuration of the PIM routing instance, RPF can use the unicast routing table, the multicast table populated by the unicast routing protocols, or both to determine the upstream sources of multicast streams. PIM forwards a multicast packet only if it is received on an upstream interface that is associated with a source address of an upstream router. This RPF check assures that there are no loops in the distribution tree.

PIM uses a multicast domain to group receiver hosts on a router called the rendezvous point (RP). A bootstrap router (BSR) elects an RP from available candidates. The BSR manages RP information, disseminates it to all PIM routers in the multicast domain, and elects a new RP in the case of RP unavailability.

A receiver host becomes a member of a multicast domain by sending an IGMP join request for a multicast stream to a PIM designated router (DR). If the router does not currently receive the multicast stream, PIM updates the DR routing table with the receiver host IP address and requests the multicast stream from the RP. The RP adds the router to the distribution tree. Packets sent to

the multicast IP address are propagated down the distribution tree to the receiver host. DRs use the RP as the source for a multicast stream unless a source with a lower path cost is available.

PIM stops sending a multicast stream to a router when it determines that there are no active receiver hosts for the multicast stream in that branch of the distribution tree.

70.10.6 MVR on VPLS

PIM is not supported on 7450 ESSs. When receiver hosts are connected to a PIM DR by way of a 7450 ESS, MVR must be configured on the switch. MVR allows multicast traffic to be forwarded downstream from the DR to the receiver host over an MVR VPLS.

70.10.7 IGMP

IGMP is a multicast protocol which service providers can use to establish multicast group memberships on a LAN. Within the LAN, end users use IGMP to communicate with a local multicast router, which then uses PIM to distribute the IGMP messages to other local and remote multicast routers. Multicast routers send regular membership queries to IGMP hosts which respond with membership reports. Multicast routers can use these reports to determine which hosts are interested in receiving particular multicast messages.

IGMP operates above the network layer on IPv4 networks.

70.10.8 MLD and MLD-snooping

The Multicast Listener Discovery protocol is essentially the IPv6 version of IGMP. It is used by IPv6 routers to discover the presence of multicast listeners (that is, NEs that wish to receive multicast packets) on their directly attached links, and to discover specifically which multicast addresses are of interest to those neighboring NEs.

MLD version 2, or MLDv2, can interoperate with MLD version 1, or MLDv1. MLDv2 adds the ability for an NE to report interest in listening to packets with a specific multicast address only from specific source addresses or from all sources except for specific source addresses.

Most NFM-P NEs support MLD-snooping but not MLD. The 7450 ESS, 7750 SR, and 7950 XRS routers allow the enabling of MLD snooping for VPLS services. All variants of the 7705 SAR support MLD but not MLD-snooping.

70.11 BTV multicast configuration examples

70.11.1 Overview

Figure 70-17, “BTV multicast delivery examples” (p. 1933) shows a simple BTV network and three methods of content delivery, examples A, B, and C. The sequence of specific configuration steps for each example follows general device, network and multicast configuration information common to all examples.

Note: In the examples on the following pages, references to “IGMP-snooping” may generally be read as “IGMP- or MLD-snooping”, provided the routers employed in the configurations support the MLD protocol.

70.11.2 Device preconfiguration

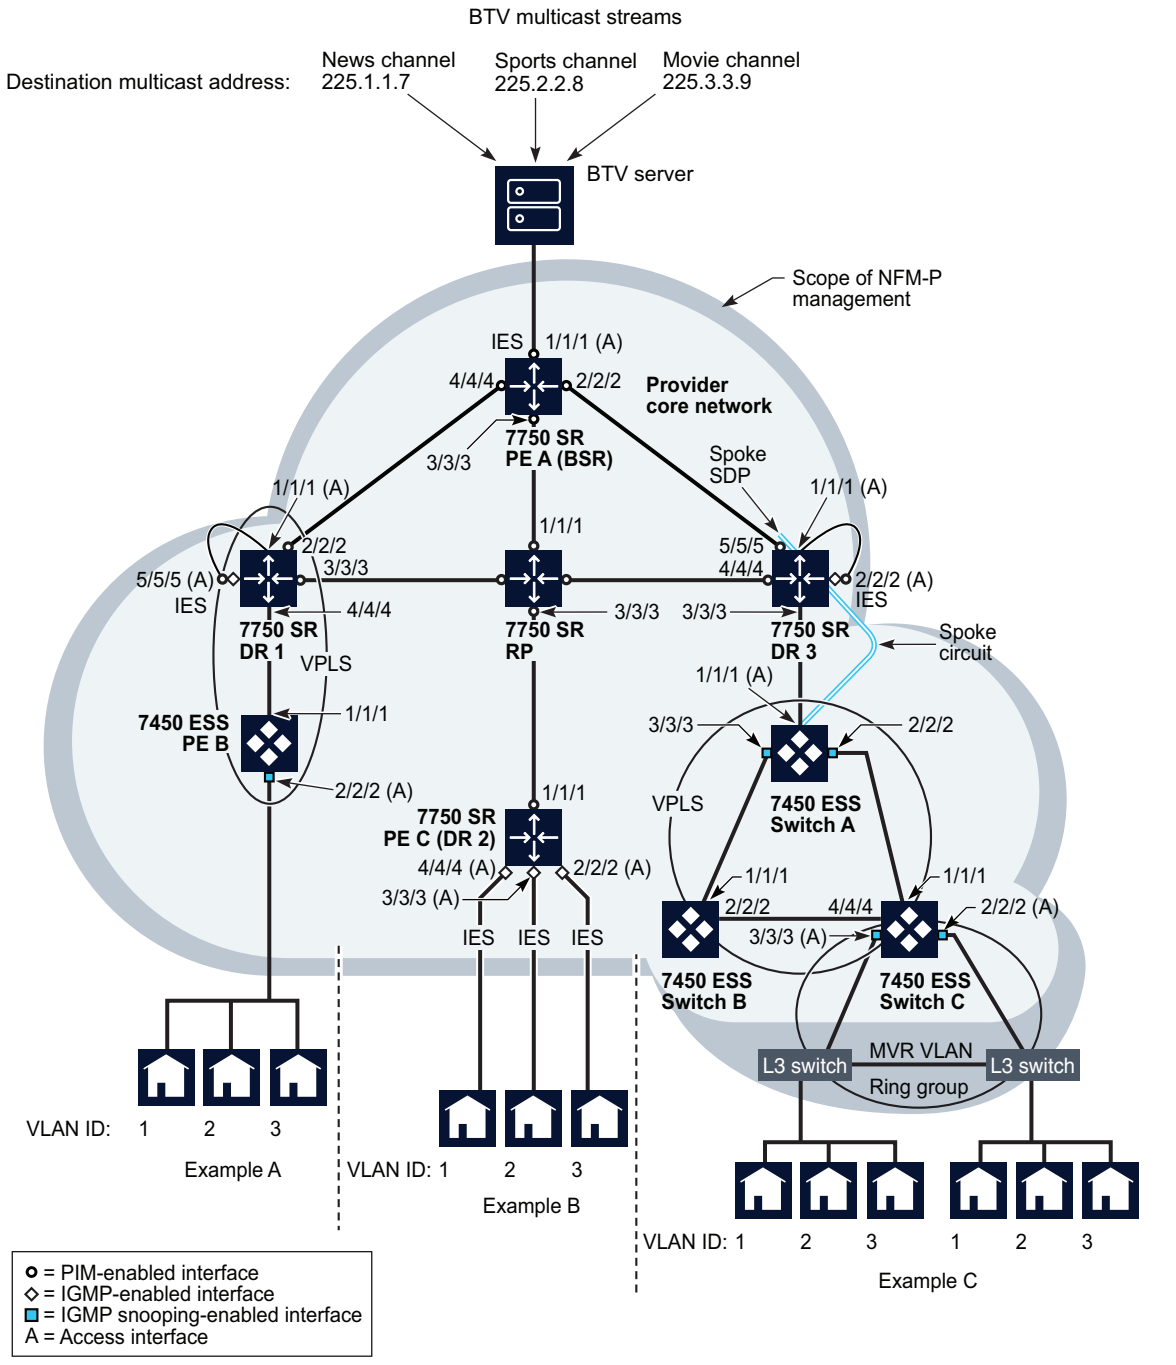
A network device requires CLI preconfiguration before it can be managed by the NFM-P.

The primary CLI preconfiguration actions for a device are:

- Assigning a system ID to the device
- Enabling and configuring SNMP on the device
- Enabling Telnet access on the device

See Chapter 8, “Device commissioning and management” and the specific device documentation for more information about enabling device functionality before using the NFM-P.

Figure 70-17 BTV multicast delivery examples



After CLI preconfiguration, further actions are required:

- Discover devices, including mediation configuration with CLI user names and passwords.
- Use NFM-P to set the discovered device in a managed state.

See Chapter 9, “Device discovery” for more information about device discovery and management using NFM-P.

70.11.3 Network preconfiguration

The core network shown in Figure 70-17, “BTV multicast delivery examples” (p. 1933) represents a fully meshed group of devices. For simplicity, only the devices relevant to the BTV multicast examples are shown.

Network preconfiguration consists of the following sequence of actions:

1

Configure network devices for in-band or out-of-band management. See Chapter 8, “Device commissioning and management” for more information.

2

Configure a system interface on each device to serve as the identifier for the device. See Chapter 27, “NE routing and forwarding” for more information.

3

Configure network interfaces on each router to establish a full mesh of interconnectivity between devices. In Figure 70-17, “BTV multicast delivery examples” (p. 1933) the interfaces to be configured are PE A, ports 1/1/1, 2/2/2, 3/3/3, and 4/4/4; DR 1, port 2/2/2; RP, ports 1/1/1, 2/2/2, and 4/4/4; and DR 3, ports 1/1/1 and 4/4/4. See Chapter 27, “NE routing and forwarding” for more information.

4

Cable the network-interface ports between routers in the core network to establish the physical connectivity shown in Figure 70-17, “BTV multicast delivery examples” (p. 1933) .

5

Use CLI ping commands to check IP connectivity between devices. See the device documentation for more information.

6

Enable IGPs such as RIP, OSPF, or IS-IS on devices according to network size and complexity. See Chapter 28, “Routing protocol configuration” for information about enabling routing protocols.

7

Enable an inter-AS routing protocol such as BGP or OSPF to PE routers, if required. See Chapter 28, “Routing protocol configuration” for more information.

8

Create routing policies as required. Create one multicast group for each BTV multicast destination address during policy creation. See Chapter 27, “NE routing and forwarding” for more information.

9

Configure routing protocols and apply routing policies as required. See Chapter 28, “Routing protocol configuration” for more information.

10

Configure LDP and MPLS, if required. See Chapter 28, “Routing protocol configuration” for information about configuring LDP. See Chapter 31, “MPLS” for information about configuring MPLS.

- Enable MPLS and LDP on the routing instance of each device that is participating in the MPLS network.
- Assign a Layer 3 interface to the MPLS instance on each MPLS-enabled device.
- Create a mesh of MPLS paths.
- Create a mesh of LSPs.
- Use the NFM-P to create MPLS administrative groups, and assign the groups to MPLS interfaces and LSP paths as required.

70.11.4 Multicast configuration common to all examples

The network connections shown between PE A and DR 1 and between PE A and DR 3 represent redundant multicast routes used by PIM in the event of an RP failure. PIM dynamically adjusts to BSR or RP failure by electing a replacement BSR or RP or by using a previously defined backup BSR or RP. PIM chooses the most appropriate source for a multicast stream based on path cost and source availability and bypasses the RP if a better source for a multicast stream is found. For simplicity, Figure 70-17, “BTV multicast delivery examples” (p. 1933) does not show routes to PE C (DR 2) from DR 1 or DR 3. As shown, PE C (DR 2) is isolated from multicast traffic in the event of RP failure.

Network multicast configuration common to all three examples involves the following sequence of actions:

1

Enable IGMP on routers DR 1, PE C (DR 2), and DR 3. See 28.103 “To enable IGMP on a routing instance” (p. 1016) for more information.

2

Configure IGMP on routers DR 1, PE C (DR 2), and DR 3. See 28.104 “To configure an IGMP site on a router” (p. 1017) for more information.

3

Enable PIM on routers PE A, RP, DR 1, PE C (DR 2), and DR 3. See 28.97 “To enable PIM on a routing instance” (p. 998) for more information.

4

Configure PIM on routers PE A, RP, DR 1, PE C (DR 2), and DR 3. See 28.98 “To configure PIM on a routing instance” (p. 998) for more information.

- Specify PE A as the candidate bootstrap router.
- Specify RP as the candidate rendezvous point. You can also specify it as a static RP for a multicast domain, if there are multiple BTV domains, and configure a second router as a redundant RP.
- Specify IES as the Apply to parameter value on routers PE A, DR 1, PE C (DR 2), and DR 3.

5

Create PIM interfaces at PE A, ports 1/1/1, 2/2/2, 3/3/3, and 4/4/4; RP, ports 1/1/1, 2/2/2, 3/3/3 and 4/4/4; DR 1, ports 2/2/2 and 3/3/3; DR 2, port 1/1/1 and DR 3, ports 4/4/4 and 5/5/5. See 28.101 “To create a PIM interface on a base routing instance or VPRN routing instance” (p. 1013) for more information.

6

Create QoS, scheduling, and accounting policies for the ingress BTV traffic. See Chapter 49, “Policies overview” for more information.

7

Create an IES from PE A, port 1/1/1, to the BTV multicast provider's network. See 78.3 “To create an IES” (p. 2430) and 78.5 “To configure an IES site” (p. 2431) for more information. Enable PIM on the IES SAP during IES creation.

70.11.5 Example A configuration

In Example A, IGMP join requests from residential hosts ingress a VPLS SDP. IGMP snooping on the VPLS registers the join requests on the local switch. The switch sends the requests over the VPLS, which is physically cross-connected to an IGMP- and PIM-enabled IES SAP on the DR. PIM on the DR requests the desired multicast stream, if not present, from the RP. The requested stream then traverses the VPLS and is sent to end users.

1

Configure PE B, port 1/1/1 and DR 1, port 4/4/4 as network ports. See 16.24 “To configure Ethernet ports” (p. 599) for more information.

2

Configure PE B, port 2/2/2 and DR 1, port 1/1/1 as access ports. See 16.24 “To configure Ethernet ports” (p. 599) for more information.

3

Cable DR 1, port 3/3/3, and PE B, port 1/1/1 to establish physical connectivity.

4

Configure DR 1, port 5/5/5 as an access port. See 16.24 “To configure Ethernet ports” (p. 599) for more information.

5

Create an IES on DR 1, port 5/5/5. See 78.3 “To create an IES” (p. 2430) and 78.5 “To configure an IES site” (p. 2431) for more information.

- Enable IGMP on the IES SAP during IES creation.
- Enable PIM on the IES SAP during IES creation.

6

Connect a cable between ports 1/1/1 and 5/5/5 on DR 1 as a service cross connect.

7

Create QoS, scheduling, filter, and accounting policies to apply to egress BTV traffic during service creation. See Chapter 49, “Policies overview” for information about policy creation.

8

Create a distributed VPLS with endpoints at PE B, port 2/2/2 and DR 1, port 1/1/1. See 77.5 “To create a VPLS” (p. 2249) and 77.33 “To configure a VPLS site” (p. 2294) for more information.

- Enable IGMP snooping on the VPLS SDP at PE B, port 2/2/2.
- Apply previously defined QoS, scheduling, filter, and accounting policies to the VPLS SDP at PE B, port 2/2/2.

70.11.6 Example B configuration

In Example B, an IGMP join request ingresses an IES SAP on the DR. PIM on the DR requests the desired multicast stream, if not present, from the RP. The requested stream is then delivered over an IES to an end user.

1

Configure PE C (DR 2), ports 2/2/2, 3/3/3, and 4/4/4 as access ports. See 16.24 “To configure Ethernet ports” (p. 599) for more information.

2

Create QoS, scheduling, filter, and accounting policies to apply to egress BTV traffic during IES creation. See Chapter 49, “Policies overview” for information about policy creation.

3

Create IES services on PE C (DR 2), ports 2/2/2, 3/3/3, and 4/4/4 that terminate on the CE set-top devices. See 78.3 “To create an IES” (p. 2430) for more information.

- Enable IGMP on each IES SAP during IES creation.
- Apply previously defined QoS, scheduling, filter, and accounting policies to each IES, as required.

70.11.7 Example C configuration

In Example C, IGMP join requests from residential hosts pass over an MVR VLAN to an VPLS. IGMP snooping on the VPLS registers the join requests on the local switch, which passes them over the VPLS to a spoke SDP on the DR. The spoke SDP' port is physically cross-connected to an IGMP- and PIM-enabled IES SAP on the DR. PIM on the DR requests the desired multicast stream, if not present, from the RP, then sends the stream over the VPLS and MVR VLAN to the end users.

1

Create a BTV MVR VLAN of L3 switches in a ring group with endpoints on Switch A, ports 2/2/2 and 3/3/3. See 75.4 “Sample BTV VLAN configuration” (p. 2069) and 75.9 “To create an OmniSwitch BTV VLAN service” (p. 2078) for more information. For redundancy, the MVR VLAN can be configured with endpoints on different switches. A VLL between the two switches acts as an unbreakable connection.

2

Enable and configure IGMP snooping on the bridge instances for the L3 switches included in the MVR VLAN.

3

Create QoS, scheduling, filter, and accounting policies to apply to egress BTV traffic during service creation. See Chapter 49, “Policies overview” for information about policy creation.

4

Configure the following as network ports:

- Switch A, ports 1/1/1, 2/2/2, and 3/3/3
- Switch B, ports 1/1/1 and 2/2/2
- Switch C, ports 1/1/1, 2/2/2, 3/3/3 and 4/4/4

  See 16.24 “To configure Ethernet ports” (p. 599) for more information.

5

Create a distributed VPLS consisting of Switch A, Switch B, and Switch C. See 77.5 “To create a VPLS” (p. 2249) and 77.33 “To configure a VPLS site” (p. 2294) for more information.

- Apply previously defined QoS, scheduling, filter, and accounting policies to the VPLS SDPs.
- Enable and configure IGMP snooping on the VPLS SDPs that are part of the MVR VLAN.
- Ensure that the encapsulation value of the VPLS SDPs that are part of the MVR VLAN matches the MVR VLAN ID.
- Create a split horizon group during VPLS creation to allow later addition of a spoke circuit to the VPLS.
- Configure STP on the VPLS, as required.

6

Configure DR 3, port 2/2/2 as an access port. See 16.24 “To configure Ethernet ports” (p. 599) for more information.

7

Create an IES on DR 3, port 2/2/2. See 78.3 “To create an IES” (p. 2430) and 78.5 “To configure an IES site” (p. 2431) for more information.

- Enable IGMP on the IES SAP during IES creation.
- Enable PIM on the IES SAP during IES creation.

8

Connect a cable between ports 1/1/1 and 2/2/2 on DR 3 as a service cross connect.

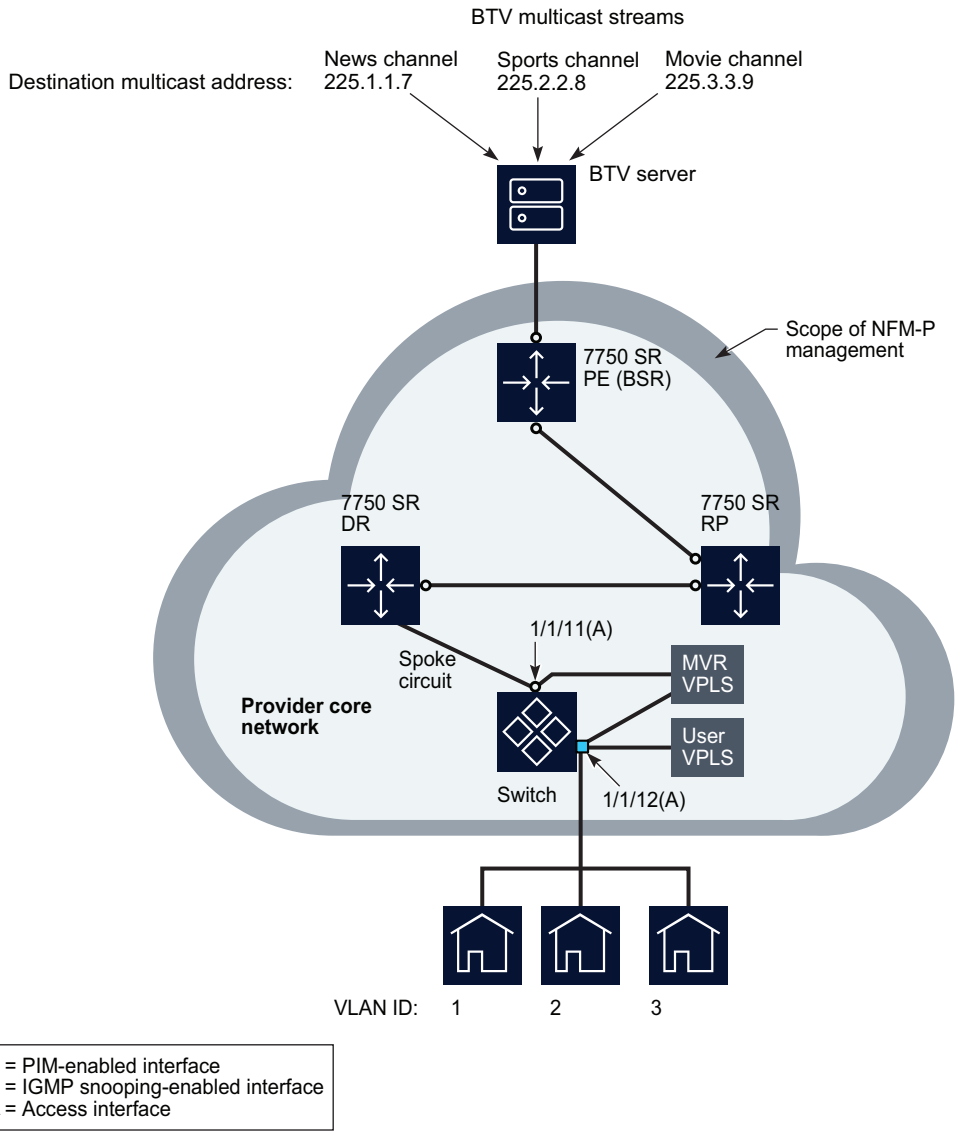
9

Create a VPLS spoke SDP at DR 3, port 1/1/1. See 77.6 “To create an HVPLS” (p. 2249) for more information.

70.11.8 Example D configuration

Figure 70-18, “BTV multicast delivery using MVR on VPLS example” (p. 1940) shows an example of BTV multicast delivery using MVR on VPLS. See Figure 70-17, “BTV multicast delivery examples” (p. 1933) , and 70.11.3 “Network preconfiguration” (p. 1934) and 70.11.4 “Multicast configuration common to all examples” (p. 1935) for common network configuration information.

Figure 70-18 BTV multicast delivery using MVR on VPLS example



70.11.9 BTV multicast delivery using MVR on VPLS

In Example D, IGMP join requests from residential hosts are sent to a user VPLS on the 7450 ESS. IGMP snooping on the user VPLS registers the join requests on the switch, which sends them to the 7750 SR DR. PIM on the DR requests the desired multicast stream, if not present, from the RP, then sends the stream over the MVR VPLS to the user VPLS, from which the multicast stream is sent to the end users.

1

Create a multicast package policy to apply to the 7450 ESS that belongs to the MVR VPLS. See Chapter 52, “Multicast policies” for more information.

2

Configure the following ports as access ports. See 16.24 “To configure Ethernet ports” (p. 599) for more information.

- 7450 ESS, port 1/1/11
- 7450 ESS, port 1/1/12

3

Create an MVR VPLS on the 7450 ESS with SAPs 1/1/11 and 1/1/12. Apply the previously defined multicast package policy to the MVR VPLS.

4

Create a user VPLS on SAP 1/1/12 of the 7450 ESS.

- Associate the user VPLS with the previously created MVR VPLS to identify the MVR VPLS as the source of the multicast traffic.
- Enable and configure IGMP snooping on the site.

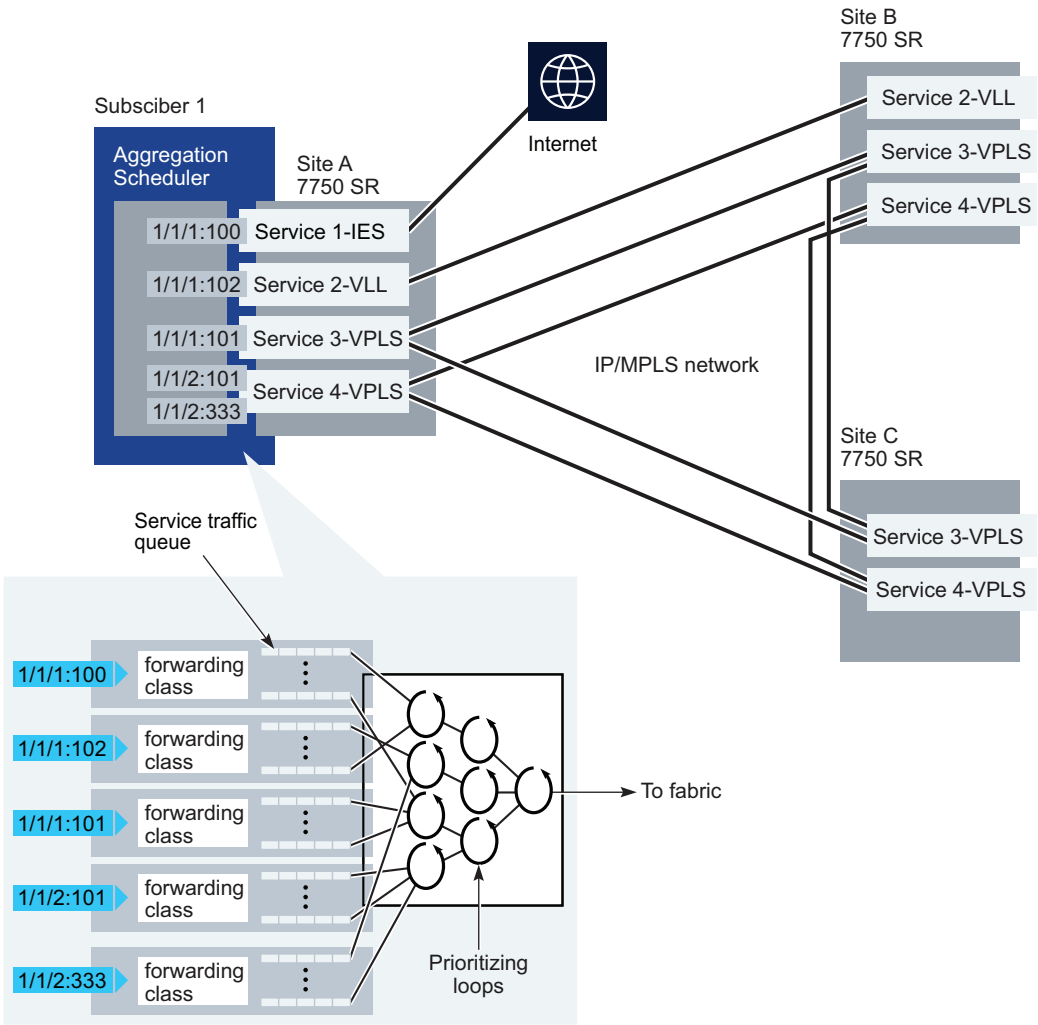
5

Create a spoke circuit between the 7450 ESS (endpoint 1/1/11) and the 7750 SR DR.

70.12 Sample network QoS configuration

70.12.1 Overview

Figure 70-19 Example of a service configuration using QoS



70.12.2 Workflow to configure network QoS

Note: In this configuration, the following services are provisioned:

- Service 1: IES for Internet access, which requires a CIR of 10 Mb/s and a PIR of 100 Mb/s
- Service 2: VLL service for FTP connectivity between Site A and Site B, which requires a CIR of 10 Mb/s and a PIR of 20 Mb/s

- Service 3: VPLS for video-conference service over sites A, B, and C, which requires a CIR of 20 Mb/s and a PIR of 50 Mb/s
- Service 4: VPLS for voice traffic, which requires a CIR of 10 Mb/s and a PIR of 20 Mb/s

The cumulative rate at site A needs to be limited to 70 Mb/s.

The following high-level steps are required to create the Figure 70-19, “Example of a service configuration using QoS” (p. 1942) configuration with rate limiting using QoS at Site A. Similar steps are required to configure QoS for Subscriber 1 on Sites B and C:

1

Configure a scheduler policy.

2

Create Subscriber 1.

3

Create the aggregation scheduler for Subscriber 1 on site A and assign ingress and egress scheduler policies to the aggregation scheduler.

4

Create IES, VLL, and VPLS for Subscriber 1.

- Specify sites for the services.
- Specify access interfaces for the sites.
- Specify the aggregation scheduler policy for the access interfaces.
- Bind the services to tunnels for transport through the IP/MPLS network.

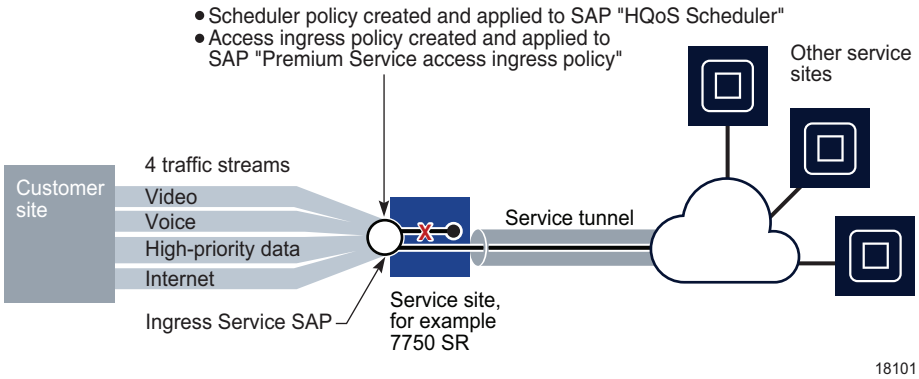
70.13 Sample SAP QoS configuration

70.13.1 Overview

You can use NFM-P to configure and enforce traffic rate limiting, based on the priority of the traffic entering the ingress SAP of a service. This configuration limits bandwidth, to ensure that SLAs are met and higher priority traffic is processed first.

The figure below shows traffic of different priorities from a customer site to an ingress SAP.

Figure 70-20 Example showing ingress traffic to a service SAP



Based on the example, use the NFM-P client GUI to perform the following actions:

- Configure a parent scheduler that handles scheduling for a child scheduler.

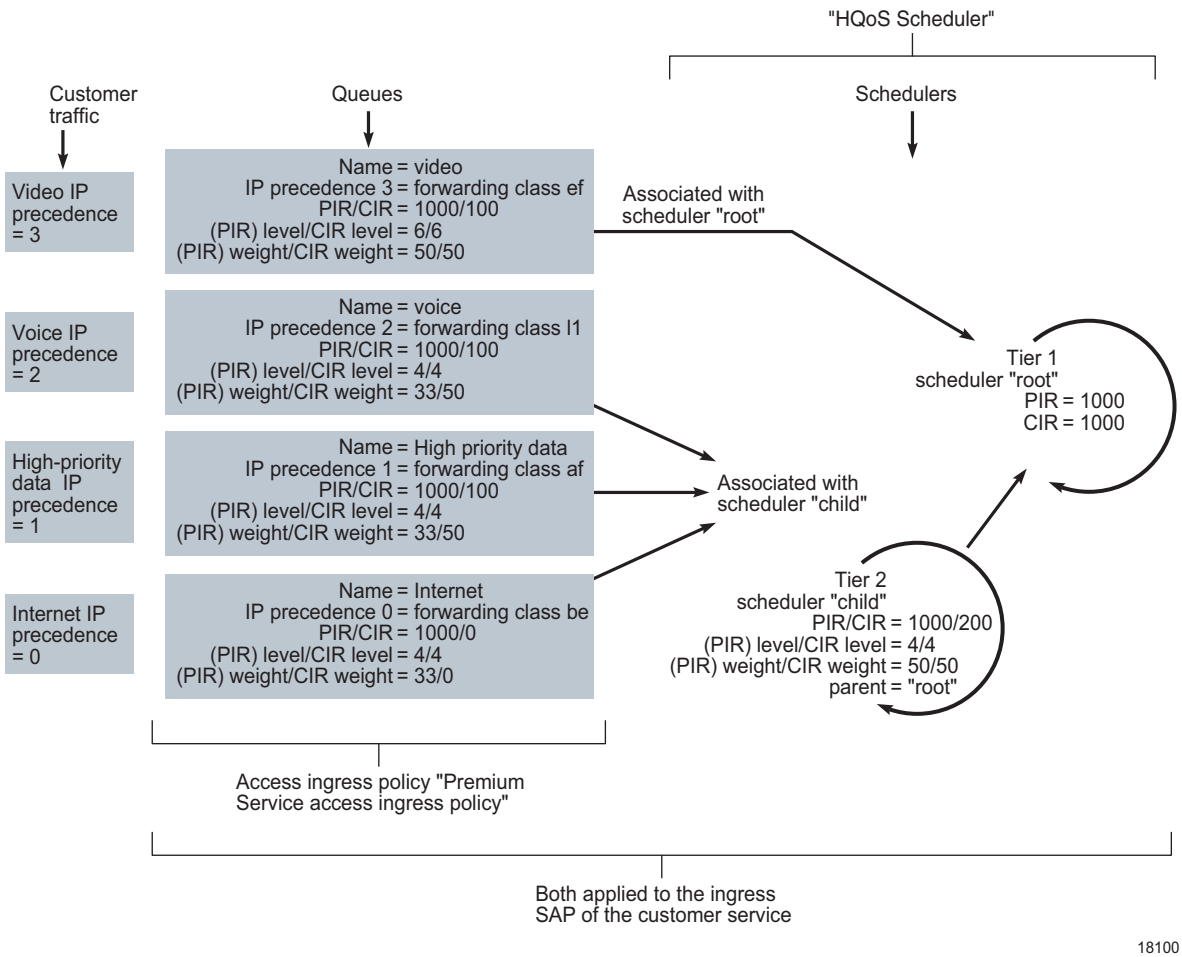
  You do not have to configure a parent tier 1 scheduler for a child tier 2 scheduler. You can create a tier 2 scheduler on its own, with no parent. This example is meant to show hierarchical QoS.
  - Add a root tier 1 scheduler.
  - Add one child tier 2 scheduler with the root scheduler as a parent.

Create an access ingress policy named Premium service access ingress policy.

- Create 4 queues within the access ingress policy, one for each type of traffic from the customer site.
- Associate each queue with a forwarding class
- Classify the incoming customer site traffic to a forwarding class. For this sample, IP precedence is used to classify traffic. You could classify traffic other ways, for example, based on filters for IP address or DSCP marking.
- Associate each queue with the appropriate scheduler.

Apply the schedulers and access ingress policy to the appropriate L2 or L3 interface for the customer service, for example, a VPLS L2 interface.

Figure 70-21 Traffic handling based on ingress access policy and scheduler queue



70.13.2 Sample configuration steps for SAP QoS

Note: In this sample:

- higher-priority video traffic, with IP precedence bit 3 set, goes into queue 4 with a PIR of 1000 Kb/s and a CIR of 100 Kb/s. This traffic is handled by the tier 1 scheduler. The levels and weights associated with the video queue (forwarding class of ef, level of 6, PIR/CIR weights of 50/50) ensure this traffic gets all required bandwidth.
- all other traffic goes into its appropriate queues, based on the mapping of the IP precedence bit with the forwarding class.
- The voice, high-priority data, and Internet queues are serviced by the tier 2 scheduler.
- Because the voice and high-priority data queues have higher PIR/CIR weight than the Internet queue, when there is contention for bandwidth, the voice and high-priority data queues are processed first.

Preconfiguration

1

Before you begin, you must have:

- the service ingress SAP configured as access
- all necessary cabling and network routing protocol configurations complete to handle routing packets to and from the CPE equipment

Configuration

2

Choose Policies→QoS→SROS QoS→Scheduler→Scheduler from the NFM-P main menu. The manage scheduler policies form opens.

3

Click Create. The scheduler policy create form opens.

4

Configure the parameters. Set the displayed name to High QoS.

5

Click on the Schedulers tab.

6

Click Create. The scheduler entry form opens.

7

Create a root, tier 1 scheduler entry.

1. Configure the parameters.
   - Displayed name to root
   - tier to 1
   - Summed CIR to false
   - PIR (kbps) to 1000
   - CIR (kbps) to 1000
2. Click OK. The root scheduler appears in the list of scheduler entries.

8

Create a child, tier 2 scheduler entry.

1. Click Create.
2. Configure the parameters.
   - Displayed name to child
   - tier to 2
   - Summed CIR to false
   - PIR (kbps) to 1000
   - CIR (kbps) to 200
   - Parent scheduler to root, using the Select button to choose root from the list.
   - Level (PIR level) to 4
   - Weight (PIR weight) to 50
   - CIR Level to 4
   - CIR Weight to 50
3. Click OK. The child scheduler appears in the list of scheduler entries.

9

Click Apply.

10

Close the Scheduler form.

11

Choose Policies→QoS→SROS QoS→Access Ingress→SAP Access Ingress from the NFM-P main menu. The SAP Access Ingress Policies form opens.

12

Click Create. The SAP Access Ingress Policy, Global Policy [Create] form opens.

13

Configure the parameters. Set the displayed name to Premium service access ingress policy.

14

Click on the Queues tab. Create four queues. For this sample, default queue 1 is modified, and three new queues are added. The default multicast queue 11 is unchanged.

15

Select queue 1 from the list.

1. Click on the Properties button. The queue 1 edit form opens.
2. Configure the parameters.
   - Displayed Name to Internet
   - Scheduler to child by using the Select button and choosing child from the list
   - Level (PIR level) to 4
   - CIR Level to 4
   - Weight (PIR weight) to 33
   - CIR Weight to 0
3. Click on the CIR/PIR tab.
4. Configure the parameters.
   - Rate Type to kbps
   - Policed to false
   - deselect both MAX buttons
   - Cir (kbps) to 0
   - Pir (kbps) to 1000
5. Click OK.

16

Add queue 2.

1. Click Create. The queue create form opens.
2. Configure the parameters.
   - ID to 2
   - Displayed Name to High-priority traffic
   - Scheduler to child by using the Select button and choosing child from the list
   - Level (PIR level) to 4
   - CIR Level to 4
   - Weight (PIR weight) to 33
   - CIR Weight to 50
3. Click on the CIR/PIR tab.
4. Configure the parameters.
   - Rate Type to kbps
   - Policed to false
   - deselect both MAX buttons
   - Cir (kbps) to 100
   - Pir (kbps) to 1000
5. Click OK. The queue is added to the list.

17

Add queue 3.

1. Click Create. The queue create form opens.
2. Configure the parameters.
   - ID to 3
   - Displayed Name to Voice
   - Scheduler to child by using the Select button and choosing child from the list
   - Level (PIR level) to 4
   - CIR Level to 4
   - Weight (PIR weight) to 33
   - CIR Weight to 50
3. Click on the CIR/PIR tab.
4. Configure the parameters.
   - Rate Type to kbps
   - Policed to false
   - deselect both MAX buttons
   - Cir (kbps) to 100
   - Pir (kbps) to 1000
5. Click OK. The queue is added to the list.

18

Add queue 4.

1. Click Create. The queue create form opens.
2. Configure the parameters.
   - ID to 4
   - Displayed Name to Video
   - Scheduler to root by using the Select button and choosing root from the list
   - Level (PIR level) to 6
   - CIR Level to 6
   - Weight (PIR weight) to 50
   - CIR Weight to 50
3. Click on the CIR/PIR tab.
4. Configure the parameters.
   - Rate Type to kbps
   - Policed to false
   - deselect both MAX buttons
   - Cir (kbps) to 100
   - Pir (kbps) to 1000
5. Click OK. The queue is added to the list.

19

Click Apply to save the changes. Confirm the action.

20

Associate each queue with a forwarding class.

1. Click on the Forwarding Classes tab.
2. Click Create. The forwarding class create form opens.
3. Configure the parameters.
   - Forwarding class to be
   - Queue ID to 1. This is the best-effort Internet traffic queue.
4. Click OK. Confirm the action.
5. Click Create. The forwarding class create form opens.
6. Configure the parameters.
   - Forwarding class to af
   - Queue ID to 2. This is the high-priority data traffic queue.
7. Click OK. Confirm the action.
8. Click Create. The forwarding class create form opens.
9. Configure the parameters.
   - Forwarding class to l1
   - Queue ID to 3. This is the voice traffic queue.
10. Click OK. Confirm the action.
11. Click Create. The forwarding class create form opens.
12. Configure the parameters.
    - Forwarding class to ef
    - Queue ID to 4. This is the highest priority, video traffic queue.
13. Click OK. Confirm the action.

21

Click Apply. Confirm the action.

22

Associate the IP precedence bits of the incoming customer traffic with the forwarding class. The forwarding class is already associated with a queue. For this sample, IP precedence bits are used to associate different types of traffic with the forwarding class. You could classify traffic other ways, for example, based on filters for IP address or DSCP marking.

1. Click on the Precedence tab.
2. Click Create. The precedence create form opens.
3. Configure the parameters to associate IP precedence 0 (Internet traffic from the customer site) with forwarding class be (the be forwarding class is associated with queue 1)
   - Precedence is 0

- Forwarding Class is be

4. Click OK. Confirm the action. The association between precedence 0 and the be forwarding class is added to the list.
5. Click Create. The precedence create form opens.
6. Configure the parameters to associate IP precedence 1 (high-priority data traffic from the customer site) with forwarding class af (the af forwarding class is associated with queue 2)
   - Precedence is 1
   - Forwarding Class is af
7. Click OK. Confirm the action. The association between precedence 1 and the af forwarding class is added to the list.
8. Click Create. The precedence create form opens.
9. Configure the parameters to associate IP precedence 2 (voice traffic from the customer site) with forwarding class l1 (the l1 forwarding class is associated with queue 2):
   - Precedence is 2
   - Forwarding Class is l1
10. Click OK. Confirm the action. The association between precedence 2 and the l1 forwarding class is added to the list.
11. Click Create. The precedence create form opens.
12. Configure the parameters to associate IP precedence 3 (video traffic from the customer site) with forwarding class ef (the ef forwarding class is associated with queue 3)
    - Precedence is 3
    - Forwarding Class is ef
13. Click OK. Confirm the action. The association between precedence 3 and the ef forwarding class is added to the list.

23

Click Apply. Confirm the action.

24

Associate a service SAP with the created High QoS scheduler and the created Premium service access ingress policy. There are many ways to associate policies with L2 or L3 interfaces used as service SAPs, for example, from the service creation form or the port properties form. This sample modifies an existing L2 interface for an existing VPLS.

1. Choose Manage→Service→Services from the NFM-P main menu. The manage services form opens.
2. Set the filters and click on the Search button. A list of filtered services appears.
3. Select the service and click on the Properties button. The service form opens.
4. Click on the L2 Access Interfaces tab.
5. Choose an interface and click on the Properties button. The L2 interface edit form opens.
6. Click on the QoS tab.

7. Configure the parameter. Use the Select button to set the Ingress Policy to Premium service access ingress policy. The policy ID and displayed name appear.
8. Click on the Schedulers tab.
9. Configure the parameter. Use the Select button to set the Ingress Scheduler to High QoS. The displayed name appears.
10. Click Apply to save the changes. Confirm the action.

70.14 Sample QoS configuration on the 7450 ESS, 7705 SAR, 7750 SR, and 7950 XRS

70.14.1 Stages

Planning and configuration

1

Perform network planning activities:

1. Determine the required types of services or applications; for example, voice, video, and data.
2. Review SLAs.
3. Perform traffic engineering activities at the IP/MPLS core level to ensure that resources are available.

2

Configure the IP and MAC ACL filters, as required. See 51.5 “To configure an ACL IP filter policy” (p. 1671) and 51.4 “To configure an ACL MAC filter policy” (p. 1668) for more information.

3

Configure the slope policies. See 50.49 “To configure a WRED slope policy” (p. 1587) and 50.51 “To configure an HSMDA WRED slope policy” (p. 1591) for more information.

4

Configure the scheduler policies. Scheduler policies can be shared between ingress and egress policies, depending on your specific requirements. See 50.55 “To configure a scheduler policy” (p. 1596) for more information.

5

Configure the port scheduler policies. See 50.57 “To configure a port scheduler policy” (p. 1599) for more information.

6

As required, create the aggregation schedulers. See 50.56 “To create an Aggregation Scheduler” (p. 1597) for more information.

7

Configure the SAP access ingress policies. See 50.28 “To configure a SAP access ingress policy” (p. 1538) for more information.

1. Configure the forwarding classes.
2. Configure the queues.
3. Map QoS markings on ingress packets to the forwarding classes.
4. Map forwarding classes to the queue definitions.
5. Map queue definitions to the scheduler policies.

8

Configure the SAP access egress policies. See 50.30 “To configure a SAP access egress policy” (p. 1550) for more information.

1. Configure the queues.
2. Map forwarding classes to the queue definitions.
3. Map queue definitions to the schedulers policies.

9

Configure the network policies. See 50.41 “To configure a QoS network policy” (p. 1567) for more information.

1. Configure for ingress:
   - Map QoS markings on ingress packets to the forwarding classes.
   - Map forwarding classes to the queue definitions.
2. Configure for egress:
   - As required, configure remarking.
   - As required, map QoS markings to the forwarding classes.

10

Configure the network queue policies. See 50.46 “To configure a network queue policy” (p. 1580) for more information.

11

Configure the time of day policies.

1. Configure the time ranges. See 53.3 “To configure a time range policy” (p. 1732) for more information.

2. Create time of day suites. See 53.4 “To configure a time-of-day suite policy” (p. 1733) for more information.

Application of policies and schedulers to equipment and interfaces

12

Associate the slope policies with ports or daughter cards. See 16.24 “To configure Ethernet ports” (p. 599) and 15.78 “To configure an MDA” (p. 536) for more information.

13

Associate the network queue policies with MDAs. See 16.24 “To configure Ethernet ports” (p. 599) and 16.72 “To configure an L3 interface on a DS3/E3 channel on a channelized ASAP MDA” (p. 674) for more information.

Configuration of customers and services

14

Configure the customers. See the appropriate service chapter for more information.

15

Create the customer services, and assign policies during the configuration. See the appropriate service chapter for more information.

16

Assign the aggregation schedulers at the interface level, if required. See the appropriate service chapter for more information.

70.15 Sample QoS configuration on the 7210 SAS

70.15.1 Overview

Quality of service configuration for 7210 SAS devices is based on the NFM-P policy framework, and is similar to support for other Nokia devices. However, some configurations are specific to 7210 SAS devices. The NFM-P provides separate QoS policies for 7210 SAS NEs. See 50.23 “7210 SAS QoS policies” (p. 1528) for more information.

Some 7210 SAS QoS settings are not configured within the policy framework. Instead, they are configured as device or port properties, or during SAP configuration. See 70.15.2 “Stages” (p. 1955) for more information.

For some 7210 SAS QoS policies and functions, device system resources must be appropriately allocated. See 6.5.13 “System resource profile” (p. 220) and the NE documentation for more information about system resource allocation.

On supporting 7210 SAS NEs, you can configure QoS for self-generated traffic on routing instances and VPRN sites; see27.1.13 “Self-generated traffic and QoS” (p. 822).

See the 7210 SAS OS Quality of Service Guides for more information about 7210 SAS QoS and QoS policies.

70.15.2 Stages

The following workflow provides an overview of the tasks required to configure QoS on 7210 SAS NEs. The required configurations vary, depending on the chassis type and network requirements. See the 7210 SAS OS Quality of Service Guides for more information about 7210 SAS QoS.

1

Based on SLAs and network capacity, determine the bandwidth and line rate requirements for the NEs and services for which you are configuring QoS.

2

Configure the required NE properties:

a. Two WRED slopes; see 12.48 “To configure two WRED slopes on a 7210 SAS” (p. 379)

b. Frame-based accounting; see 12.49 “To configure frame-based accounting for QoS policies on a 7210 SAS” (p. 380)

c. System resource profile; see 12.50 “To configure the global system resource profile on a 7210 SAS or 7250 IXR” (p. 380) or 12.51 “To configure a system resource profile policy for the 7210 SAS-R/T/Mxp, 7210 SAS-S/Sx, or 7210 SAS-S/Sx VC” (p. 382)

d. Port-based scheduling; see 12.53 “To configure port-based scheduling on the 7210 SAS” (p. 384)

e. Buffer management (port decommissioning); see 12.54 “To configure buffer management for the 7210 SAS” (p. 385)

3

Configure the required port properties:

a. Port egress rate limiting; see 16.24 “To configure Ethernet ports” (p. 599)

b. DEI classification; see 16.24 “To configure Ethernet ports” (p. 599)

c. Egress scheduler mode (for the 7210 SAS-X); see 16.24 “To configure Ethernet ports” (p. 599)

d. SAP-based remarking (for the 7210 SAS-X); see 16.24 “To configure Ethernet ports” (p. 599)
.

4

Configure and distribute the required QoS policies:

a. 7210, 7250 and 1830 SAP access ingress; see 50.29 “To configure a 7210, 7250, and 1830 SAP Access Ingress policy” (p. 1544)

b. 7210 and 1830 port access egress; see 50.31 “To configure a 7210 and 1830 port access egress policy” (p. 1556)

c. 7210 SAP access egress; see 50.32 “To configure a 7210 SAP access egress policy” (p. 1558)

d. 7210 and 1830 network; see 50.42 “To configure a 7210 and 1830 network policy” (p. 1571)

e. 7210 and 1830 network queue; see 50.47 “To configure a 7210 and 1830 network queue policy” (p. 1583)

f. 7210 and 1830 slope; see 50.50 “To configure a 7210 and 1830 slope policy” (p. 1589)

g. 7210 and 7250 queue management; see 50.52 “To configure a 7210 and 7250 Queue Management policy” (p. 1592)

h. 7210, 7250 and 1830 port scheduler; see 50.60 “To configure a 7210, 7250 and 1830 Port Scheduler policy” (p. 1601)

i. 7210/7250 Dot1p classification; see 50.84 “To configure a 7210/7250 Dot1p classification policy” (p. 1637)

j. 7210/7250 DSCP classification; see 50.85 “To configure a 7210/7250 DSCP classification policy” (p. 1638)

k. 7210/7250 MPLS LSP-EXP classification; see 50.86 “To configure a 7210/7250 MPLS LSP-EXP classification policy” (p. 1639)

l. 7210 remarking; see 50.80 “To configure a 7210 remarking policy” (p. 1630)

m. 7210 MPLS LSP-Exp map; see 50.83 “To configure a 7210 MPLS LSP-EXP Mapping policy” (p. 1635)

n. 7210 multipoint bandwidth management; see 52.16 “To configure a 7210 multipoint bandwidth management policy” (p. 1725)

5

Assign QoS policies to network resources.

a.

Assign 7210/7250 Dot1p and DSCP classification policies to:

- SAP access ingress policies; see 50.29 “To configure a 7210, 7250, and 1830 SAP Access Ingress policy” (p. 1544)
- network policies; see 50.42 “To configure a 7210 and 1830 network policy” (p. 1571)
- Ethernet ports (7210/7250 DSCP classification policies only), for table-based color-aware ingress classification on supporting NEs; see 16.45 “To assign QoS policies to a 7210 SAS Ethernet port” (p. 636).
- L3 interfaces configured for RVPLS (7210/7250 DSCP classification policies only), for table-based color-aware ingress classification on supporting NEs; see 78.30 “To bind an IES L3 access interface to a VPLS site or VPLS I-site” (p. 2475) and 79.98 “To bind a VPRN L3 access interface to a VPLS site or VPLS I-site” (p. 2673)

b. Assign 7210/7250 MPLS LSP-EXP classification policies to network policies; see 50.42 “To configure a 7210 and 1830 network policy” (p. 1571).

c.

Assign slope policies to queues configured in:

- SAP access ingress policies; see 50.29 “To configure a 7210, 7250, and 1830 SAP Access Ingress policy” (p. 1544)
- SAP access egress policies; see 50.32 “To configure a 7210 SAP access egress policy” (p. 1558)
- network queue policies; see 50.47 “To configure a 7210 and 1830 network queue policy” (p. 1583)
- network policies; see 50.42 “To configure a 7210 and 1830 network policy” (p. 1571)

d.

Assign queue management policies to queues configured in:

- SAP access ingress policies; see 50.29 “To configure a 7210, 7250, and 1830 SAP Access Ingress policy” (p. 1544)
- port access egress policies; see 50.31 “To configure a 7210 and 1830 port access egress policy” (p. 1556)
- SAP access egress policies; see 50.32 “To configure a 7210 SAP access egress policy” (p. 1558)
- network queue policies; see 50.47 “To configure a 7210 and 1830 network queue policy” (p. 1583)

e.

Assign remarking policies to:

- port access egress policies; see 50.31 “To configure a 7210 and 1830 port access egress policy” (p. 1556)
- SAP access egress policies; see 50.32 “To configure a 7210 SAP access egress policy” (p. 1558)
- network policies; see 50.42 “To configure a 7210 and 1830 network policy” (p. 1571)

f. Assign MPLS LSP-Exp Map policies to network policies of network interface type; see 50.42 “To configure a 7210 and 1830 network policy” (p. 1571) .

g.

Assign SAP access ingress and SAP access egress policies to SAPs; see the relevant procedure, depending on the service type:

- 76.43 “To assign ingress and egress QoS policies to a VLL L2 access interface on a 7210 SAS site” (p. 2184) for VLL
- 77.70 “To assign ingress and egress QoS policies to a VPLS L2 access interface on a 7210 SAS site” (p. 2343) for VPLS
- 78.33 “To assign ingress and egress QoS policies to an IES L3 access interface on a 7210 SAS site” (p. 2479) for IES

- 79.90 “To assign ingress and egress QoS policies to a VPRN L3 access interface on a 7210 SAS site” (p. 2665) for VPRN
- 93.10 “To create an L2 access interface on a destination site” (p. 3174) for mirror services (SAP access egress policies only)

h. Assign network policies to network interfaces; see 27.17 “To create an L3 network interface on a routing instance” (p. 856) and 27.18 “To configure L3 network interfaces” (p. 863) .

i. Assign port access egress, network, network queue, and port scheduler policies to ports; see 16.45 “To assign QoS policies to a 7210 SAS Ethernet port” (p. 636) .

j. Assign slope policies to buffer pools on ports; see 16.24 “To configure Ethernet ports” (p. 599) .

k. Assign multipoint bandwidth management policies to 7210 SAS-X NEs; see 52.16 “To configure a 7210 multipoint bandwidth management policy” (p. 1725) .

6

Configure table-based color-aware ingress classification on supporting NEs; see 50.23.3 “Workflow to configure table-based DSCP ingress classification” (p. 1529).

7

Configure hierarchical ingress policing (H-metering) for access ingress meters:

1. Configure a 7210, 7250 and 1830 SAP access ingress policy with all meters set to trTCM (RFC 4115); see 50.29 “To configure a 7210, 7250, and 1830 SAP Access Ingress policy” (p. 1544) .
2. Assign the policy to L2 or L3 access interfaces and configure the aggregate rate limit parameters for ingress meters; see the relevant procedure, depending on the service type:
   - 76.43 “To assign ingress and egress QoS policies to a VLL L2 access interface on a 7210 SAS site” (p. 2184) for VLL
   - 77.70 “To assign ingress and egress QoS policies to a VPLS L2 access interface on a 7210 SAS site” (p. 2343) for VPLS
   - 78.33 “To assign ingress and egress QoS policies to an IES L3 access interface on a 7210 SAS site” (p. 2479) for IES
   - 79.90 “To assign ingress and egress QoS policies to a VPRN L3 access interface on a 7210 SAS site” (p. 2665) for VPRN

8

Configure hierarchical ingress queues (ingress scheduling) for 7210 SAS-K and 7210 SAS-X NEs:

1. Enable the Queues function in the system resource profile for the 7210 SAS-X NE; see 12.50 “To configure the global system resource profile on a 7210 SAS or 7250 IXR” (p. 380) .

2. Configure ingress queues in a 7210, 7250 and 1830 SAP access ingress policy; see 50.29 “To configure a 7210, 7250, and 1830 SAP Access Ingress policy” (p. 1544) .
3. Assign the policy to access interfaces and configure the aggregate shaper rate parameters; see the relevant procedure, depending on the service type:
   - 76.43 “To assign ingress and egress QoS policies to a VLL L2 access interface on a 7210 SAS site” (p. 2184) for VLL
   - 77.70 “To assign ingress and egress QoS policies to a VPLS L2 access interface on a 7210 SAS site” (p. 2343) for VPLS
   - 78.33 “To assign ingress and egress QoS policies to an IES L3 access interface on a 7210 SAS site” (p. 2479) for IES
   - 79.90 “To assign ingress and egress QoS policies to a VPRN L3 access interface on a 7210 SAS site” (p. 2665) for VPRN

9

Configure egress policing (egress meters) for SAPs on the 7210 SAS-D, 7210 SAS-M, 7210 SAS-R, 7210 SAS-S, 7210 SAS-Sx, and 7210 SAS-T:

1. Enable the SAP Egress Aggregate Meter parameter in the global system resource profile for the NE; see 12.50 “To configure the global system resource profile on a 7210 SAS or 7250 IXR” (p. 380) .

   For 7210 SAS-R NEs, enable the Egress SAP Aggregate Meter parameter in the system resource profile policy assigned to the device; see 12.51 “To configure a system resource profile policy for the 7210 SAS-R/T/Mxp, 7210 SAS-S/Sx, or 7210 SAS-S/Sx VC” (p. 382).
2. For 7210 SAS-Mxp and 7210 SAS-R NEs, enable port-based scheduling; see 12.53 “To configure port-based scheduling on the 7210 SAS” (p. 384).
3. Configure egress meters for access interfaces; see the relevant procedure, depending on the service type:
   - 76.43 “To assign ingress and egress QoS policies to a VLL L2 access interface on a 7210 SAS site” (p. 2184) for VLL
   - 77.70 “To assign ingress and egress QoS policies to a VPLS L2 access interface on a 7210 SAS site” (p. 2343) for VPLS
   - 78.33 “To assign ingress and egress QoS policies to an IES L3 access interface on a 7210 SAS site” (p. 2479) for IES
   - 79.90 “To assign ingress and egress QoS policies to a VPRN L3 access interface on a 7210 SAS site” (p. 2665) for VPRN

10

Configure egress scheduling for 7210 SAS-K NEs.

1. If required, configure port-level egress rate limiting; see 16.24 “To configure Ethernet ports” (p. 599) .
2. For SAP-based access egress scheduling, configure queues in a 7210 SAP access egress policy; see 50.32 “To configure a 7210 SAP access egress policy” (p. 1558) . Assign the policy to an L2 access interface; see the relevant procedure, depending on the service type:
   - 76.43 “To assign ingress and egress QoS policies to a VLL L2 access interface on a 7210 SAS site” (p. 2184) for VLL

- 77.70 “To assign ingress and egress QoS policies to a VPLS L2 access interface on a 7210 SAS site” (p. 2343) for VPLS

3. For network egress scheduling, configure queues in a 7210 and 1830 network queue policy; see 50.47 “To configure a 7210 and 1830 network queue policy” (p. 1583) . Assign the policy to ports; see 16.45 “To assign QoS policies to a 7210 SAS Ethernet port” (p. 636) .
4. Configure the aggregate rate limit values for SAPs; see the relevant procedure, depending on the service type:
   - 76.43 “To assign ingress and egress QoS policies to a VLL L2 access interface on a 7210 SAS site” (p. 2184) for VLL
   - 77.70 “To assign ingress and egress QoS policies to a VPLS L2 access interface on a 7210 SAS site” (p. 2343) for VPLS

11

Configure egress scheduling for 7210 SAS-Mxp, 7210 SAS-R, and 7210 SAS-X NEs.

1. If required, configure port-level egress rate limiting; see 16.24 “To configure Ethernet ports” (p. 599) .
2. For SAP-based access egress scheduling, configure queues in a 7210 SAP access egress policy; see 50.32 “To configure a 7210 SAP access egress policy” (p. 1558) . Assign the policy to L2 or L3 access interfaces; see the relevant procedure, depending on the service type:
   - 76.43 “To assign ingress and egress QoS policies to a VLL L2 access interface on a 7210 SAS site” (p. 2184) for VLL
   - 77.70 “To assign ingress and egress QoS policies to a VPLS L2 access interface on a 7210 SAS site” (p. 2343) for VPLS
   - 78.33 “To assign ingress and egress QoS policies to an IES L3 access interface on a 7210 SAS site” (p. 2479) for IES
   - 79.90 “To assign ingress and egress QoS policies to a VPRN L3 access interface on a 7210 SAS site” (p. 2665) for VPRN
3. For port-based access egress scheduling on the 7210 SAS-Mxp and 7210 SAS-R, configure the QoS function in the system resource profile for the device; see 12.53 “To configure port-based scheduling on the 7210 SAS” (p. 384) . Configure queues in a 7210 port access egress policy; see 50.31 “To configure a 7210 and 1830 port access egress policy” (p. 1556) .
4. For network egress scheduling, configure queues in a 7210 and 1830 network queue policy; see 50.47 “To configure a 7210 and 1830 network queue policy” (p. 1583) . Assign the policy to ports; see 16.45 “To assign QoS policies to a 7210 SAS Ethernet port” (p. 636) .
5. For access ports on the 7210 SAS-X, configure the Egress Scheduler Mode parameter for FC-based or SAP-based scheduling; see 16.24 “To configure Ethernet ports” (p. 599) .
6. Configure the aggregate rate limit values for SAPs; see the relevant procedure, depending on the service type:
   - 76.44 “To configure scheduling on a VLL L2 access interface” (p. 2186) for VLL
   - 77.71 “To configure scheduling on an L2 access interface” (p. 2345) for VPLS

- 78.34 “To configure scheduling on an IES L3 access interface” (p. 2481) for IES
- 79.91 “To configure scheduling on a VPRN L3 access interface” (p. 2666) for VPRN

12

Configure overrides for access ingress meters, as required; see 50.98 “To configure QoS policy overrides on access ingress meters for the 7210 SAS” (p. 1657) .

13

Configure overrides for access ingress queues, as required; see 50.99 “To configure QoS policy overrides on access ingress queues for a 7210 SAS-X” (p. 1659) .

14

Configure overrides for port access egress queues, as required; see50.100 “To configure QoS policy overrides on port access egress queues for a 7210 SAS” (p. 1660).

15

For the 7210 SAS-K, preserve ingress dot1p values for egress traffic on L2 interfaces; see the relevant procedure, depending on the service type:

- 76.43 “To assign ingress and egress QoS policies to a VLL L2 access interface on a 7210 SAS site” (p. 2184) for VLL
- 77.70 “To assign ingress and egress QoS policies to a VPLS L2 access interface on a 7210 SAS site” (p. 2343) for VPLS

70.16 Sample QoS configuration on an OmniSwitch

70.16.1 Stages

1

Enable QoS on the OmniSwitch and configure global settings such as global port parameters, default disposition for flows, and timeouts. The parameters that you need to configure globally depend on the types of policies that you need to configure.

Typically, you do not need to change any of the global defaults. See 28.128 “To configure bridging on an OmniSwitch” (p. 1043) for information.

2

Configure QoS port parameters, which includes setting QoS parameters on a per port basis. Typically you do not need to change the port defaults. See Step 12 of 16.56 “To configure OmniSwitch Ethernet ports” (p. 647) for information.

3

Configure QoS policies. See Chapter 50, “QoS policies” for more information.

71 Queue groups

71.1 Overview

71.1.1 General information

Queue groups are objects created on access or network Ethernet ports that allow SAP or IP interface forwarding classes to be redirected from standard queue mapping to a shared queue. This provides some flexibility to maintain QoS and helps save resources on the node.

Access ingress ports support a single queue group for each ingress port. Access egress and network egress ports support the creation of multiple queue groups.

71.1.2 Queue Group Template policies

Queue Group Template policies allow you to define the queuing and parenting structure for queue groups on Ethernet ports. The policy defines the number and types of queues within the port queue group, and provides the default queue parameters.

Before you create a queue group on an Ethernet port, you must first create a Queue Group Template.

See 50.19 “Queue Group policies” (p. 1526) in “QoS policy types” (p. 1507) for more information.

71.1.3 Port queue groups

The port queue group contains the queue groups that are created based on the queue IDs defined within the associated Ingress/Egress Queue Group Template policies. Port queue groups are supported on Ethernet ports and can be created on ports within a LAG. Port queue groups are not supported on HSMDA Ethernet ports and VSM MDAs.

Network egress queue groups are not supported on the following IOM-1 cards:

- IOM-10 G
- IOM-20 G
- IOM-20 G-B

You can create a port queue group on an Ethernet port after creating an Ingress/Egress Queue Group Template policy.

Note: You must use the same name for the port queue group and Ingress/Egress Queue Group Template policy.

71.1.4 Port queue group LAGs

When a port queue group is created on a LAG, the group is individually instantiated on each link in the LAG. The queue parameters for a queue within the queue group are used for each port queue.

You can create, modify, or delete a port access ingress, access egress, or network egress queue group on the primary port of the LAG. (The primary port is the port with the lowest port ID.) The NE automatically replicates the create, modify, or delete action for the queue group on all other ports within the LAG.

Note: The NFM-P does not allow you to create, modify, or delete an Access Ingress, Access Egress, or Network Egress queue groups on non-primary ports.

When you add a port to a LAG, the port must use the same access ingress, access egress, or network egress queue groups as the existing ports on the LAG. To ensure this requirement for the port, the NFM-P implements the following sequential comparison:

- number of queue groups
- queue group names
- queue group Instance IDs
- number of queue overrides
- individual parameters

Note: Nokia recommends that you add all required ports to the LAGs before the configuration of the port queue group.

In the services context, the following requirements must be observed:

- For any service SAP that associates its connection to a LAG, the forwarding plane must exist on the card for the LAG's primary port to be selectable.
- Whenever you add a port from a different card to a LAG, the forwarding plane redirect name and associated Instance ID parameters you configure must be identical to those that have already been configured for the service.

71.1.5 Access SAP forwarding class-based redirection

Typically, each SAP has dedicated ingress and egress queues that are only used by that specific SAP. Individual SAP queuing requires a more complex provisioning model to configure the ingress and egress SLAs of the SAP. The configuration requires service awareness at the aggregation locations in the network. There are cases where individual SAP queuing is not preferred. In these cases, you can use a shared queue or an individual port queue model. You can configure a shared queue by creating access ingress and access egress queue groups, and mapping the forwarding classes of the SAP to the queues within the queue group.

You can configure forwarding class redirection on a SAP to a queue group queue ID using the access ingress/egress QoS policy. In each policy, the forwarding class to queue ID mapping can specify a queue group name.

See 71.2 "Workflow to configure access SAP forwarding class-based redirection" (p. 1967) for more information.

71.1.6 Network IP interface forwarding class-based redirection

You can create queue groups on egress network ports to provide network IP interface queue redirection. A single set of egress port-based forwarding class queues are available by default, and

all IP interfaces on the port share the queues. The creation of a network queue group allows one or more IP interfaces to selectively redirect forwarding classes to the group to override the default behavior.

The redirection of the egress forwarding class on an IP interface to an egress queue group queue ID is provisioned using the Network policy. The actual queue group name can be specified when the Network Policy is applied to the IP interfaces.

You can configure dedicated queues for each IP interface using network egress queue groups.

See 71.3 “Workflow to configure network IP interface forwarding class-based redirection” (p. 1968) for more information.

71.1.7 Queue group statistics

The packets sent to the queue of a SAP are statistically tracked by a set of counters associated with the queue group queue, not the SAP counters. The tracking occurs when a forwarding class is redirected to an ingress or egress port queue group queue.

On a network interface, the counter sets are created for each egress IP interface, not for each egress queue. The same counter set is used when a forwarding class for an egress IP interface is redirected from the default egress port queue to a queue group queue.

See “Statistics collection in the NFM-P” in the *NSP NFM-P Statistics Management Guide* for information about managing statistics collection and to view a list of the MIB counters that are available for collection using the NFM-P.

71.1.8 Queue group configuration validation rules

Table 71-1 Validation requirements for queue group configurations

Component		Validation action
Ingress Queue Group Template policy	Queue deletion	The deletion is blocked if there is an Access Ingress QoS policy with a forwarding class that is associated with the queue ID. The deletion can be blocked by the NFM-P or the NE. You can use the name binding list to verify dependencies.
	Policy deletion	The deletion is blocked if there is an Access Ingress QoS policy with a forwarding class that is associated with the policy.
Egress Queue Group Template policy	Queue deletion	The deletion is blocked if there is an access egress QoS policy with a forwarding class that is associated with the queue ID. The deletion can be blocked by the NFM-P or the NE. You can use the name binding list to verify dependencies.
		The deletion is blocked if there is a network policy with a forwarding class that is associated with the queue ID.
	Policy deletion	The deletion is blocked if there is an access egress QoS policy with a forwarding class that is associated with the policy.
		The deletion is blocked if there is a network IP interface associated with the policy.

Table 71-1 Validation requirements for queue group configurations (continued)

Component		Validation action
Port queue groups	Port Access Ingress Queue Group deletion	The deletion is blocked if there is an access ingress QoS policy, applied to the SAP, with a forwarding class that is associated with the port queue group. The SAP is directly or indirectly bound to the port by a LAG associated with the port queue group.
	Port Access Egress Queue Group	The deletion is blocked if there is an access egress QoS policy, applied to the SAP, with a forwarding class that is associated with the port queue group. The SAP is directly or indirectly bound to the port by a LAG associated with the port queue group.
	Network Egress Queue Group	The deletion is blocked if there is a network IP interface that is directly or indirectly bound to the port by a LAG associated with the port queue group.
Access SAP forwarding class-based redirection	Access ingress QoS policy	The Queue Group name must exist as an Ingress Queue Group Templates policy.
		The Queue ID must exist within the associated Ingress Queue Group Templates policy with appropriate queue type.
		Only one unique Queue Group may be referenced within one Access Ingress QoS policy.
		The current access ingress QoS policy should not be applied to the SAPs on a non-Ethernet port or an Ethernet port where the specified Access Ingress Queue Group does not exist.
		The current access ingress QoS policy should not be applied to a SLA Profile policy.
	Access egress QoS policy	The Queue Group name must exist as an Egress Queue Group Templates policy.
		The Queue ID must exist within the associated Egress Queue Group Templates policy.
		The current access egress QoS policy should not be applied to the SAPs on a non-Ethernet port or an Ethernet port where the specified Access Egress Queue Group does not exist.
		The current access egress QoS policy should not be applied to a SLA Profile policy.
	SAP Access Ingress/Egress QoS policy assignment	When a SAP Access Ingress/Egress QoS policy with a forwarding class redirection to a Queue Group Queue ID is applied to a SAP, the following configurations are verified: • The Queue Group specified in any forwarding class redirection must exist as an Access Ingress/Egress Queue Group on the port associated with the SAP • The Access Ingress/Egress QoS policy with Queue Group specified cannot be applied to SLA Profile policy

Table 71-1 Validation requirements for queue group configurations (continued)

Component		Validation action
Network IP Interface forwarding class-based redirection	Network policy	The specified queue ID must exist within the Egress Queue Group Templates policy for all IP interfaces where the Network policy is applied. If the Network policy is currently applied to any IP interfaces without an explicit Network Egress Queue Group specified, the configuration fails.
		The following configurations are verified when the Network policy is applied to a network IP interface: • The network policy with a redirected queue group cannot be applied to the network IP interface without a port binding. • The redirected queue group name must exist as a Network Egress Queue Group on the port or LAG associated with the IP interface. • The queue ID for the redirected queue group in the associated Network policy must exist within the associated Egress Queue Group Templates policy.

71.2 Workflow to configure access SAP forwarding class-based redirection

71.2.1 Stages

The following workflow describes the steps required to configure access SAP forwarding class-based redirection.

1

Create a global ingress/egress queue group template policy, as required.

a. Create an ingress queue group template policy. See 50.74 “To configure a queue group ingress template policy” (p. 1617) for more information.

b. Create an egress queue group template policy. See 50.75 “To configure a queue group egress template policy” (p. 1619) for more information.

2

Distribute the global ingress/egress queue group template policy to the NEs. See 49.6 “To release and distribute a policy” (p. 1476) for more information.

3

Create an ingress/egress queue group on the Ethernet access port. See 16.37 “To add a queue group to an Ethernet port” (p. 627) for more information.

4

Create or configure a global access ingress/egress QoS policy with the forwarding class mapped to the queue group queue ID. The queue group queue ID must be included in the queue group template policy. Perform the following, as required:

a. Create a SAP access ingress QoS policy. See 50.28 “To configure a SAP access ingress

policy” (p. 2656) for more information.

b. Create a SAP access egress QoS policy. See 50.30 “To configure a SAP access egress policy” (p. 1550) for more information.

5

Distribute the global access ingress/egress QoS policy to the NEs. See 49.6 “To release and distribute a policy” (p. 1476) for more information.

6

On the SAP configuration form, assign the access ingress/egress QoS policy to the SAP bound to the port on which the access ingress/egress queue group was created in Stage 3 . Perform one of the following, as required:

a. Assign an access ingress/egress QoS policy to an L2 access interface on a VLL. See 76.43 “To assign ingress and egress QoS policies to a VLL L2 access interface on a 7210 SAS site” (p. 2184) for more information.

b. Assign an access ingress/egress QoS policy to an L2 access interface on a VPLS. See 77.67 “To create a VPLS or MVPLS L2 access interface” (p. 2332) , 77.87 “To create a VPLS or MVPLS B-L2 access interface” (p. 2366) , and 77.88 “To create a VPLS I-L2 access interface” (p. 2372) for more information.

c. Assign an access ingress/egress QoS policy to an L3 access interface on an IES. See 78.28 “To configure an L3 access interface on an IES site” (p. 2472) for more information.

d. Assign an access ingress/egress QoS policy to an L3 access interface on a VPRN. See 79.83 “To configure an L3 access interface on a VPRN site” (p. 2656) for more information.

71.3 Workflow to configure network IP interface forwarding class-based redirection

71.3.1 Stages

The following workflow describes the steps required to configure a network IP interface forwarding class-based redirection.

1

Create a new global egress queue group template policy. See 50.75 “To configure a queue group egress template policy” (p. 1619) for more information.

2

Distribute the global egress queue group template policy to the NEs. See 49.6 “To release and distribute a policy” (p. 1476) for more information.

3

Create an egress queue group on the Ethernet network port. See 16.37 “To add a queue group to an Ethernet port” (p. 627) for more information.

4

Create or configure a global network policy with the forwarding class mapped to the queue group queue ID. The queue group queue ID must be included in the egress queue group template policy, which is specified when the network policy is applied to the IP interface. See 50.41 “To configure a QoS network policy” (p. 1567) for more information.

5

Distribute the global network policy to the NEs. See 49.6 “To release and distribute a policy” (p. 1476) for more information.

6

On the network interface configuration form, assign the network policy and the queue group template policy to the network interface. The network egress queue group must be created on the port to which the network interface is bound. The network egress queue group must use the same name as the selected queue group template policy. See 27.17 “To create an L3 network interface on a routing instance” (p. 856) for more information.

71.4 Workflow to configure statistics collection for queue groups

71.4.1 Stages

The following workflow describes the steps required to enable the collection of queue groups statistics.

1

Create or modify an accounting policy. See “To configure an accounting policy” in the *NSP NFM-P Statistics Management Guide* for more information.

2

Configure the Type parameter on the Accounting Policy form to collect one of the following statistics options:

- Combined Queue Group
- Queue Group Octets
- Queue Group Packets

3

Enable the Collect Accounting Statistics parameter on the port’s queue group Physical Port (Edit) form. See 16.37 “To add a queue group to an Ethernet port” (p. 627) for more information about adding an access ingress/egress queue group on an Ethernet access port.

72 Virtual ports

72.1 Overview

72.1.1 Purpose

A 7750 SR can act as a Broadband Network Gateway (BNG), fairly distributing bandwidth among the subscriber host sessions by accounting for the packet encapsulation overhead and ATM bandwidth expansion for each type of broadband session. In this way, subscriber packets are less likely to be dropped downstream in the DSLAM DSL port. Furthermore, the BNG shapes the aggregate rate of each subscriber and the aggregate rate of all subscribers destined to a given DSLAM to prevent congestion of the DSLAM.

In the BNG application, when a set of per FC queues are applied to each subscriber host context, the host per FC queue packet rate is overridden by the rate provided in the Radius access-accept message. This rate represents the ATM rate that will be seen on the last mile and includes the encapsulation offset and the per packet expansion due to ATM segmentation into cells at the BSAN.

In order to enforce the aggregate rate of each destination BSAN, a virtual port must be configured. Virtual ports are scheduling nodes that operate like port schedulers, with the exception that multiple virtual ports can be created on the egress context of an access/hybrid Ethernet port. A virtual port and a port scheduler cannot exist simultaneously on a single port.

Virtual ports can be configured on a port that is a member of a LAG. When a virtual port is created, modified, or deleted on the primary port of a LAG, this action is replicated on all other ports within the LAG. These actions can only be performed on the primary port. When a port is added to a LAG, it must have the same virtual ports defined as the existing ports on the LAG. The name of a virtual port is local to the port on which it is applied, but must be the same for all member ports of a LAG.

Virtual ports are supported on Ethernet ports on IOM3/IMM on the 7750 SR, 7750 SR-c4, and 7450 ESS.

Virtual ports are not supported on the 7750 SR-1 and the 7450 ESS-1, HSMDA Ethernet ports, or VSM MDA.

Virtual port statistics can be collected and displayed for all queues forwarding to a virtual port configured on an egress of an Ethernet port. This is only supported on an 7750 SR or 7450 ESS equipped with a 2 x XP MDA IOM-3. The collected data is available on the Statistics tab of the Egress Scheduling Virtual Port properties form.

SLA Profiles

A subscriber host queue with the port-parent option enabled can be scheduled within the context of a port scheduler policy associated with a port or a virtual port. To specify that a subscriber host queue with the port-parent option enabled be scheduled within the context of a virtual port, the Scheduler Type parameter must be set to Virtual port when configuring an SLA Profile.

See 64.5 “To configure an SLA profile” (p. 1845) for more information.

Subscriber Profiles

The subscriber aggregate rate is adjusted to account for the fixed offset and per packet variable expansion of the last mile for the specific session used by the subscriber host. The adjustment is based on the average frame size.

See 64.4 “To configure a subscriber profile” (p. 1840) for more information.

72.1.2 Contents

Virtual ports procedures

72.2 Workflow to configure and manage virtual ports

72.2.1 Overview

The following workflow describes the steps required to configure and manage virtual ports.

72.2.2 Stages

1

Configure an SLA Profile, as described in 64.5 “To configure an SLA profile” (p. 1845) .

2

Configure a Subscriber Profile, as described in 64.4 “To configure a subscriber profile” (p. 1840) .

3

Configure virtual ports, as required.

a. Configure a virtual port using the navigation tree, as described in 72.3 “To configure a virtual port using the navigation tree” (p. 1973) .

b. Configure a virtual port using the Port QoS form, as described in 72.4 “To configure a virtual port using the Port QoS form” (p. 1975) .

c. Copy a virtual port using the Port QoS form, as described in 72.5 “To copy a virtual port” (p. 1976) .

72.3 To configure a virtual port using the navigation tree

72.3.1 Steps

1

On the Equipment navigation tree, expand *NE*→Shelf→Card Slot→Daughter Card Slot, right-click on an access/hybrid Ethernet port and choose Properties. The Port (Edit) form opens.

This applies to ports on the IOM3 and IMM on the 7750 SR, 7750 SR-c4 and 7450 ESS.

2

Click on the Egress Scheduling Virtual Port tab.

3

Click Create. The Egress Scheduling Virtual Port (Create) form opens.

4

Configure the required general parameters.

5

Select a port scheduler policy in the Port Scheduler Policy panel.

You cannot select a port scheduler policy for the virtual port if you have already selected a port scheduler policy for the associated channel. Likewise, selecting a port scheduler policy for the virtual port prevents you from selecting a port scheduler policy for the associated channel.

6

Select a scheduler policy in the Scheduler Policy panel.

7

If you did not select a scheduler policy in Step 6 , configure the parameters in the Aggregate Rate Limit panel.

The Limit Unused Bandwidth parameter is only available on access ports and on SONET channels when an ATM MDA is used.

8

Configure the Status parameter in the Egress Rate Modify panel.

9

Configure the parameters in the Hardware Aggregate Shaper Scheduler panel.

1. Enter the Displayed Name parameter.
2. Select Enable to monitor the hardware aggregate shaper scheduler mentioned in the previous step.

10

Click on the Host Matching tab.

11

Click Create. The Host Matching (Create) form opens.

12

Configure the Destination String parameter.

13

Save your changes and close the forms.

END OF STEPS

72.4 To configure a virtual port using the Port QoS form

72.4.1 Steps

1

Choose Manage→Equipment→Port QoS from the NFM-P main menu. The Manage Port QoS form opens.

2

Click Add →Virtual Port(s). The Egress Scheduling Virtual Port (Create) form opens.

3

Configure the required general parameters.

4

Select a port scheduler policy in the Port Scheduler Policy panel.

5

Select a scheduler policy in the Scheduler Policy panel.

6

If you did not select a scheduler policy in Step 6 , configure the parameters in the Aggregate Rate Limit panel.

The Limit Unused Bandwidth parameter is only available on access ports and on SONET channels when an ATM MDA is used.

7

Configure the Status parameter in the Egress Rate Modify panel.

8

Click on the Host Matching tab.

9

Click Create. The Host Matching (Create) form opens.

10

Configure the Destination String parameter.

11

Save your changes and close the form.

12

Click on the Targeted Physical Ports tab.

13

Click Add. The Select Site form opens.

14

Select one or more sites.

The count displayed on the form reflects the total number of found ports and may not align with the number of applicable ports displayed in the list.

15

Save your changes and close the forms.

END OF STEPS

72.5 To copy a virtual port

72.5.1 Steps

1

Choose Manage→Equipment→Port QoS from the NFM-P main menu. The Port QoS list form opens.

2

Select Egress Scheduling Virtual Port from the object type drop-down menu.

3

Select a virtual port and click Copy. The Egress Scheduling Virtual Port (Create) form opens with the values of the virtual port you selected to copy.

4

Click on the Targeted Physical Ports tab.

5

Click Add. The Select Site form opens.

6

Click Search. The form displays a list of sites.

7

Select one or more sites.

8

Save your changes and close the forms.

END OF STEPS

73 Customer configuration and service management

73.1 Overview

73.1.1 Purpose

This chapter provides overview and procedural information on customer configuration and service management in the NFM-P.

73.1.2 Contents

Customer configuration and service management

73.2 Overview

73.2.1 General information

The NFM-P allows you to create a customer profile and manage the services the customer subscribes to.

An end user is the recipient of application content that is delivered through a service. The service transports the application content and is owned by a service customer. For example, an end user has high-speed Internet access through a service owned by a service provider who is a customer of the network provider.

On the General tab of a customer properties form, you can configure basic customer information. From the other tabs on the form, you can configure and monitor service objects associated with the customer.

Each customer is associated with an ID that is assigned when the customer account is created. Depending on the NE release, you can also configure a customer name. When configuring a service, you can use the ID or the listed name of the customer to associate a customer with a service.

A customer can own more than one service, but an individual service is owned by only one customer. Two or more services can be joined to form a composite service. The individual services that comprise the composite service can be owned by different customers. Each customer that owns a service in a composite service is associated with the composite service.

73.2.2 Managing the size of a service associated with a customer

A customer service can become very large over time if new sites are continually added. As a result, a service containing thousands of sites or instances may become cumbersome to manage. The NFM-P allows you to easily move sites from one service to another in order to reduce the overall size of a particular service.

Sites can be moved for the following service types supported in NFM-P: VPRN, VPLS, MVPLS, IES, and all VLL types. However, the following restrictions apply:

- You can only move a site between like services, that is, from one VPLS to another VPLS, but not between a VPLS and a VPRN, for instance.
- The services that you are moving sites to and from must have the same Service ID.
- The services that you are moving sites to and from must have the same Customer ID.

If you need to reduce the size of an existing service, you can use another existing service that meets these restrictions. Alternatively, you can create a new service of the same type for this purpose. The service and customer identifiers (name or ID number) of the new service must match those of the existing service.

In addition, if the existing service which you are moving sites from is a member of a composite service, then the newly-created service you are moving the sites to will also belong to the same composite service. This action will only take place after moving the sites that form the composite

service connectors. See 73.8 “To move sites from one service to another” (p. 1984) for more information about how to move sites from one service to another.

73.3 Workflow to create a customer profile and manage customer services

73.3.1 Stages

1

Create a customer profile. See 73.4 “To create a customer profile” (p. 1982) .

a. Configure or modify key customer contact and billing information.

b. Assign or associate equipment or resources to the customer, as appropriate.

2

As required, configure the system preferences of services associated with a customer such as specifying the default service priority or the automatic removal of empty service. See the procedure to configure NFM-P system preferences in the *NSP System Administrator Guide* for more information.

3

Create, modify, or delete existing services such as IES, VPLS, VPRN, or VLL that are associated with customers. See the relevant service chapter in this guide.

4

Monitor or troubleshoot customers, based on SLAs between the customer and the service provider.

a. Retrieve customer information and contact the customer when service problems or maintenance windows occur. See 73.5 “To list the services associated with a customer” (p. 1982) .

b. View a service map for a customer. See 73.6 “To view a service map for a customer” (p. 1983) .

c. Perform diagnostics as appropriate to troubleshoot service problems associated with customers. See the relevant service chapter in this guide.

d. As required, view and modify the inventory of all the services, interfaces, circuits, and other information that are associated with a customer. See 73.7 “To modify and manage customer information” (p. 1983) .

e. If required, reduce the service size associated with a customer by moving sites from one service to another. See 73.8 “To move sites from one service to another” (p. 1984) .

5

As required, delete a customer from the NFM-P database. See 73.9 “To delete customers” (p. 1986) .

Customer configuration and service management procedures

73.4 To create a customer profile

73.4.1 Steps

1

Choose Manage→Service→Customers from the NFM-P main menu.

2

Click Create. The Customer (Create) form opens.

3

Configure the required general parameters.

4

Save the changes and close the forms.

END OF STEPS

73.5 To list the services associated with a customer

73.5.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens with Service (Service Management) selected in the filter list.

2

Sort the Customer Name column to filter the list results.

3

Click Search. A list of services matching the filter criterion appears.

END OF STEPS

73.6 To view a service map for a customer

73.6.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Use the filter for the Customer Name column to filter the list results.

3

Click Search. A list of services matching the filter criterion appears.

4

Choose a service from the list and click Topology View. A dialog box appears.

5

Click Yes. The Service Topology - *Service Name* form opens.

6

Scroll the map to view the topology of the service and the devices used for the service.

7

Close the forms.

END OF STEPS

73.7 To modify and manage customer information

73.7.1 Purpose

View and modify the inventory of all the services, interfaces, circuits, and other information that are associated with a customer.

Note: Starting with NE release 15.1 R1, the Customer Name parameter can only be configured during creation of the customer. It cannot be changed after the policy is created. However, the name can be changed if the NE release is 15.0, R4 or later.

CAUTION

Service Disruption

Ensure configuration changes do not affect customer services. Use the Turn Down button to turn down a service before making any changes that may affect customer traffic.

73.7.2 Steps

1

Choose Manage→Service→Customers from the NFM-P main menu. The Manage Customers form opens.

2

Choose a customer and click Properties. The Customer (Edit) form opens.

3

View or modify the information for the customer.

Each tab lists parameters that you can view or modify, or contains functions that you can perform.

- General—lists the customer ID, name, and contact information
- NSP Analytics Parameters—lists the Apdex and MOS thresholds that the customer can set
- Services—lists the services associated with the customer.
- Sites—lists the PE NEs of the customer
- Aggregation—lists the aggregation schedulers of the customer; see Chapter 50, “QoS policies” for information about creating aggregation schedulers
- Spans—lists the span of control over customers

4

Save the changes and close the forms.

END OF STEPS

73.8 To move sites from one service to another

73.8.1 Purpose

Sites can be moved between services. The following service types are supported: VPRN, VPLS, MVPLS, IES, and all VLL types including Wavence VLL.

The following restrictions apply:

- You can only move a site between like services, that is, from one VPLS to another VPLS, but not between a VPLS and a VPRN, for example.
- The services that you are moving sites to and from must have the same Service ID.
- The services that you are moving sites to and from must have the same Customer ID.
- The OLC state of the service site may change based on the destination service configuration.

See 73.2.2 “Managing the size of a service associated with a customer” (p. 1980) in this chapter, for more information.

Note: When you perform a service size reduction, the NFM-P does not create a composite service for services that have only mesh SDP bindings.

See Chapter 85, “Composite service management” for more information about composite services.

Note: The performance of the NFM-P may be affected if you attempt to move a high number of sites or large sites. If you need to move large sites, move fewer sites at one time.

73.8.2 Steps

1

To move more than 25 sites at a time, or to create composite services after moving sites, go to Step 2 . Otherwise, go to Step 5 .

2

Choose Administration→System Preferences from the NFM-P main menu. The System Preferences form opens.

3

In the Services tab, in the Composite Services panel, enable Auto Discover Spoke, CCAG, SCP, RVPLS Connectors. You can also change the Maximum number of sites that can be moved parameter, to up to 50.

Note: The Auto Discover Composite Services parameter can be modified only by a user with administration privileges.

4

Save the changes and close the form.

5

Perform one of the following:

a. Choose Manage→Service→Services from the NFM-P main menu.

The Manage Services form opens.

b. Choose Manage→Service→Composite Service from the NFM-P main menu.

The Manage Composite Services form opens.

6

Click Search to populate the list.

7

Choose the service from which you want to move the sites or the composite service that the service belongs to and click Properties. The *Service*(Edit) |*Composite Service*(Edit) form opens.

8

In the service navigation tree, expand Sites, right-click on the site you want to move and choose Move to Another Service from the contextual menu. A dialog box appears.

9

Click Yes. The Select Services form opens and displays a list of applicable services to which you can move the selected site.

10

Choose the required service and click OK. A progress message is displayed, followed by a confirmation message, after the move is complete.

The NFM-P creates a composite service if:

- The Auto Discover parameter is enabled.
- There are connections between the moved sites and the remaining sites, if the services are not already part of composite services.

11

To view the composite service that is automatically created by the NFM-P after a successful move, click Properties in the Composite Service panel. The Composite Service (Edit) form opens with the General tab displayed.

12

Close the forms.

END OF STEPS

73.9 To delete customers

Note: You cannot delete customers that have associated services.

73.9.1 Steps

1

Choose Manage→Service→Customers from the NFM-P main menu. The Manage Customers form opens.

2

CAUTION

Service Disruption

Removing a customer deletes all information associated with the customer. Ensure that the correct customer has been selected.

Choose the customer that you want to delete from the list and click Delete. A Confirm dialog box appears.

3

Perform one of the following:

a. Click No to avoid deleting the customer. The Confirm dialog box closes.

b. Click Yes. The customer is deleted from the NFM-P database.

END OF STEPS

74 Residential subscriber management

74.1 Residential subscriber management

74.1.1 Overview

The emergence of residential broadband networks and the availability of multiple service offerings, such as triple play applications create a requirement for greater service differentiation and control at the level of the individual service recipient. The NFM-P provides functions for the efficient provisioning of access, QoS, and security features on IES, VPLS, and VPRN for residential subscribers.

In the context of the NFM-P, a residential subscriber, sometimes called a subscriber, is a unique identifier that associates a group of end-user devices with policies. A subscriber can be associated with multiple SAPs on multiple NEs, and a customer can be associated with multiple subscribers.

A subscriber host, sometimes called a host, is an end-user device, such as a computer, VoIP telephone, or set-top box, that connects to the provider network and receives the service traffic. Hosts with the same subscriber identifier share overall HQoS and accounting characteristics as defined in a customer SLA, but may use QoS policies and queues that differ by the type and class of service offering.

A subscriber is an abstract entity created by the NFM-P when the first end user of a service connects to the service. A subscriber instance is created on the NE through which the end user connects. When multiple end users connect to the same service through multiple NEs that act as sites for the service, one subscriber instance is created on each NE. When the NFM-P instantiates a subscriber on an NE, the policies and profiles associated with the subscriber are automatically distributed to the NE and associated with the new subscriber instance.

Residential subscriber management, also called enhanced subscriber management, supports service delivery models in a routed or bridged configuration, such as one VLAN per host, one VLAN per application, one VLAN for all applications, and one VLAN per service provider per application.

74.1.2 Configuration requirements

The following must be true before you can enable residential subscriber management on a SAP or deploy a profile to an NE.

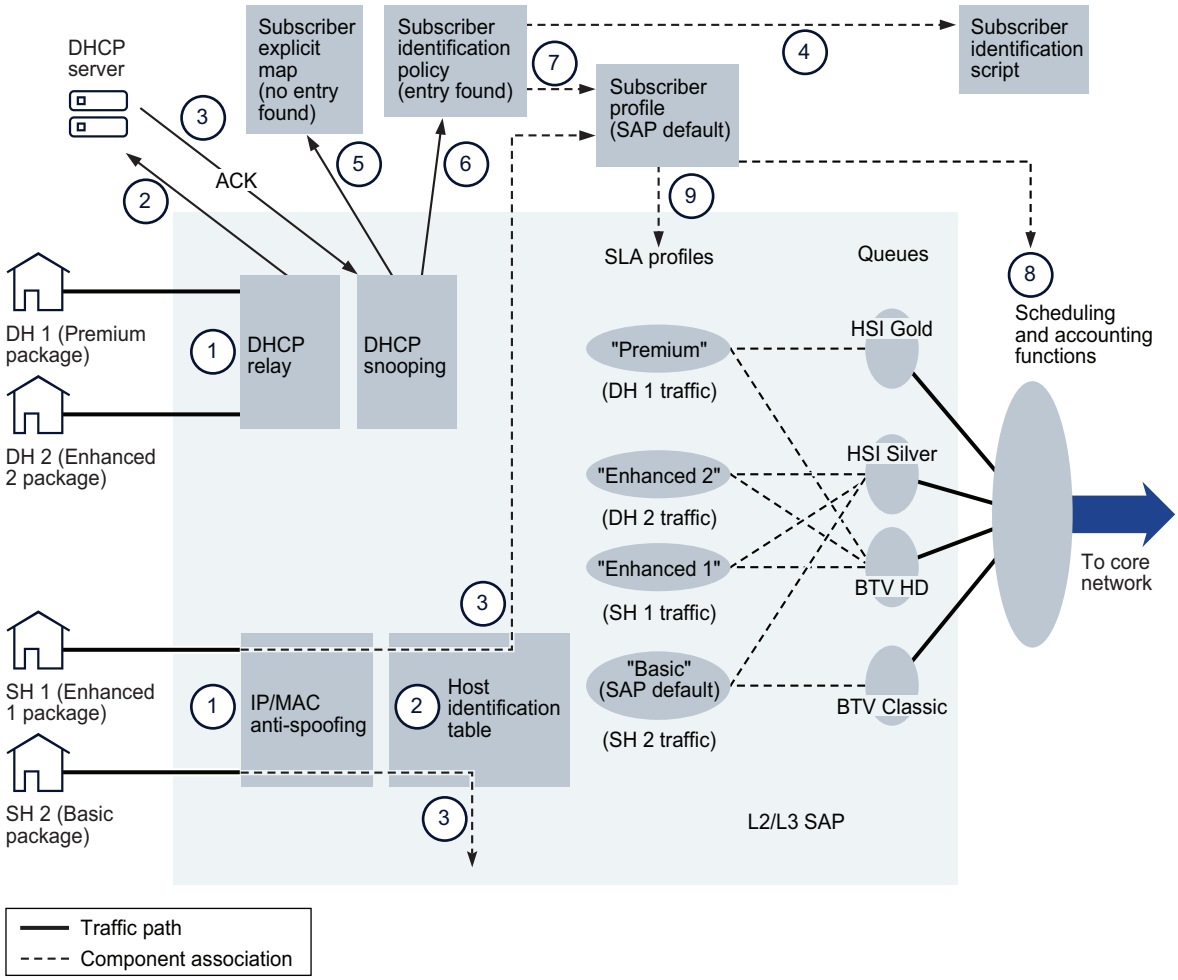
- For dynamic hosts on the SAP:
  - DHCP snooping is enabled on the upstream SAP or SDP.
  - For IES, DHCP relay is enabled on the downstream SAP.
- The NE has sufficient resources for creating the SLA profile instances, queues, and schedulers.
- For new or existing static hosts on the SAP:
  - Anti-spoofing on the SAP is configured with at least IP matching criteria.
  - A subscriber identification string is assigned.
  - A subscriber profile is assigned.
  - An SLA profile is assigned.

– An IP address is assigned.

74.1.3 Residential subscriber management sample configuration

The figure below shows how residential subscriber management assigns resources to dynamic and static hosts. Many different configurations are possible; the sample portrays the residential subscriber management mechanism rather than a particular service delivery model. For simplicity, the sample consists of one subscriber instance on one SAP, and two types of service offering. Each service offering is available in two classes.

Figure 74-1 Residential subscriber management sample configuration



The customer provides a subscriber identification string, the names of the four end-user service packages, and the bandwidth and class requirements for each package. Each package is a combination of HSI and BTV. An NFM-P operator creates four queues and four SLA profiles with

which the queues are associated, as shown in the table below. Nokia recommends that the NFM-P operator give the SLA profiles the same names as the packages to prevent confusion.

Table 74-1 Sample configuration service packages

Subscriber host	Package name	SLA profile name	Associated queues
DH 1	Premium	Premium	HSI Gold, BTV HD
DH 2	Enhanced 2	Enhanced 2	HSI Silver, BTV HD
SH 1	Enhanced 1	Enhanced 1	HSI Gold, BTV Classic
SH 2	Basic	Basic	HSI Silver, BTV Classic

The customer offers two classes of BTV and HSI services:

- BTV HD: high-definition broadcast television
- BTV Classic: regular-definition broadcast television
- HSI Gold: high-bandwidth broadband Internet access
- HSI Silver: regular broadband Internet access

The following steps, which correspond to the numeric labels in the upper part of Figure 74-1, “Residential subscriber management sample configuration” (p. 1990), define the sequence of events for dynamic subscriber hosts that attempt to join the network.

1. Dynamic Host 1 (DH 2) and Dynamic Host 2 (DH 2) each send a DHCP request to the SAP.
2. DHCP relay on the SAP forwards the DHCP requests to the DHCP server.
3. The DHCP server authorizes the requests and responds with a DHCP ACK message for each subscriber host.
4. The subscriber identification policy uses a script to obtain the subscriber identification string, an optional subscriber profile string, and an optional SLA profile string from the Option 82 information in each ACK message. DH 1 and DH 2 provide the same subscriber profile identification string but different SLA profile strings.
5. The NE checks the subscriber identification string values against the entries in the subscriber explicit map and finds no matching entries for the hosts.
6. The NE checks the subscriber profile string and the SLA profile string values for each host against the subscriber identification policy.
7. The NE assigns the same subscriber profile to DH 1 and DH 2 based on the subscriber profile string provided by each host.
8. DH 1 is the first host to join the network, so the scheduling and accounting functions associated with the assigned subscriber profile are instantiated on the SAP.
9. The NE matches the SLA profile string provided by each host to an SLA profile. The NE assigns the Premium SLA profile to DH 1 and the Enhanced 2 SLA profile to DH 2 based on the provided SLA profile strings. These are the first hosts of the subscriber to join the network, so

the appropriate queues are instantiated on the SAP based on the SLA profile specifications, and host traffic subsequently flows.

The following steps, which correspond to the numeric labels in the lower part of Figure 74-1, "Residential subscriber management sample configuration" (p. 1990), define the sequence of operations for static subscriber hosts that join the network.

1. Static Host 1 (SH 1) turns on the computer, and Static Host 2 (SH 2) turns on the television.
2. The host devices request network access; IP- matching (and optional MAC-matching) anti-spoofing on the SAP checks the static host table on the NE and validates both requests.
3. The NE assigns resources to each static host based on subscriber profile and SLA profile designations, and host traffic subsequently flows.
   - The static host table entry for SH1 names a subscriber profile and an SLA profile. Although SH 1 is the first host to use this SLA profile, the queues defined in the profile are already instantiated because of the application of the SLA profiles for DH 1 and DH 2.
   - For SH 2, there is no explicit association between the host and a subscriber profile or an SLA profile, so the NE assigns the SAP default subscriber and SLA profiles, which define the most basic service package the customer offers to end users.

74.1.4 Migrating to the TPSDA model

The NFM-P facilitates the migration of hosts from SAP-based aggregation to the TPSDA model. You can use residential subscriber management functions to:

- Associate a subscriber with a SAP by using the SAP identifier as the subscriber identification string. The existing hosts on a SAP can then be automatically associated with a subscriber.
- Rename a subscriber. This changes the subscriber identification string for all hosts and facilitates a move from a default subscriber identification string to a string that complies with a particular naming scheme.
- Configure an intermediate destination identifier, such as a DSLAM name, for a static host and obtain the identifier from the Option 82 information in a DHCP packet. This function enables the listing of the hosts for a specific DSLAM and facilitates interworking with other TISPAN components.
- Configure a default subscriber identification string for the hosts on a SAP. This enables residential subscriber management functionality without the use of a subscriber identification policy or RADIUS authentication. This default string is associated with hosts when a string is not available from another source.
- Interpret an SLA profile string or subscriber profile string from a host as the profile name when a profile with a matching profile string is not found. This eliminates the need to map a profile string to a profile.

74.2 Residential subscriber components

74.2.1 Overview

Configuring residential subscriber management on the NFM-P involves the configuration of a variety of components, depending on the service delivery model.

For detailed NE-specific information about residential subscriber management, see the NE documentation. For information about configuring residential subscriber policies and profiles, see Chapter 64, “Residential subscriber policies”.

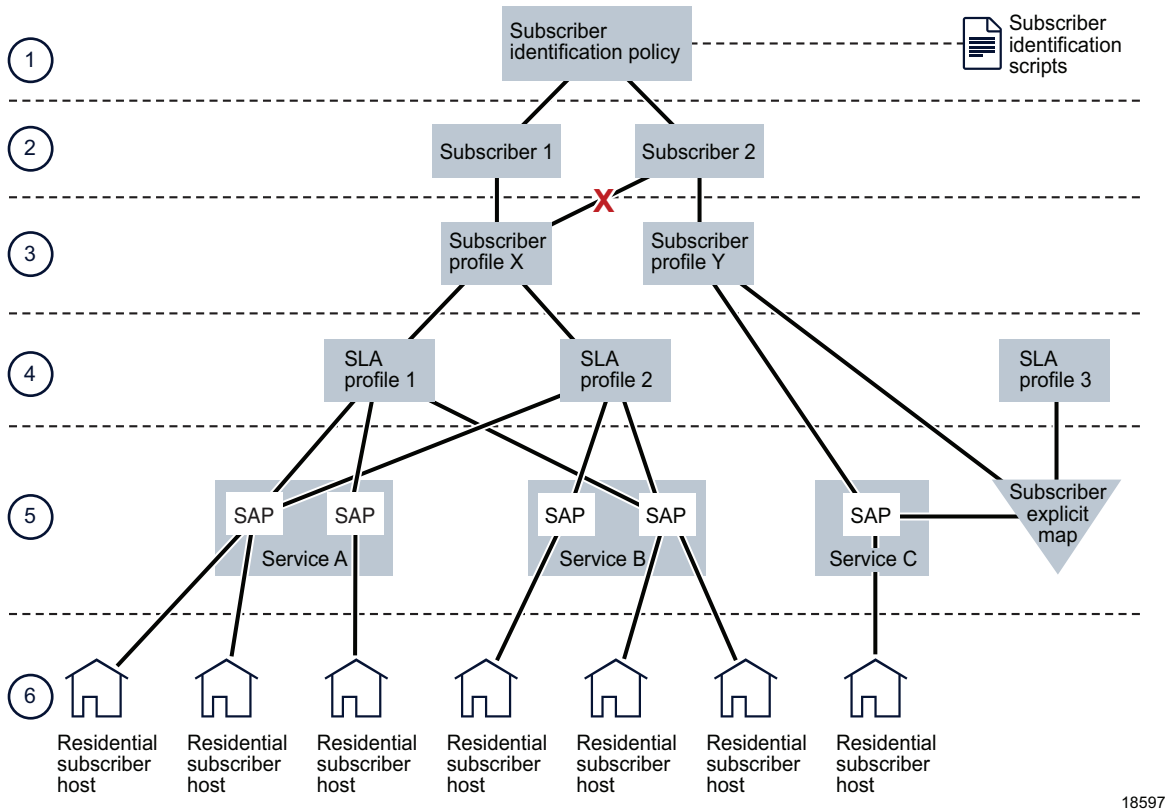
A host requires subscriber-profile and SLA-profile associations to gain access to the network. Profiles define service attributes for hosts such as scheduling, accounting, security, and traffic prioritization by application type. A profile uses existing NFM-P policy definitions and allows the customization of policy parameters using override values.

An NFM-P user who is assigned the administrator, subscriber management, service management, or policy management scope of command role can perform all residential subscriber management functions, such as managing profile or DHCP-lease information.

The NFM-P allows the configuration of multiple components in one operation, but limits configuration to those parameters that are not specific to a component. For example, when a policy is applied to multiple profiles, the NFM-P removes pre-existing policy override values in the profiles.

The figure below shows a conceptual model of the main component relationships in residential subscriber management. The model does not represent a specific type of service or service delivery mechanism and does not show all possible component configurations.

Figure 74-2 Residential subscriber management component relationships



As shown in Figure 74-2, “Residential subscriber management component relationships” (p. 1993), there is a one-to-one relationship between a subscriber and a subscriber profile and a many-to-many relationship between subscriber profiles and SLA profiles. A subscriber profile or an SLA profile can apply to multiple SAPs or NEs, and can be specified as the default profile for the SAP or the NE.

The table below lists where to find configuration information for residential subscriber components. The numbered levels segregate components for clarity only.

Table 74-2 Residential subscriber management components

Leve	Component	Description	For more information, see	Procedure
1	Subscriber identification policy	Associates a dynamic host with a subscriber	64.1.2 “Subscriber identification policies” (p. 1827)	64.3 “To configure a subscriber identification policy” (p. 1838)
	Subscriber identification script	Parses DHCP Option 82 field to extract subscriber identification for a host, and optional profile, ANCP, and intermediate destination identification strings.	64.1.2 “Subscriber identification policies” (p. 1827)	74.19 “To modify the primary subscriber identification script or URL” (p. 2040)
2	Subscriber	Unique identifier that associates a group of subscriber hosts with policies	74.1 “Residential subscriber management” (p. 1989)	—
2	Subscriber instance	An instantiation of a subscriber on an NE	74.1 “Residential subscriber management” (p. 1989)	—
3	Subscriber profile	Names existing ingress and egress scheduler policies and an accounting policy for use by all hosts of a subscriber	64.1.3 “Subscriber profiles” (p. 1828)	64.4 “To configure a subscriber profile” (p. 1840)
4	SLA profile	Names existing QoS policies to define the traffic shaping for different classes of service within an application such as HSI, VoIP, VoD, or BTV Names existing ACL policies to filter the ingress and egress traffic	64.1.4 “SLA profiles” (p. 1829)	64.5 “To configure an SLA profile” (p. 1845)
5	Subscriber explicit map	Lists subscriber identifiers and the associated SLA and subscriber profiles	64.1.5 “Subscriber explicit maps” (p. 1829)	64.6 “To configure a subscriber explicit map entry” (p. 1848)

Table 74-2 Residential subscriber management components (continued)

Leve	Component	Description	For more information, see	Procedure
6	Residential subscriber host (static)	A device such as a computer or set-top box that receives service traffic using a fixed IP address	74.2.7 “Static subscriber hosts” (p. 1998)	74.24 “To create a static host for residential subscriber management on a SAP” (p. 2045) , 78.55 “To configure anti-spoofing filters for an IES L3 access interface” (p. 2501), and79.111 “To configure anti-spoofing filters for a VPRN L3 access interface” (p. 2686) access interface anti-spoofing configuration steps
	Residential subscriber host (dynamic)	A device such as a computer or set-top box that receives the service traffic using a temporarily assigned IP address	64.1.2 “Subscriber identification policies” (p. 1827), 64.1.3 “Subscriber profiles” (p. 1828), 64.1.4 “SLA profiles” (p. 1829), 64.1.5 “Subscriber explicit maps” (p. 1829), 74.4.3 “Managed SAP (MSAP)” (p. 2018), and 64.2.3 “PPPoE policies” (p. 1831)	74.34 “To view and configure residential subscriber hosts on a SAP” (p. 2057)
7	Local DHCP server and PPPoE group interface	A local user database is created and associated to a local DHCP server and PPPoE group interface configuration	74.2.4 “Local DHCP server” (p. 1996)	64.9 “To configure a PPP policy” (p. 1851) 74.9 “To configure a local user database for subscriber host authentication” (p. 2025) 79.5 “To create a VPRN service” (p. 2534) 78.19 “To configure a group interface on an IES” (p. 2449)

The NFM-P treats residential subscriber management components like policies. Depending on the distribution mode configuration of a local instance, when you modify a global component using the NFM-P, all local instances of the residential subscriber management component on the associated NEs can be updated. The Local Definitions tab of a component management form lists the local instances of the component.

Note: You cannot delete an active component of a residential subscriber management configuration.

74.2.2 Residential subscriber component and policy deployment

Global residential subscriber management components are created in draft mode. This allows operators to verify the configuration before they distribute it to the network elements; see Chapter 49, “Policies overview” for information about global and local policy instances and policy distribution modes.

The NFM-P deploys the components associated with a subscriber, such as policies and profiles, to an NE when one of the following occurs:

- The deployment of a subscriber identification policy with profile specifications
- The provisioning of the first static host for the subscriber on a SAP
- The provisioning of a capture SAP with an MSAP Policy to automatically create an MSAP; see 74.4.3 “Managed SAP (MSAP)” (p. 2018)

After the NFM-P deploys the subscriber and SLA profiles, the NE creates the queues, ACL filters and HQoS schedulers specified in the profiles. The NE ignores pre-existing queue or ACL filter policies on a SAP when subscriber management is enabled on the SAP.

74.2.3 Subscriber identification strings

The NFM-P identifies the subscriber for a dynamic host by obtaining a subscriber identification string from a source such as the following:

- information that the host passes in the Option 82 field of a DHCP packet
- a RADIUS server
- the local user database

A static host requires explicit provisioning on the NFM-P that includes the association of a subscriber identification string.

You can optionally specify a default subscriber identification string for a SAP. You can enter the string or configure the NFM-P to use the SAP ID as the string.

Obtaining subscriber identification strings from DHCP packets

When a dynamic residential subscriber host requests an IP address using DHCP, the host can include a subscriber ID string and optional profile ID strings in the Option 82 field of the DHCP packet. If the request is approved by a DHCP server, the NE obtains the subscriber ID string for the host from the Option 82 information in the returning ACK message. The subscriber ID string is a match criterion for the assignment of SLA and subscriber profiles to the host unless profile ID strings are explicitly encoded in the DHCP option information by the host or configured as SAP default profiles. You can also configure a default subscriber ID string on a SAP.

Note: If adding Option 82 information to a DHCP relay packet causes the packet to exceed the DHCP relay maximum of 1500 bytes, the NE forwards the DHCP request without the Option 82 information. For this reason, short strings can be used as aliases for profile names.

74.2.4 Local DHCP server

A local DHCP server leases IP addresses to clients in the network. Options are configured to define the IP address properties, such as, the length of time an IP address is active and which DNS server

must be used. A local user database is used to authenticate and authorize clients requesting IP addresses from the local DHCP server. If the local DHCP server does not use the local user database, the server can use the GI address to assign free IP addresses, however it is not possible to configure match or authentication parameters.

Three applications are targeted for the local DHCP server.

- Subscriber aggregation using a single NE or TPSDA.
- Business services running VPRN and locally attached to the host can request and obtain IP addresses directly from the server.
- The DHCP server identifies an IP request from a PPPoE client and provides an IP address and options.

DHCP servers can be integrated with Enhanced Subscriber Management for DHCP and PPPoE clients. A local DHCP server can be created in the routing instance window or VPRN service site window. A local DHCP server created in the VPRN service site can be associated with the L3 access interface on a VPRN service only. A local DHCP server created in the routing instance window can be associated with a network interface or L3 access interface on an IES.

Failover support

You can configure failover support on local DHCPv4 and DHCPv6 servers, as well as on individual IP address pools on the servers. The same IPv6 prefix or IPv4 address range can be shared between the two peering DHCP servers in a redundant configuration. Either DHCP server can allocate a new lease from the same address range or prefix. To avoid IP address duplication, a single active path is available from the clients to one of the DHCP servers in a redundant configuration. The single active path is ensured through a protection mechanism in a dual homed environment in the access side of the network. The supported protection mechanisms are SRRP or MC-LAG.

Sticky leases

You can configure a sticky lease object on a local DHCPv4 or DHCPv6 server to reserve an IP address, preventing the address from being allocated to another device. The reserved IP address can be defined as a public address for a dynamic host; see 34.22 “To configure an IES or VPRN IPsec gateway” (p. 1256).

74.2.5 Local user database

A local user database is configured and associated with the local DHCP server to provide local authentication. The local DHCP server must have a pool of IP addresses configured, otherwise it is not able to lease IP addresses.

A create local user database configuration form is available from the Manage Residential Subscribers form; see 74.9 “To configure a local user database for subscriber host authentication” (p. 2025). Once a local user database is configured, it can be associated with a local DHCP server and PPPoE configuration on a group interface.

When a local user database is not configured, you can use GI addresses to access free IP addresses, however the clients requesting the IP address will not be authenticated.

74.2.6 ARP host

You can use the NFM-P to configure and retrieve ARP hosts on a 7750 SR. ARP hosts are a subtype of enhanced subscriber host objects. The creation of the object is triggered by the reception of ARP messages from end-user devices. ARP hosts can be configured as an alternative to DHCP subscriber hosts or PPPoE sessions.

ARP host configuration can be performed on VPLS and MVPLS L2 access interfaces, IES and VPRN group interfaces, and VPRN retailer subscriber interfaces. The configuration includes enabling the functionality, setting the maximum limit of hosts per SAP or interface, and setting the default authentication interval.The configuration must be performed in conjunction with other enhanced subscriber management configuration on these interfaces. ARP hosts can be retrieved from the VPLS, MVPLS, and IES or VPRN SAPs. ARP hosts can also reside on MSAPs.

74.2.7 Static subscriber hosts

Static subscriber hosts require explicit provisioning rather than an association with a subscriber identification policy. Static hosts for VPLS are configurable on the anti-spoofing tab of the L2 access interface management form. For IES and VPRN services, static hosts are configurable using the management form for a SAP on a group interface.

Static host configuration involves the following elements:

- IP address
- MAC address (optional)
- subscriber ID string, or the use of the SAP ID as the subscriber ID
- valid subscriber profile
- valid SLA profile
- ANCP string
- intermediate destination, such as a DSLAM
- application profile

Note: When residential subscriber management is enabled on a VPLS SAP that is part of an operational MC ring group, the following must be configured on each static host:

- an intermediate destination that is a ring node in the MC ring group
- subscriber identification, such as a subscriber ID string or the use of the SAP ID as the subscriber ID
- a subscriber profile
- an SLA profile

74.2.8 Subscriber host connectivity verification

Aside from relatively infrequent IP-address lease renewal, DHCP has no session-monitoring or connection-monitoring capability. Residential subscriber management provides this functionality for DHCP hosts and static hosts using subscriber host connectivity verification, or SHCV.

When SHCV is enabled on a SAP, an NE issues a periodic ARP request to each host on the SAP. If the NE receives no reply to an ARP request within the specified interval, the NE raises an event. When SHCV is configured to drop a lost host, the NE immediately removes the host from its active subscriber host table.

SHCV records the state information that it collects for hosts on a SAP and maintains a history of connectivity-related events for troubleshooting purposes. The size of the history log is restricted by a size-constraint policy.

SHCV operates in conjunction with DHCP snooping and is configurable on VPLS, VPRN, and IES SAPs and on IES group interfaces. Because it uses ARP, SHCV automatically populates the FIBs of bridging devices in the access and provider networks.

The configurable items for SHCV on a SAP include:

- frequency of connectivity checks
- source of the ARP request
- action to take when a host loses connectivity

Note: On an L2 access interface, SHCV uses the NE system IP address as the source of the ARP request. On an L3 access interface, SHCV uses the IP- and MAC-address combination of the interface or the VRRP state for the interface as the ARP source. On IES group interfaces, SHCV uses the address of the subscriber interface as the source.

The behavior that an NE exhibits toward SHCV events is configurable using the residential subscriber management form.

The configurable NE SHCV items include:

- maximum host connectivity loss rate
- action to take when the connectivity loss rate exceeds the maximum
- action to take when the NE drops an event trap, as such an event may indicate a high connectivity loss rate

SHCV event handling on an NE is disabled by default. When SHCV is enabled on a SAP but is disabled on the NE, the NFM-P records the blocking of SHCV events in the SHCV log. This ensures that an operator is aware of SHCV activity when viewing the SHCV log, even if the NE is configured to suppress SHCV events.

The following conditions represent an SHCV host connectivity loss:

- absence of a host response
- inconsistency between the reply data and the DHCP lease state

An NE makes more than one SHCV attempt before it raises an event against a host to ensure that the absence of a host response indicates a host connectivity problem and is not simply the result of occasional packet loss.

When a SAP becomes operationally down, the NE generates one trap for the SAP rather than one trap for each host on the SAP. When the SAP returns to service, the NE forwards a trap for each host as it verifies the restoration of connectivity.

SHCV generates the following event traps:

- SAP up
- SAP down
- host up
- host down
- trap dropped

SHCV policies

The SHCV policy provides consistent BNG behavior when handling RG replacement and mobility across different (IP and/or MAC) address types. The SHCV policy is configured on VPRN or IES group interfaces, and VPRN or IES L3 access interfaces.

An SHCV policy specifies uniform Action, Interval, Retry Count, and Timeout parameters for periodic SHCV. The policy also specifies uniform Retry Count and Timeout parameters for each of the following SHCV event triggers:

- Host limit exceeded: the number of hosts specified on the SLA profile is exceeded.
- IP conflict: Can occur when an IP address/prefix is assigned to a SAP.
- Mobility: A MAC or IP address conflict resulting from a UE moving from SAP to SAP.
- MAC learning: Triggered at static host no-shutdown. SHCV attempts to continue until the MAC address is learned for the static host.
- Inactivity: Host inactivity.

To create an SHCV policy, see 64.31 “To configure an SHCV policy” (p. 1872).

74.2.9 Routed CO

A broadband access network typically requires the aggregation of the traffic from access equipment before routing of the traffic is possible. Routed CO functionality allows a network operator to directly connect a DSLAM or similar multiplexer to a router such as the 7750 SR.

Residential subscriber management, combined with the use of DSCP or dot1p values, supports access-integration models such as the following:

- one SAP for all subscribers and service offerings
- one SAP per service offering
- one SAP per subscriber

Routed CO allows the configuration of subscriber interfaces and group interfaces on IES and VPRN. A subscriber interface defines the subnets that are available to a subscriber. A group interface is a child object of a subscriber interface that allows the configuration of multiple SAPs as part of a single interface. Routed CO functionality depends on residential subscriber management to maintain the subscriber host information.

There is no direct association between the subnets and the group interfaces. Subnets can be shared between group interfaces. If the host IP address is not in one of the subnets, packets from the network to that host IP are not received by the subscriber or group interfaces.

A subscriber interface defines a maximum of 16 subscriber subnets and acts as the DHCP relay agent for a subscriber. For the forwarding of DHCP packets to a subscriber server, a subscriber interface requires the specification of a gateway address that is in one of the subscriber subnets. Group interfaces below the subscriber interface inherit this gateway address but can specify an override value if required.

All SAPs in a group interface use the same port. The first SAP on a group interface determines which port the group interface uses. Additional SAPs for the group interface must be associated with the group-interface port during SAP creation.

A group interface is similar to a regular IES interface except for the following.

- Multiple SAPs are configurable.
- No IP addresses are specified.
- No broadcast traffic is permitted.
- No loopback mode exists.
- No static ARP can be specified.
- VRRP is not supported.

When a subscriber interface or a group interface is operationally disabled, no packets are sent to or from the subscriber hosts on the SAPs of the interface, but the state information for a static or dynamic host persists until the static host is removed from the NE by an operator or the DHCP lease of the dynamic host expires.

Because the configuration of multiple SAPs on a group interface makes normal forwarding of DHCP responses to hosts impossible, DHCP relay for routed CO maintains a cache of DHCP requests. If a DHCP server response does not arrive within the specified interval time, the NE discards the cache entry. The NFM-P operator can choose to have the NE use the Option 82 circuit ID field in a DHCP request as the match criterion for the returning DHCP ACK message.

You can configure NAT for dynamic subscriber hosts in a routed CO deployment. NAT for routed CO requires a NAT policy that is associated with a subscriber profile. In an IES routed CO deployment, NAT is configured on the base routing instance of an NE. In a VPRN routed CO deployment, NAT is configured on the VPRN routing instance; see Chapter 30, “NAT” for information about configuring and deploying NAT, and about configuring a NAT policy; see 64.4 “To configure a subscriber profile” (p. 1840) for information about associating a NAT policy with a subscriber profile.

Lease populate is enabled on a group interface by default, and the number of allowable lease entries is set to one. All SAPs on the group interface inherit this configuration during creation.

See Chapter 78, “IES management” and Chapter 79, “VPRN service management” for more information on configuring subscriber and group interfaces for IES and VPRN services.

Wholesale and retail configurations for VPRN services

A VPRN routed CO allows a service provider to resell wholesale carrier services while providing direct DSLAM connectivity. You can create a VPRN service for the retailer and also define

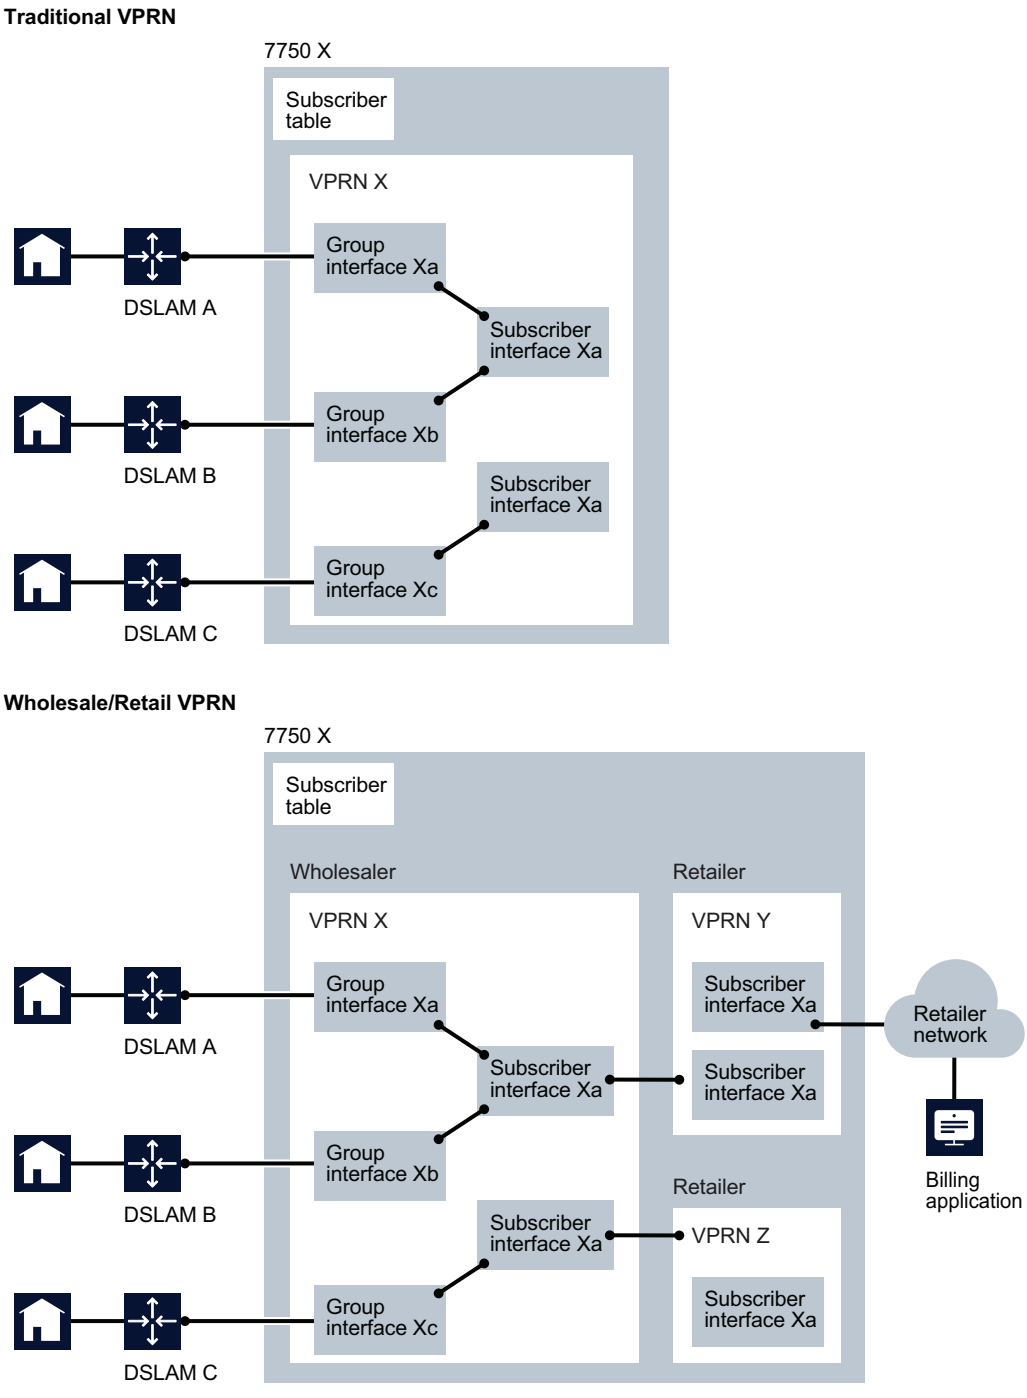
subscriber access and configuration information for the retailer network. The implementation of configuration changes occurs as if the VPRN is a standalone router using the routed CO model. The benefit of this model is flexibility for the retailer and decreased involvement for the wholesaler.

You must use a subscriber SAP to support shared access for multiple retailers. Another dependency of shared access is the requirement for the wholesaler to maintain separate access nodes for each retailer with network scaling issues.

In the wholesale and retail model, the wholesaler instance connections that are common to the access nodes are distributed to many retail instances. Upstream subscriber traffic ingresses into the wholesaler instance and, after identification, is then forwarded into the retail instance. The reverse principle occurs for traffic in the opposite direction. The wholesale and retail traffic flow is controlled with minimal communication to the RADIUS server. A RADIUS policy is defined in the wholesaler instance. The RADIUS response used during the subscriber instantiation provides the service context of the retailer VPRN. If the wholesaler has a retail business, the operator can configure a separate VPRN for their retail services.

The retailer subscriber interface primarily controls the DHCP configuration. The single exception to this model is the lease-populate value. The lease-populate value in the wholesale context controls the individual SAP limits. The lease-populate value in the retail subscriber interface controls the limits for that retailer interface. The wholesale and retail limits must be met before the instantiation of a new subscriber.

Figure 74-3 Routed CO for traditional and wholesale/retail VPRNs



See Chapter 79, “VPRN service management” for information on configuring the forwarding service component for wholesale and retail VPRN services.

74.2.10 Subscriber host polling and monitoring

Subscriber hosts can be periodically polled and monitored for certain DHCP event changes. A subscriber host monitoring configuration form is available from the Manage Residential Subscribers form.

The maximum number of hosts that can be selected for monitoring is configurable through XML; the default is five. Host monitoring has a performance impact, so only a small number are typically monitored at one time.

The Monitored Subscriber Host form displays a variety of polled information about the host that is obtained from the NE. You can also open a DHCP event log for the host from the Host Properties form. The logged events include information on DHCP lease renewals, lease expiration, and profile changes. An entry is added to the table whenever a new event occurs. You can purge event entries using the Host Properties form.

Host monitoring can be started, stopped, or removed from the monitoring configuration form, and the monitoring period and polling interval can be configured.

The Host monitored objects and associated events are stored in the NFM-P database. The monitoring continues until the monitoring period elapses or the monitoring is stopped by an NFM-P operator.

74.2.11 Subscriber services

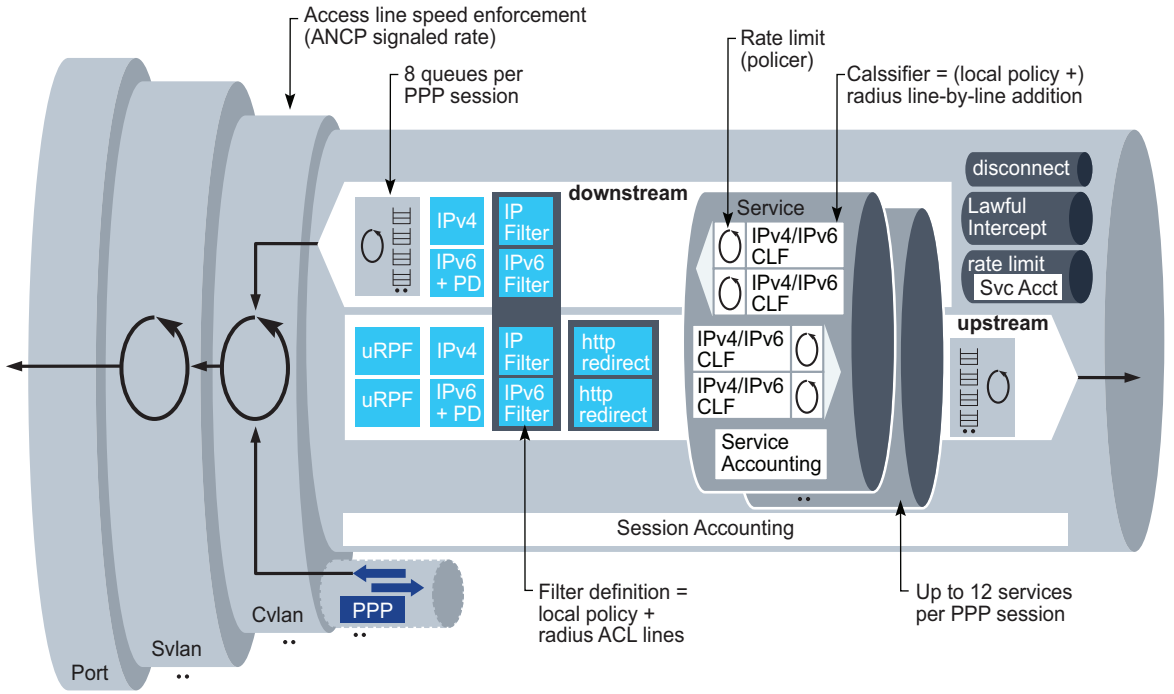
The NFM-P supports the retrieval of subscriber services and related attributes from PPP or IPoE subscriber hosts. A subscriber service specifies a mode of operation in which a subscriber-specific service is activated and deactivated on a PPPoE session via a RADIUS Access-Accept message or a CoA-Request message. This function is sometimes referred to as Radius Based Policy control, or RaBaPol.

Single or multiple subscriber service activation and/or deactivation calls can be included in Access-Accept messages for new PPPoE sessions, or in CoA-Request messages for existing PPPoE sessions. PPPoE sessions can be IPv4, IPv6 or dual stack. Subscriber services can also operate on the PPPoE session itself.

Examples of subscriber services are:

- apply or change the dynamic bandwidth of a PPPoE session
- apply or change a QoS profile
- activate or deactivate HTTP redirection
- apply or change a rate-limiting service
- a Disconnect Request for a PPPoE session

Figure 74-4 Subscriber services model



74.2.12 BNG integrated virtual CPE

In a redundant configuration, the vRGW runs in an active/standby redundancy model. When a switch-over occurs, subscriber hosts are re-created via data trigger. In order to avoid assigning the same address to multiple hosts, allocated IP addresses are tracked in the address pool assigned to a subscriber. To support this functionality, the Standby IP Lifetime is configured on the DHCP pool on a BRG profile. Additionally, the BRG instance displays the standby IP address, remaining hold time, and a list of BRG address pools.

74.2.13 Managed routes

The NFM-P can retrieve managed route (also known as framed route) information from the NE for hosts instantiated on IES and VPRN services. A routed subscriber host is a subscriber with subnets behind the routed gateway in order to support subscriber hosts with regular routers. The subscriber host associated subnets are learned through RADIUS VSAs (up to 16 routes).

Framed routes (IPv4 subnets) are displayed on the following ESM session types:

- DHCP lease
- ARP host

- PPP session

Framed IPv6 routes (IPv6 prefixes) are displayed on the following ESM session types:

- DHCPv6 lease
- PPP DHCPv6 session
- PPP SLAAC session
- IPoE SLAAC host (displayed within the subscriber host object)

74.2.14 IPoE sessions

An IPoE session is a logical grouping of multiple subscriber hosts that represent different IP stacks on the same end user device. The grouping is based on a configurable data key, available in a trigger packet. An IPoE session can be single-stack IPv4, single-stack IPv6,or dual-stack, depending which host types or stacks are associated with the session.

The creation of a new IPoE session triggers authentication in the same way as for a subscriber host. A unique accounting session ID is generated for the IPoE session. The authentication data is stored in the IPoE session state for future reference.

Subscriber hosts with a matching key in the trigger packet are associated with an existing session without re-authentication: the data stored in the session state is used to instantiate the subscriber host. Deleted subscriber hosts are no longer associated with the IPoE session.

During the lifetime of an IPoE session, the state is maintained by control plane events for the associated IP stacks (such as DHCP lease state renewals or SHCV checks). Mid-session changes can occur.

An IPoE session is terminated when the last associated IP stack is deleted, or by policy control. The corresponding IPoE session state is then deleted from the system.

The NFM-P specifies IPoE session trigger packet information and session termination control by means of an IPoE session policy. The IPoE session policy is bound to a VPLS capture SAP, and to an IES or VPRN service group interface.

74.2.15 HSQ

HSQ (High Scale QoS) is an evolution of egress Q chip traffic management functions on an enhanced version 4 IOM (iom4-e-hs). The functionality of HSQ is similar to the HSMDAv2, with expanded queue and shaping scale, and an added level of aggregate shaping. Because HSQ functions at the egress forwarding plane level, all egress ports on supported MDA types utilize HSQ QoS functions. Ingress ports on attached MDAs are provisioned using the standard HQoS (Hierarchical Quality of Service) feature set. HSQ supports ports, LAGs, and PW ports.

The following services support HSQ:

- VPRN
- IES
- VPLS, B-VPLS, I-VPLS, and MVPLS
- VLL Epipe and Ipipe

HSQ supports two SLA modes for ESM: Expanded and Single. The SLA mode is configurable on the subscriber profile. In Single mode, the subscriber aggregate rate and the SLA profile queuing are both performed using a single CVLAN context for the subscriber.

A unique SLA profile instance is required when one or both of the following conditions occur:

- A subscriber host references a unique SLA profile name not currently associated with an existing subscriber host.
- A subscriber host is associated with a different egress SAP than an existing subscriber host.

In Single mode, the first condition causes the new SLA profile context to alter the existing SLA profile instance associated with the subscriber. The second condition is not supported for a subscriber configured in Single mode. In Expanded mode, multiple SLA profile instances are supported by moving the subscriber aggregate shaping function to an SVLAN specifically created for the subscriber instance. A unique CVLAN is created for each unique SLA profile instance for the subscriber.

For configuration information, see 74.3.5 “Workflow to configure HSQ” (p. 2013).

74.2.16 ESM over GTP hybrid access

Hybrid access technology provides higher bandwidth to areas where there is limited network infrastructure (typically copper wire-based), and provides the option for the service provider to make a smooth transition to LTE technology in the future. GPRS Tunnelling Protocol (GTP) is used to terminate wireless connections on S11 interfaces, allowing the service provider to use ESM over GTP on hybrid access (WLAN GW and BNG). GTP can be used with and without bonding. The Access Point Name (APN) policy defines subscribers with an access point name and authentication parameters. GTP is configured on VPRN and base routing instances, including APN policy configuration on S11 interfaces.

For configuration information, see 74.3.6 “Workflow to configure ESM over GTP hybrid access” (p. 2014).

74.2.17 Home LAN extension

In a home LAN extension configuration, a bridge domain is created for each residential subscriber on the BNG, the bridge domain is extended by a VXLAN tunnel to the VM in the domain controller. All L3 routing and services on a residential CPE are moved out of the CPE to run in the service provider’s network. These L3 services can be integrated on the BNG or run in a VM per CPE in the data-center. The home CPE runs in bridged mode. It provides local-bridging for traffic between devices on the home LAN, and any traffic destined to an address that is not on the local subnet is bridged towards the BNG. From BNG’s perspective this looks like a bridged residential subscriber with ESM and L2-aware NAT for routed traffic. Each device on the home LAN gets a unique address from the DHCP Server or DHCP proxy on the BNG. In this manner, the VM appears to be on the home LAN.

For more information, see 74.3.8 “Workflow to configure home LAN extension functionality in a network” (p. 2016).

74.2.18 ISA service chaining

Value Added Service (VAS) is a set of service functions in a data center (DC) providing optional services to ESM hosts on a vRGW or BNG. These service functions in the DC can live on virtual machines (VMs) behind a network virtualization edge (NVE) or a third party NVE. ESM hosts corresponding to residential subscribers on the vRGW or BNG (and corresponding NAT outside IP addresses) can be in a different subnet than the VMs in the DC. The vRGW or BNG can access the VAS in DC over an EVPN or VxLAN overlay.

Based on ingress/egress VAS filters associated with L2-aware subscribers, traffic is steered towards service functions (VMs or appliances behind an NVE in an EVPN-enabled data center). The vRGW/BNG shares a local subnet and an overlay routing context (VPRN) with the NVE (behind which the service functions sit), and acts as the next-hop router for the NVEs to reach the NAT outside IP addresses on the vRGW/BNG. NAT outside service can be same as the overlay routing context shared with the NVEs in the DC, or can be a different context. In case it is a different context, NAT routes are leaked into the overlay VPRN, and announced via EVPN prefix routes.

Traffic after NAT on the vRGW/BNG is directed to the MAC address of the service function, resolved by tracking EVPN updates, and is VxLAN tunneled towards VTEP on an NVE in the DC. The NVE bridges this traffic to the service function, or traffic after NAT on vRGW/BNG is directed to the MAC address of the NVE (resolved by tracking appropriate EVPN routes), and is VxLAN tunneled towards VTEP on the NVE. The NVE routes the traffic in appropriate routing context (based on the VNI) to the VM/VA sitting behind it.

Workflow to configure ISA service chaining

Complete the following procedures to configure ISA service chaining:

1. Configure an NE with a MAC prefix for ISA service chaining; see 12.27 “To configure ISA service chaining on an NE” (p. 363).
2. Configure the base routing instance for ISA service chaining, with ISA groups and VXLAN VTEP ranges; see 27.2 “To configure a routing instance or a VRF instance” (p. 826).
3. Configure a service chaining EVPN policy, see 64.33 “To configure a service chaining EVPN policy” (p. 1873).
4. Configure a service chaining VAS Filter policy, see 64.34 “To configure a service chaining VAS filter policy” (p. 1874).

74.3 Residential subscriber management configuration workflows

74.3.1 Workflow to manage residential subscribers

1

Create a service that effectively delivers the proposed residential service offering; see Chapter 70, “Service management and QoS”.

2

Depending on your service delivery model, configure the following policies as required:

a. subscriber identification policy; see 64.3 “To configure a subscriber identification policy” (p. 1838).

b. ANCP policy; see 64.7 “To configure an ANCP policy” (p. 1849).

c. PPP policy; see 64.9 “To configure a PPP policy” (p. 1851).

d. MSAP policy; see 64.10 “To configure an MSAP policy” (p. 1852).

e. host tracking policy; see 64.12 “To configure a host tracking policy” (p. 1855).

f. category map policy; see 64.13 “To configure a category map policy” (p. 1855).

g. credit control policy; see 64.14 “To configure a credit control policy” (p. 1857).

h. IGMP policy; see 64.15 “To configure an IGMP policy” (p. 1858).

i. BGP Peering policy; see 64.17 “To configure a BGP Peering policy” (p. 1859).

j. diameter policy; see 64.18 “To configure a diameter policy” (p. 1860).

k. diameter application policy; see 64.26 “To configure a diameter application policy” (p. 1867).

l. subscriber multicast CAC policy; see 64.19 “To configure a subscriber multicast CAC policy” (p. 1861).

m. mobile gateway/peer profile; see 64.20 “To configure a mobile gateway/peer profile” (p. 1862).

n. host lockout policy; see 64.21 “To configure a host lockout policy” (p. 1863).

o. RADIUS script policy; see 64.23 “To configure a RADIUS script policy” (p. 1865).

See Chapter 64, “Residential subscriber policies” for more information about policies related to residential subscribers.

3

Create ingress and egress scheduler policies for the subscriber hosts in accordance with the customer SLA; see 50.55 “To configure a scheduler policy” (p. 1596).

4

Create an accounting policy for the customer; see the *NSP NFM-P Statistics Management Guide*.

5

Create access ingress and access egress QoS policies for the different applications, for example, HSI and VoIP, and levels of service, for example, gold, silver, and bronze, that subscriber hosts are to receive; see 50.28 “To configure a SAP access ingress policy” (p. 1538) and 50.30 “To configure a SAP access egress policy” (p. 1550). Associate the queues in the QoS policies with the previously created ingress and egress scheduler policies.

6

Specify a unique subscriber identification string for the subscriber, according to your customer specifications; see 74.2.1 “Overview” (p. 1992) for the different options for specifying a subscriber identification string.

7

Create a RADIUS-based accounting policy for the subscriber, as required; see 57.3 “To configure a RADIUS-based accounting policy” (p. 1793).

8

Create a policer control policy for the subscriber, as required; see 50.62 “To configure a policer control policy” (p. 1605).

9

Create SLA profiles that name the previously created QoS policies; see 64.5 “To configure an SLA profile” (p. 1845).

1. Create a different SLA profile for each class of service offering.
2. Use override values to customize the policy values, as required.
3. Use override values to customize the policer values, as required.

10

Create a subscriber profile; see 64.4 “To configure a subscriber profile” (p. 1840).

1. Choose the previously created ingress and egress scheduler policies.
2. Choose the previously created accounting policy.
3. Enable accounting.
4. Assign the previously created RADIUS-based accounting policy, as required.
5. Assign the previously created ingress and egress policer control policies, as required.
6. Associate one or more of the previously created SLA profiles with the subscriber profile.

11

Create, configure, and manage SAPs, as required.

a. Enable automatic generation of subscriber IDs; see 74.5 “To enable automatic generation of subscriber IDs” (p. 2021).

b. Assign the subscriber profile and SLA profiles to the service SAP; see 74.22 “To configure residential subscriber management components on a SAP” (p. 2043).

c. Enable or disable residential subscriber management on a SAP; see 74.23 “To enable or disable residential subscriber management on a SAP” (p. 2044).

d. Specify a subscriber identifier, subscriber profile, and SLA profile for each static host, as required, if default values are not configured on the SAP; see 74.24 “To create a static host for residential subscriber management on a SAP” (p. 2045).

e. Configure a MEP on a SAP; see 74.25 “To configure a MEP on a SAP” (p. 2047).

12

Create, configure, and manage MSAPs, as required.

a. Create a capture SAP that will enable the creation of an MSAP; see 74.26 “To configure a capture SAP” (p. 2049).

b. List MSAPs and view MSAP properties; see 74.27 “To list MSAPs and view MSAP properties” (p. 2052).

c. View an MSAP event log, modify the global MSAP log policy, and purge MSAP log records; see 74.28 “To view an MSAP event log, modify the global MSAP log policy, and purge MSAP log records” (p. 2052).

d. Modify and re-evaluate an MSAP policy on an MSAP; see 74.29 “To modify and re-evaluate an MSAP policy on an MSAP” (p. 2053).

e. Modify an MSAP policy and re-evaluate the MSAPs; see 74.30 “To modify an MSAP policy and re-evaluate the MSAPs” (p. 2054).

13

Configure or monitor DHCP or NE SHCV events or databases, as required.

a. Configure DHCP event monitoring for a SAP; see 74.32 “To configure DHCP event monitoring for a SAP” (p. 2056).

b. Monitor DHCP events for a SAP; see 74.33 “To monitor DHCP events for a SAP” (p. 2056).

c. Configure DHCP lease management for a subscriber host; see 74.6 “To renew or terminate a DHCP lease on a subscriber host” (p. 2022).

d. Configure DHCP event monitoring for a subscriber host; see 74.7 “To configure DHCP event monitoring for a subscriber host” (p. 2023).

e. Monitor DHCP events for a subscriber host; see 74.8 “To manage DHCP event monitoring for a subscriber host” (p. 2024).

f. Configure a local user database to authenticate DHCP clients; see 74.9 “To configure a local user database for subscriber host authentication” (p. 2025).

g. Configure NE SHCV event handling; see 74.13 “To configure NE SHCV event handling” (p. 2034).

14

Turn up the service.

15

Provide the customer with the necessary IP information for provisioning dynamic and static hosts in the customer network.

16

Perform one or more of the following, as required.

a. Create a subscriber explicit map, if required; see 64.6 “To configure a subscriber explicit map entry” (p. 1848).

b. Configure a MEP on an SDP Binding; see 74.14 “To configure a MEP on an SDP Binding” (p. 2035).

c. Configure L2Aware static port forwarding on a subscriber instance; see 74.15 “To configure L2Aware static port forwarding on a subscriber instance” (p. 2036).

d. Resynchronize static port forwarding entries; see 74.16 “To resynchronize static port forwarding entries” (p. 2037).

74.3.2 Workflow to configure IPoE sessions

1

Configure an IPoE session policy; see 64.16 “To configure an IPoE session policy” (p. 1859) .

2

Configure a VPLS capture SAP with IPoE session information. Associate the capture SAP with the IPoE session policy configured in Stage 1; see 74.26 “To configure a capture SAP” (p. 2049).

3

Configure IPoE session information, including the IPoE session policy configured in Stage 1, on the following service objects, as required:

- IES group interface (78.19 “To configure a group interface on an IES” (p. 2449))
- VPRN group interface (79.37 “To configure a group interface on a VPRN” (p. 2586))

74.3.3 Workflow to configure data-triggered host creation on IPoE sessions

1

Configure a local user database IPoE host with a Match List type of IP, and a host identification option of IP Address Prefix; see 74.10 “To configure IPoE hosts on a local user database” (p. 2026).

2

Configure a VPLS capture SAP with a Trigger Packet type of Data; see 74.26 “To configure a capture SAP” (p. 2049).

3

Configure the Data-triggered Administrative State parameter on the following service objects, as required:

- IES group interface (78.19 “To configure a group interface on an IES” (p. 2449))
- VPRN group interface (79.37 “To configure a group interface on a VPRN” (p. 2586))

74.3.4 Workflow to configure diameter NASREQ

1

Configure one or more diameter peer policies, specifying the NASREQ application type; see 57.13 “To configure a diameter peer policy” (p. 1804) .

2

Configure a diameter application policy, specifying the NASREQ application type. Associate the diameter application policy with the diameter peer policies configured in Stage 1; see 64.26 “To configure a diameter application policy” (p. 1867).

3

Configure the diameter application policy (as a Diameter Authentication Policy) on the following objects, as required:

- Local user database IPoE host (74.10 “To configure IPoE hosts on a local user database” (p. 2026))
- Local user database PPP host (74.11 “To configure PPP hosts on a local user database” (p. 2030))
- VPLS capture SAP (74.26 “To configure a capture SAP” (p. 2049))
- IES group interface (78.19 “To configure a group interface on an IES” (p. 2449))
- VPRN group interface (79.37 “To configure a group interface on a VPRN” (p. 2586))

74.3.5 Workflow to configure HSQ

1

Configure the HS Egress Aggregate Rate Limit and HS SLA Profile Handling Mode parameters on a subscriber profile; see 64.4 “To configure a subscriber profile” (p. 1840).

2

Configure an SLA profile with the following (see 64.5 “To configure an SLA profile” (p. 1845)):

- HS Aggregate Rate Limit and HS Queue Stats Mode parameters
- Access egress queue override with Override WRR Weight and Override Class Weight queue override parameters, and an HS override slope policy
- HS WRR group override with Override PIR and Override Class Weight parameters

3

Configure an L2 or L3 access interface with the following (see 50.97 “To configure QoS policy overrides on an L2 or L3 access interface” (p. 1654)):

- HS WRR group override with Override PIR and Override Class Weight parameters

- Access egress queue override with HS WRR Weight, HS Class Weight, and Burst Limit queue override parameters, and an HS WRED queue slope policy

4

Configure an HS secondary shaper on an access interface on any of the following services:

- Service tunnel; see 33.10 “To configure a service tunnel” (p. 1198).
- VLL; see 76.42 “To assign ingress and egress QoS policies to a VLL L2 access interface” (p. 2181).
- VPLS; see 77.69 “To assign QoS policies or to enable a MAC override address to a VPLS or MVPLS L2 access interface” (p. 2340).
- VPLS or MVPLS B-L2 access interface; see 77.87 “To create a VPLS or MVPLS B-L2 access interface” (p. 2366).
- VPLS I-L2 access interface; see 77.88 “To create a VPLS I-L2 access interface” (p. 2372).
- IES group interface; see 78.21 “To configure a SAP on an IES group interface” (p. 2457).
- VPRN group interface; see 79.39 “To configure a SAP on a VPRN group interface” (p. 2594).

74.3.6 Workflow to configure ESM over GTP hybrid access

1

Configure an APN policy, specifying an authentication type; see 64.38 “To configure an APN policy” (p. 1878).

2

As required, configure any of the following policy types with the appropriate attributes:

- Subscriber authentication policy RADIUS attributes: APN, IMEI, MSISDN, RAT Type, ULI, GPRS Negotiated QoS Profile; see 57.11 “To configure a subscriber authentication policy” (p. 1802)
- RADIUS accounting policy RADIUS attributes: MSISDN, IMEI, APN; see 34.15 “To configure a RADIUS accounting policy” (p. 1244)
- Diameter application policy Gx diameter attributes: PDN Connection ID, APN AMBR, User Location Info, SGSN MCC MNC, RAI; see 64.26 “To configure a diameter application policy” (p. 1867)
- Diameter application policy NASREQ diameter attributes: IMEI, User Location Info, RAT Type; see64.26 “To configure a diameter application policy” (p. 1867)
- Diameter application policy Gx 3GPP QoS downlink mapping types: arbiter, policer, queue, scheduler, aggregateRate, and hsSlaAggregateRate; see64.26 “To configure a diameter application policy” (p. 1867)
- Diameter application policy Gx 3GPP QoS uplink mapping types: arbiter, policer, queue, and scheduler; see 64.26 “To configure a diameter application policy” (p. 1867)

3

Configure a mobile gateway/peer profile with an Interface Type of S11, and MME node parameters (QoS, Dowlink, Uplink, and AMBR); see 64.20 “To configure a mobile gateway/peer profile” (p. 1862).

4

Configure subscriber management extensions on an FPE; see 12.41 “To create an FPE” (p. 374).

5

Configure GTP on a VPRN site; see 79.16 “To configure GTP on a VPRN site” (p. 2549).

6

Configure GTP on a base routing instance; see 27.14 “To configure GTP on a routing instance” (p. 853).

7

Configure a VPRN group interface as Interface Type GTP, and configure GTP settings; see 79.37 “To configure a group interface on a VPRN” (p. 2586).

8

Configure an IES group interface as Interface Type GTP, and configure GTP settings; see 78.19 “To configure a group interface on an IES” (p. 2449).

74.3.7 Workflow to configure ESM connection bonding

1

Configure subscriber management extensions on an FPE; see 12.41 “To create an FPE” (p. 374).

2

Configure a VPRN bonding group interface or an IES bonding group interface; see 79.38 “To create a bonding group interface on a VPRN” (p. 2593) or 78.20 “To create a bonding group interface on an IES” (p. 2456).

3

Configure RADIUS accounting policy with new attributes: Bonding ID, Active Bonding connections; see 34.15 “To configure a RADIUS accounting policy” (p. 1244).

4

Configure a routing policy statement with the From Criteria > Origin parameter set to Bonding; see 54.5 “To configure a routing policy statement” (p. 1745).

5

Configure an IPv4 ACL filter policy entry with the Primary Action parameter set to Forward (Bonding Connection) and Bonding Connection ID parameter configured; see 51.5 “To configure an ACL IP filter policy” (p. 1671).

6

Configure an IPv6 ACL filter policy entry with the Primary Action parameter set to Forward (Bonding Connection) and Bonding Connection ID parameter configured; see 51.6 “To configure an ACL IPv6 filter policy” (p. 1677).

7

Configure an SLA Profile with Bonding Selection parameters; see 64.5 “To configure an SLA profile” (p. 1845).

74.3.8 Workflow to configure home LAN extension functionality in a network

1

Configure a RADIUS accounting policy with the following attributes: LAN Extension Route Distinguisher, LAN Extension Route Target, LAN Extension Bridge ID, LAN Extension Route Device Type, LAN Extension Route VNI; see 57.3 “To configure a RADIUS-based accounting policy” (p. 1793).

2

Configure an ISA RADIUS policy with the following attributes: Cross-connect Tunnel Local IPv6 Address, Cross-connect Tunnel Remoute IPv6 Address, Cross-connect Tunnel Service, Cross-connect Tunnel Type: see 57.12 “To configure an ISA RADIUS policy” (p. 1803).

3

Configure an NE with a router target AS number under Subscriber Management; see 12.26 “To configure home LAN extension functionality on an NE” (p. 362).

4

Enable home LAN extension functionality on a base routing instance. Configure home LAN extension parameters on the routing instance and cross-connect parameters on the WLAN GW; see 27.2 “To configure a routing instance or a VRF instance” (p. 826).

5

Configure Cross-Connect parameters on a VPRN site; see 79.65 “To configure WLAN GW functionality on a VPRN site” (p. 2630).

6

Configure home LAN extension and cross-connect parameters on a WLAN GW on a VPRN group interface; see 79.66 “To configure a WLAN GW for a VPRN group interface” (p. 2631).

7

Configure home LAN extension and cross-connect parameters on a WLAN GW on a IES group interface; see 78.23 “To configure a WLAN GW on an IES group interface” (p. 2462).

74.4 SAP and MSAP management overview

74.4.1 General information

You can use residential subscriber profiles and policies to manage SAPs. Enabling residential subscriber management on a SAP does not affect an existing dynamic host on a SAP until the host DHCP lease expires, at which point a subscriber identification policy manages lease renewal. Static hosts require the provisioning of a subscriber identification string for continued network access.

When residential subscriber management on a SAP is enabled, each subscriber host that connects to the SAP requires a subscriber identification string to associate the host with a subscriber instance on the NE, or network access is denied. A subscriber identification string uniquely identifies a subscriber in the NFM-P.

The maximum number of subscribers that can use a SAP is configurable. When a SAP is limited to one subscriber, you can specify the treatment of traffic that does not match the subscriber profile, such as BTV traffic, which uses an IP address in the multicast range as the destination address. During single-subscriber SAP configuration, the NFM-P operator specifies whether to allow non-profile traffic and specifies the SLA and subscriber profiles to use for non-profile traffic, if it is allowed.

74.4.2 SAP DHCP monitoring

You can monitor the DHCP events on one or more SAPs. A SAP monitoring form is available from the Manage Residential Subscribers form.

Table 74-3 SAP DHCP monitoring events

DHCP event	Description
DHCP Lease Entries Exceeded	The number of DHCP lease state entries on a SAP has reached the configured maximum.
DHCP Lease State Overridden	An existing DHCP lease state was overridden by a new lease state with the same IP address and a new MAC address.
Suspicious DHCP Packet	A DHCP packet containing suspicious content was received.
DHCP ACK Dropped	A DHCP ACK message was discarded because the related lease state could not be updated.
Host Connectivity Lost	The connection to the specified host was lost.
Host Connectivity Restored	The connection to the specified host was regained.

The maximum number of SAPs that can be selected for monitoring is configurable through XML; the default is five. SAP monitoring has a performance impact, so only a small number are typically monitored at one time.

The Monitored Access Interface form displays a variety of DHCP-related events or notifications about subscriber hosts on a SAP that are compiled using traps received from NEs. You can also open an event log for the SAP from the SAP Properties form. The logged events include information on DHCP lease entries, lease states, and host connectivity. An entry is added to the table whenever a new event occurs. You can purge event entries using the Monitoring Configuration form.

SAP monitoring can be started, stopped, or removed from the monitoring configuration form, and the monitoring period can be configured.

The SAP monitored objects and the associated events are stored in the database. The monitoring continues until the monitoring period elapses or the monitoring is stopped by an NFM-P operator.

74.4.3 Managed SAP (MSAP)

You can configure the NFM-P to automatically create a SAP for a subscriber; this SAP is called a managed SAP, or MSAP. MSAPs are used in network models where each subscriber has a separate VLAN, and multiple subscriber hosts share a SAP. MSAP creation uses the authentication mechanisms that an NE supports to provide an MSAP for the one-subscriber-per-SAP model. An MSAP behaves the same as a regular SAP, but the MSAP configuration is not editable. MSAPs count towards the maximum number of SAPs allowed on an NE.

An MSAP is typically used by only one subscriber, although the NFM-P supports MSAPs shared by multiple subscribers. However, if more than one subscriber is allowed and an MSAP has been defined by a host, when a new host installation attempts to change the MSAP policy the installation fails and raises an event.

The creation of an MSAP is triggered by a capture SAP. When a capture SAP is configured, triggering packets initiate RADIUS authentication, and the RADIUS reply provides a service context. The authentication and the service context are used by the NE to create an MSAP; see 74.4.4 “Capture SAP” (p. 2018).

Although MSAPs are not configurable, a user with a Policy Management or Subscriber Management role can create, list, delete, or modify an MSAP policy to control how the parameters apply during MSAP creation.

An MSAP remains active as long as there is at least one subscriber host on the MSAP; see 74.4.5 “MSAP management” (p. 2019).

MSAPs are supported in HA and dual-homing environments. In dual homing, the MSAP is synchronized with the other NE during MSAP creation. For both HA and dual-homing environments, each participating NE must use the same MSAP policy.

74.4.4 Capture SAP

A capture SAP must be defined to trigger the process that automatically creates an MSAP. A capture SAP does not forward traffic; see 74.26 “To configure a capture SAP” (p. 2049).

You can create a capture SAP only in a VPLS. A capture SAP can create MSAPs in the routed CO configuration of an IES or VPRN, and in a VPLS TPSDA configuration. IES and VPRN MSAPs are

restricted to group interfaces. You can configure the capture SAP to allow Dot1Q MSAP creation when the terminating port for the capture SAP is configured for QinQ encapsulation.

The following triggers are supported to initiate MSAP creation:

- DHCPv4 and DHCPv6 trigger packets—DHCP Discover (or Requests if configured) for DHCP clients; the MSAP lifetime is defined by the lease time.
- PPPoE trigger packets—PPPoE PADI for PPPoE client; the MSAP lifetime is defined by the session time. The MSAP is installed after an IP address is provided.
- IPoE trigger packets—IPoE session key, as defined in IPoE session policy bound to the capture SAP. The MSAP lifetime is also defined on the IPoE session policy.
- ARP trigger packets—ARP for static-ip hosts; the MSAP lifetime is defined by ARP entry time. Current ARP entry refresh behavior is maintained.
- Data trigger packets—receipt of data packets triggers RADIUS authentication and subscriber host creation.

After you configure the capture SAP, every DHCP packet, PPPoE packet, or ARP packet received on the SAP is sent to the CPM, which triggers RADIUS authentication to provide a service context. The MSAP is created in the specified service. Non-triggering packets captured by the capture SAP are dropped.

If RADIUS does not provide all of the required information to install the host (for example, RADIUS lacks the IP address), the MSAP is created with a short timer while waiting for the host to be installed. Default SAP polices are available on the NE and will be used if the MSAP policy is not configured.

The authentication policy used in the capture SAP must be the same as the policy used for the MSAP. For L3, the authentication policy is defined under the group-interface.

Note: When PPPoE is used with MSAPs, the authentication policy must not use the username for MSAP creation.

The MSAP is not created (and an event is generated) if the group-interface name returned from RADIUS points to a different authentication policy than the policy defined by the capture SAP.

For MSAPs, the authentication policy is defined in the MSAP policy. Based on the configuration, the system reauthenticates the sessions when they are renewed. If the authentication policy is not used or when only PPPoE is used, the MSAPs stay active when the session is renewed.

An MSAP is created with dual-pass (shared) queuing. The SLA profile of the host may change the queuing later in the process. An MSAP is always created with the default QoS and scheduling.

74.4.5 MSAP management

An MSAP cannot be modified directly, so MSAP management is performed using MSAP policies. To make changes to an MSAP, alter the MSAP policy for the MSAP and then re-evaluate the MSAP. During re-evaluation, the NE updates the MSAP based on the changes to the MSAP policy; see 74.29 “To modify and re-evaluate an MSAP policy on an MSAP” (p. 2053).

The NFM-P treats the setup and teardown of MSAPs as state transitions to offset the load imposed by constant SAP creation and deletion. There are two states that an MSAP can have, active or inactive. These states cannot be configured. The state is automatically set to active when the

MSAP is created on the NE. When the NE deletes the MSAP, the state changes to inactive, and the MSAP continues to be available in the NFM-P but is not used until it is reactivated by the NE. When the MSAP is reactivated, it will have the same identification so that the NFM-P can identify it with the same FDN.

The state information is not automatically updated in the NFM-P GUI. You must perform a resynchronization to retrieve the current state information. When the state is inactive, performance statistics for the MSAP are not retrievable; however, historical statistical records are available. You can schedule MSAP statistics or collect the statistics on demand; see the *NSP NFM-P Statistics Management Guide* for more information about scheduling and collecting statistics.

Inactive services that previously contained MSAPs consume database space. MSAPs that have been in an inactive state for a long period of time or that are no longer used must be manually deleted.

Note: If there is a disruption on the NE and the NE recovers by restarting, all MSAPs are re-evaluated and any policy changes are applied.

Note: The creation of a SAP that uses the same port and encapsulation values as an existing inactive MSAP fails under the following conditions:

- If you try to use the NFM-P to create a SAP, the configuration fails and the NFM-P displays an error message.
- If you use a CLI to create a SAP in a service other than the service that contains the MSAP, the configuration succeeds but the MSAP remains inactive until the regular SAP is deleted. Although the NFM-P displays the SAP and MSAP, the MSAP remains inactive and consumes resources.
- If you use a CLI to create a SAP in the service that contains the MSAP, the SAP creation fails.

Nokia recommends that you delete an inactive MSAP from the NFM-P if you need to create a regular SAP on the same port using the same encapsulation values.

74.4.6 MSAP Re-evaluate Lease States function

The NFM-P Re-evaluate Lease States function allows you to push SLA profile or subscriber profile changes out to residential subscribers without reinstantiating the hosts; see 74.31 “To re-evaluate lease states for an MSAP” (p. 2055).

74.4.7 MSAP alarm suppression

An IES or VPRN MSAP that is created on a LAG in an SRRP deployment uses an NFM-P mechanism to suppress unnecessary AccessInterfaceDown alarms. The mechanism uses the SRRP states of the redundant BNGs, and determines whether to raise the alarm based on the following rules:

- When the active BNG is in the master SRRP state and the standby BNG is in the initialize or backupShunt SRRP state, no AccessInterfaceDown alarm is raised against the standby BNG.
- If the standby BNG reboots, or if there is a link failure between the standby BNG and the access network, the MSAP AccessInterfaceDown alarms are suppressed for the standby BNG. The

active BNG continues to remain in the master SRRP state. In this scenario, there may be other alarms on the standby BNG for card or link failures.

- After a fault that results in an SRRP failover, for example, active BNG reboot or loss of access network connectivity on the active BNG, an AccessInterfaceDown alarm is raised against each BNG. The alarms clear after SRRP state convergence.
- After a fault that affects both BNGs concurrently and disables SRRP redundancy, an AccessInterfaceDown alarm is raised against each BNG. The alarms clear when a BNG regains connectivity and assumes the role of SRRP master.

Note: The alarm-suppression mechanism can function correctly only when SRRP is correctly configured. If an SRRP peer is missing or disabled, the alarms may not be suppressed for the BNG that the NFM-P perceives to be the standby BNG.

74.4.8 MSAP event logs

An MSAP event log records the date, time, and active state for each state change that occurs after the MSAP is created. An event log is not recorded when the MSAP is created, although the information is recorded in a time stamp; see 74.28 “To view an MSAP event log, modify the global MSAP log policy, and purge MSAP log records” (p. 2052).

74.4.9 MSAP time stamps

You can view the following MSAP state time stamps:

- date and time that the MSAP was created
- date and time of the last active state change

See 74.27 “To list MSAPs and view MSAP properties” (p. 2052).

74.4.10 Workflow to manage MSAPs

1

Create an MSAP policy; see 64.10 “To configure an MSAP policy” (p. 1852).

2

Create a capture SAP that references the MSAP policy you created in Stage 1; see 74.26 “To configure a capture SAP” (p. 2049).

3

Change an existing MSAP by modifying and re-evaluating an MSAP policy, as required. To modify a single MSAP, see 74.29 “To modify and re-evaluate an MSAP policy on an MSAP” (p. 2053); to modify multiple MSAPs that use the same policy, see 74.30 “To modify an MSAP policy and re-evaluate the MSAPs” (p. 2054).

4

Perform the following MSAP maintenance tasks, as required:

a. List MSAPs; see 74.27 “To list MSAPs and view MSAP properties” (p. 2052).

b. View or purge MSAP logs, or modify the MSAP log policy; see 74.28 “To view an MSAP event log, modify the global MSAP log policy, and purge MSAP log records” (p. 2052).

74.5 To enable automatic generation of subscriber IDs

74.5.1 Steps

1

Choose Manage→Residential Subscribers from the NFM-P main menu. The Manage Residential Subscribers form opens.

2

Choose Auto Subscriber ID Key (Residential Subscribers) and click Search.

3

Select the site ID of the NE you want to query and click Properties. The Auto Subscriber ID Key (Edit) form opens.

4

As required, disable the Default parameter and configure the following parameters in the PPP Subscriber ID Key panel:

- PPP Key 1
- PPP Key 2
- PPP Key 3
- PPP Key 4
- PPP Key 5

5

As required, disable the Default parameter and configure the following parameters in the IPoE Subscriber ID Key panel:

- IPoE Key 1
- IPoE Key 2
- IPoE Key 3
- IPoE Key 4

6

Save your changes and close the form.

END OF STEPS

74.6 To renew or terminate a DHCP lease on a subscriber host

74.6.1 Purpose

DHCP is used to assign IP addresses to hosts or workstations on the network. This function is usually performed by a DHCP server, which leases out addresses for specific times to the various hosts. If a host does not use a specific address for a set period of time, that IP address can be assigned to another machine by the DHCP server.

In order to allow the DHCP client to lease out an address for specific times, the NFM-P allows an operator to force the DHCP client to change its state by manually sending a Renew command. Upon receipt of the Renew command from the NFM-P, the DHCP client changes to the renewal state and negotiates with the DHCP server for lease times.

Conversely, an operator can also manually terminate (clear) a lease for a particular host from within the Residential Subscriber Host form of the NFM-P.

Note: The DHCP lease renewal and termination are supported only on dynamic hosts; not on static hosts or subscriber hosts.

74.6.2 Steps

1

Choose Manage→Residential Subscribers from the NFM-P main menu. The Manage Residential Subscribers form opens.

2

Select Residential Subscriber Host (Residential Subscriber) and search for the SAP on which the subscriber hosts you want to manage are located.

3

Select one or more host entries.

You can renew a lease for multiple entries, but you can only terminate leases one host at a time.

4

Perform one of the following steps:

a. To renew the lease, click Force Renew.

b. To terminate the lease, click Clear Lease State.

5

Confirm the action.

6

Repeat Step 3 and Step 4 to perform additional lease renewals or terminations.

7

Close the form.

END OF STEPS

74.7 To configure DHCP event monitoring for a subscriber host

74.7.1 Steps

1

Choose Manage→Residential Subscribers from the NFM-P main menu. The Manage Residential Subscribers form opens.

2

Select Monitored Subscriber Host (Monitor) and search for the SAP on which the subscriber hosts you want to manage are located.

3

Select a host entry and click Create Monitored Host. The Monitored Subscriber Host form opens.

A maximum of five hosts or five SAPs can be monitored simultaneously. If more than the maximum number of hosts is selected and configured for monitoring an error message will be displayed.

4

Configure the required parameters.

5

Save your changes and close the form.

Note: You must complete 74.8 “To manage DHCP event monitoring for a subscriber host” (p. 2024) to enable and schedule subscriber host monitoring.

END OF STEPS

74.8 To manage DHCP event monitoring for a subscriber host

74.8.1 Steps

1

Choose Manage→Residential Subscribers from the NFM-P main menu. The Manage Residential Subscribers form opens.

2

Select Monitored Subscriber Host (Monitor) and search for the SAP on which the monitored subscriber hosts you want to manage are located.

3

Select a host entry and click Properties. The Monitored Subscriber Host form opens.

4

Perform one or more of the following:

a. To start monitoring the chosen subscriber host, click Start Monitor.

b. To stop monitoring the chosen subscriber host, click Stop Monitor.

c. To remove monitoring of the chosen subscriber host, click Delete.

d. To change the monitoring period of the chosen subscriber host, click Stop Monitor, type the desired value in the field, and select an appropriate unit from the adjacent menu.

e. To change the Polling Interval of the chosen subscriber host, click Stop Monitor and select the desired value from the menu.

5

Save your changes and close the form.

END OF STEPS

74.9 To configure a local user database for subscriber host authentication

74.9.1 Purpose

Perform this procedure to configure a base local user database object on a local DHCP server. Additionally, you may need to configure IpoE hosts (74.10 “To configure IPoE hosts on a local user database” (p. 2026)) or PPP hosts (74.11 “To configure PPP hosts on a local user database” (p. 2030)) on the local user database.

74.9.2 Steps

1

Choose Manage→Residential Subscribers from the NFM-P main menu. The Manage Residential Subscribers form opens.

2

Choose Local User Database (Local User DB) and click Search.

3

Click Create Local User Database or select an existing local user database entry and click Properties. The Local User Database (Create|Edit) form opens.

4

Select a site for the local user database.

5

Configure the required parameters.

6

Click Apply.

7

To configure IPoE hosts for the local user database, see 74.10 “To configure IPoE hosts on a local user database” (p. 2025).

8

To configure PPP hosts for the local user database, see 74.11 “To configure PPP hosts on a local user database” (p. 2030).

9

Save your changes and close the forms.

END OF STEPS

74.10 To configure IPoE hosts on a local user database

74.10.1 Steps

1

Choose Manage→Residential Subscribers from the NFM-P main menu. The Manage Residential Subscribers form opens.

2

Choose Local User Database (Local User DB) and click Search.

3

Select a local user database entry and click Properties. The Local User Database (Edit) form opens.

4

Click on the IPoE tab and configure the Match Type IPoE parameters.

You cannot set two parameters to the same value.

5

Click on the Circuit ID Mask tab and configure the required parameters.

6

Click on the Masks tab.

1. Click Create or select an existing IPoE mask entry and click Properties. The Local User Database IPoE Mask form opens.
2. Configure the required parameters.
3. Save your changes and close the form.

7

Click on the Hosts tab.

1. Click Create or select an existing host entry and click Properties. The Local User Database IPoE Host (Create|Edit) form opens.
2. Configure the required parameters.
3. Select a diameter application policy.
4. Select a subscriber authentication policy.

   If you are using LLID pre-authentication, choose a subscriber authentication policy that is associated with the pre-authentication server.
5. Select a diameter authentication policy.
6. Select a RIP policy.
7. In the MSAP Defaults panel, select the following objects:
   - MSAP policy
   - MSAP service ID
   - MSAP group interface

   You can also specify an MSAP group interface by manually typing its name. If the port ID is not included in the typed name, set one of the following parameters to Port ID, depending on whether the port ID is to be the prefix or suffix of the group interface name:
   - MSAP Group Interface Prefix
   - MSAP Group Interface Suffix
8. Select a RADIUS accounting policy and a duplicate RADIUS accounting policy.
9. Configure IPv6 lease times for the IPoE host, if required.

   The Valid Life and Preferred Life parameters can be set to infinite by placing check marks in the Infinite check boxes.

8

Click on the Address tab.

1. Configure the required parameters.
2. If you configure IPv6 parameters, select an IPv6 SLAAC prefix pool.

   You can also manually type an IPv6 SLAAC prefix pool name.

9

Click on the Host Identification tab.

1. Configure up to four of the following parameter groups.
   - Circuit ID Format, Circuit ID
   - MAC Address
   - Option 60 Format, Option 60
   - Remote ID Format, Remote ID
   - SAP ID
   - Service ID
   - IPoE String
   - System ID
   - Derived ID
   - IP Address Prefix, Prefix Length
2. If one of the match criteria specified in Step 4 is Encapsulation Tag Range, configure the Type parameter.

   Configure the following parameters to define the outer encapsulation range:
   - Outer Start Value (Tag1)
   - Outer End Value (Tag1)
3. If you set the Type parameter to Q in Q, configure the following parameters to define the inner encapsulation range:
   - Inner Start Value (Tag2)
   - Inner End Value (Tag2)

10

Click on the Identification Strings tab.

1. Configure the Option Number parameter. The form displays additional parameters.
2. Configure the required identification strings parameters.

11

Click on the WPP tab to configure WPP-based host authentication.

1. Configure the Routing Instance parameter.

2. If you specify the VPRN option in 1, you must configure the VPRN Service parameter. You can manually type a VPRN service ID, or select a VPRN service.
3. Configure the Portal Name parameter. You can manually type a portal name, or select a WPP portal.
4. Configure the Initial Subscriber Profile parameter. You can manually type a subscriber profile name, or select a subscriber profile.
5. Configure the Initial SLA Profile parameter. You can manually type an SLA profile name, or select an SLA profile.
6. Configure the Initial Application Profile parameter. You can manually type an application profile name, or select an application profile.
7. Configure the Restore Default Profile On Disconnection parameter.

12

Click on the Options tab.

13

To configure IPv4 options, perform the following steps:

1. Click Create or select an existing IPv4 option entry and click Properties. The Local User Database DHCP IPv4 Option (Create|Edit) form opens.
2. Configure the Option parameter.
3. Configure any additional parameters that appear. The configurable parameters vary, depending on the Option parameter value.
4. Save your changes and close the form.

14

Click on the IPv6 tab to configure IPv6 options.

1. Click Create or select an existing IPv4 option entry and click Properties. The Local User Database DHCP IPv6 Option (Create|Edit) form opens.
2. Configure the required IPv6 address parameters.
3. Save your changes and close the form.

15

Click on the RADIUS Proxy Cache tab to configure a RADIUS proxy cache for the IPoE host.

1. Configure the Routing Instance parameter.
2. If you set the Routing Instance parameter to Base, select a RADIUS proxy server.
3. If you set the Routing Instance parameter to VPRN, select a VPRN service.
4. Configure the Match Type parameter.
5. Configure any additional parameters that appear. The configurable parameters vary, depending on the Match Type parameter value.

6. Configure the Match Failure Action parameter.

16

Click on the To Client Options tab to configure relay to client options for the IPoE host.

1. Click Create or select an existing options instance and click Properties. The To Client Options (Create|Edit) form opens.
2. Configure the required parameters.
3. Configure any additional parameters that appear in the Option Value panel. The configurable parameters vary, depending on the Type parameter value.
4. Save your changes and close the form.

17

Save your changes and close the forms.

END OF STEPS

74.11 To configure PPP hosts on a local user database

74.11.1 Steps

1

Choose Manage→Residential Subscribers from the NFM-P main menu. The Manage Residential Subscribers form opens.

2

Choose Local User Database (Local User DB) and click Search.

3

Select a local user database entry and click Properties. The Local User Database (Edit) form opens.

4

Click on the PPP tab and configure the Match Type PPP parameters.

You cannot set two parameters to the same value.

5

Click on the Masks tab.

1. Click Create or select an existing PPPmask entry and click Properties. The Local User Database PPP Mask form opens.
2. Configure the required parameters.

You must configure the Mask Type parameter before you configure the remaining parameters.

3. Save your changes and close the form.

6

Click on the Hosts tab.

1. Click Create or select an existing host entry and click Properties. The Local User Database PPP Host (Create|Edit) form opens.
2. Configure the required parameters.
3. Select a diameter application policy.
4. Select a subscriber pre-authentication policy.
5. Select a subscriber authentication policy.
6. Select a diameter authentication policy.
7. Select a RIP policy.
8. Select a user database.
9. In the MSAP Defaults panel, select the following objects:
   - MSAP policy
   - MSAP service ID
   - MSAP group interface

   You can also specify an MSAP group interface by manually typing its name. If the port ID is not included in the typed name, set one of the following parameters to Port ID, depending on whether the port ID is to be the prefix or suffix of the group interface name:
   - MSAP Group Interface Prefix
   - MSAP Group Interface Suffix
10. Select a RADIUS accounting policy and a duplicate RADIUS accounting policy.
11. Configure access loop parameters for the PPP host, if required.

    The Circuit ID parameter must be configured if the Circuit ID Type parameter is set to ASCII. The Remote ID parameter must be configured if the Remote ID Type parameter is set to ASCII.
12. Configure IPv6 lease times for the PPP host, if required.

    The Valid Life and Preferred Life parameters can be set to infinite by placing check marks in the Infinite check boxes.

7

Click on the Address tab.

1. Configure the required parameters.
2. If you configure IPv6 parameters, select an IPv6 SLAAC prefix pool.

   You can also manually type an IPv6 SLAAC prefix pool name.

8

Click on the Host Identification tab.

1. Configure up to three of the following parameter groups:
   - Circuit ID
   - MAC Address
   - Remote ID
   - Service Name
   - SAP ID
   - Derived ID
2. Configure the parameters in the User panel.
3. If one of the match criteria specified in Step 4 is Encapsulation Tag Range, configure the Type parameter.

   Configure the following parameters to define the outer encapsulation range:
   - Outer Start Value (Tag1)
   - Outer End Value (Tag1)
4. If you set the Type parameter to Q in Q, configure the following parameters to define the inner encapsulation range:
   - Inner Start Value (Tag2)
   - Inner End Value (Tag2)

9

Click on the Identification Strings tab.

1. Configure the Option Number parameter. The form displays additional parameters.
2. Configure the required identification strings parameters.

10

Click on the L2TP tab to select a tunnel group.

L2TP configuration is required on an NE that has the LAC role if RADIUS authentication is not used for PPP clients.

11

Click on the Options tab.

12

To configure IPv4 options, perform the following steps:

1. Click Create or select an existing IPv4 option entry and click Properties. The Local User Database DHCP IPv4 Option (Create|Edit) form opens.
2. Configure the Option parameter.
3. Configure any additional parameters that appear. The configurable parameters vary, depending on the Option parameter value.

4. Save your changes and close the form.

13

Click on the IPv6 tab to configure IPv6 options.

1. Click Create or select an existing IPv4 option entry and click Properties. The Local User Database DHCP IPv6 Option (Create|Edit) form opens.
2. Configure the required IPv6 address parameters.
3. Save your changes and close the form.

14

Click on the Access Loop tab.

1. Click Create or select an existing access loop entry and click Properties. The Access Loop (Create|Edit) form opens.
2. Configure the required parameters

   If the Encap Offset Mode parameter is set to Auto, you must configure the Encap Offset parameter.
3. Save your changes and close the form.

15

Click on the To Client Options tab to configure relay to client options for the PPP host.

1. Click Create or select an existing options instance and click Properties. The To Client Options (Create|Edit) form opens.
2. Configure the required parameters.
3. Configure any additional parameters that appear in the Option Value panel. The configurable parameters vary, depending on the Type parameter value.
4. Save your changes and close the form.

16

Save your changes and close the forms.

END OF STEPS

74.12 To enable or disable subnet draining on a local DHCPv4 server

74.12.1 Purpose

Perform this procedure to configure IP address draining for a subnet on a local DHCPv4 server. When subnet draining is enabled, the server stops leasing IP addresses from the subnet to new subscriber hosts; existing leases are not affected.

74.12.2 Steps

1

Perform one of the following.

a. Configure subnet draining on a base routing instance:

1. Choose Routing from the navigation tree view selector.
2. Expand *Network→NE→Routing Instance*.
3. Right-click on the routing instance and choose Properties. The Routing Instance (Edit) form opens.

b. Configure subnet draining on a VPRN routing instance:

1. Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.
2. Select a VPRN service and click Properties. The VPRN Service (Edit) form opens.
3. In the navigation tree, expand the Sites object.
4. Select a routing instance object. The Site (Edit) form opens.

2

Click on the RADIUS/DHCP/Diameter tab. The Local DHCP Servers tab is displayed.

3

Select the required DHCPv4 or DHCPv6 server and click Properties. The Local DHCP Server (Edit) form opens.

4

Click on the IP Address Pools tab.

5

Select a pool and click Properties. The IP Address Pool (Edit) form opens.

6

Click on the Subnets tab.

7

Select a subnet and click Properties. The Subnet (Edit) form opens.

8

Enable or disable the Subnet Drain parameter and click Apply.

If the Subnet Drain parameter is enabled, the DHCP server stops leasing IP addresses from the subnet.

If the Subnet Drain parameter is disabled, the DHCP server leases IP addresses from the subnet.

9

Close the forms.

END OF STEPS

74.13 To configure NE SHCV event handling

74.13.1 Steps

1

Choose Manage→Residential Subscribers from the NFM-P main menu. The Manage Residential Subscribers form opens.

2

Click View SHCV. The Subscriber Host Connectivity Verification form opens.

3

Choose Network Element SHCV and click Search.

4

Select an NE and click Properties. The Network Element SHCV (Edit) form opens.

5

Configure the required parameters.

6

Save your changes and close the forms.

END OF STEPS

74.14 To configure a MEP on an SDP Binding

74.14.1 Purpose

You can configure a MEP on an SDP binding for VPLS, VPRN, and VLL Epipe services.

74.14.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select a service and click Properties. The service configuration form opens.

3

On the navigation tree, expand Sites→*Routing Instance*→Spoke SDP Bindings→*SDP*.

4

Select one or more Spoke SDP Bindings, right-click, and choose Properties. The Spoke SDP Binding configuration form opens.

5

Click on the OAM tab.

6

On the ETH-CFM tab, MEPs panel, click Create or select an existing MEP entry and click Properties. The MEP (Create|Edit) form opens.

7

Select a maintenance entity group.

8

Configure the required parameters.

The CCM Padding Packet Size parameter cannot be configured when the CCM interval parameter is set to 10 ms or 100 ms.

9

If the MD for the MEP has a Name Type of none and the associated MEG has a Name Format of icc-based, the Y.1731 Tests and AIS tabs are configurable. Click on the Y.1731 Tests tab and configure the required parameters.

The Eth Test Pattern parameter is configurable when the Eth Test Enabled parameter is enabled.

10

Click on the AIS tab and configure the required parameters.

The AIS Meg Level parameter is configurable when the AIS Enabled parameter is enabled.

11

Save your changes and close the forms.

END OF STEPS

74.15 To configure L2Aware static port forwarding on a subscriber instance

74.15.1 Steps

1

Choose Manage→Residential Subscribers from the NFM-P main menu. The Manage Residential Subscribers form opens.

2

Choose Residential Subscriber Instance (Residential Subscriber) and click Search.

3

Select a subscriber instance and click Properties. The Residential Subscriber Instance (Edit) form opens.

4

Click on the NAT Static Port Forwarding tab.

1. Click Create or select an existing static port forwarding entry and click Properties. The NAT Static Port Forwarding Display (Create|Edit) form opens.
2. Configure the required parameters.

   You cannot specify the same set of Inside Port and Protocol values in more than one static port mapping to an Inside IP Address.

   You can specify the same Outside Port value in multiple mappings to an Inside IP Address.
3. Save your changes and close the form.

5

Perform the following steps to synchronize NAT static port forwards.

1. Select one or more static port forward entries and click Sync. The NAT Static Port Forwarding Sync form opens. You can select up to 100 static port forward entries.
2. Select a targeted router instance.
3. Configure the Lifetime parameter.

6

Save your changes and close the forms.

END OF STEPS

74.16 To resynchronize static port forwarding entries

74.16.1 Purpose

Because of the potentially large number of static port forwarding entries, the entries are not resynchronized during a full NE resynchronization. Perform this procedure to manually resynchronize the entries.

Note: The NFM-P static port forwarding entries are current and do not require resynchronization if the following conditions are true.

- The NFM-P is used to create, maintain, and delete each entry.
- Each entry has an infinite lifetime, so is truly static.

74.16.2 Steps

1

Right-click on an NE in the Equipment navigation tree and choose Resync→Customized Resync. The Resync Sites wizard opens.

2

Select Choose MIB Entries.

3

Click Next. The Choose MIB Entries step is displayed.

4

Select tmnxNatFwd2Entry.

5

Click Next. The Force Resync step is displayed.

6

Select the Ignore Timestamps parameter.

7

Click Finish. The entries are refreshed.

You can view the static port forwarding entries on the NAT Static Port Forwarding tab of the NAT Configuration form for the following:

- base or service routing instances
- subscriber instances

END OF STEPS

74.17 To change the identification of a subscriber

74.17.1 Purpose

Perform this procedure to change the identification of a subscriber, for example, when you no longer want hosts on the SAP to use the SAP ID as the subscriber ID.

CAUTION

Service Disruption

Renaming a subscriber can be service-affecting because it changes the subscriber identification string of all associated subscriber hosts. Before you proceed, ensure that no subscriber hosts require the subscriber identification string associated with the subscriber.

Renaming a subscriber changes the SAP default subscriber identification strings that are associated with it.

74.17.2 Steps

1

Choose Manage→Residential Subscribers from the NFM-P main menu. The Manage Residential Subscribers form opens.

2

Choose Residential Subscriber Instance (Residential Subscriber) and click Search

3

Select a residential subscriber and click Modify. The Residential Subscriber (Edit) form opens.

4

Configure the New Subscriber Identification parameter.

5

Save your changes and close the form.

END OF STEPS

74.18 To reset a subscriber’s subscription credit limit

74.18.1 Steps

1

Choose Manage→Residential Subscribers from the NFM-P main menu. The Manage Residential Subscribers form appears.

2

Choose Residential Subscriber Instance (Residential Subscriber) and click Search

3

Perform one of the following:

a. Select a host from the list and click Reset Credit. Go to Step 7.

b. Select a host from the list and click Properties. The Subscriber Host form opens.

4

Click on the Credit Control Operational values tab.

5

Select an entry and perform one of the following:

a. Click Reset Credit. Go to Step 7.

b. Click Properties. A form opens.

6

Review the credit control data and close the form.

7

Save your changes and close the forms.

END OF STEPS

74.19 To modify the primary subscriber identification script or URL

74.19.1 Purpose

This procedure allows an NFM-P operator to modify the primary subscriber identification script without service disruption. Perform this procedure only when the primary script and URL are operational.

CAUTION

Service Disruption

Modifying the primary subscriber identification script is potentially service-affecting if no functional backup script is administratively enabled. Modifying a backup (secondary or tertiary) subscriber identification script is unlikely to be service-affecting if the other backup script (secondary or tertiary) functions properly and is administratively enabled. Ensure that at least one administratively enabled backup script is accessible to the NFM-P and the NEs to which it applies before you proceed.

74.19.2 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Manage Subscriber Policies form opens.

2

Select a subscriber identification policy and click Properties. The Subscriber Identification Policy (Edit) form opens.

3

Copy the operational primary script URL and paste it to the secondary position. This action ensures that an operational backup script is in place in the event that there is a problem with the new primary script or URL.

1. Set the Secondary Script Administrative State parameter to Disabled.
2. Click Apply and confirm the operation. The NFM-P administratively disables the secondary script.
3. Configure the Secondary Script URL parameter with the value of the Primary Script URL parameter.
4. Set the Secondary Script Administrative State parameter to Enabled.
5. Click Apply and confirm the operation. The NFM-P administratively enables the secondary script.

   You must administratively disable and enable a script URL to cause the NEs to which the subscriber identification policy applies to load the script using the URL.

4

Modify a renamed copy of the former primary script or create a replacement script, as required. Record the new or modified script URL.

5

Configure the new URL as the primary script URL.

1. Set the Primary Script Administrative State parameter to Disabled.
2. Click Apply and confirm the operation. The NFM-P administratively disables the primary script. The secondary (former primary) script is the active script.
3. Configure the Primary Script URL parameter with the new URL value.
4. Set the Primary Script Administrative State parameter to Enabled.
5. Click Apply and confirm the operation. The NFM-P administratively enables the primary script. The new primary script is the active script.

   You must administratively disable and enable a script URL to cause the NEs to which the subscriber identification policy applies to load the script using the URL.

6

Save your changes and close the forms.

END OF STEPS

74.20 To delete an inactive subscriber instance

74.20.1 Purpose

Use this procedure to remove the record of an inactive subscriber instance from the NFM-P database. Subscriber instances become inactive in the NFM-P when the subscriber is deleted from the NE.

Note: AA statistics data can be lost when you delete a subscriber instance before the NFM-P is finished collecting and processing AA statistics. Nokia recommends waiting at least two statistics collection intervals before deleting an inactive subscriber instance.

74.20.2 Steps

1

Choose Manage→Residential Subscribers from the NFM-P main menu. The Manage Residential Subscribers form opens.

2

Choose Residential Subscriber Instance (Residential Subscriber) and click Search.

The Active property indicates the status of each subscriber instance in the list. An inactive subscriber instance has no check mark under the Active heading.

3

Select the inactive subscriber instance you want to delete and click Delete. The inactive subscriber instance is removed from the list.

4

Close the form.

END OF STEPS

74.21 To view WLAN GW UEs on an NE

74.21.1 Purpose

Use this procedure to query different types of WLAN GW UEs configured on an NE ISA.

74.21.2 Steps

1

Choose Manage→Residential Subscribers from the NFM-P main menu. The Manage Residential Subscribers form opens.

2

Choose WLAN GW Query-based User Equipment and click Search.

3

Select the site ID of the NE you want to query.

4

Specify a WLAN GW ISA group, WLAN GW ISA group member, or UE MAC address to narrow your search, and then click Search.

5

Select a UE item in the list and click Properties. The WLAN GW DSU UE properties form opens.

6

View the read-only information as required and then close the form.

END OF STEPS

74.22 To configure residential subscriber management components on a SAP

74.22.1 Purpose

Perform this procedure to manage the subscriber configuration on one or more SAPs. You can configure the subscriber-related SAP parameters and assign one or more of the following residential subscriber management components:

- subscriber identification policy
- default subscriber identification string
- default subscriber profile
- default SLA profile
- non-subscriber traffic subscriber profile
- non-subscriber traffic SLA profile

74.22.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select a service and click Properties. The service configuration form opens.

3

On the navigation tree, expand *site*→*routing instance*.

4

Click on the Access Interfaces icon to display the site SAPs.

5

Select one or more SAPs, right-click, and choose Properties from the menu. The SAP configuration form opens.

Note: You can configure subscriber management on multiple SAPs at once from any list of SAP search results that the NFM-P generates. For simplicity, the procedure uses the term SAP to refer to one or more SAPs, and focuses only on SAPs that belong to the same service site.
The NFM-P commits changes to a SAP configuration only when subscriber management is enabled on all SAPs that you are configuring.

6

Click on the Subscriber Management tab. The Host Connectivity tab is displayed.

7

Click on the Profiles tab.

8

Perform one of the following steps for a component.

a. Associate a component with the SAP by selecting a component in the Policies panel.

b. Remove a component, by clicking Clear beside the component in the Policies panel.

Note: Removing or replacing a residential subscriber management component on a SAP that is in use by subscriber hosts can be service-affecting to hosts that attempt to join the network. Ensure that removing the component does not affect the subscriber hosts before you proceed.

9

Save your changes and close the form.

END OF STEPS

74.23 To enable or disable residential subscriber management on a SAP

74.23.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select a service and click Properties. The service configuration form opens.

3

On the navigation tree, expand *site*→*routing instance*.

4

Click on the Access Interfaces icon to display the site SAPs.

5

Select one or more SAPs, right-click, and choose Properties from the menu. The SAP configuration form opens.

6

Click on the Subscriber Management tab.

7

Click on the Profiles tab.

8

Configure the Admin Status parameter by performing one of the following.

a. Set the parameter to Enabled to enable residential subscriber management on the SAP.

b. Set the parameter to Disabled to disable residential subscriber management on the SAP.

9

Save your changes and close the form.

END OF STEPS

74.24 To create a static host for residential subscriber management on a SAP

Note: If you are configuring an IPv6 static host, ensure that the IPv6 Allowed parameter is enabled on the parent group interface and subscriber interface for the SAP.

74.24.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select a service and click on the Properties button. The service configuration form opens.

3

On the navigation tree, expand the site on which you want to create a static host for residential subscriber management on a SAP.

4

Navigate to the SAPs that support subscriber management. Perform one of the following, depending on the type of service that you are configuring:

a. For an IES, expand *IES*→*site*→Subscriber Interfaces→*subscriber_interface*→*group_interface*→Service Access Points.

b. For a VPLS, expand *VPLS_service*→*site*→Access Interfaces→*SAP*.

c. For a VPRN service, expand *VPRN_service*→*site*→Subscriber Interfaces→*subscriber_interface*→*group_interface*→Service Access Points→*SAP*.

5

Select one or more SAPs, right-click, and choose Properties from the menu. The SAP configuration form opens.

6

If you are configuring an IPv6 static host, click on the Subscriber Management tab > Profiles tab, and ensure that the Admin Status parameter is set to Enabled.

7

Click on the Anti-Spoofing tab and configure the Anti-Spoofing parameter.

You must set the Anti-Spoofing parameter to IP-address matching or to IP- and MAC-address matching before you can enable subscriber management for the static hosts on a SAP.

8

To configure an IPv4 static host, click on the Static Hosts tab.

1. Click Create or select an existing static host and click Properties. The Access Interface Anti-Spoofing Static Host (Create|Edit) form opens.
2. Configure the required parameters.

To enable residential subscriber management for a static host, you must specify values for the IP Address and Subscriber Identification parameters.

3. Select a subscriber profile for the static host.
4. Select an SLA profile for the static host.
5. Select an application profile for the static host, if required.
6. Configure the Scope parameter, if applicable.
7. Select a RIP policy for the static host, if required.
8. Set the Administrative State parameter to Up and confirm the operation.
9. Save your changes and close the form.

9

To configure an IPv6 static host, click on the IPv6 Static Hosts tab.

1. Click Create or select an existing IPv6 static host and click Properties. The Access Interface Anti-Spoofing IPv6 Static Host (Create|Edit) form opens.
2. Configure the required parameters.

   To link the IPv6 static host to an existing IPv4 static host, configure the MAC Linking parameter with the IP address of the IPv4 static host.

   To enable residential subscriber management for a static host, you must specify values for the IP Address and Subscriber Identification parameters.
3. Select a subscriber profile for the IPv6 static host.
4. Select an SLA profile for the IPv6 static host.
5. Select an application profile for the IPv6 static host, if required.
6. Configure the Scope parameter, if applicable.
7. Set the Administrative State parameter to Up and confirm the operation.
8. Save your changes and close the form.

10

Click on the Managed Routes tab.

1. Click on the Create button. The Access Interface Anti-Spoofing Static Host Managed Route Display (Create) form opens.
2. Configure the required parameters.
3. Save your changes and close the forms.

11

Save your changes and close the forms.

END OF STEPS

74.25 To configure a MEP on a SAP

74.25.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select a service and click Properties. The service configuration form opens.

3

On the navigation tree, expand the Sites icon.

4

Perform one of the following steps.

a. To create a MEP on an Access Interface SAP, expand *site_n*→Access Interfaces. The site SAPs are displayed.

   MEPs can be configured on an Access Interface SAP for VPLS, VPRN, IES, and VLL Epipe services.

b. To create a Down MEP on a Subscriber Group Interface SAP, expand *site_n*→Group Interfaces. The site group interface SAPs are displayed.

   Down MEPs can be configured on a Subscriber Group Interface SAP for VPRN and IES.

5

Select one or more SAPs and click Properties. The SAP configuration form opens.

6

Click on the MEP tab.

1. Click Create or select an existing MEP entry and click Properties. The MEP (Create|Edit) form opens.
2. Configure the required parameters.

   The Control MEP parameter is only displayed if the Interface Type parameter is set to Ethernet Tunnel Path Endpoint.

   The CCM Padding Packet Size (Bytes) parameter cannot be configured when the CCM interval parameter is set to 10 ms or 100 ms.

   When configuring a Down MEP on a Subscriber Group Interface SAP, the Direction parameter cannot be configured.
3. If the MD for the MEP has a Name Type of none and the associated MEG has a Name Format of icc-based, the Y.1731 Tests and AIS tabs are configurable. Configure the required parameters on the tabs.

The Eth Test Pattern parameter is configurable when the Eth Test Enabled parameter is enabled.

The AIS Meg Level parameter is configurable when the AIS Enabled parameter is enabled.

7

Save your changes and close the forms.

END OF STEPS

74.26 To configure a capture SAP

74.26.1 Purpose

Perform this procedure to create a capture SAP to trigger MSAP creation.

Created MSAPs are on the same port as the associated capture SAP. A capture SAP must be the default SAP on a port.

74.26.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select a VPLS in the list and click Properties. The VPLS Service (Edit) form opens.

3

In the navigation tree, expand Sites→*site_n*→Access Interfaces.

4

Right-click on the Access Interfaces icon and choose Create VPLS L2 Access Interface, or right-click an existing access interface object and choose Properties. The VPLS L2 Access Interface (Create|Edit) form opens.

1. Set the SAP Sub Type parameter to Capture. The form displays a different array of tabs and panels.
2. Configure the Description and Administrative State parameters.
3. Select a host lockout policy, if required.
4. Select a subscriber authentication policy, if required.

5

Click on the Port tab.

1. Select a terminating port for the capture SAP.

2. Configure the encapsulation values for the SAP, if required. The encapsulation type of the terminating port determines the encapsulation values that are available. The table below describes the encapsulation values for each encapsulation type.

   The capture SAP is used if a more specific match for the dot1q or QinQ tags is not found.

   Some providers use QinQ encapsulation to represent a service.sub or sub.service SAP. When configured, the full QinQ represents a subscriber.

Table 74-4 Encapsulation types

Encapsulation type	Encapsulation values
dot1q	4095 only, which appears as an asterisk (*)
QinQ	1 to 4095 for the outer encapsulation value, and 4095 only for the inner encapsulation value
LAG	1 to 4095 for both encapsulation values

6

Click on the ACL tab to select an ACL filter.

7

Click on the QoS tab to specify an ingress or egress queue group policy.

1. Select an NE DoS protection policy.
2. Configure the MAC Monitoring parameter OR the Ethernet CFM Monitor Flags parameter.
3. Select a DDoS protection policy.

8

If the capture SAP is an ATM SAP, click on the ATM tab.

1. Configure the AAL5 Encapsulation parameter.
2. Click on the VC Ranges tab.
3. Click Create or select an existing ATM configuration and click Properties. The ATM Configuration (Create|Edit) form opens.
4. Configure the required parameters.
5. Save your changes and close the form.

9

Click on the Capture Access Interface tab.

1. Enable the Allow Dot1Q MSAPs parameter, if required. This parameter can only be configured when the terminating port for the capture SAP is configured for QinQ encapsulation.
2. Select one or more of the following parameters on the Trigger Packet panel to specify the types of packets that will trigger RADIUS authentication:
   - DHCPv4
   - PPP
   - PPPoE
   - ARP
   - DHCPv6
   - Data

   The PPPoE parameter is selectable only on an ATM SAP. The ARP, DHCPv4, and DHCPv6 parameters are selectable only on a non-ATM SAP.
3. Select a MSAP policy in the MSAP Defaults panel.
4. Select or manually type an MSAP Service ID.
5. Select or manually type an MSAP Group Interface Name.
6. Select a PPP policy in the PPP panel, if required.

   A PPP policy is configurable only on an ATM SAP.
7. Select a PPP policy in the PPPoE panel, if required.
8. Select a local user database for the following protocols, as required:
   - PPP
   - PPPoE
   - DHCPv4
   - DHCPv6

   A PPP local user database is selectable on only an ATM SAP.

   A DHCPv4 or DHCPv6 local user database is selectable on only a non-ATM SAP.
9. Select a python policy for the following protocols, as required:
   - PPPoE
   - DHCPv4
   - DHCPv6
10. Select an SRRP instance in the Redundancy panel.
11. Select a diameter authentication policy.
12. If the capture SAP is to be used for data-triggered authentication in a dynamic services configuration, select a dynamic service policy and configure its administrative state.

10

If the capture SAP is to be used to instantiate IPoE sessions, click on the IPoE Session tab.

1. Configure the Administrative State and Description parameters.

The Administrative State parameter must be set to Disabled before IPoE session policy and local user database configurations can be changed.

2. Select an IPoE session policy.
3. Select a local user database.

11

Save your changes and close the forms.

END OF STEPS

74.27 To list MSAPs and view MSAP properties

74.27.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Perform one of the following to display the MSAPs associated with each service:

a. For VPLS MSAPs:
   1. Click on the object type drop-down menu and expand Access Interface (Service Management)→L2 Access Interface (Service Management)→Abstract L2 Access Interface (VPLS)→L2 Access Interface (VPLS)→VPLS L2 Access Interface.
   2. Select VPLS MSAP and click Search.

b. For IES MSAPs:
   1. Click on the object type drop-down menu and expand Access Interface (Service Management)→Service Access Point (Service Management)→IES Service Access Point (IES).
   2. Select IES MSAP and click Search.

c. For VPRN MSAPs:
   1. Click on the object type drop-down menu and expand Access Interface (Service Management)→Service Access Point icon (Service Management)→VPRN Service Access Point (VPRN).
   2. Select VPRN MSAP and click Search.

3

Select an MSAP and click on the MSAP Properties tab.

END OF STEPS

74.28 To view an MSAP event log, modify the global MSAP log policy, and purge MSAP log records

74.28.1 Steps

1

Perform 74.27 “To list MSAPs and view MSAP properties” (p. 2052) to list the MSAPs and choose the appropriate MSAP.

2

Click on the Events tab to display the MSAP event log.

3

Perform any of the following:

a. View an event log record:
   1. Select a record in the event log and click Properties. The Statistics Record - MSAP Event Log form opens, displaying the MSAP record properties.
   2. Close the form.

b. Modify the global MSAP event log policy:
   1. Click Log Policy. The Log Policy - Ressubscr. MSap Event Log form opens.

      The global MSAP log policy affects all MSAP event logs.
   2. Configure the Retention Time and Administrative State parameters.
   3. Save your changes and close the form.

c. Purge the MSAP event log records:
   1. Click Purge Log Records.
   2. Confirm the purge and close the form.

4

Close the form.

END OF STEPS

74.29 To modify and re-evaluate an MSAP policy on an MSAP

74.29.1 Purpose

Perform this procedure to re-apply an MSAP policy on an existing MSAP. MSAPs cannot be edited; however, MSAP policies on existing MSAPs can be changed and re-applied.

74.29.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form appears.

2

Configure the filter criteria; see 74.27 “To list MSAPs and view MSAP properties” (p. 2052) for information about configuring the filter to list MSAPs. A list of MSAPs for the service appears.

3

Select an MSAP and click Properties. The service configuration form opens.

4

Click on the MSAP Properties tab.

5

Click Properties in the Creation MSAP Policy panel and enter the required changes.

6

Click Apply and confirm the changes.

7

Click on the MSAP Properties tab.

8

Specify the Do Action option for the Creation MSAP Policy Re-evaluation parameter to apply the new policy parameter values.

If you specify Not Applicable, the new policy parameter values are not applied, but remain on the policy until you specify the Do Action option.

9

Save your changes and close the form.

END OF STEPS

74.30 To modify an MSAP policy and re-evaluate the MSAPs

74.30.1 Purpose

Perform this procedure to re-apply an MSAP policy on existing MSAPs. MSAPs cannot be edited; however, MSAP policies on existing MSAPs can be changed and re-applied.

74.30.2 Steps

1

Choose Policies→Residential Subscriber from the NFM-P main menu. The Residential Subscriber Policies form appears.

2

Select MSAP Policy from the object type drop-down menu and click Search. A list of MSAP policies appears.

3

Select an MSAP policy and click Properties. The MSAP Policy (Edit) form appears.

4

Enter the required changes.

5

Click Apply and confirm the changes.

6

Click Reevaluate MSAPs. The MSAPs are re-evaluated with the changed MSAP policy.

7

Save your changes and close the form.

END OF STEPS

74.31 To re-evaluate lease states for an MSAP

74.31.1 Purpose

Perform this procedure to push SLA profile or subscriber profile changes out to an MSAP. MSAPs cannot be edited; however, SLA profiles or subscriber profiles on existing default SAPs can be changed and re-applied. The Re-evaluate Lease States command updates all residential subscriber hosts associated with the MSAP without reinstantiating the hosts.

This procedure describes how to perform a Re-evaluate Lease States function from a residential subscriber GUI context. The same function can be performed from an IES or VPRN group interface GUI context.

74.31.2 Steps

1

Choose Manage→Residential Subscribers from the NFM-P main menu. The Manage Residential Subscribers form opens.

2

Choose IES Service Access Point or VPRN Service Access Point from the object menu and click Search.

3

Select the site ID of the IES or VPRN site on which you want to perform a Re-evaluate Lease States function and click Search.

A list of applicable SAPs appears.

4

Select a SAP and click Re-evaluate Lease States.

An information window appears, indicating the number of hosts that were sent a Re-evaluate Lease Sates request, and the number of hosts that were skipped.

5

Close the forms.

END OF STEPS

74.32 To configure DHCP event monitoring for a SAP

74.32.1 Steps

1

Choose Manage→Residential Subscribers from the NFM-P main menu. The Manage Residential Subscribers form opens.

2

Select one of the available SAP types and click Search.

3

Select a SAP entry and click Create Monitored SAP. The Monitored Access Interface (Create) form opens.

You can configure a maximum of five hosts or five SAPs for simultaneous DHCP event monitoring.

4

Configure the Monitoring Period and Units parameters.

5

Save your changes and close the forms.

Note: You must complete 74.33 “To monitor DHCP events for a SAP” (p. 2056) to enable and schedule SAP monitoring.

END OF STEPS

74.33 To monitor DHCP events for a SAP

74.33.1 Steps

1

Choose Manage→Residential Subscribers from the NFM-P main menu. The Manage Residential Subscribers form opens.

2

Choose Monitored Access Interface (Monitor) and click Search.

3

To initiate or view DHCP monitoring for a particular SAP, select the entry and click Properties. The Monitored Access Interface (Edit) form opens.

4

You can perform one or more of the following on the form:

a. To start monitoring the chosen SAP, click Start Monitor.

b. To stop monitoring the chosen SAP, click Stop Monitor.

c. To remove monitoring of the chosen SAP, click Delete.

d. To change the monitoring period, click Stop Monitor, type the desired value in the Monitoring Period field, and select an appropriate unit from the drop-down menu.

5

To view DHCP events for the chosen SAP, click on the Events tab. The DHCP Events list is displayed. The NFM-P supports monitoring of the following DHCP events:

- DHCP Lease Entries Exceeded
- DHCP Lease State Overriden
- Suspicious DHCP Packet
- DHCP ACK Dropped
- Host Connectivity Lost
- Host Connectivity Restored

6

Select an event and click Properties to view detailed information about the event.

7

Save your changes and close the forms.

END OF STEPS

74.34 To view and configure residential subscriber hosts on a SAP

74.34.1 Purpose

Use this procedure to retrieve the residential subscriber hosts configured on a single SAP. You can view the configuration of individual subscriber hosts for troubleshooting purposes, and make configuration changes where required.

Note: The NFM-P retrieves active host data directly from NEs and displays results only after all of the hosts have been retrieved. Because this process can take minutes, Nokia recommends that you specify a single SAP address when searching subscriber hosts. Although it is possible to search subscriber hosts for an entire site or service ID, the time required could cause the NFM-P GUI to timeout before the search process completes, with no search results displayed. Searching without specifying a SAP should be reserved for LNS or WiFi Offload subscriber hosts.

74.34.2 Steps

1

Select Manage→Residential Subscribers from the NFM-P main menu. The Manage Residential Subscribers form opens.

2

Select Residential Subscriber Host in the drop-down list.

3

Select the site ID, service ID, and SAP from which you want to retrieve subscriber hosts.

4

Click Search to retrieve the subscriber hosts.

5

To view the information for a subscriber host, select the host entry and click Properties. The Subscriber Host form opens with the subscriber host information displayed.

If you need to make configuration changes to the subscriber host, proceed to the remaining steps in this procedure. Otherwise, close the forms.

6

CAUTION

Service Disruption

Changing the subscriber profile string directly on a subscriber host is potentially service-affecting to all hosts on all SAPs that belong to the subscriber. Because a subscriber is associated with only one subscriber profile, when you change the subscriber profile string for one host, all dynamic or PPPoE hosts associated with the subscriber on all SAPs are automatically configured with the new subscriber profile.

Configure the Subscriber Profile String parameter for the dynamic host or PPPoE host, if required. Select a subscriber profile string, or simply type a subscriber profile string in the field.

7

Configure the SLA Profile String parameter for the dynamic host or PPPoE host, if required. Select an SLA profile, or simply type an SLA profile string in the field.

8

Configure the ANCP String and Intermediate Destination ID parameters, if required.

9

Configure the parameters on the Subscriber Profile/SLA Profile Aliases panel, as required.

10

Configure the Application Profile parameter for the dynamic host PPPoE host, if required. Select an application profile string, or simply type an application profile string in the field.

11

Save your changes and close the forms.

END OF STEPS

74.35 To clear IPoE sessions from an IES or VPRN SAP or MSAP

74.35.1 Purpose

Perform this procedure to clear IPoE sessions from one or more selected SAPs or MSAPs on a specified IES or VPRN site.

You can also clear individual IPoE sessions from a VPRN or IES service site configuration form (*[Subscriber_interface]*→*[Group_interface]*→Subscriber Management tab→*[SAP]*).

74.35.2 Steps

1

Choose Manage→Residential Subscribers from the NFM-P main menu. The Manage Residential Subscribers form opens.

2

Choose one of the following from the object menu.

- VPRN Service Access Point
- VPRN Service Access Point→VPRN MSAP
- IES Service Access Point
- IES Service Access Point→IES MSAP
- IPoE Session

3

Specify the following objects to narrow the search results.

- IES or VPRN site ID
- Service ID (for individual IPoE session search only)
- Service Access Point (for individual IPoE session search only)

4

Click Search.

5

Select a SAP, MSAP, or IPoE session and click Clear IPoE Session(s).

6

Close the form.

END OF STEPS

75 VLAN service management

75.1 Overview

75.1.1 Purpose

VLANs are created to provide the segmentation services traditionally provided by routers in LAN configurations. VLANs address issues such as scalability, security, and network management. Routers in VLAN topologies provide broadcast filtering, security, address summarization, and traffic flow management. The following table lists the types of VLAN services that are supported on the NFM-P by device type:

Table 75-1 Device VLAN support

Device	Supported VLAN types
7450 ESS	• Standard VLAN • L2 VPN (TLS/VLAN-Stacking) VLAN • Broadcast TV (MVR/IPMV) VLAN
All OmniSwitches	• Standard VLAN • L2 VPN (TLS/VLAN-Stacking) VLAN
All OmniSwitches except for the OS 6900 and OS 10K	• Broadcast TV (MVR/IPMV) VLAN
OS 6900 and OS 10K	• IPC VLAN • VIP VLAN
Wavence SM [1]	• Wavence (dot1ad) VLAN • Wavence P2P (dot1q) VLAN • Wavence P2MP (dot1q) VLAN

Notes:

1. See “Wavence microwave backhaul service management” in the *NSP Wavence Device Support Guide* for more information.

Several 7450 ESS, Wavence and OmniSwitch VLAN services can be interconnected through a backbone VPLS.

The NFM-P supports end-to-end VLAN configuration using tabbed configuration forms with an embedded navigation tree.

75.1.2 Contents

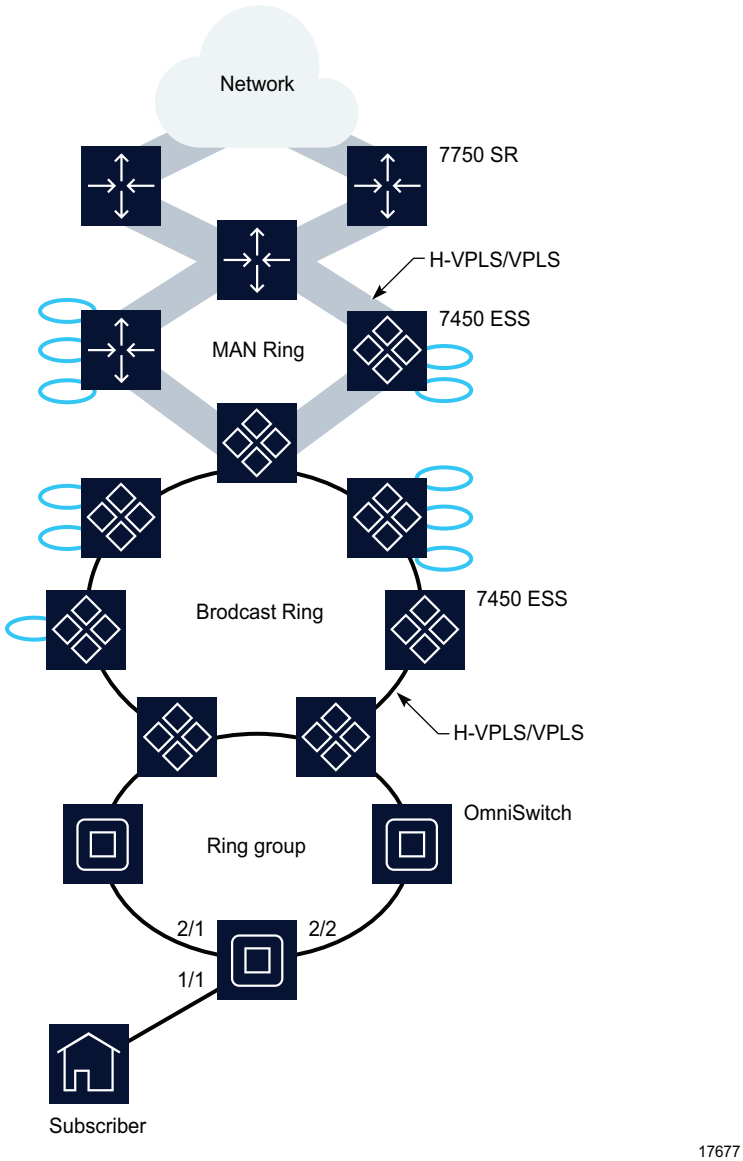
VLAN service management overview

75.2 VLAN service management overview

75.2.1 VLAN ring groups

VLAN ring groups are used to send traffic across an Ethernet ring using copper or fiber optic connections from the source traffic device, for example, from a 7450 ESS, to all devices in the ring. STP configuration on OmniSwitch devices ensures that there is a constant stream of traffic in either direction by rerouting traffic around breaks in the physical links between the devices. The following figure shows an example of a ring group that is part of a larger metropolitan area network.

Figure 75-1 Ring in a metropolitan and broadcast network



The NFM-P provides OAM tools for service validation and for troubleshooting service and network transport issues.You can run the OAM Validation test suite for the VLAN service by clicking on the Validate button or by clicking on the More Actions button and choosing Validate. Alternatively, you can also perform a One Time Validation. If a check mark appears beside the OAM Validation Failed state cause indicator, the test has failed. In addition, the Tested Entity Result tab on the Tests tab

displays more detailed information about the OAM test result. See Chapter 89, “Service Test Manager” for more information about how to configure OAM validation test suites.

The Aggregated Service Site Operational State parameter has four possible values. The value is derived from the operational states of the sites that are part of the service, as follows:

- Up—all sites are operationally up
- Partially Down—at least one site is operationally down
- Down—all sites are operationally down
- Unknown—the service has no provisioned sites

When the Aggregated Service Site Operational State parameter is Partially Down or Down, a check mark appears beside the appropriate State Cause indicator to identify the type of fault to the NFM-P operator. You can view alarms on the Faults page.

When you use the NFM-P to create or discover a service, the NFM-P assigns a default tier value to the service. The Service Tier parameter value is relevant only in the context of composite service topology map views. See Chapter 85, “Composite service management” for more information about the hierarchical organization of composite services.

75.2.2 VLAN groups

The NFM-P supports the configuration and provisioning of VLAN groups which are used by the following NEs.

- OmniSwitch devices to configure VLAN services
- Wavence SM ANSI/ETSI (2.x and 3.x streams) to configure VLAN and VLL services

You can use VLAN groups to:

- logically group OmniSwitch and Wavence SM devices to represent a typical network topology. An OmniSwitch and a Wavence SM cannot belong to the same VLAN group.
- manage the VLAN IDs that are assigned to Wavence SM VLAN group members.

See 75.13 “To create a VLAN group” (p. 2083) for more information about creating OmniSwitch VLAN groups. See “Wavence microwave backhaul service management” in the *NSP Wavence Device Support Guide* for information about creating Wavence VLAN groups.

75.2.3 OmniSwitch VLAN service policies

Policies can be assigned to ports on an OmniSwitch. Policies are defined at a global level and then applied to components of the service, such as a port.

The policy on the component is then a local version of the global policy. The following policies are common to VLAN services:

- QoS policies define ingress classification, policing, shaping, and marking on the device.
- UNI policies define how control frames that are received on a port are processed. UNI policies are applied to a port that is used as a SAP in a L2 VPN TLS (stacked) VLAN.

- SAP policies define traffic engineering parameters for bandwidth sharing, rate limiting, CVLAN translation (or double-tagging), and priority bit mapping. SAP policies are applied to the service access multi-point.
- Filter policies control network traffic into or out of an interface or device based on IP or MAC matching criteria.

See Chapter 49, “Policies overview” for more information about policies.

75.2.4 OmniSwitch network management

The NFM-P manages OmniSwitch devices using SNMP and CLI messages. OmniSwitch devices support termination of all VLAN types on Ethernet ports.

75.2.5 Spanning tree protocols

The STP configuration on an OmniSwitch device in a VLAN group detects loops in the topology and ensures that there is a constant stream of traffic by rerouting traffic around breaks in the physical links between the devices. OmniSwitch devices support STP, MSTP and RSTP.

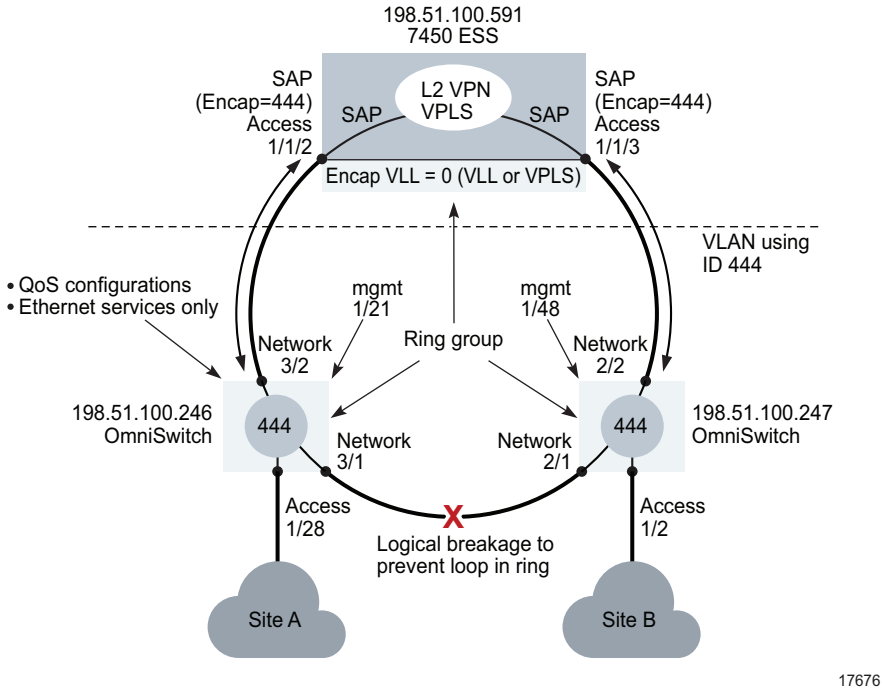
Sample VLAN configurations

75.3 Sample L2 VPN VLAN configuration

75.3.1 Overview

The following figure shows a sample L2 VPN VLAN service configuration. Transparent LAN services such as a L2 VPN are used to transport large numbers of customer VLANs while keeping the traffic in each VLAN segregated. The configuration depends on the specific network requirements.

Figure 75-2 Sample L2 VPN VLAN configuration



75.3.2 Pre-configuration tasks

Verify that the following preconfigurations are complete.

- Ensure that the appropriate preconfigurations have been performed on the OmniSwitch devices.
  - pre-discovery CLI modifications
  - discovery including mediation configuration with the CLI user names and passwords
  - configure protocol to manage topology loops, such as MSTP or RSTP

- Ensure that the VPLS that feeds the ring VLAN service is configured on the 7450 ESSs. The encapsulation of the SAPs that belong to the VPLS on the 7450 ESSs must match the VLAN ID of the ring VLAN.
- Configure the OmniSwitch ports as access (ports that are part of the VLAN) and network (ports that are used for uplinks), as required, from the navigation tree.
- Devices that belong to the ring, and the 7450 ESS that the ring connects to, must be added to the ring group.
- Ensure that the appropriate preconfigurations have been performed on the 7450 ESS.
  - A VLL is created with 0 encapsulation between the SAPs (1/1/2 and 1/1/3) on the 7450 ESS
  - The SAPs on the 7450 ESS that are part of the VPLS use the same encapsulation as the VLAN ID for the ring group
  - A L2 VPN VPLS is created on the 7450 ESS.

Note: Only Ethernet services are supported on an OmniSwitch L2 VPN VLAN service.

75.3.3 Configuration tasks

The following high-level tasks are required to configure this sample VLAN L2 VPN service:

1

Ensure that the required configurations are completed to equipment, including configuring access and network ports, enabling CLI configuration on managed OmniSwitch devices.

2

Configure the required policies, including QoS, scheduling and IGMP filter policies.

3

Distribute configured policies to the devices. The policies are used during the creation of VLAN services.

4

Create VLAN services using a series of configuration forms.

Ensure that the VLAN created for the ring group uses ID 444.

5

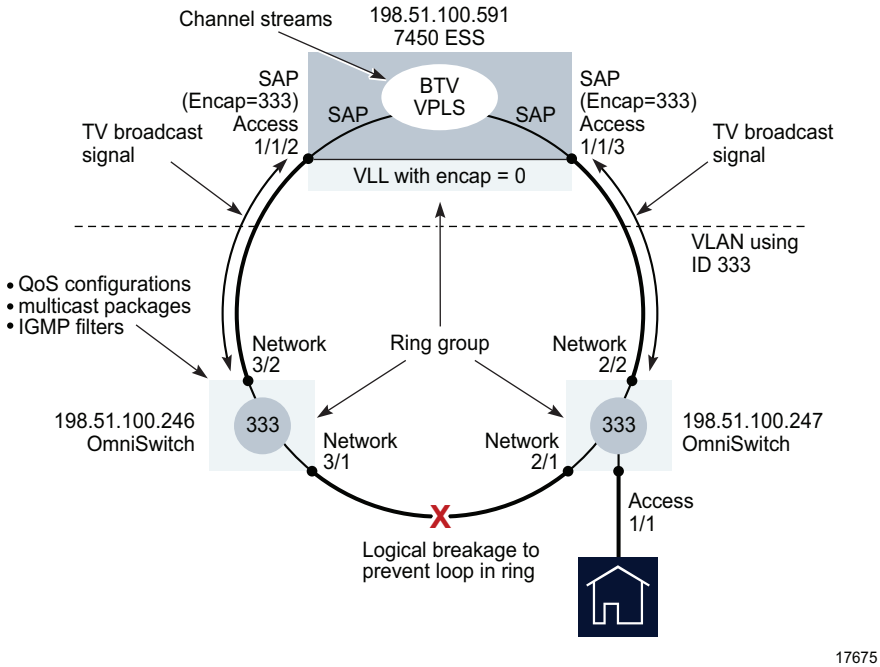
Associate access interfaces (similar to SAPs) with VLAN services, that are the physical ports to which end users connect. Use the L2 Interfaces tab on the VLAN properties form to associate VLAN services with the ports used by end users.

75.4 Sample BTV VLAN configuration

75.4.1 Overview

The following figure shows a sample broadcast TV VLAN configuration. BTV VLANs are shared VLANs, where the multicast broadcast channels or pay per view channels are available across the ring, and based on subscriptions and privileges determined using IGMP snooping, the user gains or is denied access. The configuration depends on the specific network requirements.

Figure 75-3 Sample BTV VLAN configuration



75.4.2 Pre-configuration tasks

Verify that the following preconfigurations are complete.

- Ensure that the appropriate preconfigurations have been performed on the OmniSwitch devices:
  - pre-discovery CLI modifications
  - SNMP trap forwarding to the NFM-P
  - discovery, including mediation configuration with the CLI user names and passwords
  - configure protocols to manage topology loops, such as MSTP or RSTP
- Ensure that the BTV VPLS that feeds the ring VLAN service is configured on the 7450 ESSs. The encapsulation of the SAPs that belong to the VPLS on the 7450 ESSs must match the VLAN ID of the ring VLAN.

- Configure OmniSwitch ports as access (ports that are part of the VLAN) and network (ports that are used for uplinks), as required, from the navigation tree.
- OmniSwitch devices that belong to the ring, and the 7450 ESS that the ring connects to, must be added to the ring group.
- Ensure that the appropriate preconfigurations have been performed on the 7450 ESS.
  - A VLL is created with 0 encapsulation between the SAPs (1/1/2 and 1/1/3) on the 7450 ESS
  - The SAPs on the 7450 ESS that are part of the VPLS use the same encapsulation as the VLAN ID for the ring group
  - A BTV VPLS is created on the 7450 ESS.
- Create and manage the necessary broadcast TV policies, including multicast package and IGMP filtering.

75.4.3 Configuration tasks

The following high-level tasks are required to configure this sample broadcast TV VLAN service.

1

Ensure that the required configurations are completed to equipment, including configuring access and network ports, enabling CLI configuration on managed OmniSwitch devices, and the creation of ring groups.

2

Configure the required policies, including QoS, scheduling and IGMP filter policies.

3

Distribute configured policies to the devices. Policies are used during the creation of VLAN services.

4

Create VLAN services using a series of configuration forms:

Ensure that the VLAN created for the ring group uses ID 333.

5

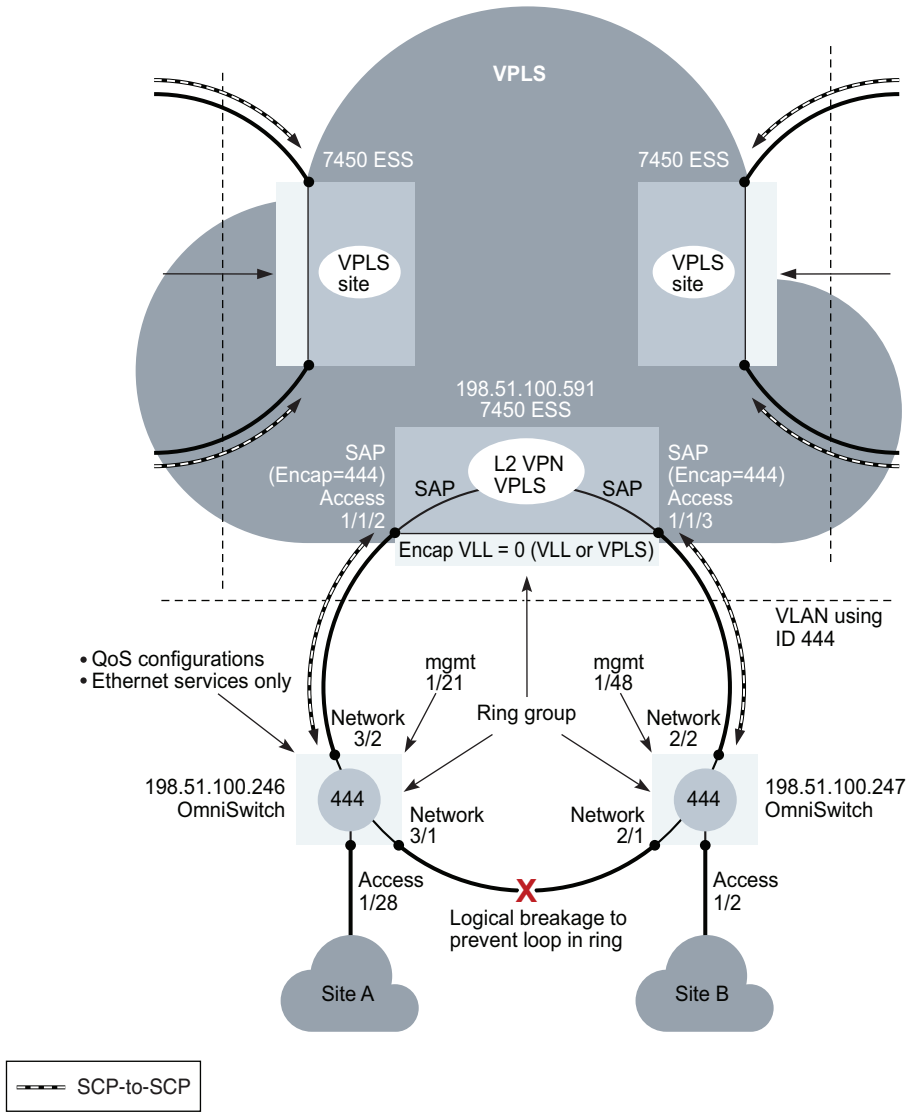
Associate access interfaces (similar to SAPs) with VLAN services, that are the physical ports to which end users connect. You use the L2 Interfaces tab on the VLAN properties form to associate VLAN services with the ports used by end users.

75.5 Sample interconnection VLAN configuration

75.5.1 Overview

The following figure shows a sample configuration of an interconnection of VLANs across a VPLS backbone.

Figure 75-4 Sample interconnection VLAN



75.5.2 Pre-configuration tasks

Verify that the following preconfigurations are complete:

- Ensure that the appropriate preconfigurations have been performed on the OmniSwitch devices.
  - pre-discovery CLI modifications
  - SNMP trap forwarding to the NFM-P
  - discovery including mediation configuration with the CLI user names and passwords

  - ports are configured as access (ports that are part of the VLAN) and network (ports that are used for uplinks)
  - configure protocol to manage topology loops, such as MSTP or RSTP, using CLI
- Configure OmniSwitch ports as access and network, as required, from the navigation tree.
- OmniSwitch devices that belong to the ring, and the 7450 ESS that the ring connects to, must be added to the ring group.

75.5.3 Configuration tasks

The following high-level tasks are required to configure this sample interconnection of VLAN services.

1

Ensure that the required configurations are completed to equipment as described in 75.3.3 “Configuration tasks” (p. 2068) , including access and network ports, enabling CLI configuration on managed OmniSwitch devices, and configuring and distributing policies.

2

Create VLAN services using a series of configuration forms.

Ensure that the VLAN created for the ring group uses ID 444.

3

Configure the VPLS:

- Ensure that the encapsulation value of the ports that contain the SAPs on the 7450 ESS matches the VLAN ID of each VLAN service in the ring group.
- Ensure that the encapsulation value of the ports that contain the SAPs on the 7450 ESS at each VPLS site is Dot1 Q.

See 77.5 “To create a VPLS” (p. 2249) for more information about creating a VPLS.

4

Create a composite service to interconnect the VLAN services with the VPLS.

- Create the composite service.
- Define general properties for the composite service.
- Specify the services that are participating in the composite service. You can specify multiple services in one operation.
- Create SCP-to-SCP connectors to link the dot1q-encapsulated VPLS SAP and the adjacent L2 switch uplinks of the VLAN ring group.

See Chapter 85, “Composite service management” for more information about creating composite services.

VLAN service management procedures

75.6 Workflow to create VLAN services (OmniSwitch)

75.6.1 Overview

The following workflow lists the high-level steps required to create a VLAN service on OmniSwitch devices. As a prerequisite for creating a VLAN service, this workflow assumes that the following appropriate preconfigurations have been performed:

- pre-discovery CLI modifications
- discovery including mediation configuration with CLI usernames and passwords
- addition of the OmniSwitches that participate in the VLAN to a VLAN group
- configure OmniSwitch network ports, as required, from the navigation tree. The Automatic VLAN Binding parameter associated with a network port or LAG must be enabled before the NFM-P can identify the network port or LAG as a network interface. This parameter is only supported on Stacked VLANs.
- configure QoS policies, as required

75.6.2 Stages

1

Provision a Standard VLAN service. See 75.7 “To create a standard VLAN service on OmniSwitch devices” (p. 2075) .

1. Create the VLAN (setting the application parameter to Standard VLAN) and associate a customer with the VLAN.
2. Associate access interfaces with the VLAN service. See 75.11 “To associate an access interface with a VLAN service” (p. 2081) .

2

Provision a L2 VPN VLAN service. See 75.8 “To create an OmniSwitch L2 VPN TLS VLAN service” (p. 2076) .

1. Create the VLAN (setting the application parameter to L2-VPN (TLS/VLAN-Stacking)) and associate a customer with the VLAN.
2. Add Ethernet services to the VLAN site. See 75.12 “To add Ethernet services to a VLAN Site” (p. 2082) .

3

Provision a BTV VLAN service. See 75.9 “To create an OmniSwitch BTV VLAN service” (p. 2078) .

1. Create the VLAN (setting the application parameter to Broadcast TV (MVR/IPMV)) and associate a customer with the VLAN.

2. Associate access interfaces with the VLAN service. See 75.11 “To associate an access interface with a VLAN service” (p. 2081) .
3. Add Ethernet services to the VLAN site. See 75.12 “To add Ethernet services to a VLAN Site” (p. 2082) .

4

Provision a VIP VLAN service. See 75.10 “To create an OmniSwitch VIP VLAN service” (p. 2080) .

1. Create the VLAN (setting the application parameter to VIP VLAN) and associate a customer with the VLAN.
2. Associate access interfaces with the VLAN service. See 75.11 “To associate an access interface with a VLAN service” (p. 2081) .

5

Provision a Backbone VLAN service. See 80.3 “To create an OmniSwitch Backbone VLAN service” (p. 2695) .

6

As required:

a. Create VLAN groups and add members to each group as required. See 75.13 “To create a VLAN group” (p. 2083) .

b. Delete a VLAN group or group member. See 75.14 “To delete a VLAN group or group member” (p. 2084) .

c. Add a MEP to an OmniSwitch VLAN service access interface. See 75.15 “To manually add MEPs to an OmniSwitch VLAN service access interface” (p. 2085) .

d. Configure IGMP on an OmniSwitch VLAN site. See 75.16 “To configure IGMP on an OmniSwitch VLAN site” (p. 2086) .

7

Turn up the service.

Network interface VLAN bindings are created between the newly-created VLAN and all of the network ports on the node.

8

As required, run an OAM validation test on a VLAN service. See 75.19 “To run an OAM validation test on a VLAN service” (p. 2090) .

9

View the VLAN service operational status. See 75.20 “To view the VLAN service operational status” (p. 2091) .

75.7 To create a standard VLAN service on OmniSwitch devices

Note: Nokia recommends that you specify the OmniSwitch ports that will be network interfaces before you configure a standard VLAN service.

75.7.1 Steps

1

Choose Create→Service→VLAN from the NFM-P main menu. The VLAN (Create) Service form opens.

2

Select a customer to associate with the VLAN.

3

Configure the required general parameters.

The Service ID and SVC Mgr Service ID parameters are configurable when the Auto-Assign ID parameter is disabled.

4

Click on the VLAN tab and set the Application parameter to Standard VLAN.

5

Select a group to associate with the VLAN in the Group panel.

6

On the service navigation tree, right-click on VLAN and choose Create VLAN Site to choose a site for the VLAN. The Site (Create) form opens.

7

Configure the required general parameters.

8

Click on the VLAN tab and configure the required parameters.

9

Perform 75.11 “To associate an access interface with a VLAN service” (p. 2081) to create one or more access interfaces on the site.

10

To enable DHCP/DHCPv6 snooping on the VLAN:

1. Click on the DHCP/DHCPv6 Snooping tab.

2. Click Create. The VLAN Level DHCP/DHCPv6 Snooping (Create) form opens.
3. Configure the required parameters.

   These parameters are automatically enabled when DHCP/DHCPv6 snooping is enabled on a VLAN.
4. Save the changes and close the form.

11

To add one or more static entries to the DHCP binding table:

1. Click on the Binding Database tab.
2. Click Create. The DHCP Snooping Binding Database (Create) form opens.
3. Configure the MAC Address parameter.
4. Select a port.
5. Configure the required parameters.
6. Save the changes and close the form.

12

Save the changes and close the forms.

END OF STEPS

75.8 To create an OmniSwitch L2 VPN TLS VLAN service

Note: The TLS Mode must be set to Ethernet Service before a sL2 VPN TLS (stacked) VLAN service can be created on an OmniSwitch. See 28.128 “To configure bridging on an OmniSwitch” (p. 1043) to configure the TLS Mode.

Nokia recommends that you configure OmniSwitch network ports before you configure a L2 VPN TLS VLAN service.

75.8.1 Steps

1

Choose Create→Service→VLAN from the NFM-P main menu. The VLAN Service (Create) form opens.

2

Select a customer to associate with the L2 VPN TLS VLAN.

3

Configure the required general parameters.

The Service ID parameter is configurable when the Auto-Assign ID parameter is disabled.

The SVC Mgr Service ID parameter is configurable when the Auto-Assign ID parameter is disabled.

4

Click on the VLAN tab and set the Application parameter to L2-VPN (TLS/VLAN-Stacking).

5

Select a group to associate with the L2 VPN in the Group panel.

6

On the navigation tree, right-click on VLAN and choose Create VLAN Site to select a site for the VLAN. The Site (Create) form opens.

7

Configure the required general parameters.

8

Perform 75.12 “To add Ethernet services to a VLAN Site” (p. 2082) to add one or more Ethernet services to the VLAN site.

9

Click on the STP tab and configure the parameters.

10

To enable DHCP snooping on the VLAN:

1. Click on the DHCP Snooping tab.
2. Click Create. The VLAN Level DHCP Snooping (Create) form opens.
3. Configure the required parameters.

   These parameters are automatically enabled when DHCP snooping is enabled on a VLAN.
4. Save the changes and close the form.

11

To add one or more static entries to the DHCP binding table:

1. Click on the Binding Database tab.
2. Click Create. The DHCP Snooping Binding Database (Create) form opens.
3. Configure the MAC Address parameter.
4. Select a port.
5. Configure the required parameters.
6. Save the changes and close the form.

12

Save the changes and close the forms.

END OF STEPS

75.9 To create an OmniSwitch BTV VLAN service

75.9.1 Steps

1

Choose Create→Service→VLAN from the NFM-P main menu. The VLAN (Create) Service form opens.

2

Select a customer to associate with the VLAN.

3

Configure the required general parameters:

The Service ID parameter is configurable when the Auto-Assign ID parameter is disabled.

The SVC Mgr Service ID parameter is configurable when the Auto-Assign ID parameter is disabled.

4

Click on the VLAN tab and set the Application parameter to Broadcast TV (MVR/IPMV).

5

Select a group to associate with the VLAN in the Group panel.

6

Configure the Type parameter in the IPMVLAN panel.

7

On the navigation tree, right-click on VLAN and choose Create VLAN Site to select a site for the VLAN. The Site (Create) form opens.

8

Configure the required general parameters.

9

Perform 75.11 “To associate an access interface with a VLAN service” (p. 2081) to create one or more access interfaces on the site.

10

Perform 75.12 “To add Ethernet services to a VLAN Site” (p. 2082) to add one or more Ethernet services to the VLAN site.

11

Click on the STP tab and configure the parameters.

12

To enable DHCP snooping on the VLAN:

1. Click on the DHCP Snooping tab.
2. Click Create. The VLAN Level DHCP Snooping (Create) form opens.
3. Configure the required parameters.

   These parameters are automatically enabled when DHCP snooping is enabled on a VLAN.
4. Save the changes and close the form.

13

To add one or more static entries to the DHCP binding table:

1. Click on the Binding Database tab.
2. Click Create. The DHCP Snooping Binding Database (Create) form opens.
3. Configure the MAC Address parameter.
4. Select a port.
5. Configure the required parameters.
6. Save the changes and close the form.

14

To add one or more multicast group addresses to the site:

1. Click on the Multicast Groups tab.
2. Click Create. The Multicast Group (Create) form opens.
3. Configure the Multicast Address parameter.
4. Save the changes and close the form.

15

To add one or more customer VLAN tags to the site:

1. Click on the Customer VLAN Tags tab.
2. Click Create. The Customer VLAN Tag (Create) form opens.
3. Configure the Customer VLAN Tag parameter.
4. Save the changes and close the form.

16

Save the changes and close the forms.

END OF STEPS

75.10 To create an OmniSwitch VIP VLAN service

75.10.1 Steps

1

Choose Create→Service→VLAN from the NFM-P main menu. The VLAN (Create) Service form opens.

2

Select a customer to associate with the VLAN.

3

Configure the required general parameters:

The Service ID parameter is configurable when the Auto-Assign ID parameter is disabled.

The SVC Mgr Service ID parameter is configurable when the Auto-Assign ID parameter is disabled.

4

Click on the VLAN tab and set the Application parameter to VIP VLAN.

5

Select a group to associate with the VLAN in the Group panel.

6

On the navigation tree, right-click on VLAN and choose Create VLAN Site to select a site for the VLAN. The Site (Create) form opens.

7

Configure the required general parameters.

8

Click on the CFM tab and configure the required parameters.

9

Save the changes and close the forms.

10

Perform 75.11 “To associate an access interface with a VLAN service” (p. 2080) to create one or more access interfaces on the site.

END OF STEPS

75.11 To associate an access interface with a VLAN service

75.11.1 Purpose

Associate access interfaces with VLAN services. These access interfaces are the physical ports to which end users connect. Use the L2 Interfaces tab on the VLAN properties form to associate VLAN services with the ports used by end users.

75.11.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select a VLAN service.

3

On the service navigation tree, expand the site on which you want to associate the new access interface, right-click on L2 Access Interfaces and choose Create VLAN Access Interface. The VLAN Access Interface (Create) form opens.

4

Configure the required general parameters.

5

Click on the Port tab and select a port for the VLAN access interface.

Note: The form lists only ports in access or hybrid mode. To choose a port that is not listed, you must set the Mode parameter for the port to Access or Hybrid. After you do this, the port is listed when you click on the Search button.
To configure an access interface, a L2 VPN TLS VLAN user port must be created. See 75.8 “To create an OmniSwitch L2 VPN TLS VLAN service” (p. 2076) .

6

Configure the required parameters.

7

Save the changes and close the forms.

END OF STEPS

75.12 To add Ethernet services to a VLAN Site

75.12.1 Purpose

During Ethernet service creation, you can create one or more service access multipoints. A service access multipoint is assigned a user-selected or auto-generated ID when the multipoint is created.

VLAN service access points, a SAP policy, and customer VLANs are associated with service access multipoints. Customer VLANs associate customer traffic with a VLAN-stacking SAP and identify the type of customer traffic that is received on the SAP UNI ports.

75.12.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select a VLAN service.

3

On the service navigation tree, expand the site on which you want to add the Ethernet service, right-click on Ethernet Services and choose Create Ethernet Service. The Ethernet Service (Create) form opens.

4

Configure the Ethernet Service Name parameter.

5

On the service navigation tree, right-click on Ethernet Service and choose Create Service Access Multipoint. The Service Access MultiPoint (Create) form opens

6

Configure the required general parameters.

7

If you need to apply a SAP policy other than the default one, click on the Clear button to clear the default SAP policy from the SAP Profile panel. Otherwise, go to Step 9 .

8

Select a SAP profile to associate with the service access multipoint.

9

On the service navigation tree, right-click on Service Access Points and choose Create VLAN Service Access Point. The VLAN Service Access Point (Create) form opens.

10

Configure the required general parameters.

11

Click on the Port tab.

12

Select a port for the VLAN SAP.

Note: The form lists only ports in access or hybrid mode. To choose a port that is not listed, you must set the Mode parameter for the port to Access or Hybrid. After you do this, the port is listed when you click on the Search button.

13

Save the changes and close the form.

14

To add one or more customer VLANs to the service access multipoint:

1. On the Service Access MultiPoint (Create) form, click on the Customer VLANs tab.
2. Click Create. The Customer VLAN (Create) form opens.
3. Configure the required parameters.

15

Save the changes and close the forms.

END OF STEPS

75.13 To create a VLAN group

75.13.1 Steps

1

Choose Manage→VLAN Groups from the NFM-P main menu. The Manage VLAN Groups form opens.

2

Click Create. The VLAN Group (Create) form opens.

3

Configure the parameters.

You can configure the Head Ends parameter when the Node Type parameter is set to OMNI.

4

Click Apply.

5

Click on the Group Members tab.

6

Click Create and choose one or more NEs. Only NE types specified by the Node Type parameter are displayed in the list.

7

To add head end NEs to the group:

1. Ensure that the Head Ends parameter is enabled in Step 3 .
2. Click Add Headend Node to select one or more NEs. Only 7750 SR, and 7450 ESS NE types can be selected.

8

To apply a span of control to a group, other than the default:

1. Click on the Spans tab.
2. Click Create to select one or more spans of control to apply to the VLAN group.

9

Save the changes and close the forms.

END OF STEPS

75.14 To delete a VLAN group or group member

Note: You must delete all members from a group before you can delete the group.

75.14.1 Steps

1

Choose Manage→VLAN Groups from the NFM-P main menu. The Manage VLAN Groups form opens.

2

Choose a VLAN group and click Properties. The VLAN Group (Edit) form opens.

3

Click on the Group Members tab.

4

Choose one or more members of the VLAN group and click Delete button.

If the group does not contain any members, go to Step 5 .

5

Close the form.

6

On the Manage VLAN Groups form choose the VLAN group that you need to delete.

7

Click Delete.

8

Close the Manage VLAN Groups form.

END OF STEPS

75.15 To manually add MEPs to an OmniSwitch VLAN service access interface

75.15.1 Overview

See Chapter 91, “Ethernet CFM” for more information about MEPs.

75.15.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VLAN Service and click Properties. The VLAN - *Service Name* (Edit) form opens.

3

On the service navigation tree, expand the site to which you want to add the MEP, right-click on the access interface and click Properties. The VLAN Access Interface (Edit) form opens.

4

Click on the MEPs tab and click Create. The Select Maintenance Entity Group form opens.

5

Select an entry and click OK.

6

Configure the required parameters.

7

Save the changes and close the forms.

END OF STEPS

75.16 To configure IGMP on an OmniSwitch VLAN site

75.16.1 Purpose

OmniSwitch IGMP parameters can be configured globally and per VLAN site. You can configure VLAN site IGMP parameters only after you create the VLAN. VLAN IGMP configuration settings override global IGMP settings. See 28.105 “To configure IGMP on an OmniSwitch” (p. 1019) for information about configuring global OmniSwitch IGMP parameters.

75.16.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an OmniSwitch VLAN service and click Properties. The VLAN *Service Name* (Edit) form opens.

3

On the service navigation tree, right-click on the site on which you want to configure IGMP parameters. The Site (Edit) form opens.

4

Click on the IGMP tab.

5

Choose an entry from the list and click Properties. The IGMP (Edit) form opens.

6

Configure the required parameters.

When the Administrative State parameter is Up, IP multicast switching is enabled on the OmniSwitch for standard and L2 VPN (TLS/VLAN-Stacking) VLAN services.

7

To create one or more static IGMP groups:

1. Click on the Multicast Group tab.
2. Click Create. The Group (Create) form opens.
3. Select a terminating port.
4. Configure the Multicast Group IP Address parameter.
5. Save the changes and close the form.

8

To create one or more static IGMP neighbors:

1. Click on the Multicast Neighbor tab.
2. Click Create. The Neighbor (Create) form opens.
3. Select a terminating port.
4. Save the changes and close the form.

9

To create one or more static IGMP queriers:

1. Click on the Multicast Querier tab.
2. Click Create. The Querier (Create) form opens.
3. Select a terminating port.
4. Save the changes and close the form.

10

Save the changes and close the forms.

END OF STEPS

75.17 To configure MLD on an OmniSwitch VLAN site

75.17.1 Purpose

OmniSwitch MLD parameters can be configured globally and per VLAN site. You can configure VLAN site MLD parameters only after you create the VLAN.

75.17.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an OmniSwitch VLAN service and click Properties. The VLAN *Service Name* (Edit) form opens.

3

On the service navigation tree, right-click on the site on which you want to configure MLD parameters. The Site (Edit) form opens.

4

Click on the MLD tab.

5

Choose an entry from the list and click Properties. The MLD (Edit) form opens.

6

Configure the required parameters.

7

Save the changes and close the forms.

END OF STEPS

75.18 To configure RA filtering on an OmniSwitch VLAN site

75.18.1 Purpose

Perform this procedure to configure RA (Router Advertisement) filtering that can be used to prevent the spread of unwanted RAs from unauthorized systems. Once enabled on an interface, any received RAs will be dropped without being forwarded to other connected IPv6 clients. One or more trusted ports or link aggregation group members can be specified for an interface. RAs received on these trusted ports or link aggregation group members will be allowed to continue on to all other IPv6 clients reached via the interface.

Note: You can configure RA filtering only after the VLAN site is created. RA filtering cannot be enabled on a VLAN site that is used as an OpenFlow VLAN, Ethernet service VLAN, mirrored port, or IPM VLAN.

75.18.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an OmniSwitch VLAN service and click Properties. The VLAN *Service Name* (Edit) form opens.

3

On the service navigation tree, right-click on the site on which you need to configure RA filtering parameters. The Site (Edit) form opens.

4

Click on the RA Filter tab. By default, the RA Filter Status parameter is set to Disabled.

If you are configuring the RA Filter for 6900/6860/6865/6465, an additional RA Filter Interface parameter is displayed.

5

Choose Enable from the drop-down menu.

If you are configuring the RA Filter for 6900/6860/6865/6465, enter the RA Filter Interface name. The RA Filter status can be enabled only if the RA Filter Interface name is entered. Providing the RA Filter Interface name along with the RA Filter in enabled status will create a default IPv6 interface on the node.

6

Click on the Trusted Ports/LAGs tab.

7

Click on the Create tab and configure RA filtering on the trusted ports/LAGs. By default, all the ports/LAGs are untrusted.

8

Click Apply to save the changes and close the form.

END OF STEPS

75.19 To run an OAM validation test on a VLAN service

75.19.1 Prerequisites

A validator test suite must be created for the tested entity. See Chapter 90, “OAM diagnostic tests” for more information about how to create a validator test suite.

Note: As an alternative, you can also run an OAM validation test on the service by performing a One Time Validation. This is a mostly automated procedure and is described in 90.55 “To run a one-time validation test on a service” (p. 3084) .

75.19.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a service and click Properties. The VLAN (Edit) form opens.

3

Click Validate. If the Validate button is not visible, click on the More Actions button and choose Validate. If a validator test suite is not associated to the service, a dialog box appears.

Perform the following steps:

1. Click OK to associate the service with an existing validator test suite. The Choose Validator Test Suite form appears.
2. Select a validator test suite and click OK button. The Choose Validator Test Suite form closes.

4

View the State Cause indicators. When the validation test fails, a check mark beside the OAM Validation Failure indicator.

5

Click on the Tests tab.

6

Click on the Tested Entity Result tab.

7

Select an entry and click Properties. The Tested Entity Result form opens and displays information about the validation test.

8

Close the forms.

END OF STEPS

75.20 To view the VLAN service operational status

75.20.1 Purpose

The Aggregated Operational State and State Cause indicators on the General tab of the service management form display information about service faults.

75.20.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a service and click Properties. The VLAN *Service Name* (Edit) form opens.

3

View the Aggregated Operational State and State Cause indicators. When the Aggregated Operational State is Down or Partially Down, a check mark beside the appropriate State Cause indicator identifies the type of associated service fault.

4

Click on the appropriate tab to view or edit an object that is identified as faulty by a State Cause indicator.

5

Click on the Faults tab to view the alarms for the object. The Object Alarms tab appears.

6

Click on the Aggregated Alarms tab to view the aggregated alarms for the object. The Aggregated Alarms tab appears.

7

Close the forms.

END OF STEPS

75.21 To delete a VLAN service

CAUTION

Service Disruption

Network service disruption

Deleting a service may result in a service disruption for customers. Consider the implication of deleting the service before proceeding.

CAUTION

Service Disruption

NFM-P service disruption

Do not delete any VLANs that are used for network management, otherwise connectivity between the NFM-P and the OmniSwitch devices is lost.

75.21.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a service or a range of services from the list.

3

Click Delete. A warning form appears. This message is dynamic based on the priority of the service. Perform one of the following:

a. For services with a low priority, go to Step 4 .

b. For services with a medium priority, configure the “Enter the highest priority of the service being deleted” text field by typing: Medium. Go to Step 4 .

c. For services with a high priority, configure the “Enter the highest priority of the service being deleted” text field by typing: High. Go to Step 4 .

4

For all services regardless of how their priority is configured, acknowledge the check box that prompts you confirm that you understand the implications of deleting the service.

Note: If you select multiple services with different priorities, you must enter the highest priority level of selected services before you can delete the services.

5

Click Yes to confirm the action. The service is deleted and removed from the list.

6

Close the forms.

END OF STEPS

76 VLL service management

76.1 Overview

76.1.1 Purpose

The NFM-P supports the provisioning of VLL services on edge devices. A VLL service is an L2 point-to-point service that connects access interfaces. A VLL service is completely transparent to customer or subscriber data and to control protocols. Because of this, the device performs no MAC learning in a VLL service.

The NFM-P supports multiple variations of VLL services. See 76.2 “VLL service management overview” (p. 2100) in this section for more information.

A VLL service that connects access interfaces on one device is called a local VLL service. As there is no need for signaling between devices, a local VLL service uses no SDPs.

A VLL service that connects access interfaces on two devices is called a distributed VLL service. Subscriber or customer data enters a distributed VLL service through access interfaces on different edge devices. The VLL service encapsulates the data and transports it across a service provider IP/MPLS network through GRE, MPLS, or MPLS-TP service tunnels.

Packets that arrive at an edge device are associated with a VLL service based on the access interface on which they arrive. An access interface is uniquely identified using these parameters.

- physical port or POS port and channel
- encapsulation type
- encapsulation identifier (if required, depending on encapsulation type)

A VLL service uses T-LDP signaling, and uses MPLS or GRE as the service tunnel transport.

A new or existing VLL can be configured as the spoke of an HVPLS. See 77.2.1 “HVPLS” (p. 2210) in “VPLS management overview” (p. 2210) and Chapter 85, “Composite service management” for more information.

The NFM-P supports end-to-end VLL configuration using tabbed configuration forms with an embedded navigation tree.

Common to all device services, such as VLL, are policies that are assigned to the service. Policies are defined at a global level and can then be applied to components of the service, such as interfaces or circuits, when the service is configured or modified. The following policies are common to all device services:

- QoS policies define ingress classification, policing, shaping, and marking on the ingress side of the interface. QoS policies are configured using the SAP Access Ingress Policy form, the SAP Access Egress Policy form, and the ATM QoS Policy form. Because a VLL service is a point-to-point service, ingress QoS policies create only the unicast queues that are defined in the policy and not the multicast queues.

- (Epipe service only) Policer control policies to control access ingress policers and access egress policers under a common hierarchy. Policer control policies are configured using the Policer Control Policy Manager.
- Scheduling policies define hierarchical rate limiting and scheduling to govern the scheduling of queues. Scheduler policies are configured using the Scheduler Policy and HSMDA Scheduler Policy forms.
- Port scheduler policies define hierarchical bandwidth allocation and scheduling at the egress port level. Port scheduler policies are configured using the Port Scheduler Policy form.
- Filter policies control network traffic into or out of an interface or circuit based on IP or MAC matching criteria. Filter policies are configured using the ACL IP Filter form and the ACL MAC Filter form.
- Accounting policies measure the traffic on a service to ensure proper billing and enforcement of SLAs. Accounting policies are configured using the Accounting Policy form.
- ANCP policies provide status and control information based on port-up and port-down messages and changes to the current access line rate between the edge device and the access node. ANCP policies are configured using the Manage Subscriber Policies form.
- Time of day suites specify time and day restriction policies that are assigned to QoS policies and schedulers, ACL filters, and aggregation schedulers. Time of day suites and time range policies are configured using the Time of Day Suite form and Time Range form, respectively.

See Chapter 49, “Policies overview” for more information about policies.

OAM diagnostics can be performed on a per-service basis. See Chapter 90, “OAM diagnostic tests” for more information.

The General tab of the VLL service management form displays information about the operational state of the service and its sites through the Operational State and State Cause indicators.

The Operational State indicator identifies the states of the sites that are part of the service, as follows:

- Up—one operational path in both directions (end-to-end)
- Down—path is not operationally complete

When the Operational State is Down, a check mark appears beside the appropriate State Cause indicator to identify the type of fault to the NFM-P operator.

For Epipe services, you can configure SAPs so that if their operational state goes down, the service operational state remains up, to allow performance monitoring and ETH CFM on the service. See 76.40 “To create a VLL L2 access interface on a terminating site” (p. 2174) and the NE documentation for more information.

You can run the OAM Validation test suite for the service by clicking Validate. Alternatively, you can also perform a One Time Validation. If a check mark appears beside the OAM Validation Failed state cause indicator, the test has failed. In addition, the Tested Entity Result tab on the Tests tab displays detailed information about the OAM test result. See Chapter 89, “Service Test Manager” for more information about how to configure OAM validation test suites.

The NFM-P also monitors the status of a peer SAP after a VLL has been created and put into service. Status information includes faults detected on the service tunnel, and access and network

SAP transmissions and receptions. The States tab of the Spoke SDP Binding form displays indicators of failure in the VLL in the State Cause panel.

When you use the NFM-P to create or discover a service, the NFM-P assigns a default Service Tier value to the service. The Service Tier parameter value is relevant only in the context of composite service topology views. See Chapter 85, “Composite service management” for more information about the hierarchical organization of composite services.

76.1.2 Contents

VLL service management overview

76.2 VLL service management overview

76.2.1 VLL types

The NFM-P supports the creation of the following VLL service types:

- Epipe, or Ethernet VLL service
- Apipe, or ATM VLL service
- Fpipe, or frame relay VLL service
- Hpipe, or HDLC service
- Ipipe, or IP interworking VLL service
- Cpipe, or circuit emulation VLL service

See the *NSP Wavence Device Support Guide* for Wavence device VLAN service management configuration information.

Epipe (Ethernet VLL)

An Epipe, or Ethernet VLL service, provides a point-to-point Ethernet service. One endpoint of an Epipe uses Ethernet encapsulation, and the other endpoint uses Ethernet, ATM, frame relay, or CEM encapsulation. An Epipe effectively provides ATM and frame relay bridged encapsulation termination for interworking. The NFM-P supports local cross-connecting when the Epipe endpoints are on the same device.

The device supports these Epipe connectivity scenarios:

- a frame relay or ATM user in an ATM network communicating with an Ethernet user on an IP/MPLS network
- a frame relay or ATM user who connects to a PE device in an IP/MPLS network and communicates with an Ethernet user who connects to another PE device in the same network

ATM users connect through a UNI using AAL-5 or bridged Ethernet PDUs, and use the VCI/VPI as the ATM SAP identifier. Frame relay users connect through a UNI that uses Multiprotocol Interconnect over frame relay or bridged Ethernet PDUs, or over an Ethernet UNI interface. The DLCI is the frame relay SAP identifier. The VCI/VPI and DLCI identifier tags are transparent to the service and remain unaffected during transport.

Devices which support MEF 8 can support TDM services encapsulated on Epipe services using circuit emulation mode. A SAP with a TDM port can then be assigned to an Epipe service using CEM encapsulation. The TDM SAP defines a local and remote ECID as well as a remote MAC address. The MAC address of the TDM port is used as the source MAC address for the emulated circuit.

MEF 8 can be configured on an Epipe service in the following two scenarios:

- one TDM SAP and one Ethernet SAP
- one TDM SAP and one spoke SDP

Using MEF 8 functionality to emulate TDM services, Epipe services can interoperate with devices that support MEF 8 Epipe services, but not MPLS Cpipe services, such as the Wavence SM. MEF 8 is supported on the 7450 ESS, 7705 SAR, and 7750 SR.

The NFM-P supports the following Ethernet SAP encapsulations for an Epipe service:

- null
- dot1q
- QinQ
- SONET/SDH BCP-null
- SONET/SDH BCP-dot1q

Epipe services allow you to designate a dot1q encapsulated SAP as the default SAP for a specific port. For more information about how you can use default SAPs on an Ethernet port, see 77.2.26 “Default SAPs” (p. 2234) in “VPLS management overview” (p. 2210) .

A default SAP can co-exist with other SAPs on a port, but it cannot be implemented on a null encapsulated port. You can use the NFM-P GUI to create a default SAP by specifying an outer encapsulation value of 4095 or * for a SAP. If the XML API is used, the outer encapsulation value is always 4095.

When you enable the Enable Q in Q Untagged Sap parameter on an NE, the NFM-P allows the creation of the following two default SAP types:

- The SAP type *.null functions as a default SAP for single-tagged frames on a Q in Q port. This SAP accepts single tags in the range 0 to 4095 as well as untagged traffic.
- The SAP type *.* functions as a default SAP for double-tagged frames on a Q in Q port. This SAP accepts untagged, single-tagged, and double-tagged frames with tags in the range 0 to 4095.

SAP types X.0 and X.* as well as SAP types *.null and *.* can be configured on the same Q in Q port on an Epipe service.

QTag Manipulation

The NFM-P supports QTag Manipulation on VLL access interfaces, on supporting NEs. QTag Manipulation allows you to define actions for inner and outer VLAN IDs, and assign tag values where required. For example, you can configure QinQ Tunneling, VLAN Translation, or other manipulations for L2 traffic that ingresses and egresses the interface. QTag Manipulation is configured on the Port tab of the L2 Access Interface properties form. See the NE documentation for more information about QTag Manipulation actions.

3-plus-tag Epipe service

You can configure a 3-plus-tag Epipe service on supporting 7210 SAS NEs. A 3-plus-tag Epipe service enables processing of packets with more than two tags when received on a QinQ SAP. A 3-plus-tag Epipe service requires a QinQ SAP as one endpoint and one of the following as the other endpoint:

- a spoke SDP binding
- a dot1q L2 access interface
- a QinQ L2 access interface

The spoke SDP binding must be of VC type VLAN, and the encapsulation values, or tags, must be configured to match. See 76.28 “To configure a VLL site” (p. 2154) , 76.34 “To configure a spoke SDP binding on a VLL site” (p. 2161) , 76.40 “To create a VLL L2 access interface on a terminating site” (p. 2174) , and the NE documentation for more information.

Support for 3-plus-tag Epipe services on 7210 SAS NEs varies, depending on the chassis type and release. See the NE documentation for support information.

Ethernet CFM is supported for 3-plus-tag Epipe services.

Apipe (ATM VLL)

An Apipe, or ATM VLL service, provides a point-to-point ATM service between users who connect to 7750 SR, 7705 SAR, 7950 XRS, or 7450 ESS NEs in an IP/MPLS network directly or through an ATM access network. One endpoint of an Apipe uses ATM encapsulation and the other endpoint uses ATM or frame relay encapsulation. An ATM PVC—for example, a VC or a VP—is configured on the managed device. As a result, the ATM switches at the service endpoints appear to be directly connected over an ATM link. The NFM-P supports VPI/VCI translation in an Apipe and supports local cross-connecting when the Apipe endpoints are on the same managed device.

An Apipe encapsulates standard UNI/NNI cells that ingress the ATM SAP into a pseudowire packet using N:1 cell mode encapsulation or AAL-5 SDU mode encapsulation. When using N:1 cell mode encapsulation, an Apipe supports cell concatenation into a pseudowire packet and the setup of both VC- and VP-level connections.

For ATM and frame relay interworking, an Apipe provides a point-to-point service between a user who connects to an existing ATM network and another user who connects to a PE in an IP/MPLS network. An ATM AAL-5 SDU pseudowire or a frame relay 1-to-1 mode pseudowire connects the nodes. The PE performs an FRF.5 interworking function to join the ingress and egress data paths.

An ATM VT SAP on a PE is identified by the physical port and VPI range. Cells that arrive on a specified port and are within the specified VPI range go into a single pseudowire for transport through the IP/MPLS network. A user can configure the whole ATM port as a VT and does not need to specify a VPI range. There is no ingress or egress VPI/VCI translation or loss of cell order.

The 7705 SAR uses N>1 cell mode encapsulation to support multiple VCs on an Apipe. You can multiplex VCs on a 7705 SAR Apipe service using SAP aggregation groups. See 76.19 “To create a SAP aggregation group on a 7705 SAR Apipe” (p. 2140) for more information about how to configure SAP aggregation groups.

The NFM-P supports the ATM N:1-N>1 VC type to allow interoperability between 7705 SAR and 7750 SR Apipe services, despite each site using different cell mode encapsulation. An interoperating Apipe service uses the ATM N:1-N>1 VC type, while the 7705 SAR site uses ATM VCC and the 7750 SR uses ATM Cell. An interoperating Apipe service combines SAP aggregation groups from the 7705 SAR Apipe with connection profiles from the 7750 SR Apipe onto a single Apipe service. See Chapter 63, “Connection profile policies” for more information about connection profiles.

Fpipe (frame relay VLL)

An Fpipe, or frame relay VLL service, provides a point-to-point frame relay service between users who connect to PE 7750 SR or 7450 ESS NEs in an IP/MPLS network. Both endpoints of an Fpipe use frame relay encapsulation. An Fpipe connects users through frame relay PVCs. An Fpipe

receives standard Q.922 core frames on the frame relay SAP and encapsulates them in a pseudowire packet according to the 1-to-1 frame relay encapsulation mode. This is the VC type used on the SDP by default. The NFM-P does not support the many-to-one, or port encapsulation, mode. Fpipe creation supports local cross-connecting when the endpoints are on the same managed device.

Hpipe (HDLC VLL)

An Hpipe, or HDLC VLL service, is used to carry HDLC PDUs over an MPLS network. HDLC PWs enable service providers to offer emulated HDLC services over existing MPLS networks. HDLC mode provides port-to-port transport of HDLC-encapsulated traffic.The HDLC PDU is transported in its entirety, including the HDLC address and control fields, but the HDLC flags and the FCS are excluded. If the optional control word is used, the flag bits in the control word are not used and must be set to 0 for transmitting and must be ignored upon receipt.

Before HDLC SAPs can be configured, the mda-mode command must be set to cem-fr-hdlc-ppp at the card level. Only ports that are configured with HDLC encapsulation can be mapped to an Hpipe SAP.HDLC encapsulating ports do not terminate the HDLC. The ports pass the HDLC frames through the Hpipe. HDLC encapsulated ports can pass through any HDLC-framed traffic, such as Cisco-HDLC, FR, PPP, etc.

Ipipe (IP interworking VLL)

An Ipipe, or IP interworking VLL service, uses the IP/MPLS network to provide Layer 3 connectivity between different Layer 2 technologies. An Ipipe service provides point-to-point IP connectivity between a user on a frame relay, ATM, cHDLC, or PPP access circuit with routed PDU IPv4 encapsulation and a user on an Ethernet interface. The Ethernet SAP interface can terminate on a 7705 SAR, 7750 SR, 7450 ESS, or 7950 XRS.

The following table summarizes the supported SAP types.

Table 76-1 Supported SAP types

SAP Types	Frame relay	ATM	PPP/IPCP	cHDLC	Ethernet
Frame relay					✓
ATM					✓
PPP/IPCP			✓		✓
cHDLC				✓	✓
Ethernet	✓	✓	✓	✓	✓

In an Ipipe service, both CE devices appear to be on the same IP interface. The PE devices must therefore resolve Layer 2 addresses when different resolution protocols are used on either SAP. Each PE device is manually configured with the IP addresses of both CE devices, or alternatively, can be set to automatically discover the IP addresses of the CE routers. The PE device maintains an ARP cache context for each IP interworking VLL, and responds to ARP request messages received on the Ethernet SAP. The PE device responds with the Ethernet SAP configured MAC address as a proxy for an ARP request for the frame relay, ATM, or PPP user access circuit IP address, and silently discards any ARP request message received on the Ethernet SAP for any

other address. The PE device maintains a record of the association of IP addresses with MAC addresses for ARP requests that it receives over the Ethernet SAP.

An Ipipe SAP can be bound to a physical or logical port with PPP, cHDLC, ATM, or FR encapsulation. ATM users connect through a UNI using AAL-5 MUX IP or AAL-5 SNAP routed PDU encapsulation. Frame relay users connect using routed PDU IPv4 encapsulation. PPP interfaces use PPP/IPCP encapsulation of an IPv4 packet. Users of cHDLC connect using routed IPv4 encapsulation.

The NFM-P supports the following Ethernet SAP encapsulations for an Ipipe service:

- Null
- dot1q
- QinQ

Note: IPCP SAPs on the 7705 SAR can be configured to assign primary and secondary DNS addresses to the remote peer.

The following identifiers are used for packet forwarding:

- VCI/VPI as the ATM SAP identifier
- DLCI as the frame relay SAP identifier

Cpipe (circuit emulation VLL)

A Cpipe, or circuit emulation VLL service, provides a point-to-point CEM service between supporting devices. The endpoints of a Cpipe use CEM encapsulation.

The Cpipe L2 access interface can be bound to a unstructured DS1 or E1 channel, a channelized DS0 channel group, or a DS0 group with CAS signaling. Consider the following when creating a Cpipe:

- The Time Slots parameter of the DS0 channel must be configured with at least one time slot.
- Time slots are automatically configured for unstructured E1 and T1 endpoints.
- The Clock Source parameter of the DS1 channel must be set to Node-Timed.

76.2.2 VLL spoke switching

VLL spoke switching allows you to create a VLL service by cross-connecting two spoke SDPs. Spoke switching allows you to scale L2 services, such as VLLs and H-VPLS, over a multi-area network without the requirement for a full mesh T-LDP. The NFM-P supports spoke switching on all VLL types, however, all service instances must be the same type.

The NFM-P supports VLL services with spoke switching on the 7210 SAS, 7250 IXR, 7450 ESS, 7750 SR, and 7950 XRS. Support for 7210 SAS NEs varies depending on the chassis type and release; see the NE documentation for information.

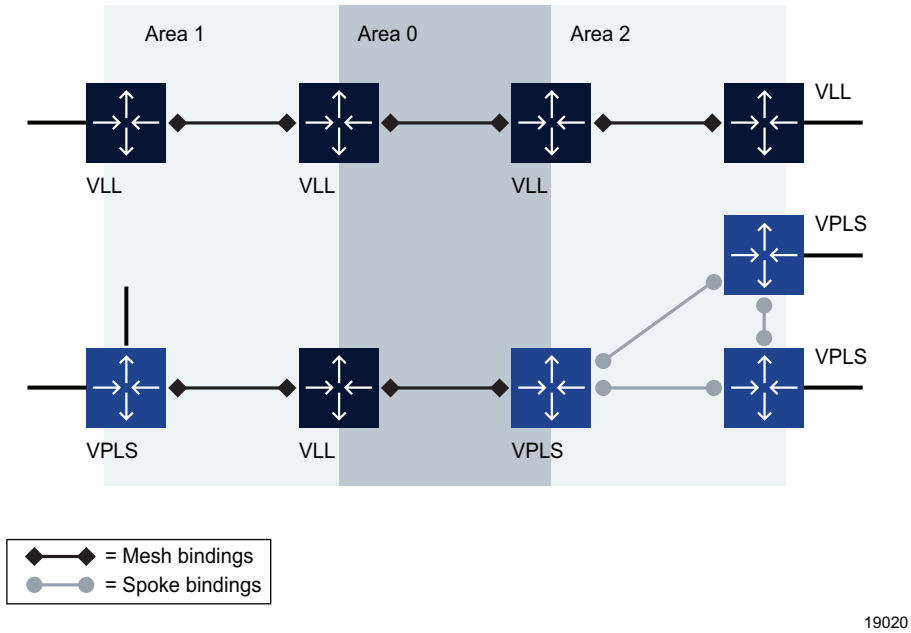
The following table describes the VLL site types that you can use in a spoke switching configuration.

Table 76-2 VLL site types

VLL site type	Description
Terminating	VLL instance has one or two VLL SAPs.
Switching	VLL instance cross-connects two spoke bindings.

The following figure shows a switching VLL that connects two VPLS. The configuration uses two T-PEs, three S-PEs, and two pairs of spoke bindings to connect the two VPLS.

Figure 76-1 VLL spoke switching



Configuration requirements

You must consider the following configuration rules when provisioning VLL services with spoke switching:

- Service type must be a VLL at the switching node.
- VC IDs can be different for the segments in the service.
- Segments in the service can run on different types of tunnels; for example, LDP, GRE, and RSVP SDPs.
- VLL instances in a service must use the same service ID to avoid the discovery of multiple and composite services.
- VLL with one or more switching sites must have two or more terminating sites.
- Autobinding creation service is not supported for switching VLLs.

76.2.3 VLL redundancy

VLL redundancy requires that you associate the SAP or SDP bindings to an endpoint. You can configure the endpoint association as active or standby so that you can create a redundant configuration. The associated nodes use signaling to determine the active SAP or SDP binding. The NFM-P supports VLL redundancy on SR OS NEs.

A VLL service site can have up to two local endpoints. A local endpoint combines a SAP with a binding (access) or a group of bindings (network). A SAP or an SDP binding can also exist without an endpoint association.

The 7450 ESS, 7750 SR, and 7950 XRS support HSDPA offload fallback for VLL Apipe and Epipe services by allowing fallback from an active PW on a primary spoke SDP to a secondary SAP.

The following table describes the components in redundant VLL configurations.

Table 76-3 VLL components for redundant configurations

VLL component	Description
Primary or Redundant binding	Primary or redundant binding is the same as a regular spoke binding. Up to four spoke bindings can form a VLL instance network endpoint. Only one binding can be configured as the primary; up to 3 others can only be configured as redundant spokes. Each redundant spoke has a precedence value to decide which spoke is the immediate backup. Only the terminating VLL instance can have multiple bindings on the network side endpoint. A switching VLL instance has up to 2 bindings, one on each side.
Inter-Chassis Backup	You can use an ICB in conjunction with a redundant SAP to provide protection for the SAP. The SAP must also be associated with a MC-LAG or MC-APS port. The ICB transports network traffic to the SAP on the second PE when the local SAP is unavailable. You must define a switching state for the redundant SAP. You must also configure the return ICB on the opposite endpoint of the protected site.

Configuration options

The following table describes the redundancy configuration options for each VLL site.

Table 76-4 VLL redundancy configuration options

Option	Configuration	Description
1	SAP SDP binding	You can create an endpoint without any SAP or SDP.
2	SAP SAP	You can create an endpoint without any SAP or SDP.
3	SDP binding SDP binding	You can configure this option for switching sites only.
4	SAP Endpoint with SDP bindings (maximum of 4 spokes and 1 ICB)	Figure 76-2, “VLL redundancy configuration - option 4” (p. 2107) shows the configuration of this option on the PE nodes.
5	Endpoint with SAP/ICB SDP binding	Figure 76-3, “VLL redundancy configuration - option 5” (p. 2108) shows the configuration of this option on Node B.

Table 76-4 VLL redundancy configuration options (continued)

Option	Configuration	Description
6	Endpoint with SAP/ICB endpoint with SAP/ICB	Figure 76-4, “VLL redundancy configuration - option 6” (p. 2108) shows the configuration of this option.
7	Endpoint with SAP/ICB Endpoint with up to 4 SDP bindings	Figure 76-5, “VLL redundancy configuration - option 7” (p. 2109) shows the configuration of this option.

Figure 76-2 VLL redundancy configuration - option 4

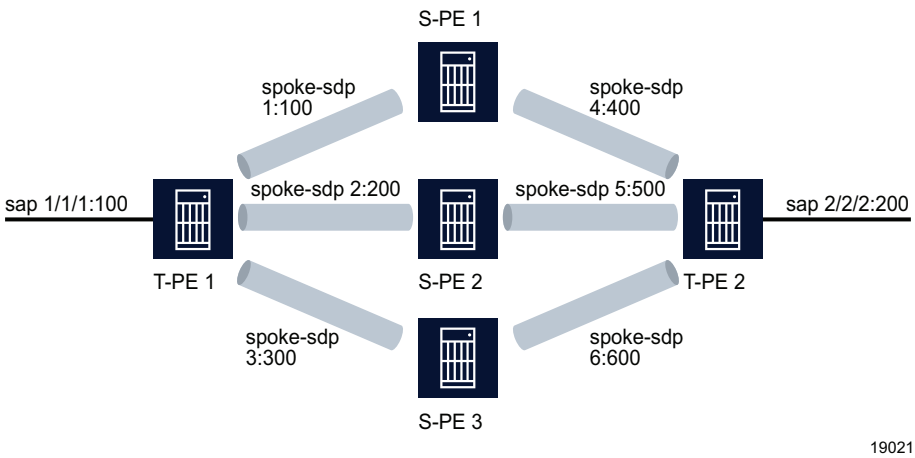


Figure 76-3 VLL redundancy configuration - option 5

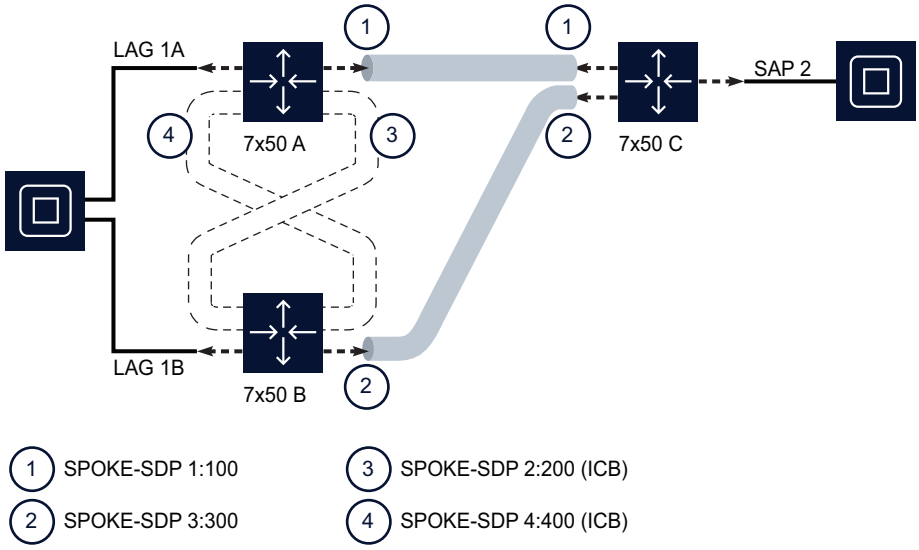

Figure 76-4 VLL redundancy configuration - option 6

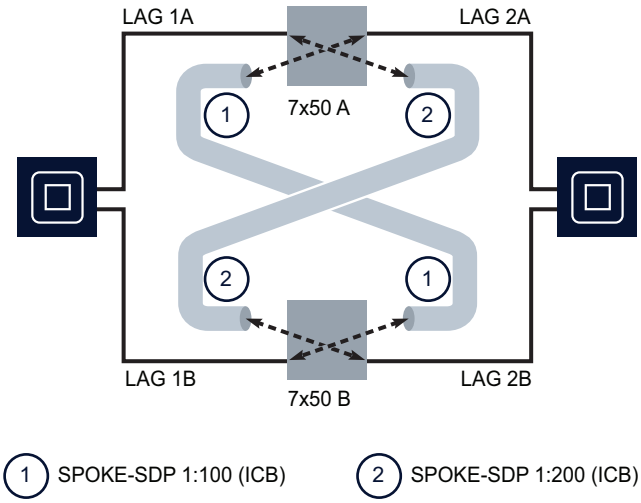

Figure 76-5 VLL redundancy configuration - option 7

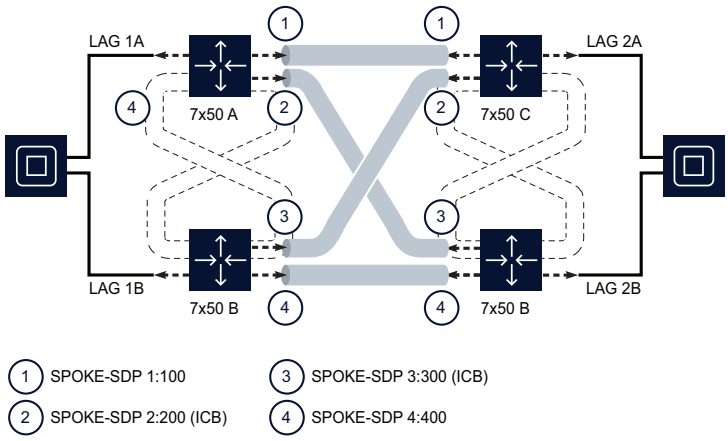


Configuration requirements

You must consider the following configuration rules when provisioning VLL services with spoke switching and redundancy:

- A VLL service can have one or more VLL instances.
- Local endpoint rules:
  - A VLL instance has a maximum of two endpoints. A terminating VLL instance has at least one access endpoint and a switching VLL instance has two network endpoints.
  - A network endpoint has a maximum of four spoke-bindings, which can include any combination of the following: a single primary spoke, one or more secondary spokes with precedence, and one ICB spoke.
  - A SAP or a binding has a maximum of one endpoint association.
  - An endpoint has a maximum of one SAP.
  - A SAP or a binding with association to an endpoint can be moved to another endpoint or removed from that endpoint.
- SAP rules:
  - A MC-LAG SAP or MC-APS SAP cannot be deleted when there is an ICB on the same endpoint.
  - SAPs cannot exist on switching sites.
  - A maximum of two SAPs can exist for each site.
  - A SAP with a non-ICB spoke cannot exist on the same endpoint.
  - Apipe and Epipe services support MC-APS.
- Spoke binding rules:
  - The SDP types (GRE, MPLS) used by the redundant spoke bindings do not have to be the same when you manually create the spoke bindings.

- Redundant configurations are not supported for S-PE because there are a maximum of two spoke bindings for a switching VLL instance.
- An ICB SDP binding should not be created on an endpoint without a MC-LAG SAP or MC-APS SAP.
- Only one ICB can exist for each endpoint.
- ICB SDP binding can only have a precedence of 4, the lowest priority.
- Only one primary spoke can exist for each endpoint.
- Spoke SDP binding cannot associate with an endpoint on a switching site.

- HSDPA offload fallback rules:
  - Apipe and Epipe services support HSDPA offload fallback on ATM interfaces.
  - The spoke SDP must be configured with primary precedence.
  - The SAP must be configured with MC-APS or ATM channel.
  - When the SAP is configured with MC-APS, the spoke SDP can be configured with ICB.

76.2.4 HSDPA Offload Resiliency

Mobile service providers deliver both voice and data services to their customers using mobile handsets. The data services provided require significantly more bandwidth than voice services. In order to minimize the operational costs (specifically, bandwidth), service providers typically separate the voice and data traffic at the mobile base station. The voice traffic may be backhauled over an ATM infrastructure, while a Metro Ethernet infrastructure (their own or third-party) is used to backhaul the data traffic. The separation of data traffic onto a separate network for backhaul is referred to as High Speed Data-Link Packet Access offload.

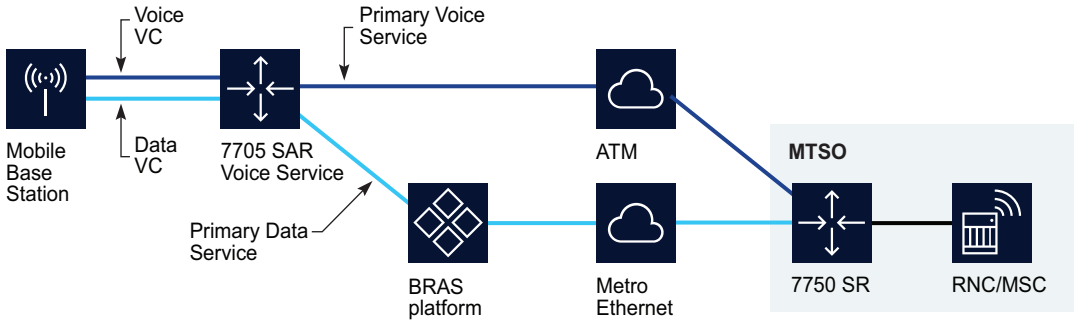
The HSDPA Apipe services traverse a path over the Metro Ethernet network which contains single potential points of failure that are unprotected. The ATM network can be used to provide a transient path for the data service in the event of a failure in the Metro Ethernet infrastructure, as long as the voice traffic is not impacted (data traffic is given lower QoS priority by the 7705 SAR and 7750 SR NEs). Clearly there is potential for the data service to suffer degradation (depending on the bandwidth required), until the fault in the Metro Ethernet network is resolved. However the SLA requirements for the data service are typically best effort.

The ability to switch to this alternate transient pathway for the data service is referred to as HSPDA resiliency.

HSPDA resiliency is implemented through the use of VLL Apipes on the 7705 SAR. The network architecture used in the ATM backhaul scenario is shown in Figure 76-6, “ATM-based HSDPA offload architecture - nominal operation” (p. 2111) .

Note: For HSPDA offload resiliency, the primary and secondary services must be on the same NE.

Figure 76-6 ATM-based HSDPA offload architecture - nominal operation



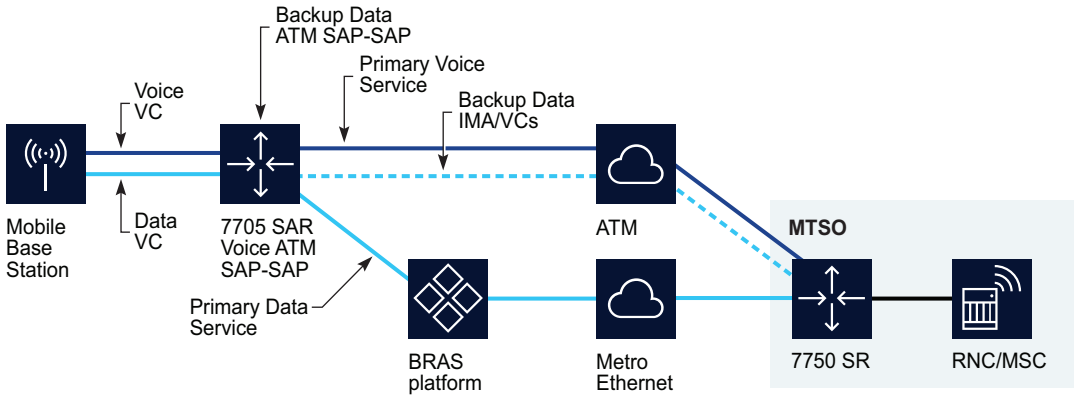
The mobile base station node separates the voice and data traffic and delivers the two different traffic types to the 7705 SAR on different VCs. Both the voice and data services use Apipe pseudo-wires to carry the traffic over the backhaul network to the 7705 SAR. The HSDPA Apipe service is paired with an OAM service (not shown in Figure 76-6, “ATM-based HSDPA offload architecture - nominal operation” (p. 2111)) which is used by the wireless infrastructure to monitor the end-to-end path between the wireless endpoints.

For the ATM voice traffic, an internal Apipe is used on the 7705 SAR to switch ATM cells between the access VC/IMA group and the network side VC/IMA group. The service does not span the radio access network between the 7705 SAR and the 7750 SR located at the Mobile Telephone Switching Office (MTSO).

Data Apipe services (HSDPA/OAM) use service tunnels based on either MPLS or GRE. GRE is generally used in the context of a third-party Metro Ethernet network, since there is a Broadband Remote Access Server (BRAS) in the path between the DSLAM and the 7750 SR located at the MTSO (BRAS platforms do not support MPLS). MPLS is typically used when the mobile provider owns the Metro Ethernet network.

When the resiliency solution described below detects a failure in the Metro Ethernet network, its protection mechanism switches the traffic associated with the data service from the path over the Metro Ethernet network to a path which traverses the ATM (shown in the following figure). The detection, switchover, and switchback mechanisms are implemented by the NFM-P.

Figure 76-7 HSDPA Offload Protection - ATM data backhaul



A backup (secondary) data service for an active (primary) data service is pre-configured on the 7705 SAR. For a typical 7705 SAR deployment at a cell site, two backup services are required, one for the HSDPA service and one for the OAM service. These backup services are created by the operator during the deployment of the 7705 SAR. A peer resiliency relationship between the active and backup services must also be configured.

The backup services used are internal Apipes. The switchover from primary to secondary is triggered by an event from the 7705 SAR sent to NFM-P, which indicates that the service tunnel (SDP) has failed. When the failure event is processed by NFM-P, the SAPs on the active data services are moved (along with the associated VCs) from the active service to its peer backup service and are enabled. After the re-configuration of the SAPs on the backup services completes, the traffic is moved to the backup services, which then carry the traffic over the ATM portion of the network. When the switchover is complete, an alarm is raised against the primary service indicating that it has been switched to the secondary service.

Other considerations include the following:

- If a service configured as primary is deleted from NFM-P or the CLI, then the corresponding resiliency is also deleted.
- If a service configured as secondary is deleted from NFM-P, this is blocked and a pop-up message indicates that the corresponding resiliency must first be deleted.
- If a service configured as secondary is deleted from the CLI, an alarm is raised indicating that the resiliency is misconfigured. If a secondary service is then subsequently added to the resiliency, this alarm is cleared.
- If the SAP initially configured on the primary service is deleted, the NFM-P raises an alarm. If the SAP is restored in the same service, the alarm clears.
- When the NFM-P detects that a failed SDP is up, which indicates that the primary service has recovered, the resiliency is set to the Secondary (Debounced) state and a damping timer is started. If the SDP goes down while the resiliency is in the Secondary (Debounced) state, the resiliency changes to the Secondary state and the damping timer stops. If the SDP changes state during the damping time, the value of the damping timer doubles until it rises to the maximum damping time. This prevents the service from flapping between primary and

secondary. If the SDP does not change operational state during the damping time, the resiliency is set to Primary, the SAP is moved from the secondary to the primary service, and the alarm related to the service switch clears.

- After the primary service is restored, the damping timer value is set back to its initial value. The damping timer value is not displayed. The initial damping time is 30 000 ms; the time doubles, if required, to a maximum of 480 000 ms.

76.2.5 SDP bindings bandwidth allocation

You can administratively account for the bandwidth used by VLL services inside an RSVP SDP that consists of RSVP LSPs. The SR service manager keeps track of the available bandwidth for each SDP.

When you create a service tunnel, you configure an SDP Bandwidth Booking Factor percentage, which is applied to the SDP available bandwidth. You then assign an SDP Admin Bandwidth value (in kbps) to the spoke SDP. When you bind a VLL service to this SDP, this amount of bandwidth is subtracted from the adjusted available SDP bandwidth. If you subsequently delete the VLL service binding from this SDP, this bandwidth amount is added back into the adjusted SDP available bandwidth. If you overbook the total adjusted SDP available bandwidth when adding a VLL service, a warning is issued and the binding is rejected.

This feature does not guarantee bandwidth to a VLL service, as there is no change to the data path to enforce the bandwidth of an SDP by means such as shaping or policing of the constituent RSVP LSPs. Also, this feature does not provide a CAC capability for a local VLL service which consists of a cross-connect between two SAPs.

In addition, if multipoint services such as VPLS and VPRN are using the same SDP for forwarding packets, the amount of bandwidth consumed by these services is also not accounted for. Therefore, it is advisable to dedicate an SDP for VLL services for which bandwidth reservation is required. Furthermore, VPLS and VPRN services which use separate SDPs but which forward packets over the same network port as the VLL SDP also do not have their bandwidth accounted for. This may impact the bandwidth available to the VLL services.

Auto SDP binding (for all spoke bindings or just the return binding) cannot be used when there is a bandwidth request for the binding. The converse also applies. An error message appears when saving the configuration if this conflict occurs. NFM-P checking is done for the XML API.

76.2.6 Port redundancy

CAUTION

Service Disruption

Nokia recommends that you set the OLC state of a service to Maintenance before you switch to a redundant port or channel, and reset it to the previous state after the switch is complete. See the NSP System Administrator Guide for more information.

Cpipe and Epipe services on 7450 ESS, 7705 SAR, and 7750 SR devices support port redundancy, which allows you to define a backup port or channel for a VLL SAP. The backup port or channel can be on the local site, for what is called on-node switching, or on a remote site, for what is called off-

node switching. In the event of a failure on the SAP, you can manually switch to the backup port or channel using a button on the VLL service, site, or SAP properties form, or from the port properties form.

When a SAP is switched to a backup port using off-node switching, the primary SAP on which the switching is performed is deleted along with the site and site child objects, including the associated SDP bindings. The site is subsequently created on the backup NE, as are the SAP and the other site child objects, using the same tunnel type and tunnel profile for SDP bindings as the primary site.

See 76.40 “To create a VLL L2 access interface on a terminating site” (p. 2174) for configuration information. See 76.55 “To switch to the redundant port for a VLL SAP from an L2 access interface properties form” (p. 2199) and 76.18 “To switch to the redundant port for one or more VLL SAPs” (p. 2138) for information about switching between the redundant ports of one or multiple VLL SAPs.

Note: Ethernet OAM objects, for example, MEPs, that are associated with the protected SAP are not copied to the new SAP.

When multiple SAPs are selected, switching is attempted only for the SAPs that support port redundancy and on which port redundancy is properly configured.

Port redundancy switching fails if the SAP or port is included in one of the following redundancy objects:

- BGP-MH
- MC-APS
- MC-LAG
- MC-ring

76.2.7 Copying and moving SAPs between ports

You can copy and move SAPs between ports. See 16.6 “Copying and moving SAPs” (p. 574) in Chapter 16, “Port and channel object configuration” for more information.

76.2.8 DoS protection

To protect a VLL from a high incoming packet rate that characterizes a DoS attack, you can use the NFM-P to create DoS protection policies for VLL Epipe or Ipipe L2 access interfaces. A DoS protection policy limits the number of control-plane packets that an interface receives each second, and optionally logs a violation notification if a policy limit is exceeded. You can use the NE System Security form to view the violations for a specific NE.

You can configure a DoS protection policy to control the following on a VLL Epipe or Ipipe L2 access interface:

- the control-plane packet arrival rate per subscriber host on the interface
- the overall control-plane packet arrival rate for the interface
- whether an NE sends a notification trap if a policy limit is exceeded

Each VPLS L2 access interface on an NE that supports DoS protection is automatically assigned a default DoS protection policy. The default policy limits only the overall packet arrival rate for the interface, and cannot be deleted or modified. See the *NSP System Administrator Guide* for information about creating a DoS protection policy.

76.2.9 DDoS protection

You can configure a DDoS protection policy on a VLL Epipe or Ipipe L2 access interface. See the *NSP System Administrator Guide* for information about configuring a DDoS protection policy.

76.2.10 BGP VPWS

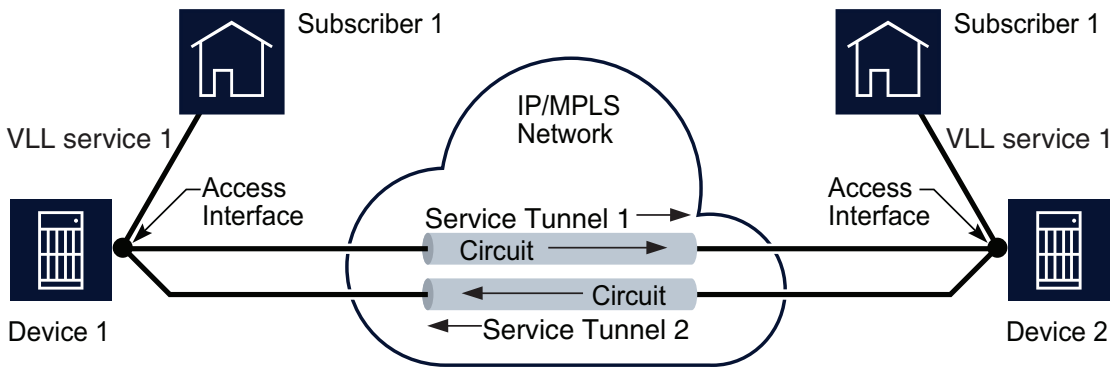
You can use the NFM-P to create a BGP VPWS, which is an L2 VPN service that uses BGP pseudowire signaling. BGP VPWS is implemented in the NFM-P under an Epipe site, which is configured to use BGP to establish a pseudowire with a remote Epipe site. See 76.24 “To create a BGP VPWS” (p. 2147) for information about configuring a BGP VPWS.

76.3 Sample VLL service configuration

76.3.1 Sample VLL service

The following figure shows a sample VLL service.

Figure 76-8 Sample VLL service



76.3.2 Configuration steps

Assuming the core IP/MPLS network and service tunnels have already been configured, the following high-level tasks are required to configure this sample VLL service.

1

Configure policies as required, for example, access ingress and egress interface, ATM, Scheduler, ACL IP and ACL MAC, Accounting, and ANCP policies.

2

Configure ports as access ports for use in the service, if applicable.

3

Configure service tunnels as required.

4

Create and configure Subscriber 1.

5

Create and configure Service 1.

VLL service management procedures

76.4 Workflow to create a VLL service

76.4.1 Overview

The following workflow lists the high-level steps required to create a VLL service. As a prerequisite for creating a VLL service, this workflow assumes the following:

- a group or customer with the required user access privileges has been configured.
- the IP or IP/MPLS core network exists.
- any required service tunnels are created including the static, dynamic or SR-TE LSP required to create the service tunnel; see 33.9 “To create an IP/MPLS service tunnel” (p. 1190) .
- the access ports for the service are created; see Chapter 16, “Port and channel object configuration” for more information.
- any required pre-defined routing, QoS, scheduling, filter, accounting, and time of day suite policies are created; see Chapter 49, “Policies overview” for more information. You do not have to create pre-defined policies if policies are created on a per-service basis.
- any required MP-BGP for PE-to-PE routing is configured; see Chapter 28, “Routing protocol configuration” for more information about protocol configuration.

76.4.2 Stages

1

Create and configure the VLL service:

1. Define the VLL service type as Epipe, Apipe, Fpipe, Hpipe, Ipipe, or Cpipe.
2. Specify the NEs (sites) used in the service based on the following topologies:
   - Traditional VLL: terminating site only
   - Switching VLL: switching site with two or more terminating sites
   - Redundant VLL: ICB spoke to MC-LAG (Epipe) or MC-APS (for Apipe and Epipe)
3. Specify the following information for redundant VLL services:
   - endpoints
   - access interfaces for VLL terminating sites
4. Specify the following information to create a VLL Apipe or Epipe HSDPA offload fallback solution:
   - endpoints
   - SAP on endpoint one with MC-APS or ATM channel
   - spoke SDP with ICB on endpoint one
   - spoke SDP with primary precedence on endpoint two
   - SAP on endpoint two with MC-APS
   - spoke SDP with ICB on endpoint two
5. Specify aggregation on a service basis, or across a card or port.

6. Specify QoS, scheduling, accounting, ANCP, MEP association and filter policies.
7. Specify the time of day suite.

2

For VLL services created on an OmniSwitch:

a. Create VLAN groups and add members to each group as required. See 75.13 “To create a VLAN group” (p. 2083) .

b. Delete a VLAN group or group member. See 75.14 “To delete a VLAN group or group member” (p. 2084) .

3

Turn up the service.

4

Perform one or more of the following as required.

a. Configure a GNE site on a VLL service. See 76.29 “To configure a GNE site on a VLL service” (p. 2155) .

b. Create a VLL L2 access interface on a terminating site. See 76.40 “To create a VLL L2 access interface on a terminating site” (p. 2174) .

c. Create a SAP aggregation group for a 7705 SAR Apipe. See 76.19 “To create a SAP aggregation group on a 7705 SAR Apipe” (p. 2140) .

d. Configure an Epipe site for EVPN VXLAN. See 76.20 “To configure EVPN on an Epipe site” (p. 2142).

e. Create an HSDPA resiliency configuration. See 76.21 “To create an HSDPA resiliency configuration” (p. 2144) .

f. Activate and manually operate an HSDPA resiliency configuration. See 76.22 “To activate and manually operate an HSDPA resiliency configuration” (p. 2145) .

g. Run an OAM validation test for a VLL service. See 76.23 “To run an OAM validation test for a VLL service” (p. 2146) .

h. Configure a BGP VPWS. See 76.24 “To create a BGP VPWS” (p. 2147) .

5

As required, view VLL service-related information:

a. View the ECMP/LAG hashing of Epipe services to monitor the distribution of Epipe service traffic into the network. See 76.25 “To view ECMP/LAG hashing of Epipe services” (p. 2150) .

b. View the local status information associated with the VLL service. See 76.26 “To view the local PW status information for a VLL service” (p. 2151) .

c. View the peer status information associated with the VLL service. See 76.27 “To view the peer PW status information for a VLL service” (p. 2152) .

d. View the VLL service operational status. See 76.6 “To view the VLL service operational status” (p. 2120) .

e. View the service topology map associated with a VLL service. See 76.10 “To modify a VLL service using the topology view” (p. 2127) .

6

As required, modify a VLL service:

a. Using the Manage Services form. See 76.8 “To modify a VLL service” (p. 2124) .

b. Using the topology view. See 76.10 “To modify a VLL service using the topology view” (p. 2127) .

7

As required, delete a VLL service. See 76.11 “To delete a VLL service” (p. 2131) .

76.5 To create a VLL service

76.5.1 Purpose

VLL Apipe services are configurable only on the 7450 ESS in mixed mode, 7750 SR, 7950 XRS, and 7705 SAR.

VLL Hpipe services are configurable only on the 7705 SAR and 7705 SAR-M.

In order to configure a VLL Hpipe service on a supporting NE, the daughter card MDA Mode must be set to cem-fr-hdlc-ppp. For more information, see 15.78 “To configure an MDA” (p. 536) . Only ports that are configured with an Encap Type of HDLC can be mapped to an Hpipe SAP. For more information, see 16.24 “To configure Ethernet ports” (p. 599) .

VLL Cpipe services are configurable only on the 7750 SR, 7705 SAR, 7210 SAS-M, and 7450 ESS NEs. Consider the following when creating a VLL Cpipe:

- The Time Slots parameter of the DS0 channel must be configured with at least one time slot.
- Time slots are automatically configured for unstructured E1 and T1 endpoints
- The Clock Source parameter of the DS1 channel must be set to Node-Timed.

76.5.2 Steps

1

Choose Create→Service→VLL→Epipe (Ethernet to Ethernet/ATM/FR/CEM) | Apipe (ATM to ATM/FR) | Ipipe | Fpipe (FR to FR) | Hpipe (HDLC to HDLC) | Cpipe (CEM to CEM) from the NFM-P main menu. The VLL Service (Create) form opens.

2

Select a customer in the Customer panel.

3

Configure the required general parameters.

The Service ID and SVC Mgr Service ID parameters are configurable when the Auto-Assign ID parameter is disabled.

The Default VC ID parameter is configurable when the Inherit Service ID Value parameter is disabled.

4

This operation cannot be reversed.

If you will be using an MLPPP link for Epipe bandwidth management, perform the following steps to convert bandwidth units to Kbps:

1. Choose Administration→System preferences from the NFM-P main menu. The System Preferences form opens.
2. Choose the Services tab.
3. Disable Service Bandwidth Management.
4. Click Execute in the Convert to Kbps parameter.
5. Click Yes in the warning dialog box to proceed.
6. Enable Service Bandwidth Management.

5

If you enabled the Automatic SDP Binding/PBB Tunnel Creation parameter in Step 3 , select a tunnel selection profile in the Auto Tunnel Selection panel.

6

Save the changes and close the forms.

You can use the topology maps to view the service. See Chapter 4, “Topology map management” for more information about service topology maps.

END OF STEPS

76.6 To view the VLL service operational status

76.6.1 Purpose

The Operational State and State Cause indicators on the General tab of the service management form display information about service faults.

76.6.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a service and click Properties. The VLL *Type_of_VLL* (Edit) form opens.

3

View the Operational State and State Cause indicators. When the Operational State is Down, a check mark beside the appropriate State Cause indicator identifies the type of associated service fault.

4

Click on the appropriate tab to view or edit an object that is identified as faulty by a State Cause indicator.

5

Click on the Faults tab to view the alarms for the object. The Object Alarms tab is displayed.

6

Click on the Aggregated Alarms tab to view the aggregated alarms for the object. The Aggregated Alarms tab is displayed.

7

Close the VLL *Type_of_VLL* (Edit) form.

8

Close the Manage Services form.

END OF STEPS

76.7 To move a VLL service

76.7.1 Purpose

Perform this procedure to move a VLL service from one NE to another NE. The VLL service site and all of the children objects, including SAPs, SDP bindings, MEPs on the SAPs and related CFM tests, are moved to the destination site. MEPs and associated CFM tests are included in VLL move operations for L2 SAPs and SDP bindings (including return SDP bindings). Return SDP bindings (from remote site to the source site) for SDP bindings from the source site to a remote site are moved. Ingress and egress, scheduler, policer, accounting, and IP/MAC filters (ACLs) policies are moved and distributed to the destination NE.

If there are SAPs on different ports within a VLL, you must move the service port by port. When the service does not already exist on the destination NE—that is, before an move operation—the service site and children objects are moved to the destination NE. Only SAPs on the specified port are moved to the destination site. After an initial move, moving the remaining SAPs on other ports is a SAP move operation. See 16.32 “To copy or move L2 SAPs between ports” (p. 614) .

Note: Consider the following site limitations when you move a service:

- Moving services is only supported on 7750 SR, 7450 ESS, and 7950 XRS NEs.
- The NE type and major software release of the source and destination NEs must be the same.
- The chassis mode of the destination NE must be the same or higher than the chassis mode of the source NE.
- The NFM-P copies the source site and children objects and creates them on the destination NE.
- You cannot move sites that are used in a backbone configuration.
- You cannot move sites created by a RADIUS script for dynamic service.

Consider the following SAP limitations when you move a service:

- The source and destination ports must be compatible, for example, have the same encapsulation type, be HSMDA ports or not, or both be access or hybrid.
- You cannot move SAPs that are configured on PW ports and Ethernet tunnel endpoints.
- SAPs with connection profiles (ATM/VLAN) can be moved when there is at least one SAP configured on the source port with the encap value in the specified range on the source service site.
- If the source site only contains SAPs with connection profiles, the site will not be moved.
- If the source site contains SAPs associated with connection profiles on the specified port, and SAPs on a different port, or SAPs on the specified source port but with encap values out of the range, the site will not be moved.
- The ranges specified in the connection profiles (ATM/VLAN) on source SAPs must not overlap with SAPs on the destination port or fall in a range where a SAP on the destination port may exist.

  The Encap value ranges specified in the move procedure do not apply to connection profiles.
- If there is a Ethernet Ring Path Endpoint associated with the source SAP, the association is not be copied to destination SAP.

Take into account the following service tunnel considerations when you move a service:

- If the spoke SDP bindings on the source NE use an SR-ISIS or SR-OSPF service tunnel, the NFM-P looks for a matching tunnel on the destination NE. If no matching tunnel exist, then the NFM-P creates one.
- If the spoke SDP bindings on the source NE use an MPLS-TP service tunnel, the copy/move operation is allowed, but an MPLS-TP service tunnel must exist on the destination NE.
- You cannot move SDP bindings that use L2TPv3 service tunnels.
- You cannot move spoke SDP bindings if they are not manually created.

76.7.2 Steps

1

Choose Tools→Copy/Move→Service from the NFM-P main menu. The Service Copy/Move form opens.

2

Set the Action Type parameter to Move.

3

Set the Service Type parameter to a VLL service or VPLS+VLL.

Note: Only VPLS is supported for the action type Copy.

4

In the Source panel, choose the NE from which you want to move the service.

5

In the Source Port panel, choose the source port from which you want to move the service.

6

Configure required parameters in the Source panel.

7

In the Destination panel, choose the NE to which you want to move the service.

8

In the Destination Port panel, choose the port to which you want to move the service.

9

Configure the required parameters in the Execution Details panel.

The NFM-P creates SAPs on the destination port with the same encapsulation values as the source SAP if you set the Outer Encap Value Offset and Inner Encap Value Offset parameters to 0. Otherwise, the NFM-P creates SAPs on the destination port encapsulation values equal to the source encapsulation value plus the Outer Encap Value Offset or Inner Encap Value Offset parameter.

10

Click Result Export Path and specify the file name and location in which to save a text file that contains the results of service move operation.

11

Click Execute.

12

Click on the Results tab to view the results of the copy or move action.

END OF STEPS

Note:

If the new site is created successfully with all children copied from the source site, the source site is deleted.

A service move searches for all of the SAPs with specified service type on the source NE, within the encapsulation value range that you specified in Step 6 on the specified port. The NFM-P creates the associated service sites on the destination NE with the corresponding SAPs on the destination port, including all children objects, such as SDP bindings, that existed on the source site.

The source site is not deleted if the new site is created successfully with only some of the SAPs from source site, for instance, there are SAPs remaining on the source site on different ports or with outer or inner encapsulation values out of the specified range. The SAPs that are within the specified encapsulation range that you specified in Step 6 will be deleted from the source port after the move, along with all corresponding SDP bindings.

If the corresponding service site exists on the destination NE, only the SAPs within the specified encapsulation range are copied/moved to the destination site. All other children objects, such as SDP bindings, under the source site are not copied or moved to the destination site. In this case, the source site will be deleted along with all other children objects when the last SAP is moved.

If a SAP exists on the destination site with same encapsulation values as the source SAP (the source SAP encapsulation values plus the Outer Encap Value Offset or Inner Encap Value Offset parameters that you specified in Step 9), the move action fails.

If there is a failure when moving a site or any of the child objects, the move action for this site fails and nothing from this site is moved to the destination NE.

If there are multiple service sites being copied or moved along with the SAPs as specified by source port and encapsulation range, the copy or move action continues to the next site if there is an individual failure.

The NFM-P reports that the copy or move action is finished when the NFM-P database transaction has completed; deployment operations on the node may continue after the database transaction is complete.

76.8 To modify a VLL service

CAUTION

Service Disruption

Modifying parameters can be service-affecting.

76.8.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Configure the filter criteria. A list of services appears.

3

Choose a VLL service and click Properties. The *VLL_type* Service (Edit) form opens.

The following tabs list the service elements that can be individually or collectively selected and configured.

Some service elements do not apply to all VLL services.

- Bandwidth tab — displays service tunnel bandwidth booking information for the service.
- Sites tab — lists the sites that are included in the service
- Endpoints tab — lists the service endpoints
- Interface tab — lists the access interfaces that are included in the service
- Spoke SDP Bindings tab — displays the spoke SDP bindings that are associated with the service
- VLAN Path Instance - list VLAN path instances associated with a Wavence service
- OAM tab
- Faults tab — displays the faults associated with the service
- Schedulers tab — configures the rate type and displays the egress aggregate rate limit

4

Modify the parameters for the service as required.

To configure items on the tabs that contain lists of service elements, select the items and click Properties.

5

Click OK. A dialog box appears.

6

Click Yes to confirm the action. The *VLL_type* Service (Edit) form closes and the Manage Services form reappears.

7

Close the Manage Services form.

END OF STEPS

76.9 To view VLL service contents

76.9.1 Purpose

Use this procedure to view various contents of a VLL L2 service and any modifications you make to it before deploying the changes.

Note: The procedure also provides information on the following policy types associated with the service:

- QoS SAP ingress and QoS SAP egress polices
- ACL IP/IPv6 filters and ACL MAC filter policies

Note: The displayed contents of a service is applicable to only one service site.

Two information views are available. The Committed info view displays the current contents of a service, and the Committed menu item is always enabled. The Modified info view allows you to review any changes you make to a service before committing them. Modified, created, and deleted attributes and objects are displayed.

76.9.2 Steps

1

Choose Manage Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Click Search and select the service that you want to view or modify.

3

On the service navigation tree, expand the Sites icon and click on the required site. The site properties form is displayed.

4

Perform one of the following:

a. To view the currently committed service contents, go to Step 5 .

b. To view modified service contents before committing any changes, go to Step 6 .

5

Click on the Show Info and choose the Committed menu item. A Committed Values form is displayed and shows various policy attributes that have been previously configured and saved in the local policy. The CLI information of the QoS policies and ACL filters associated with the service is also displayed. The information displayed in the form is similar to the information retrieved in CLI by running the “config>service>*Service Type#* info” command, where *Service Type#* is the type of service (followed by its Service ID, for example: vll37) that you want to query.

6

Modify any service parameters or objects, as required. Otherwise go to Step 9 .

7

Click on the Show Info and choose the Modified menu item. A Modified Values form is displayed. The table lists modified, created, and deleted actions, as well as specific attributes and objects, along with their old value, new value, and tab location. The Attribute Title corresponds to the attribute or object name acted upon by your current modifications. For created objects, the values of mandatory attributes are shown in comma-separated format.

8

Select an item in the Modified Values form and then click Show on Form. The service form tab containing the changed item is displayed and the modified attribute is highlighted in blue.

9

Save your changes if required, and close the form.

END OF STEPS

76.10 To modify a VLL service using the topology view

76.10.1 Purpose

The topology view for a service provides a graphical representation of the various components and their interconnections. You can also use this view to add, modify, or just navigate to service components. This provides an alternative approach to performing these functions from the navigation tree view.

Working from the topology view can expedite the creation of the components, since many of the fields you would ordinarily have to set in the configuration forms will be automatically populated using this approach. The configuration forms can also be accessed directly at any time from this view by right-clicking on a component. This allows quick access to conduct more detailed component configuration.

76.10.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Configure the filter criteria. A list of services appears.

3

Choose a VLL and click Topology View. The Service Topology map opens.

The remainder of this procedure contains a number of sub-procedures describing the various components that can be created and modified from the topology view. These include:

- Creating a new site. Go to Step 4 .
- Creating site components. Go to Step 9 .
- Creating spoke SDP bindings. Go to Step 19 .

Adding a new site

4

Right-click on any blank space in the service topology map. A contextual menu is displayed. Choose the option allowing you to create a new site. This may be an Epipe, Cpipe, Ipipe, Apipe, or Fpipe site, depending on what type of VLL service you are modifying.

The Select Network Elements form appears.

5

Choose one or more sites to add to the service and click OK. The Site (Create) form for the new site is displayed. If you selected more than one site, the Site (Multiple Instances) (Create) form for the new sites is displayed.

6

Click OK. The Site (Create) (or Site (Multiple Instances) (Create)) form closes and the new site (or sites) is displayed on the map.

7

If you want to perform detailed configuration of site properties for the new site, right-click on the site icon and select Properties from the contextual menu. The Site (Edit) form opens. See 76.28 “To configure a VLL site” (p. 2154) for detailed site configuration information for the various types of VLL services.

8

Return to Step 3 for a list of other functions you can perform from the topology view or go to Step 27 to finish.

Creating site components

9

Right-click on a site icon or a SAP aggregation group icon in the service topology map. A contextual menu is displayed. Depending on the service type and the icon you clicked on, you can choose to create one of the following:

- Endpoint. Go to Step 10 .

- L2 Access Interface. Go to Step 13 .
- SAP Aggregation Group. Go to Step 16 .

10

If you choose to create an Endpoint, the Endpoint (Create) form is displayed.

11

Configure the Name parameter for the endpoint.

12

Click OK. The Endpoint (Create) form closes and the new endpoint is displayed in the topology view.

13

If you choose to create an L2 Access Interface, then the L2 Access Interface (Create) form is displayed.

14

Click on the Port tab and assign a port to the interface.

If you assign the private port of an ISA tunnel to an Epipe, an L2TPV3 tab is added. On the L2TPV3 tab, select VPRN or Base Router in the Router ID parameter and enter the Tunnel Group name.

15

Click OK. The L2 Access Interface (Create) form closes.

16

If you choose to create a SAP aggregation group, then the SAP Aggregation Group (Create) form is displayed.

17

See 76.19 “To create a SAP aggregation group on a 7705 SAR Apipe” (p. 2140) for detailed information about configuring the SAP aggregation group.

18

Return to Step 3 for a list of other functions you can perform from the topology view or go to Step 27 to finish.

Creating spoke SDP bindings

19

Choose the sites you want to connect in the service topology map and right-click on any one of them. A contextual menu is displayed.

Note: When you create a spoke binding between two sites, the order in which you select them is important. The first site you select will become the source site and the second site will become the destination site. Therefore, it is not recommended that you do a marquee-select in the topology view, since you will not be sure of this hierarchy. Instead, select the sites individually, and hold down the Shift or Ctrl key after your first selection.

20

Choose Connect from the contextual menu and choose the Create Spoke SDP Binding option.

The Spoke SDP Binding (Create) form is displayed.

Note: For this function, it is assumed that you clicked on the source site first and then held down the Shift or Ctrl key while right-clicking on the destination site to display the contextual menu.
You can also create a spoke SDP binding between a site icon and an endpoint icon, or between two endpoint icons in the topology view. Appropriate endpoints must first exist or be created to enable this.

21

Enable the Auto-Select Transport Tunnel parameter.

22

You can manually configure other parameters here if required, or click OK. One of the following will result:

- If an available transport tunnel exists between the two sites, then the Spoke SDP Binding (Create) form closes and the new binding between the two sites is displayed in the topology view. See 76.34 “To configure a spoke SDP binding on a VLL site” (p. 2161) for more detailed information about creating and configuring spoke SDP bindings for the various types of VLL services.
- If an available transport tunnel does not exist between the two sites, then an error message is displayed to that affect. See Chapter 33, “Service tunnels” for information about how to create the required tunnel. When the tunnel is created, you can repeat this sub-procedure.

23

Assuming that the spoke SDP binding was successfully created in Step 22 , select the same two sites again in the topology view, although this time do so in the opposite order that you originally selected them. This will allow you to create a spoke binding for the return tunnel.

24

Right-click on the second site you selected and choose the Create Spoke SDP Binding... option from the contextual menu. The Spoke SDP Binding (Create) form is displayed.

25

You can manually configure other parameters here if required, or click OK. One of the following will result:

- If an available transport tunnel exists between the two sites, then the Spoke SDP Binding (Create) form closes and the new return binding between the two sites is displayed in the topology view.
- If an available transport tunnel does not exist between the two sites, then an error message is displayed to that affect. See Chapter 33, “Service tunnels” for information about how to create the required tunnel. When the tunnel is created, you can repeat this sub-procedure.

26

Return to Step 3 for a list of other functions you can perform from the topology view or go to Step 27 to finish.

27

Close the Service Topology form.

28

Close the Manage Services form.

END OF STEPS

76.11 To delete a VLL service

CAUTION

Service disruption

Deleting a service may result in a service disruption for customers.

Consider the implication of deleting the service before proceeding.

76.11.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

As required, configure the filter criteria to locate the service or range of services to be deleted. A list of services appears.

3

Choose a service or a range of services from the list.

4

Click Delete. A warning form appears. This message is dynamic based on the priority of the service. Perform one of the following:

a. For services with a low priority, go to Step 5 .

b. For services with a medium priority, configure the “Enter the highest priority of the service being deleted” text field by typing: Medium. Go to Step 5 .

c. For services with a high priority, configure the “Enter the highest priority of the service being deleted” text field by typing: High. Go to Step 5 .

5

For all services regardless of how their priority is configured, acknowledge the check box that prompts you confirm that you understand the implications of deleting the service.

Note: If you select multiple services with different priorities, you must enter the highest priority level of selected services before you can delete the services.

6

Click Yes to confirm the action. The service is deleted and removed from the list.

7

Close the Manage Services form.

END OF STEPS

76.12 To configure service tunnel required bandwidth for the service

76.12.1 Prerequisites

To configure service tunnel required bandwidth, you must enable the Multi-Segment Tunnel Selection and Service Bandwidth Management checkboxes on the Services tab on the NFM-P System Preferences form. For more information, see the procedure to configure NFM-P system preferences in the *NSP System Administrator Guide*.

The following prerequisites apply for use of CAC:

- An LSP must be created between the required NEs. See 31.10 “To create a static LSP” (p. 1124) or 31.11 “To create a Dynamic LSP” (p. 1126).
- If a Tunnel Selection profile is used, the Tunnel Selection profile must contain MPLS: RSVP. See 33.13 “To create a tunnel selection profile” (p. 1201).
- For CAC on a Static LSP, the LSP must be configured using the NFM-P for all hops.
  Static LSPs and hops configured in the NE do not appear complete in the NFM-P.
- For CAC on an MLPPP port, MLPPP physical links must be created. See 4.10 “To create a physical link” (p. 183).

CAUTION

Service Disruption

Bandwidth management configuration/Static LSP/Physical link is lost if the NE is unmanaged from the NFM-P.

If management is re-started, bandwidth management parameters must be configured again.

76.12.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VLL service and click Properties. The *VLL_type* Service (Edit) form opens.

3

Click on the Bandwidth tab.

4

Configure the Bandwidth Method parameter.

5

If the Bandwidth Method parameter is set to Input Manually or Calculate from SAPs, configure LSP Path Booking and Service Path Booking parameters.

6

If the Bandwidth Method parameter is set to Input Manually, enter a required bandwidth value for each CoS (see CoS 0 Bandwidth - CoS 7 Bandwidth).

If the bandwidth values configured in the service and the site differ, the lower number will be used by the system.

7

Save the changes and close the forms.

END OF STEPS

76.13 To create an endpoint for a redundant VLL service

76.13.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VLL service and click Properties. The *VLL_type* Service (Edit) form opens.

3

On the navigation tree, expand Site, right-click on Endpoints and choose Create Endpoint. The Endpoint (Create) form opens.

4

Configure the required parameters.

Enable PW Standby Signaling Master and Enable PW Standby Signaling Slave parameters are configurable on VLL Epipes and Hpipes.

Active Multipath parameter is configurable on VLL Cpipes.

5

Save the changes and close the forms.

END OF STEPS

76.14 To associate a MEP or MIP with a VLL Epipe SDP binding

76.14.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an Epipe VLL and click Properties. The Epipe Service (Edit) form opens.

3

On the service tree, expand Sites→Spoke SDP Bindings, right-click on the spoke SDP binding you need to configure and choose Properties. The Spoke SDP Binding (Edit) form opens.

4

Click on the OAM tab, then on the ETH-CFM tab.

5

Configure the parameters in the MIP Configuration panel.

6

Configure the parameters in the Squelch Ingress Level panel.

Levels must be assigned contiguously from Level 0. If you select a level greater than 0, then all levels lower than the one you chose will automatically be selected.

The Squelch Ingress Levels configured for all the spoke bindings on a site can be compared in one view when you click on the Spoke SDP Bindings item below a site on the navigation tree. Use the scroll bar to locate the Squelch Ingress Level columns.

7

Configure the parameters on the LMM Session Stats Collection panel as required.

8

Create one or more MEPs:

1. In the MEPs panel, Click Create. The MEP (Create) form opens.
2. Select a maintenance entity group in the Maintenance Entity Group panel.
3. Configure the required parameters in the MEPs panel.
4. Configure the required parameters in the CCM panel.

   The CCM Padding Packet Size (Bytes) parameter cannot be configured when the CCM interval parameter is set to 10 ms or 100 ms.
5. Select a MEG sub-group in the MEG Sub-Grouping panel.
6. If the MD for the MEP has a Name Type of none and the associated MEG has a Name Format of icc-based, the Y.1731 Tests and AIS tabs are configurable; click on the Y.1731 Tests tab and configure the required parameters.

   The Eth Test Pattern parameter is configurable when the Eth Test Enabled parameter is enabled.
7. Click on the AIS tab and configure the required parameters.

   The AIS Meg Level parameter is configurable when the AIS Enabled parameter is enabled.
8. Save the changes and close the form.

9

Save the changes and close the forms.

END OF STEPS

76.15 To configure an MPLS-TP static pseudowire on a VLL spoke SDP binding

76.15.1 Prerequisites

An MPLS-TP service tunnel must be used in the SDP binding, and the Control Word parameter for pseudowire OAM must be set to Preferred. See 76.34 “To configure a spoke SDP binding on a VLL site” (p. 2161) .

76.15.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select an VLL service and click Properties. The VLL Service (Edit) form opens.

3

On the service tree, expand Sites→Spoke SDP Bindings, right-click on the spoke SDP binding you need to configure and choose Properties. The Spoke SDP Binding (Edit) form opens.

4

Click on the Control Channel tab.

5

Configure the required parameters.

6

Configure the static PW:

1. Click on the Static PW tab.
2. Click Create. The PW Path ID (Create) form opens.
3. Configure the Path AGI parameter.
4. Configure the parameters in the Source Attachment Individual Identifier panel.
5. Configure the parameters in the Target Attachment Individual Identifier panel.
6. Click OK. The PW Path ID (Create) form closes.

7

Save the changes and close the forms.

END OF STEPS

76.16 To clear BFD sessions and statistics on a VLL SDP binding

76.16.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select a VLL service and click Properties. The *VLL_type* Service (Edit) form opens.

3

On the service navigation tree, expand Sites→Spoke SDP Bindings and click on the spoke SDP binding on which you want to view the BFD session information.

4

Clear BFD sessions or statistics on the spoke SDP binding:

1. Click on the BFD tab, then on the BFD Session tab.
2. Click Clear All to clear all BFD sessions.
3. Click Clear All Statistics to clear all BFD statistics.

5

Close the forms.

END OF STEPS

76.17 To view the BFD session status on a VLL SDP binding

76.17.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select a VLL service and click Properties. The *VLL_type* Service (Edit) form opens.

3

On the service navigation tree, expand Sites→Spoke SDP Bindings and click on the spoke SDP binding on which you want to configure BFD.

4

Click on the BFD tab and view the status of the BFD session on the spoke SDP binding:

1. Click on the BFD Session tab.
2. Choose a BFD session and click Properties. The BFD Session (View) form opens.

5

Close the forms.

END OF STEPS

76.18 To switch to the redundant port for one or more VLL SAPs

76.18.1 Prerequisites

CAUTION

Service Disruption

Nokia recommends that you set the OLC state of a service to Maintenance before you switch to a redundant port or channel, and reset it to the previous state after the switch is complete. See the NSP System Administrator Guide for more information.

Perform this procedure from a service or site properties form when port redundancy is configured on one or more a Cpipe or Epipe SAPs to:

- switch to the backup port or channel assigned to the SAP, for example, in the event of a fault on the primary port or channel
- switch back to the primary port or channel assigned to the SAP, for example, after a fault condition on the primary port or channel is cleared

Note: When multiple SAPs are selected, switching is attempted only for the SAPs that support port redundancy and on which port redundancy is properly configured.
Port redundancy switching fails if the SAP or port is included in one of the following redundancy objects:

- BGP-MH
- MC-APS
- MC-LAG
- MC-ring

76.18.2 Steps

1

Perform one of the following.

a. Choose the SAPs from a port properties form:
   1. Choose Manage→Equipment→Equipment from the NFM-P main menu. The Manage Equipment form opens.
   2. Choose Port from the Select Object Type drop-down menu.
   3. Choose the required port and then click Properties. The Physical Port (Edit) form opens.
   4. Click on the L2 Access Interfaces tab.
   5. Choose the required SAPs and then click Properties. The L2 Access Interface (Edit) form opens.
   6. Click on the Port tab.
   7. Go to Step 5 .

b. Go to Step 2 to choose the SAPs from a service or site properties form.

2

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

3

Select the required VLL Cpipe or Epipe service and click Properties. The *VLL_type* Service (Edit) form opens.

4

Perform one of the following.

a. Choose the SAPs from a list of all SAPs in the service.
   1. Click on the L2 Access Interfaces tab. A list of SAPs that are configured on the service is displayed.
   2. Choose the required SAPs.

b. Choose the SAPs from a list of all of the SAPs on a site.
   1. Expand the Sites object in the service navigation tree.
   2. Click on the site object. The Site (Edit) form opens.
   3. Click on the Interfaces tab.
   4. Click on the L2 Access Interfaces tab. A list of all SAPs on the site is displayed.
   5. Choose the required SAPs.

5

Click Switch to Redundant SAP. A dialog box appears.

6

Click OK. The selected SAPs in the list are deleted, and new SAPs are created on the redundant port.

7

To confirm the redundancy status of a SAP:

1. Choose the SAP in the list and click Properties. The Port (Edit) form opens.
2. Click on the Port tab. The Manual Switch Backup State indicator displays one of the following:
   - Backup SAP in Use, if you switch from primary to backup
   - Backup Port Specified, if you switch from backup to primary

   Note:

   When the Manual Switch Backup State indicator reads Backup SAP in Use, the displayed port redundancy information is for the primary port of the SAP, and is read-only.

8

Close the forms.

END OF STEPS

76.19 To create a SAP aggregation group on a 7705 SAR Apipe

Note: SAP aggregation groups can be created only on Apipe services that are configured with the ATM VCC or ATM N:1-N>1 VC Type option. See 76.5 “To create a VLL service” (p. 2119) for more information about configuring the VC type.

A SAP aggregation group can contain up to 16 SAPs.

Alternatively, you can create SAPs for a SAP aggregation group by right-clicking on the L2 Access Interfaces entry and choosing the newly created SAP aggregation group.

The QoS and Accounting tabs are dimmed when an L2 access interface is assigned to a SAP aggregation group. The QoS and accounting policies that are assigned to the SAP aggregation group are automatically assigned to all of the SAPs in the group.

76.19.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an Apipe service with at least one 7705 SAR site and click Properties. The Apipe Service (Edit) form opens.

3

On the navigation tree, expand Site, right-click and choose Properties. The Site (Edit) form opens.

4

Click on the SAP Aggregation Group tab.

5

Click Create. The SAP Aggregation Group (Create) form opens.

6

Configure the required general parameters.

7

To configure QoS:

1. Click on the QoS tab.
2. Select an ingress policy for the SAP aggregation group in the Ingress Policy panel.
3. Select an egress policy for the SAP aggregation group in the Egress Policy panel.

8

To specify an accounting policy:

1. Click on the Accounting tab.
2. Select an accounting policy in the Accounting Policy panel.
3. Configure the Collect Accounting Statistics parameter.

9

Save the changes and close the form.

10

From the service navigation tree, expand the entries of the 7705 SAR site.

11

Right-click on the newly created SAP Aggregation Group entry and choose Create L2 Access Interface. The L2 Access Interface (Create) form opens.

12

Configure the required general parameters.

13

Click on the Port tab.

14

Select a terminating port for the L2 access interface in the Termination Port panel.

15

Configure the required parameters.

16

Click on the ATM tab and configure the required parameters.

17

Click on the QoS tab and select an ingress and egress ATM policy in the Ingress and Egress ATM Policy panels.

18

Save the changes and close the forms.

END OF STEPS

76.20 To configure EVPN on an Epipe site

76.20.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select the required Epipe and click Properties. The Epipe Service (Edit) form opens.

3

On the service tree, expand Sites and click on the site on which you want to configure a VXLAN.

4

In the General tab, configure the Source IP Address parameter in the VXLAN Tunnel End Point panel.

5

Click on the BGP tab, and then on the EVPN sub-tab.

6

In the BGP EVPN panel, click Create, or choose a BGP EVPN and click Properties. The BGP EVPN - Epipe Create/Edit form opens.

7

Configure the required parameters.

8

Configure the attachment circuits.

You can configure up to two local and two remote attachment circuits, on supporting NEs.

1. In the Local Attachment Circuit panel, click Create, or choose an item in the list and click Properties. The Local Attachment Circuit - Epipe Create/Edit form opens.
2. Configure the required parameters.
3. Save your changes and close the form.
4. In the Remote Attachment Circuit panel, click Create, or choose an item in the list and click Properties. The Remote Attachment Circuit - Epipe Create/Edit form opens.
5. Configure the required parameters.
6. Save your changes and close the form.

9

Configure the parameters in the MPLS panel, as required.

10

Configure the segment routing with IPv6.

1. In the Segment Routing V6 panel, click Create, or choose an item in the list and click Properties. The SRv6 BGP EVPN - Epipe Service Create/Edit form opens.
2. Configure the required parameters.
3. Save your changes and close the form.

11

Configure the parameters in the Auto Bind Tunnel panel, as required.

12

Configure a network identifier for the VXLAN.

1. Click Create in the VXLAN panel. The VXLAN (Create) form opens.
2. Configure the network identifier.
3. Configure the remaining parameters as required.
4. Click OK and confirm to close the form.

13

Save and close the form.

END OF STEPS

76.21 To create an HSDPA resiliency configuration

76.21.1 Prerequisites

See 76.2.4 “HSDPA Offload Resiliency” (p. 2110) in “VLL service management overview” (p. 2100) for information about HSDPA resiliency.

See 76.5 “To create a VLL service” (p. 2119) to create the required service before configuring HSDPA Resiliency.

76.21.2 Steps

1

Choose Manage→Redundancy→HSDPA Resiliency from the NFM-P main menu. The HSDPA Resiliency Manager form opens.

2

Click Create. The HSDPA Resiliency (Create) form opens.

3

Configure the required parameters.

4

Select a site in the Site panel.

5

Select a primary service in the Primary Service panel.

6

Select a secondary service in the Secondary Service panel.

7

Save the changes and close the forms.

8

Perform one of the following:

a. Perform 76.22 “To activate and manually operate an HSDPA resiliency configuration” (p. 2145) to turn up or manually operate an HSDPA resiliency configuration.

b. Close the HSDPA Resiliency Manager form.

END OF STEPS

76.22 To activate and manually operate an HSDPA resiliency configuration

76.22.1 Prerequisites

See 76.2.4 “HSDPA Offload Resiliency” (p. 2110) for more information.

76.22.2 Steps

1

Choose Manage→Redundancy→HSDPA Resiliency from the NFM-P main menu. The HSDPA Resiliency Manager form opens.

2

Choose the required HSDPA resiliency configuration from the displayed list and click Properties. The HSDPA Resiliency (Edit) form opens with the properties of the configuration displayed on the General tab.

The Active Service field displays whether the Primary or Secondary Service is active. When you initially want to turn up a resiliency configuration, typically Primary is displayed.

3

Set the Administrative State parameter to Disabled. Activity for the resiliency configuration can only be manually switched from this form when this parameter is set to Disabled.

4

Perform one of the following:

a. Set the Administrative State parameter to Enabled. Activity automatically switches between the primary and secondary services as required when this parameter is enabled.

b. Click Turn Up to manually activate the HSDPA resiliency configuration. Do this if the Administrative State parameter is not enabled.

c. If the Primary Service is currently active, you can click Force Secondary Service Active. This manually forces the configuration to the Secondary Service (if up), regardless of state of damping timer. The Active Service field displays Secondary if the switchover is successful.

d. If the Secondary Service is currently active, you can click Force Primary Service Active. This manually forces the configuration to the Primary Service (if up), regardless of state of damping timer. The Active Service field displays Primary if the switchover is successful.

e. Click Shut Down to de-activate the HSDPA resiliency configuration.

f. Click on the Faults tab to view and address alarms related to the configuration.

5

Close the forms.

END OF STEPS

76.23 To run an OAM validation test for a VLL service

76.23.1 Prerequisites

An OAM validator test suite must be created for the tested entity. See Chapter 89, “Service Test Manager” for more information about how to create a validator test suite.

Note: As an alternative, you can also run an OAM validation test on the service by performing a One Time Validation. This is a mostly automated procedure and is described in 90.55 “To run a one-time validation test on a service” (p. 3084) .

76.23.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a service and click Properties. The VLL *Type_of_VLL* (Edit) form opens.

3

Click Validate. If an OAM validator test suite is not associated to the service, a dialog box appears:

1. Click OK to associate the service with an existing OAM validator test suite.
2. Select an OAM validator test suite.

4

View the State Cause indicators. When the validation test fails, a check mark appears beside the OAM Validation Failure indicator.

5

Click on the Tests tab. The Test Suite tab is displayed.

6

Click on the Tested Entity Result tab.

7

Choose an entry and click Properties. The Tested Entity Result (Edit) form opens.

8

Click on the Results tab to display the validation test results.

9

If you need to compare two test results from the same type of test, choose the two test results and click Compare; the Difference form opens. Otherwise, go to Step 12 .

10

Compare the test results.

11

Close the Difference form.

12

Close the forms.

END OF STEPS

76.24 To create a BGP VPWS

76.24.1 Steps

1

Enable and configure BGP on the NEs involved in the BGP VPWS. See "BGP configuration workflow and procedures" (p. 914) for information about how to configure BGP.

2

Create and distribute a Service PW template policy to the NEs involved in the VPWS. See Chapter 83, "Service PW template policies" for more information about how to use Service PW template policies. You must set the VC-Type parameter to VLAN.

3

Create a routing policy statement to define the required community members. See 54.5 "To configure a routing policy statement" (p. 1745) . This defines the VSI Import/Export Routing Targets.

4

Create an Epipe service. See 76.5 "To create a VLL service" (p. 2119) for information about how to create an Epipe service.

5

Create the Epipe sites for the BGP VPWS. See 76.28 "To configure a VLL site" (p. 2154) for information about how to create an Epipe site.

Note: Epipe switching sites can have only one spoke SDP binding configured when BGP VPWS is enabled.

When BGP VPWS is enabled on an Epipe switching site, the tunnel used in the spoke SDP binding must be GRE with no signaling.
You cannot enable BGP VPWS if there are more than one spoke SDP bindings on the switching site, or if there is one or more spoke SDP bindings with a non-GRE tunnel.

6

Select one of the Epipe sites you created in Step 5 . The Site Epipe Service (Edit) form appears.

7

Click on the BGP tab.

8

Enable the Enable BGP parameter. The BGP panel is displayed.

9

Click Create. The BGP Configuration form opens.

10

Configure the Route Distinguisher parameter.

11

Click on the PW Template Binding tab and perform one of the following:

a. Select an existing PW Template Binding.

b. Add a new PW Template Binding. Go to Step 12 .

12

Create one or more PW Template Bindings:

1. Click Create. The PW Template Binding (Create) form opens.
2. Select the PW Template you created in Step 2 .
3. Select an endpoint if needed.
4. Click on the BFD tab and configure the required BFD parameters.
5. Click on the PW Template Binding Route Target tab and click Create. The PW Template Binding Route Target (Create) form opens.

   Note:

   This Import Route Target is used by the NE to decide which PW Template to use to create SDP bindings. If a far-end neighbor has a matching export target (that is, to the PW Template Import Target being defined here), then this PW Template is selected by the NE to create the pseudowire that is used to link both sites of the VPWS. If nothing is entered, and multiple PW Templates are defined, the first one found by the NE is used (most likely the one with the lowest PW Template Policy ID).

Enter the required Import Route Target in the field and click OK. The PW Template Binding Route Target (Create) form closes and the entered Import Route Target is displayed in the table on the PW Template Binding Route Target tab.

6. Click OK. The PW Template Binding (Create) form closes and the new PW Template Binding is displayed in the table on the PW Template Binding tab.
7. Select the required entry or entries from the list.

13

Click on the VSI Import Policies tab and select up to five import policies. Alternatively, you can enter the policy names manually.

14

Perform one of the following:

a. Enter the Import Route Target name manually in the provided field. The format be “target:x:y”.

b. Select an import route target. The community members you defined when creating a routing policy in Step 3 can be selected.

15

Click on the VSI Export Policies tab and select up to five export policies. Alternatively, you can enter the policy names manually.

16

Perform one of the following:

a. Enter the Export Route Target name manually in the provided field. The format must be “target:x:y”.

b. Select an export route target. The community members you defined when creating a routing policy in Step 3 can be selected.

17

Save the changes and close the BGP Configuration form.

18

Configure the parameters on the VPWS tab.

19

Create a remote VE instance, if required.

1. In the Remote VE Instances panel, click Create. The BGP VPWS Remote VE (New) form opens.
2. Configure the parameters.

20

Configure the parameters in the EVPN tab.

21

Click Apply.

22

Repeat Step 6 to Step 21 for each site in the VPWS. When the sites have been configured, endpoints and associated spoke SDP bindings are automatically created by the nodes.

END OF STEPS

76.25 To view ECMP/LAG hashing of Epipe services

76.25.1 Purpose

Perform this procedure to view the distribution of Epipe service traffic over a LAG and/or ECMP paths into the network. The Show Service Hashing menu command issues a CLI tools dump command to an NE. The CLI command can be issued from a specific LAG on an NE, or from an Epipe service site.

When you issue this command from a LAG, only the actual number of Epipe services currently using the physical port of the LAG will be displayed.

Alternatively, you can issue this command from an Epipe site that uses a port associated with a LAG. When you specify a range of Epipe Service IDs, the procedure will display information on all the Epipe services within that range that are using the same LAG as their egress port.

This procedure is only applicable to 7750 SR NEs and is not supported for PBB Epipe services.

76.25.2 Steps

1

Perform one of the following:

a. To run the Show Service Hashing command from a LAG:

1. Choose Equipment from the navigation tree view selector.
2. Navigate to the LAG icon by choosing Network→<required NE>→Logical Groups→LAGs→<required LAG>.
3. Right-click on the required LAG icon and choose Show Service Hashing from the menu.

   The Epipe LAG Show Service Hashing form opens and displays the total number of Epipe services currently using the physical port of the LAG.

   If an error is detected (for example, an invalid login), then error debugging information will be provided.

b. To run the Show Service Hashing command from an Epipe site that uses a LAG:

1. Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.
2. Configure the filter criteria. A list of services appears at the bottom of the Manage Services form.
3. Select the required Epipe service and click Properties. The Epipe Service (Edit) form opens.
4. In the navigation tree on the left side of the form, navigate to the required Epipe site.
5. Right-click on the site icon and choose Show Service Hashing from the menu. The Epipe Service Show Service Hashing form opens.
6. Enter the desired value in the End Service Id field. This is the highest Service ID in a range of up to 1024 service IDs that will be examined. It can have a value of 0 to 2147483650. The Epipe service from which you issued this command has the lowest Service ID in the range of services that will be examined. So if, for example, the Epipe has a Service ID of 100, then Service IDs up to 1124 will be examined.

   Entering a value of 0 in the End Service Id field indicates that the Service ID will not be considered. In this case, only the total number of Epipe services currently using the same physical port as the site's LAG will be displayed.
7. Click OK.

   The Epipe Service Show Service Hashing form opens and displays specific information on all Epipe services currently using the same physical port as the site's LAG.

   If an error is detected (for example, an invalid login), then error debugging information will be provided.

2

Click Close. The Show Service Hashing form closes.

END OF STEPS

76.26 To view the local PW status information for a VLL service

76.26.1 Purpose

Perform this procedure to view the state cause information for the near end of a VLL spoke SDP binding.

76.26.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Configure the filter criteria. A list of services appears.

3

Choose the service and click Properties. The VLL *Type_of_VLL* (Edit) form opens.

4

Click on the Spoke SDP Bindings tab.

5

Select an entry and click Properties. The Spoke SDP Binding (Edit) form opens.

6

Click on the States tab.

7

View the information in the Local State Cause panel. When there is a local fault, a check mark beside the appropriate indicator identifies the fault type.

8

Close the Spoke SDP Binding (Edit) form.

9

Close the VLL *Type_of_VLL* (Edit) form.

END OF STEPS

76.27 To view the peer PW status information for a VLL service

76.27.1 Purpose

Perform this procedure to view the state cause information for the far end of a VLL spoke SDP binding.

76.27.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Configure the filter criteria. A list of services appears.

3

Choose the service and click Properties. The VLL *Type_of_VLL* (Edit) form opens.

4

Click on the Spoke SDP Bindings tab.

5

Choose an entry and click Properties. The Spoke SDP Binding (Edit) form opens.

6

Click on the States tab.

7

View the peer status information in the Peer State Cause panel. When the service tunnel or peer SAP is down or partially down, a check mark beside the appropriate indicator identifies the fault type.

8

Close the Spoke SDP Binding (Edit) form.

9

Close the VLL *Type_of_VLL* (Edit) form.

END OF STEPS

VLL site management procedures

76.28 To configure a VLL site

76.28.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VLL service and click Properties. The *VLL_type* Service (Edit) form opens.

3

On the navigation tree, right-click on *VLL_type* Service and choose Create *VLL_type* Site and select an NE, or right-click on a site and choose Properties. The *VLL_type* Site (Create|Edit) form opens.

4

Configure the required general parameters.

The Enable CE IP Address Discovery parameter is configurable only for VLL Ipipe terminating sites.

On Ipipe sites, the Stack Capability Signaling parameter is configurable only when the Enable IPv6 parameter and the Enable CE IP Address Discover parameters are enabled.

The VLL Site Type parameter is displayed as read-only for the 7950 XRS, as only switching VLL sites are supported.

You must set the VLL Site Type parameter to Terminating if the site is connected to a 7210 SAS-D, 7210 SAS-E, 7210 SAS-K, 7210 SAS-M, 7210 SAS-Mxp, 7210 SAS-S, 7210 SAS-Sx, or 7210 SAS-T.

On 7210 SAS sites:

- the SAP Type parameter is configurable when the VLL Site Type parameter is set to Terminating
- when you configure a 3-plus-tag Epipe service, you must set the SAP Type parameter to qinq-inner Tag-preserve. See “Epipe (Ethernet VLL)” (p. 2100) in “VLL service management overview” (p. 2100) . See 76.34 “To configure a spoke SDP binding on a VLL site” (p. 2161) and 76.40 “To create a VLL L2 access interface on a terminating site” (p. 2174) for additional configuration requirements for a 3-plus-tag Epipe service.
- when you configure a VLAN range SAP on the site, you must set the SAP Type parameter to dot1q-range.

On 7210 SAS-X sites, the PBB Epipe parameter is configurable when the VLL Site Type parameter is set to Terminating.

5

To assign test generation options to the site:

1. Click on the OAM tab, then the Configuration tab.
2. Configure the required Test Generation Options parameters.

6

Save the changes and close the forms.

END OF STEPS

76.29 To configure a GNE site on a VLL service

76.29.1 Purpose

Use this procedure to add a GNE site and GNE service interfaces to an existing VLL service. This procedure applies to VLL Epipe, Apipe, Fpipe, Ipipe, and Cpipe services. This procedure also applies to Wavence VLL Epipe, Apipe, and Cpipe services.

76.29.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select a VLL service and click Properties. The *VLL_type* Service (Edit) form opens.

3

On the component tree, right-click on *VLL_type* Service and choose Create GNE Site. The Select Network Elements - *VLL_type* Service form opens with a list of available NEs.

4

Choose a site and click OK. The GNE Site (Create) form opens.

5

Configure the required parameters.

6

Click Apply.

7

To configure an interface for the GNE site:

1. Click on the GNE Service Interfaces tab and then Click Create. The GNE Service Interface (Create) form opens.
2. Configure the parameters.
   - Name
   - Description
   - Type
3. Click on the Ports tab and then click Select beside the Interface Index field. The Select Generic NE Interface form appears.
4. Select an interface from the list and click OK. The GNE Service Interface (Create) form reappears with the interface information displayed.
5. Configure the parameters.
   - Encapsulation Type
   - Outer Encapsulation Value
   - Inner Encapsulation Value
6. Click OK. The GNE Site (Create) form reappears with the interface information displayed in the service component tree.

8

Save the changes and close the forms.

END OF STEPS

76.30 To configure service tunnel required bandwidth for the site

76.30.1 Prerequisites

To configure service tunnel required bandwidth, you must enable the Multi-Segment Tunnel Selection and Service Bandwidth Management checkboxes on the Services tab on the NFM-P System Preferences form. For more information, see the procedure to configure NFM-P system preferences in the *NSP System Administrator Guide*.

The following prerequisites apply for use of CAC:

- An LSP must be created between the required NEs. See 31.10 “To create a static LSP” (p. 1124) or 31.11 “To create a Dynamic LSP” (p. 1126).
- If a Tunnel Selection profile is used, the Tunnel Selection profile must contain MPLS: RSVP. See 33.13 “To create a tunnel selection profile” (p. 1201).
- For CAC on a Static LSP, the LSP must be configured using the NFM-P for all hops.
  Static LSPs and hops configured in the NE do not appear complete in the NFM-P.
- For CAC on an MLPPP port, MLPPP physical links must be created. See 4.10 “To create a physical link” (p. 183).

CAUTION

Service Disruption

Bandwidth management configuration/Static LSP/Physical link is lost if the NE is unmanaged from the NFM-P.

If management is re-started, bandwidth management parameters must be configured again.

76.30.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VLL service and click Properties. The *VLL_type* Service (Edit) form opens.

3

On the navigation tree, expand Sites, right-click the site on which you want configure bandwidth, and choose Properties.The VLL Site (Edit) form opens.

4

Click on the Bandwidth tab.

5

Enable the Override Service Configuration parameter.

6

Configure the Bandwidth Method parameter.

7

If the Bandwidth Method parameter is set to Input Manually, enter a required bandwidth value for each CoS (see CoS 0 Bandwidth - CoS 7 Bandwidth).

If the bandwidth values configured in the service and the site differ, the lower number will be used by the system.

8

Save the changes and close the forms.

END OF STEPS

76.31 To link an Epipe service to a backbone VPLS site

76.31.1 Prerequisites

For additional information on Provider Backbone Bridging, see Chapter 77, “VPLS management ” .

76.31.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VLL service and click Properties. The Epipe Service (Edit) form opens.

3

On the navigation tree, expand the Sites icon, right-click the site on which you want to link the VPLS site and choose Properties.The Epipe Site (Edit) form opens.

4

Click on the Backbone tab.

On the 7210 SAS-M, 7210 SAS-T, and 7210 SAS-X, the Backbone tab is configurable only if you enabled the PBB Epipe parameter in 76.28 “To configure a VLL site” (p. 2154) .

5

Select a VPLS in the Backbone VPLS Site panel.

Note: The B-Sites listed are only those that are on the same NE type as the Epipe site. See 77.24 “To create a B-site for VPLS or MVPLS” (p. 2283) for more information.
The selection of a B-Site in this step must be repeated for both Epipe sites. You must select a B-Site that is on the same NE as the Epipe site.

6

In the PBB panel, configure the required parameters.

The ISID parameter is configurable when the Inherit Service ID Value parameter is disabled.

Note: The ISID parameter should be set to the same value for both Epipe sites you create for this service.
To select a previously created Mac Name, click Select and then select a MAC Name from the list in the Select MAC Destination MAC Address Alias form. See 12.31 “To create a chassis-level PBB configuration” (p. 367) for more information about how to create a MAC Name.
The Destination MAC Address or MAC Name parameter you set for this Epipe site should be the same as the Source MAC Address of the B-Site on the other node of the Epipe service you are creating.

7

Configure the Force Q Tag Forwarding parameter.

8

Configure the Local Switching Service State parameter.

9

Save the changes and close the forms.

END OF STEPS

76.32 To associate a Facility MEP with a VLL Epipe site

76.32.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an Epipe VLL service and click Properties. The Epipe Service (Edit) form opens.

3

On the navigation tree, expand Sites, right-click the site and choose Properties. The Epipe Site (Edit) form opens.

4

Click on the OAM tab, and then on the ETH-CFM tab.

5

Configure the Tunnel Fault Notification parameter in the Facility MEPs panel.

The Tunnel Fault Notification parameter is configurable on sites where the device has ports configured in access or hybrid mode with QinQ encapsulation. If you are configuring a tunnel facility MEP, this parameter must be set to Accept, in order to accept the fault notification from the tunnel facility MEP.

6

Save the changes and close the forms.

END OF STEPS

76.33 To configure segment routing with IPv6 on a VLL Epipe site

76.33.1 Before you begin

The segment routing with IPv6 can be configured on 7450 ESS, 7750 SR, 7950 XRS, and IXR NEs. This configuration applies to SR and IXR from NFM-P Release 23.11 and node releases 22.2 and 22.10 onwards.

76.33.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an Epipe VLL service and click Properties. The Epipe Service (Edit) form opens.

3

On the navigation tree, expand Sites, right-click the site and choose Properties. The Epipe Site (Edit) form opens.

4

Click on the Segment Routing V6 tab.

5

Configure the required parameters in the General tab.

6

Create or select an entry in the Locator panel and click Properties. The SRv6 Function (Create/Edit) form opens.

1. Associate a locator under Locator panel.
2. Configure the parameters under End Function DX2 panel.
3. Save your changes and close the form.

7

Save your changes and close the forms.

END OF STEPS

76.34 To configure a spoke SDP binding on a VLL site

76.34.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VLL service and click Properties. The *VLL_type* Service (Edit) form opens.

3

On the service tree, expand Sites→Spoke SDP Bindings, right-click and choose Create SDP Spoke Binding, or expand Spoke SDP Bindings, right-click on a circuit and choose Properties. The Spoke SDP Binding (Create|Edit) form opens.

4

Specify a destination NE for the spoke SDP binding:

a. If the tunnel termination site is a managed NE, select an NE from a list of managed NEs.

b. If the tunnel termination site is an unmanaged NE, specify the system ID for the Tunnel Termination Site parameter.

5

Configure the required general parameters.

The VC ID parameter is configurable when the Auto-Assign ID parameter is disabled.

The Block On Peer Fault parameter takes effect only when PW status signaling is enabled.

The Block On Peer Fault parameter is not configurable on a spoke SDP that is on an MC LAG or an endpoint.

You must configure the VLAN VC Tag parameter with the same value as the inner tag of the QinQ SAP on the service. See “Epipe (Ethernet VLL)” (p. 2100) in “VLL service management overview” (p. 2100) for more information. See 76.28 “To configure a VLL site” (p. 2154) and 76.40 “To create a VLL L2 access interface on a terminating site” (p. 2174) for additional configuration requirements for a 3-plus-tag Epipe service.

The SDP Admin Bandwidth parameter is not configurable if you select an MPLS-TP tunnel in Step 6 .

The range of the Ingress Label parameter depends on the parameter value set for the Static Label Range on the MPLS instance. See 31.6 “To configure an MPLS instance” (p. 1116) .

The Override Service MTU parameter is only configurable on SDP bindings in a Epipe service. Configuring this parameter to any value other than -1 uses that value for the MTU size, instead of the value configured at the service level. When the value is -1, the service-level MTU is used.

6

To specify a transport tunnel for the spoke SDP binding:

a. Configure the transport tunnel manually by selecting a service tunnel for the SDP binding in the Tunnel panel.

Note: The NFM-P blocks the manual selection of a tunnel with insufficient bandwidth if the server configuration includes the following parameter setting:
<vll-CAC enforceTunnelBandwidth="true"/>
The parameter is set to false by default, which means that the NFM-P does not block the manual selection of a tunnel with insufficient bandwidth; instead, the “Insufficient Bandwidth To Allocate To SDP Binding” State Cause indicator is set.
To change the parameter setting, contact Nokia technical support.

b. For Apipe and Cpipe VLLs, configure an MPLS-TP transport tunnel manually by selecting a tunnel in the Tunnel panel. See 33.9 “To create an IP/MPLS service tunnel” (p. 1190) for more information about how to create an MPLS-TP service tunnel.

c. Let the NFM-P configure the transport tunnel automatically.

1. Enable the Auto-Select Transport Tunnel parameter.
2. Configure either the Profile Name or the Tunnel Auto-Selection Transport Preference parameter.

7

To create redundant SDP bindings, configure the endpoint in the Redundancy panel.

1. Select an endpoint in the Redundancy panel.
2. Configure the parameters.

   When the Precedence parameter is set to 0, you can configure a secondary SAP on an ATM interface, MC-APS, or APS for HSPDA offload fallback.

8

To specify a transport tunnel for the Return SDP binding:

Note: You can create a return tunnel only between sites that are in the same service. If the sites are not in the same service, the Return tab does not appear.
When the Auto Select Return Transport Tunnel parameter is enabled, NFM-P will consider and use a portion of the bandwidth you specified when setting the SDP Admin Bandwidth parameter in Step 5 .

a. Allow the NFM-P to configure the transport tunnel automatically by clicking on the Return tab, enabling the Auto Select Return Transport Tunnel parameter and selecting a tunnel selection profile beside the Profile name parameter. See 33.13 “To create a tunnel selection profile” (p. 1201) for more information about how to create a service tunnel profile.

b. Allow the NFM-P to configure the transport tunnel automatically by clicking on the Return tab, and enabling the Auto Select Return Transport Tunnel and Return Tunnel Auto-Selection Transport Preference parameters.

c. Configure the transport tunnel manually, by clicking on the Return tab, selecting a return tunnel in the Return Tunnel panel.

9

Select a return endpoint on the terminating site in the Return SDP Binding Endpoint panel.

10

Configure the parameters in the Hash Label panel, if supported.

11

Configure the Force VLAN VC Forwarding parameter in the VLAN panel.

The Force VLAN VC Forwarding parameter is configurable only on Epipe SDP bindings.

You cannot enable the Force VLAN VC Forwarding parameter if you enable the Force Q-in-Q VC Forwarding parameter in Step 12 .

12

Configure the Force Q-in-Q VC Forwarding parameter in the Q in Q panel.

The Force Q-in-Q VC Forwarding parameter is configurable only on Epipe SDP bindings.

You cannot enable the Force Q-in-Q VC Forwarding parameter if you enable the Force VLAN VC Forwarding parameter in Step 11 .

13

To configure QoS:

1. Click on the QoS tab.
2. Select a network policy and configure the required parameters in the Forwarding Plane Redirect panel.
3. Select an ingress queue group template policy in the Forwarding Plane Redirect panel.
4. Configure the Instance ID parameter in the Forwarding Plane Redirect panel.
5. Select a network policy and configure the required parameters in the Port Redirect panel.
6. Select an egress queue group template policy in the Port Redirect panel.
7. Configure the Instance ID parameter in the Port Redirect panel.

14

Click on the States tab and configure the Administrative State parameter.

15

To configure BFD:

1. Click on the BFD tab.
2. Enable the Enable BFD parameter.

3. Select a BFD template in the BFD Template panel.

16

To configure pseudowire OAM:

1. Click on the Pseudowire OAM tab.
2. Configure the Control Word parameter.

   If you are creating a spoke SDP binding using an MPLS-TP service tunnel for pseudowire static configuration, you must set the Control Word parameter to Preferred.

   For Apipes, if you set the VC Type parameter to ATM-SDU in Step 3 of 76.5 “To create a VLL service” (p. 2119) , you must set the Control Word parameter to Preferred.

   For Fpipes, if you set the VC Type parameter to FR-DLCI in Step 3 of 76.5 “To create a VLL service” (p. 2119) , you must set the Control Word parameter to Preferred.

   For Hpipes, if you set the VC Type parameter to HDLC in Step 3 of 76.5 “To create a VLL service” (p. 2119) , you must set the Control Word parameter to Preferred.

17

To assign ingress and egress filter policies to the spoke SDP binding:

1. Click on the ACL tab.
2. Select an ingress filter in the Ingress Filter panel.
3. Select an egress filter in the Egress Filter panel.
4. Select an IPv6 ingress filter in the IPv6 Ingress Filter panel.

18

To assign an accounting policy to the SDP binding:

1. Click on the Accounting tab.
2. Configure the Collect Accounting Statistics parameter.
3. Select an accounting policy in the Accounting policy panel.

19

To configure security:

1. Click on the Security tab.
2. Enable the IP Src Monitoring parameter.

20

To assign an Application Profile to the spoke SDP binding:

1. Click on the Application Assurance tab.
2. Select an application profile string.

You can select only local profiles on the NE.

3. To associate a transit IP policy with an Epipe service object, select a transit IP policy in the Transit IP Policy panel.

   See 87.46 “To configure an AA transit IP policy” (p. 2860) for more information about how to configure a transit IP policy.

4. To associate an AA transit prefix policy with the service object, select a transit prefix policy in the Transit Prefix Policy panel.

   See 87.47 “To configure an AA transit prefix policy” (p. 2861) for more information about how to configure a transit prefix policy.

5. To associate an AA redundant protocol with an Epipe service object, select an AA redundant protocol in the AA Redundant Protocol panel.

21

Perform one of the following:

a. If you are configuring a VLL with spoke switching, you must configure a switching site and two or more terminating sites. Repeat 76.28 “To configure a VLL site” (p. 2154) to configure more sites, and repeat Step 1 through Step 22 of this procedure.

b. If you are configuring a PBB Epipe, you can only configure one Spoke SDP. Go to Step 22 .

22

Save the changes and close the forms.

END OF STEPS

76.35 To configure a spoke SDP binding with an L2TPv3 tunnel on a VLL Epipe site

76.35.1 Prerequisites

See 33.11 “To configure an L2TPv3 service tunnel” (p. 1199) for more information about how to create an L2TPv3 tunnel.

Note: You can configure only one spoke SDP binding on each site.

76.35.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VLL service and click Properties. The Epipe Service (Edit) form opens.

3

On the service tree, expand Sites→Spoke SDP Bindings, right-click and choose Create SDP Spoke Binding, or expand Spoke SDP Bindings, right-click on a spoke SDP binding and choose Properties. The Spoke SDP Binding (Create|Edit) form opens.

4

Specify a destination NE for the spoke SDP binding:

a. If the destination NE is a managed NE, select an NE from a list of managed NEs.

b. If the destination NE is an unmanaged NE, specify the system ID for the Tunnel Termination Site parameter.

5

Configure the required general parameters.

The range of the Ingress Label parameter depends on the parameter value set for the Static Label Range on the MPLS instance. See 31.6 “To configure an MPLS instance” (p. 1116) .

6

Configure the L2TPv3 transport tunnel.

1. Select an L2TPv3 transport tunnel in the Tunnel panel. See 33.11 “To configure an L2TPv3 service tunnel” (p. 1199) for more information about how to create an L2TPv3 tunnel.
2. Configure the parameters in the L2TPv3 Cookie panel.

7

To configure QoS:

1. Click on the QoS tab.
2. Select a network policy and configure the required parameters in the Forwarding Plane Redirect panel.
3. Select an ingress queue group template policy in the Forwarding Plane Redirect panel.
4. Configure the Instance ID parameter in the Forwarding Plane Redirect panel.
5. Select a network policy and configure the required parameters in the Port Redirect panel.
6. Select an egress queue group template policy in the Port Redirect panel.
7. Configure the Instance ID parameter in the Port Redirect panel.

8

Click on the States tab and configure the Administrative State parameter.

9

To configure pseudowire OAM:

1. Click on the Pseudowire OAM tab.

2. Configure the Control Word parameter.

   If you are creating a spoke SDP binding using an MPLS-TP service tunnel for pseudowire static configuration, you must set the Control Word parameter to Preferred.

   For Apipes, if you set the VC Type parameter to ATM-SDU in Step 3 of 76.5 “To create a VLL service” (p. 2119) , you must set the Control Word parameter to Preferred.

   For Fpipes, if you set the VC Type parameter to FR-DLCI in Step 3 of 76.5 “To create a VLL service” (p. 2119) , you must set the Control Word parameter to Preferred.

   For Hpipes, if you set the VC Type parameter to HDLC in Step 3 of 76.5 “To create a VLL service” (p. 2119) , you must set the Control Word parameter to Preferred.

10

To assign ingress and egress filter policies to the spoke SDP binding:

1. Click on the ACL tab.
2. Select an ingress filter in the Ingress Filter panel.
3. Select an egress filter in the Egress Filter panel.
4. Select an IPv6 ingress filter in the IPv6 Ingress Filter panel.

11

To assign an accounting policy to the SDP binding:

1. Click on the Accounting tab.
2. Configure the Collect Accounting Statistics parameter.
3. Select an accounting policy in the Accounting policy panel.

12

To configure security:

1. Click on the Security tab.
2. Enable the IP Src Monitoring parameter.

13

To assign an Application Profile to the spoke SDP binding:

1. Click on the Application Assurance tab.
2. Select an application profile string.

   You can select only local profiles on the NE.
3. To associate an AA transit prefix policy with the service object, select a transit prefix policy in the Transit Prefix Policy panel.

   See 87.47 “To configure an AA transit prefix policy” (p. 2861) for more information about how to configure a transit prefix policy.

14

Save the changes and close the forms.

END OF STEPS

76.36 To create a spoke SDP FEC binding on a VLL Epipe site

76.36.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VLL service and click Properties. The Epipe Service (Edit) form opens.

3

On the service tree, expand Sites→Spoke SDP FECs, right-click and choose Create Spoke SDP FEC. The Spoke SDP FEC (Create) form opens.

4

Configure the required general parameters.

5

In the Source panel, select an SAII address.

6

In the Target panel, configure the Auto Config parameter or select a TAII address.

7

In the General Parameters panel:

1. Configure the parameters.
2. Select a path.

8

In the Redundancy panel:

1. Select an endpoint.
2. Configure the parameters.

9

In the Pseudowire Signaling panel, configure the Enable PW Standby Signaling Slave parameter.

10

Save the changes and close the forms.

END OF STEPS

76.37 To configure an Epipe site for BGP multi-homing

76.37.1 Prerequisites

Configure an Epipe site for BGP multi-homing to allow for multi-homed connectivity to G.8031 Ethernet tunnels between two CEs. G.8031 resiliency is used on the edges and then pseudowires are allowed to reach the far end, where G.8031 can again be used in a multi-chassis mode.

G.8031 is created on two CEs which are multi-homed to two PEs. Using BGP and CFM, PE routers enable or disable the CE-PE SAPs. The core is IP/MPLS and Epipe is used for transport between the PEs. The Ethernet tunnels are created on the CEs and the Epipe service on the CEs uses these tunnels.

76.37.2 Steps

1

Before you configure a site for BGP multi-homing, you must either:

a. Enable BGP on the routing instance of each NE in the Epipe BGP multi-homing configuration. See 28.29 “To enable BGP on a routing instance” (p. 916) for more information.

b. Configure global-level BGP on each NE in the Epipe BGP multi-homing configuration. See 28.31 “To configure global-level BGP” (p. 918) for more information. The following items are required:

- Enable the L2 VPN parameter on:
  - the VPN tab of the BGP site form
  - the VPN tab of the BGP Peer Group form, which contains the peers that are involved in the BGP multi-homing
- Create a peer group under BGP. This peer group is used to collectively define the peers involved in the Epipe BGP multi-homing configuration.
- Create the required peers under the peer group. These peers are the NEs involved in the Epipe BGP multi-homing configuration.

Note: For optimal processing while a BGP multi-homing site is activated or de-activated, or the system is rebooted, you should also:

- Enable the L2 VPN parameter in the Rapid Update Address Family panel on the BGP site VPN tab.

- Enable the Enable Rapid Withdrawal parameter on the BGP site Behavior tab.

2

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

3

Choose a VLL service and click Properties. The Epipe Service (Edit) form opens.

4

On the service navigation tree, right-click on Epipe Service and choose Create Epipe Site, or right-click on a site and choose Properties. The Epipe Site (Create|Edit) form opens.

Note: You can see a list of all current Epipe multi-homing service sites by viewing the BGP Multi-homing tab on the service configuration form.

5

Configure the general BGP parameters:

1. Click on the BGP tab, then on the General tab, and enable the Enable BGP parameter.
2. Configure the Route Distinguisher parameter in the RD panel. Enabling the Show Format checkbox displays a list of acceptable formats and value ranges.

   Note:

   An RD or RT configured under the BGP of an Epipe site cannot be removed as long as there is a multi-homing site configured that uses these and whose administration state is up.
3. Configure the Import Route Target and Export Route Target parameters in the RT panel. Enabling the Show Format checkbox displays a list of acceptable formats and value ranges.

   You can also configure the Export Route Target to be the same as the Import Route Target by enabling the Same as Import checkbox.

6

To configure multi-homing:

1. Click on the Multi-homing tab.
2. Click Create. The BGP Multi-homing Site (Create) form opens.
3. Configure the required parameters.

   You cannot turn up a BGP multi-homing site without specifying a Multi-homing ID. In addition, the Multi-homing ID of the site can only be removed at a later time when the site is shutdown.
4. Select a SAP for the BGP multi-homing in the Enable BGP Multi-homing to SAP panel.

You cannot turn up a BGP multi-homing site without specifying a SAP. The SAP configured under this site can be part of an endpoint, but the only other object allowed in the endpoint is an ICB spoke-SDP. In addition, an assigned SAP can only be removed at a later time when the BGP multi-homing site is shutdown.

5. Configure the parameters in the Timer panel.

   If you enable either the Use Node Level Boot Timer and/or Use Node Level Site Activation Timer parameters, then the associated Boot Timer (seconds) and/or Activation Timer (seconds) parameters are not configurable. These parameter values are inherited from the network element configuration.

   The Boot Timer (seconds) and Activation Timer (seconds) parameters can be configured for an NE on the BGP Multi-homing sub-tab under the Redundancy tab in the Network Element (Edit) form. See 12.5 “To modify NE properties” (p. 343) for more information about how to change device properties.

   If you enable the Use Node Level Site-Down Minimum Timer parameter, the Site-Down Minimum Timer (seconds) parameter and Site-Down Minimum Timer Remaining (seconds) parameters are ignored and the values configured on the NE are used.

6. Configure the Administrative State parameter in the States panel.
7. Save the changes and close the form.

7

Save the changes and close the forms.

END OF STEPS

76.38 To enable the automatic selection of an RD on a VLL Epipe site

76.38.1 Prerequisites

Since an RD must be unique on each PE in the network, you can allocate either a route distinguisher that you manually select or an NE-selected route distinguisher for each service. When you configure an auto-RD on a VLL Epipe site, a Type-1 RD is automatically allocated by the NE based on the community range that you configure.

76.38.2 Steps

1

Before you configure a site for auto-RD selection, you must:

1. Enable BGP on the routing instance of the NE. See 28.29 “To enable BGP on a routing instance” (p. 916) for more information.
2. Enable the automatic selection of an RD on the NE and specify the community range. See 12.11 “To enable the automatic selection of an RD on an NE” (p. 349) .

2

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

3

Choose a VLL service and click Properties. The Epipe Service (Edit) form opens.

4

On the navigation tree, right-click on Epipe Service and choose Create Epipe Site, or right-click on a site and choose Properties. The Epipe Site (Create|Edit) form opens.

5

Click on the BGP tab, then on the General tab, and enable the Enable BGP parameter.

6

Configure the Auto Route Distinguisher parameter in the RD panel.

The Operational RD is displayed after you apply the changes to the site and to the service.

7

Save the changes and close the forms.

END OF STEPS

76.39 To view the last cleared BFD statistics and sessions on a VLL site

76.39.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select a VLL service and click Properties. The *VLL_type* Service (Edit) form opens.

3

On the navigation tree, click on the site on which you want to view the last cleared BFD statistics and sessions.

4

Click on the Clear Status tab and view the five last cleared BFD statistics and the five last cleared BFD sessions.

5

Close the forms.

END OF STEPS

VLL access interface management procedures

76.40 To create a VLL L2 access interface on a terminating site

76.40.1 Prerequisites

If you are configuring access dual-homing with local switching over PBB tunnels, you must configure two L2 access interfaces. The L2 access interfaces can be on LAGs that participate in the MC LAG, or they can be just regular or Ethernet tunnel access interfaces.

If the Use SAP Backbone MAC Address parameter is enabled on both B-Sites:

- MC-LAG access interfaces for the PBB Epipe local switching must be on IOM3 MDAs for the feature to work properly. There is no NFM-P or CLI validation.
- Other access interfaces may be on IOM1 or IOM2 MDAs.

If you configure an L2 access interface on a PBB Epipe site you cannot configure a spoke SDP binding on the same site. They are mutually exclusive.

When you configure a 3-plus-tag Epipe service, only ports with QinQ encapsulation as one endpoint can be selected. When the other endpoint is an L2 access interface, you must choose a port with dot1q or QinQ encapsulation as the other L2 access interface. Both endpoints must be on the same site. See “Epipe (Ethernet VLL)” (p. 2100) in “VLL service management overview” (p. 2100) for more information. See 76.34 “To configure a spoke SDP binding on a VLL site” (p. 2161) and 76.40 “To create a VLL L2 access interface on a terminating site” (p. 2174) for additional configuration requirements for a 3-plus-tag Epipe service.

The parameters displayed may vary depending on the NE type or release.

76.40.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VLL and click Properties. The *VLL_type* Service (Edit) form opens.

3

On the navigation tree, expand Site, right-click on L2 Access Interfaces and choose Create L2 Access Interface. The L2 Access Interface (Create) form opens.

For information on adding a GNE service interface to a VLL service, see 76.29 “To configure a GNE site on a VLL service” (p. 2155) .

4

Configure the required parameters.

The ATM Connection Type parameter is configurable only in a VLL Apipe service that has the VC Type parameter set to ATM-cell.

The MC Ring Node and Hold Service Up On SAP Failure parameters are configurable only in a VLL Epipe service.

The Tunnel Fault Notification parameter is configurable on L2 access interfaces where the device has ports configured in access or hybrid mode with QinQ encapsulation. If you are configuring a tunnel facility MEP, this parameter must be set to Accept, in order to receive the fault notification from the tunnel facility MEP.

The Enable AIS parameter is configurable only in a VLL Epipe service where the device has ports configured in access or hybrid mode with QinQ encapsulation to forward AIS frames generated by a tunnel facility MEP.

5

If you are creating a redundant L2 access interface, select an endpoint in the Redundancy panel.

6

CAUTION

Service Disruption

The creation of a SAP that uses the same port and encapsulation values as an existing inactive MSAP fails under the following conditions:

- If you try to use the NFM-P to create a SAP, the configuration fails and the NFM-P displays an error message.
- If you use a CLI to create a SAP in a service other than the service that contains the MSAP, the configuration succeeds but the MSAP is inactive until the regular SAP is deleted. Although the NFM-P displays the SAP and MSAP, the MSAP remains inactive and consumes resources.
- If you use a CLI to create a SAP in the service that contains the MSAP, the SAP creation fails.

Nokia recommends that you delete an inactive MSAP from the NFM-P if you need to create a regular SAP on the same port using the same encapsulation values.

Configure the port:

1. Click on the Port tab.
2. Select a port in the Terminating Port panel.

   Only ports in access or hybrid mode are listed. To choose a port that is not listed, you must set the Mode parameter for the port to Access or Hybrid. The port is then listed when you click Search.

On Epipe L2 access interfaces, only PW ports that are bound to a service tunnel are listed. See 33.9 “To create an IP/MPLS service tunnel” (p. 1190) for information about how to create a service tunnel with a PW port binding.

On Epipe L2 access interfaces, SAP types X.0 and X.* as well as SAP types *.null and *.* can be configured on the same Q in Q port. You must enable the Q in Q Untagged Sap parameter on the NE which allows the creation of the following default SAP types:

- The SAP type *.null functions as a default SAP for single-tagged frames on a Q in Q port. This SAP accepts single tags in the range 0 to 4095 as well as untagged traffic.
- The SAP type *.* functions as a default SAP for double-tagged frames on a Q in Q port. This SAP accepts untagged, single-tagged, and double-tagged frames with tags in the range 0 to 4095.

See 12.23 “To enable a Q in Q untagged SAP on an NE” (p. 360) for more information.

When you configure a 3-plus-tag Epipe service, you must choose a port with QinQ encapsulation as one endpoint (SAP). When the other endpoint is an L2 access interface, you must choose a port with dot1q or QinQ encapsulation as the other L2 access interface. Both endpoints must be on the same site. See “Epipe (Ethernet VLL)” (p. 2100) in “VLL service management overview” (p. 2100) for more information. See 76.28 “To configure a VLL site” (p. 2154) and 76.34 “To configure a spoke SDP binding on a VLL site” (p. 2161) for additional configuration requirements for a 3-plus-tag Epipe service.

If you are configuring a port as a VLAN range SAP, you must choose a port with dot1q encapsulation type.

If you choose an Ethernet tunnel endpoint, the form is refreshed and an Ethernet Tunnel tab is added.

If you choose a port that is associated with a 7705 SAR MW link, the form is refreshed and a Microwave tab appears. See 15.38 “To configure a 7705 SAR MW link” (p. 499) and 15.39 “To configure a 7705 SAR MW link member” (p. 501) for more information about configuring a 7705 SAR microwave link and MW link member. If you are configuring microwave compression, see 76.51 “To configure microwave compression on an MW link SAP on a VLL L2 access interface” (p. 2195) .

If you are configuring a 7705 SAR-8 or 7705 SAR-18 that has SCADA configured, you can add SCADA branches as SAPs to an Epipe or Cpipe service site. See 15.36 “To configure SCADA on a 7705 SAR” (p. 495) for more information about configuring SCADA on a 7705 SAR.

3. Configure the required parameters.

   When the selected port uses dot1q encapsulation, you can enable the Auto-Assign ID check box to have the Outer Encapsulation Value parameter automatically assigned. If you choose this, the system assigns the lowest unused encapsulation value.

   Note:

   You can set the Auto-Assign ID parameter to be the default parameter for dot1q encapsulation by enabling the Access Interface Encap Value (Dot1q only) parameter in the User Preferences form. Choose Application→ User Preferences from the main menu.

The Inner Encapsulation Value parameter is configurable only when the port encapsulation type is QinQ.

When you configure a 3-plus-tag Epipe service with L2 access interfaces as both endpoints, you must observe the following requirements:

- One endpoint must be a QinQ SAP
- The other endpoint must be a dot1q SAP or a QinQ SAP.
- When the other endpoint is a dot1q SAP, the outer encapsulation value for the dot1q SAP must match the inner encapsulation value of the QinQ SAP that shares the L2 connection.
- When the other endpoint is a QinQ SAP, the inner encapsulation values for both QinQ SAPs on the service must match.

See "Epipe (Ethernet VLL)" (p. 2100) in this chapter for more information. See 76.28 "To configure a VLL site" (p. 2154) and 76.34 "To configure a spoke SDP binding on a VLL site" (p. 2161) for additional configuration requirements for a 3-plus-tag Epipe service

The Outer Encapsulation Value (VPI) parameter is configurable only when the port encapsulation type is ATM.

The Inner Encapsulation Value (VCI) parameter is configurable only when the port encapsulation type is ATM.

The LLF Enabled parameter is configurable only for Epipe L2 access interfaces on ports with Null encapsulation.

If the port you have chosen is an Ethernet Tunnel Endpoint, you will be able to set the Outer Encapsulation Value to 8191. This automatically enables the Ethernet Tunnel Endpoint Control SAP parameter.

For Apipes, the Encapsulation Value parameter and the Encapsulation Value parameter are configurable only when the VC Type parameter is set to ATM-cell or ATM-VPC in Step 3 of 76.5 "To create a VLL service" (p. 2119) and the ATM Connection Type parameter is set to PVT in Step 4 of this procedure.

For Apipes, the LLF Enabled parameter is configurable only for SAPs with "Port" ATM Connection Type and on a clear channel under 4 port OC3-STM1 ASAP MDA.

For Apipes, the Connection Profile ID parameter is configurable only when the Signalling VC Type Override parameter is set to ATM-VCC or None. The Connection Profile ID parameter can only be associated with an Apipe when the VC Type parameter is set to ATM-cell.

4. If you are creating an Epipe and use dot1q or QinQ encapsulation, you can enable ingress VLAN translation. Configure the required parameters in the VLAN Translation panel.
5. For QTag Manipulation on the 7250 IXR, configure the parameters in the QTag Manipulation panel.

   For the Ingress Action parameter, when you select the Push Outer or Replace Outer option, the Outer Tag parameter is available. You must configure the Outer Tag parameter.

   If required, click Reset to restore the default values.
6. For VLAN ranges on 7210 SAS Epipes, enable the VLAN Range SAP parameter and select a VLAN range.

   You can configure the VLAN Range SAP parameter only when the SAP Type parameter is set to dot1q-range. See Step 4 in 76.28 "To configure a VLL site" (p. 2154) .

See Chapter 63, “Connection profile policies” for more information about VLAN ranges for the 7210 SAS. See 63.4 “To configure a VLAN range for a 7210 SAS VPLS or VLL Epipe service” (p. 1825) for information about how to create a connection profile with a VLAN range.

7

If a VLAN Connection Profile policy was created and you want to use it for an Epipe service, configure the parameters in the VLAN Connection Profile panel on the Port tab. See Chapter 62, “VLAN Connection Profile policies” for details.

8

To configure port redundancy for a Cpipe or Epipe service:

Port redundancy is configurable only on a 7705 SAR or 7750 SR.

1. Enable the Enable Port Redundancy parameter on the Port tab.
2. Configure the Off-Node Protection parameter in the Backup Port Information panel.
3. If you enable the Off-Node Protection parameter, select the site that contains the backup port.

   Note:

   The site that you choose must be the same type and release of device as the site that you are configuring.
4. Select the redundant port.

   Note:

   Only ports with the same encapsulation type as the currently assigned port are listed.
5. Configure the required parameters.
6. If you are creating a Cpipe L2 access interface, save the changes and close the form.

9

Configure the Ethernet Tunnel Endpoint Control SAP parameter.

Note: Enabling the Ethernet Tunnel Endpoint Control SAP parameter creates the control L2 Access Interface (also known as a Control SAP). It also automatically sets the value of the Outer Encapsulation Value parameter to 8191.
If you are currently creating a same-fate SAP, the Ethernet Tunnel Endpoint Control SAP parameter must not be enabled.

10

To configure policy overrides for Epipe or Ipipe L2 access interfaces:

Note: The Override Policy Items tab contains a number of tabs. However, the tabs that are displayed depend on the port type that you have chosen for this interface.

- If you configured a non-HSMDA port, the Access Ingress Queues, Access Egress Queues, Ingress Policer, and Egress Policer tabs are active.

- If you configured an HSMDA port, the Access Ingress Queues, Access Egress HSMDA Queues, and Ingress Policer tabs are active.

1. Click on the Override Policy Items tab.
2. Set the policy overrides, as described in 50.97 “To configure QoS policy overrides on an L2 or L3 access interface” (p. 1654) .

   To configure meter overrides on a 7210 SAS, see 50.98 “To configure QoS policy overrides on access ingress meters for the 7210 SAS” (p. 1657) . To configure queue overrides on a 7210 SAS, see 50.99 “To configure QoS policy overrides on access ingress queues for a 7210 SAS-X” (p. 1659) .

11

To specify Ipipe functionality for Ipipe L2 access interfaces:

1. Click on the IPIPE tab.
2. Configure the required parameters.

   The MAC Address parameter, MAC Refresh Interval parameter, and Use Broadcast MAC Address parameters are configurable only when the port encapsulation type is dot1q, QinQ, or Null.

12

To specify Epipe functionality for Epipe L2 access interfaces:

1. Click on the Epipe tab.
2. Configure the required parameters.
3. Click on the following tabs to view or edit information:
   - General tab—displays the general Epipe properties
   - Port
   - OAM tab—create and execute service-specific diagnostic tests
   - QoS—configure the required parameters and select an Egress Remark policy, Egress VLAN QoS policy, and a Shared Policer policy, as required
   - Schedulers tab
   - ACL
   - Accounting
   - Virtual Port Name—configure the required parameters to assign a virtual port to the interface.
   - Security—configure the required parameters and select a DDoS protection policy
   - TCA
   - Deployment
   - Faults—displays the faults associated with the Epipe L2 access interface

13

To assign an Application Profile to the spoke SDP binding:

1. Click on the Application Assurance tab.
2. Select an application profile string.

   You can select only local profiles on the NE.
3. To associate a transit IP policy with an Epipe service object, select a transit IP policy in the Transit IP Policy panel.

   See 87.46 “To configure an AA transit IP policy” (p. 2860) for more information about how to configure a transit IP policy.
4. To associate an AA transit prefix policy with the service object, select a transit prefix policy in the Transit Prefix Policy panel.

   See 87.47 “To configure an AA transit prefix policy” (p. 2861) for more information about how to configure a transit prefix policy.
5. To associate an AA redundant protocol with an Epipe service object, select an AA redundant protocol in the AA Redundant Protocol panel.

14

Save the changes and close the forms.

Note: If you are configuring access dual-homing with local switching over PBB tunnels, you must configure two L2 access interfaces. The L2 access interfaces must be on LAGs that participate in the MC LAG. See Chapter 43, “MC LAG groups” for information about MC LAGs.

END OF STEPS

76.41 To configure LAG per-link hashing on a VLL Epipe or Ipipe L2 access interface

76.41.1 Prerequisites

You can configure weighted per-link hashing on an Epipe or Ipipe L2 access interface if the terminating port has LAG per-link hashing enabled. The interface must be a LAG member.

76.41.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VLL Epipe or Ipipe and click Properties. The *VLL_type* Service (Edit) form opens.

3

On the navigation tree, expand Site→L2 Access Interfaces.

4

Right-click on the L2 access interface you want to modify and choose Properties. The VLL L2 Access Interface (Edit) form opens.

5

Click on the LAG Per Link Hash tab.

6

Configure the Class and Weight parameters.

7

Save your changes and close the forms.

END OF STEPS

76.42 To assign ingress and egress QoS policies to a VLL L2 access interface

76.42.1 Before you begin

The available panels and parameters vary depending on the NE, chassis type, and release.

If you are assigning QoS policies to an access interface on a 7210 SAS NE, see 76.43 “To assign ingress and egress QoS policies to a VLL L2 access interface on a 7210 SAS site” (p. 2184).

76.42.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VLL and click Properties. The *VLL_type* Service (Edit) form opens.

3

On the navigation tree, expand Site→L2 Access Interfaces, right-click on the L2 access interface, and choose Properties. The VLL L2 Access Interface (Edit) form opens.

4

Click on the QoS tab.

5

Configure the Ingress Match QinQ Dot1P parameter.

The Ingress Match QinQ Dot1P parameter is configurable only on Epipe L2 access interfaces. The Ingress Match QinQ Dot1P parameter is not configurable if the port encapsulation type is ATM or FR.

6

Select an ingress QoS policy in the Ingress Policy panel.

Note: For Epipe and Ipipe VLL L2 access interfaces, if you select an access ingress policy which has a forwarding class mapped to an ingress queue group, you must ensure that the port you are configuring for the Epipe or Ipipe L2 access interface has the access ingress queue group with the same name created on it.
See 16.24 “To configure Ethernet ports” (p. 599) in Chapter 16, “Port and channel object configuration” for more information about how to configure Ethernet ports. See Chapter 49, “Policies overview” for more information about queue group template policies.

7

Select an ingress queue group template policy in the Forwarding Plane Redirect panel.

8

Configure the Instance ID parameter in the Forwarding Plane Redirect panel.

Note: The Instance ID parameter cannot be configured for Ipipe on Ethernet ports.

9

Configure the Egress Mark QinQ Top Bits Only parameter.

The Egress Mark QinQ Top Bits Only parameter is configurable only on Epipe L2 access interfaces.

10

Configure the required parameters in the Aggregate Rate Limit panel.

11

Select an egress policy in the Egress Policy panel.

Note: For Epipe and Ipipe VLL L2 access interfaces, if you select an access egress policy which has a forwarding class mapped to an egress queue group, you must ensure that the port you are configuring for the Epipe or Ipipe L2 egress interface has the access egress queue group with the same name created on it.
See 16.24 “To configure Ethernet ports” (p. 599) in Chapter 16, “Port and channel object configuration” for more information about how to configure Ethernet ports. See Chapter 49, “Policies overview” for more information about queue group template policies.

12

Select an egress queue group policy in the Port Redirect panel.

Note: Selecting an Egress Queue Group Template Policy permits the redirection of Ethernet traffic packets to a queue ID specified in the egress port queue group of the SAP. The following properties and restrictions apply:

- If an Egress Queue Group Template Policy is specified here, the policy must have port redirection enabled.
- You cannot use policy-based redirection with the queue group when the SAP has SAP-based redirection enabled.
- Port access egress redirection is only supported on Ethernet/LAG ports. It is not supported on SAPs bound on non-Ethernet, Eth-tunnel, or CCAG ports.
- Supported ports include access, hybrid, and HSMDA.
- Queue groups can be applied to SAPs that incorporate LAGs. The LAGs can include port members from just a single card or from multiple cards.
- If you edit a LAG incorporated by the SAP, you cannot remove the last LAG member if a queue group reference exists to the containing SAP.
- You cannot add a secondary LAG member that has a queue group mismatch with primary LAG member.

13

If you are configuring an L2 access interface for a 7705 SAR, or if the port you selected in Step 6 of 76.40 “To create a VLL L2 access interface on a terminating site” (p. 2174) is not an HSMDA port, then go to Step 21 .

14

Configure the Packet Byte Offset (bytes) parameter. You must enable the associated Override parameter.

15

Select a WRR policy in the Egress HSMDA Override panel.

16

In the Shaper Group panel, select a Shaper Group for the access ingress port or access egress port .

17

In the IXR Specific panel, select an Egress Remark policy and Egress VLAN QoS policy, as required. See 50.82 “To configure a 7250 SROS Remarking policy” (p. 1634) and 50.54 “To configure a 7250 SROS VLAN QoS policy” (p. 1594).

18

Select an HSMDA egress secondary shaper policy in the Egress HSMDA Override panel.

19

Configure the Use Shared Queue parameter.

20

Select an HS secondary shaper in the HS Overrides panel, if required.

21

Save the changes and close the forms.

END OF STEPS

76.43 To assign ingress and egress QoS policies to a VLL L2 access interface on a 7210 SAS site

Note: You can assign policies and configure parameters for 7210 SAS NEs only when the system resource profile is appropriately configured for the device. See 6.5.13 “System resource profile” (p. 220) in Chapter 6, “Device support” .

The available parameters and policies vary depending on the device type and chassis variant. The configurations that are supported on the site NE are shown on the form.

76.43.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VLL and click Properties. The *VLL_type* Service (Edit) form opens.

3

On the navigation tree, expand Site→L2 Access Interfaces, right-click on the L2 access interface, and choose Properties. The VLL L2 Access Interface (Edit) form opens.

If you are configuring an L2 Uplink SAP on a 7210 SAS-K site to preserve the dot1p values of ingress packets, expand to the Uplink SAP, open the properties form, and perform Step 4 and Step 10.

4

Click on the QoS tab and expand the 7210/7250 Specific panel.

5

Select a SAP Access Ingress policy in the Ingress Policy panel.

When you assign an ingress policy, the Color Mode parameter setting for the meters in the policy must coincide with the Enable DEI parameter setting on the physical port. When Enable

DEI is selected, the Color Mode for meters must be set to Color Aware. When Enable DEI is not selected, the Color Mode for meters must be set to Color Blind. See 16.24 “To configure Ethernet ports” (p. 599) and 50.29 “To configure a 7210, 7250, and 1830 SAP Access Ingress policy” (p. 1544) .

If you are assigning a 7210, 7250, and 1830 SAP Access Ingress policy that contains a 7210 FC Meter Map policy, you must select the Enable Table Classification parameter. See 50.29 “To configure a 7210, 7250, and 1830 SAP Access Ingress policy” (p. 1544).

To support H-metering, you must choose an ingress policy with all meter rate modes set to trTCM (RFC 4115).

For 7250 IXR sites, the selected SAP Access Ingress policy must contain an assigned 7250 Ingress CoS policy.

6

Select an egress policy in the Egress Policy panel.

See 50.32 “To configure a 7210 SAP access egress policy” (p. 1558) for more information about 7210 SAP access egress policies.

SAP-based remarking values are defined in a 7210 SAP access egress policy. To enable SAP-based remarking on the 7210 SAS-X, you must enable the SAP QoS Marking parameter on the port; see 16.24 “To configure Ethernet ports” (p. 599) .

7

To enable table-based color-aware ingress classification, select the Enable Table Classification parameter. See 50.23.2 “Table-based ingress classification on the 7210 SAS” (p. 1529).

8

Select an Egress Remarking policy in the Egress Remark Policy panel.

9

Configure the required parameters in the Aggregate Rate Limit panel.

You can configure the Ingress Meter Rate (kbps) and Ingress Meter Burst parameters only after SAP creation.

You can configure the Ingress Meter parameter only during SAP creation. The parameter must be set to true to support H-metering.

You can configure the Egress Meter Rate and Egress Meter Burst parameters only when resources are allocated to the SAP Egress Aggregate Meter parameter in the system resource profile; see 12.50 “To configure the global system resource profile on a 7210 SAS or 7250 IXR” (p. 380). To allocate resources on the 7210 SAS-R, configure the Egress SAP Aggregate Meter parameter in the system resource profile policy assigned to the device; see 12.51 “To configure a system resource profile policy for the 7210 SAS-R/T/Mxp, 7210 SAS-S/Sx, or 7210 SAS-S/Sx VC” (p. 382).

You must also enable port-based scheduling on 7210 SAS-Mxp and 7210 SAS-R NEs; see 12.53 “To configure port-based scheduling on the 7210 SAS” (p. 384).

The Enable Egress Meter Stats parameter is available when a value is configured for the Egress Meter Rate parameter.

10

For interfaces on 7210 SAS-K sites, configure the required parameters in the Egress Dot1p Remarking panel.

For access ports, configured parameters take effect only when the Remarking parameter is set to true in the 7210 SAP Access Egress policy assigned to the interface; see Step 6.

For L2 Uplink ports, configured parameters take effect only when the Remarking parameter is set to true in the 7210 and 1830 Network policy assigned to the port; see 16.45 “To assign QoS policies to a 7210 SAS Ethernet port” (p. 636).

11

Save the changes and close the forms.

END OF STEPS

76.44 To configure scheduling on a VLL L2 access interface

76.44.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VLL and click Properties. The *VLL_type* Service (Edit) form opens.

3

On the navigation tree, expand Site→L2 Access Interfaces, right-click on the L2 access interface and choose Properties. The VLL L2 Access Interface (Edit) form opens.

4

Click on the Schedulers tab.

Note: The Schedulers tab is configurable only if a port is assigned to the interface.

5

To configure egress scheduling on a 7210 SAS site, enable and configure the required parameters in the Egress Aggregate Rate Limit panel and go to Step 9 .

6

To configure scheduling on a 7705 SAR site:

Note: For the 7705 SAR, scheduler behavior is determined by the scheduler mode, which is 4-Priority by default. You can only configure the Egress and Ingress Aggregate Rate Limit parameters when the Scheduler Mode parameter is set to 16-Priority. You can set

the Scheduler Mode to 16-Priority only when the port is on an MDA that supports 16-Priority. See the 7705 SAR documentation for more information.

If you change the Scheduler Mode parameter from 16-Priority to 4-Priority, the NFM-P automatically restores the default settings for the Egress Aggregate Rate Limit and Ingress Aggregate Rate Limit panels when you click Apply or OK.

1. In the Egress Scheduler panel, configure the Scheduler Mode parameter.
2. In the Ingress Scheduler panel, configure the Scheduler Mode parameter.
3. If you set the Scheduler Mode parameter to 16-Priority in the Egress Scheduler panel or Ingress Scheduler panel, configure the required parameters in the Egress Aggregate Rate Limit panel and Ingress Aggregate Rate Limit panel. Otherwise, save the changes and close the forms.

7

To specify that an aggregation scheduler policy is not applied to the interface:

1. Set the Aggregation parameter to Off.

   Note:

   The Aggregation parameter is not configurable if the port you selected in Step 6 of 76.40 “To create a VLL L2 access interface on a terminating site” (p. 2174) is an HSMDA port.
2. Configure the required parameters.

   Note:

   The Aggregate Rate Limit (kbps), Frame-Based Accounting, and Limit Unused Bandwidth parameters are configurable only when there is no scheduler specified in the Egress Scheduler panel.

   The Frame-Based Accounting parameter is not configurable if the port you selected in Step 6 of 76.40 “To create a VLL L2 access interface on a terminating site” (p. 2174) is an HSMDA port.

   You cannot specify an egress scheduler when the Aggregate Rate Limit (kbps) parameter is set to a value greater than zero.
3. Select an ingress scheduler in the Ingress Scheduler panel.
4. If you are configuring this interface for an Ipipe service then go to 6 .
5. Select an ingress policer control policy in the Ingress Policer Control Policy panel.
6. If the port you selected in Step 6 of 76.40 “To create a VLL L2 access interface on a terminating site” (p. 2174) is an HSMDA port, save the changes and close the forms.
7. Select an egress scheduler in the Egress Scheduler panel.
8. If you are configuring this interface for an Ipipe service, save the changes and close the forms.
9. Select an egress policer control policy in the Egress Policer Control Policy panel.
10. Save the changes and close the forms.

8

To specify that an aggregation scheduler policy is applied to the interface:

1. Set the Aggregation parameter to On.

   Note:

   You cannot specify an access scheduler policy if the port you selected in Step 6 of 76.40 “To create a VLL L2 access interface on a terminating site” (p. 2174) is an HSMDA port. Go to Step 9 .

2. Select an aggregation scheduler in the Aggregation Scheduler panel.

9

Save the changes and close the forms.

END OF STEPS

76.45 To assign ingress and egress ACL filters to the VLL L2 access interface

Note: IPv6 ACL filters are not supported on the 7705 SAR.
ACL filters are not supported for CPipe L2 access interfaces.

76.45.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VLL and click Properties. The *VLL_type* Service (Edit) form opens.

3

On the navigation tree, expand Site→L2 Access Interfaces, right-click on the L2 access interface and choose Properties. The VLL L2 Access Interface (Edit) form opens.

4

Click on the ACL tab.

Note: When you configure ACL filters on a 7210 SAS NE, you must configure the system resource profile appropriately. See 6.5.13 “System resource profile” (p. 220) in 6.5 “7210 SAS” (p. 216) for more information.

5

Select the required ACL filter policies.

6

Save the changes and close the forms.

END OF STEPS

76.46 To assign an accounting policy to a VLL L2 access interface

76.46.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VLL and click Properties. The *VLL_type* Service (Edit) form opens.

3

On the navigation tree, expand Site→L2 Access Interfaces, right-click on the L2 access interface and choose Properties. The VLL L2 Access Interface (Edit) form opens.

4

Click on the Accounting tab.

5

Select an accounting policy.

6

Configure the required parameters.

The Collect Egress Queue Statistics parameter can be configured only during VLL L2 access interface creation. See 76.40 “To create a VLL L2 access interface on a terminating site” (p. 2174).

7

Save the changes and close the forms.

END OF STEPS

76.47 To configure Ethernet loopback for a VLL Epipe L2 access interface on a 7705 SAR

76.47.1 Purpose

Perform this procedure to configure OAM loopback for an Epipe SAP on a 7705 SAR NE. You can perform individual loopback tests, or enable loopback as part of Y.1564 test configuration. See

89.7 “STM Y.1564 test configuration” (p. 2924) for more information about Y.1564 tests.

76.47.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an Epipe service and click Properties. The Epipe Service (Edit) form opens.

3

On the navigation tree, expand the 7705 SAR site, then right-click on the required L2 access interface and choose Properties. The properties form for the SAP opens.

4

Click on the Ethernet Loopback tab.

5

Configure the required parameters.

If you are configuring Ethernet loopback for Y.1564 tests, set the Mode parameter to Internal, and enable the Mac Swap parameter.

6

Save the changes and close the forms.

END OF STEPS

76.48 To assign a time of day suite to the VLL L2 access interface

76.48.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VLL and click Properties. The *VLL_type* Service (Edit) form opens.

3

On the navigation tree, expand Site→L2 Access Interfaces, right-click on the L2 access interface and choose Properties. The VLL L2 Access Interface (Edit) form opens.

4

Click on the TOD Suite tab.

5

Select a time of day suite in the Time Of Day Suite panel.

Note: You cannot assign a ToD suite to a L2 access interface if accounting statistics collection is enabled on the L2 access interface. You must disable the Collect Accounting Statistics parameter in Step 6 in 76.46 “To assign an accounting policy to a VLL L2 access interface” (p. 2189) .
SapEgrQosPlcyStats and SapIngQosPlcyStats statistics are only collected if a Time Of Day Suite is applied on the SAP.

6

Save the changes and close the forms.

End of steps

76.49 To assign a DoS or DDoS protection policy to a VLL L2 access interface or SDP binding

76.49.1 Prerequisite

This procedure applies to VLL Epipe or Ipipe services.

Note: A default DoS protection policy is automatically assigned to the interface.

76.49.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VLL and click Properties. The *VLL_type* Service (Edit) form opens.

3

On the navigation tree, expand Site→L2 Access Interfaces|Spoke SDP Bindings, right-click on the L2 access interface or spoke SDP binding and choose Properties. The VLL L2 Access Interface (Edit) form opens or Spoke SDP Binding (Edit) opens.

4

Click on the Security tab.

5

Select a DoS protection policy in the NE DoS Protection panel.

6

Configure the MAC Monitoring parameter.

7

Click OK. The VLL L2 Access Interface (Edit) form or Spoke SDP Binding (Edit) closes and a dialog box appears.

8

Save the changes and close the forms.

END OF STEPS

76.50 To create MIPs and MEPs on an Epipe or Apipe L2 access interface

76.50.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VLL service and click Properties. The *VLL_type* Service (Edit) form opens.

3

On the navigation tree, expand the Sites icon and click the required site. The site's properties form is displayed.

4

Expand the required site's icon on the navigation tree to show the L2 Access Interfaces.

5

Click the required SAP and choose Properties. The L2 Access Interface (Edit) form opens.

6

Click on the OAM tab, then on the Configuration sub-tab.

7

Configure the required Test Generation Options parameters.

Note: You can propagate test generation role settings to all MEPs on a SAP or service site by clicking Propagate to MEPs.

8

Click on the ETH-CFM sub-tab.

9

To add a MIP on a 7210 SAS NE, configure the MIP and MIP MAC Address parameters in the MIP Configuration panel and then go to Step 13 .

If you set the Initial MHF-Creation parameter to default during MEG configuration (see 91.15 “To configure an Ethernet CFM MD policy and subordinate objects” (p. 3109)), you must set the MIP parameter to Enabled.

If you set the Initial MHF-Creation parameter to explicit during MEG configuration (see 91.15 “To configure an Ethernet CFM MD policy and subordinate objects” (p. 3109)), set the MIP parameter to Disabled.

You can only configure the MIP MAC Address parameter when the MIP parameter is set to Enabled.

10

To create MIPs:

1. Click Create in the MIP Configurations panel. The MIP Configuration (Create) form opens.
2. Configure the parameters, then click OK. The MIP Configuration (Create) form closes

   The Primary VLAN Enable, VLAN ID, and MAC Address parameters are configurable only when a port is assigned to the interface.
3. Repeat the previous two steps to create additional MIPs, as required.
4. Click Apply in the L2 Access Interface (Edit) form. The default MD objects are then automatically created on the service site.
5. Go to the service site's properties form and click the OAM tab and then on the ETH-CFM sub-tab.
6. Scroll down to the Default Domain panel and multi-select all required entries, then click Properties. The CFM Vlan Default Domain (Multiple Instances) form opens.
7. Configure the parameters for the selected entries and click OK. The CFM Vlan Default Domain (Multiple Instances) form closes.
8. Click Apply and then return to the L2 Access Interface (Edit) form.
9. Scroll down to the MIPs panel and click Resync MIPs. The default Up and Down MIPs that were automatically created by the NE are displayed in the list.

11

For 7705 SAR NEs, configure the Hold MEPs Up When SAP is Down parameter in the Hold MEP Up on SAP Failure panel.

Note: You can configure the Hold MEPs Up When SAP is Down parameter on only one SAP per node.

12

To enable a tunnel facility MEP on the L2 access interface, set the Tunnel Fault Notification parameter in the Facility MEPs panel to Accept.

Tunnel Fault Notification is configurable on sites where the device has ports configured in access or hybrid mode with QinQ encapsulation.

13

To create a MEP:

1. Click Create in the MEPs panel. The MEP (Create) form opens.
2. Select a MEG in the Maintenance Entity Group panel.
3. Configure the parameters in the MEP panel.

   The Type and Interface Type parameters are automatically populated based on whether the MEP is created on a SAP, SDP binding, or Ethernet Tunnel Path Endpoint.

   For 7210 SAS-K NEs, to enable the Primary VLAN Enable parameter, you must enable the Primary VLAN parameter in the system resource profile for the device; see 12.50 “To configure the global system resource profile on a 7210 SAS or 7250 IXR” (p. 380).
4. Configure the parameters in the CCM panel.

   The CCM Padding Packet Size (Bytes) parameter cannot be configured when the CCM interval parameter is set to 10 ms or 100 ms.
5. Select a MEG sub-group in the MEG Sub-Grouping panel.
6. Configure the required Test Generation Options parameters.

   Note: You can only configure Test Generation Options parameters for Epipe access interfaces.

   The Test Generation Options parameters are only displayed when you set the Direction parameter to Up.
7. If the MD for the MEP has a Maintenance Domain Name Type of none and the associated MEG has a Maintenance Entity group Name Type of icc-based, then the Y.1731 Tests and AIS tabs are configurable. Click on the Y.1731 Tests tab.
8. Configure the required parameters.

   The Eth Test Pattern parameter is configurable when the Eth Test Enabled parameter is enabled.
9. Click on the AIS tab and configure the required parameters.

   The AIS Meg Level parameter is configurable when the AIS Enabled parameter is enabled.
10. Select a MEG sub-group in the MEG Sub-Grouping panel.
11. Click OK. The MEP (Create) form closes.

14

Configure the parameters in the Squelch Ingress Level panel.

15

Configure the parameters on the LMM Session Stats Collection panel as required.

16

Save the changes and close the forms.

END OF STEPS

76.51 To configure microwave compression on an MW link SAP on a VLL L2 access interface

Note: You can configure microwave compression only on an MW link SAP associated with a 7705 SAR-8 or 7705 SAR-18.

Microwave compression cannot be configured on an MW link SAP when the Outer Encapsulation Value parameter of the port in Step 6 of 76.40 “To create a VLL L2 access interface on a terminating site” (p. 2174) is set to 0 or 1.

See 15.38 “To configure a 7705 SAR MW link” (p. 499) and 15.39 “To configure a 7705 SAR MW link member” (p. 501) for more information about configuring a 7705 SAR MW link and MW link member.

76.51.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VLL and click Properties. The *VLL_type* Service (Edit) form opens.

3

On the navigation tree, expand Site→L2 Access Interfaces, right-click on the L2 access interface and choose Properties. The VLL L2 Access Interface (Edit) form opens.

4

Click on the Microwave tab.

5

Enable the Compression parameter.

6

Configure the required parameters.

7

Save the changes and close the forms.

END OF STEPS

76.52 To configure an Ethernet tunnel on a VLL L2 access interface

Note: You can only configure an Ethernet tunnel if you are creating a same-fate SAP or a control/data SAP.

76.52.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VLL and click Properties. The *VLL_type* Service (Edit) form opens.

3

On the navigation tree, expand Site→L2 Access Interfaces, right-click on the L2 access interface and choose Properties. The VLL L2 Access Interface (Edit) form opens.

4

Click on the Ethernet Tunnel tab.

5

If you are configuring a fate-sharing Ethernet Tunnel Endpoint SAP, or same-fate SAP, go to Step 6 . Otherwise, go to Step 8 .

6

Click Create. The Ethernet Tunnel (Create) form opens.

7

Configure the required parameters.

8

Save the changes and close the forms.

END OF STEPS

76.53 To assign an ANCP policy to a VLL L2 access interface

76.53.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VLL and click Properties. The *VLL_type* Service (Edit) form opens.

3

On the navigation tree, expand Site→L2 Access Interfaces, right-click on the L2 access interface and choose Properties. The VLL L2 Access Interface (Edit) form opens.

4

Click on the ANCP Static Map tab.

5

Click Create. The ANCP Static Map (Create) form opens.

6

Configure the ANCP String parameter.

7

Select an ANCP policy.

8

Save the changes and close the forms.

END OF STEPS

76.54 To specify the CEM functionality for an Epipe or Cpipe L2 access interface with CEM encapsulation

Note: Consider the following when creating a VLL Epipe or Cpipe L2 access interface with CEM encapsulation:

- The Time Slots parameter of the DS0 channel must be configured with at least one time slot.
- Time slots are automatically configured for unstructured E1 and T1 endpoints
- The Clock Source parameter of the DS1 channel must be set to Node-Timed.

76.54.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VLL and click Properties. The *VLL_type* Service (Edit) form opens.

3

On the navigation tree, expand Site→L2 Access Interfaces, right-click on the L2 access interface and choose Properties. The VLL L2 Access Interface (Edit) form opens.

4

Click on the CEM EPipe tab or the CEM CPipe tab.

5

Configure the required general parameters.

6

For Cpipe VLL L2 access interfaces, configure the required parameters in the VLL Specifics panel.

7

For Cpipe VLL L2 access interfaces, configure the Control parameter in the Asymmetric Delay panel.

You must enable the Control parameter before you can configure the Samples parameter and the Repeat Period parameter.

You must enable the Control parameter on both ends of the Cpipe VLL to ensure symmetric delay in the jitter buffer.

8

Save the changes and close the forms.

END OF STEPS

76.55 To switch to the redundant port for a VLL SAP from an L2 access interface properties form

76.55.1 Prerequisites

CAUTION

Service Disruption

Nokia recommends that you set the OLC state of a service to Maintenance before you switch to a redundant port or channel. See the NSP System Administrator Guide for more information.

Then reset the port to the previous state after the switch is complete.

Perform this procedure from a port properties form when port redundancy is configured on one or more a Cpipe or Epipe SAPs to:

- switch to the backup port or channel assigned to the SAP, for example, in the event of a fault on the primary port or channel
- switch back to the primary port or channel assigned to the SAP, for example, after a fault condition on the primary is cleared

Note: When multiple SAPs are selected, switching is attempted only for the SAPs that support port redundancy and on which port redundancy is properly configured.
Port redundancy switching fails if the SAP or port is included in one of the following redundancy objects:

- BGP-MH
- MC-APS
- MC-LAG
- MC-ring

76.55.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VLL and click Properties. The *VLL_type* Service (Edit) form opens.

3

On the navigation tree, expand Site→L2 Access Interfaces→L2 access interface→SAP, right-click on SAP and choose Properties. The Port (Edit) form opens.

4

Click on the Port tab.

5

Click Switch to Redundant SAP. A dialog box appears.

6

Click OK. The Port (Edit) form closes and a dialog box appears indicating that the SAP object on the current site is removed.

7

Click OK.

8

Verify the following:

- For on-node switching, the SAP is deleted from the primary port, and a new SAP is created on the site.
- For off-node switching, the SAP and the parent site are deleted, and a new site, SAP, and spoke SDP bindings are created for the service.

9

Choose the SAP in the navigation tree. The Port (Edit) form opens.

10

Click on the Port tab. The Manual Switch Backup State indicator displays one of the following:

- Backup SAP in Use, if you switch from primary to backup
- Backup Port Specified, if you switch from backup to primary

Note: When the Manual Switch Backup State indicator reads Backup SAP in Use, the displayed port redundancy information is for the primary port of the SAP, and is read-only.

11

Close the forms.

END OF STEPS

76.56 To configure FPE association on a VLL Epipe site

76.56.1 Purpose

Use this procedure to configure PW Port FPE on an Epipe switching site. This will allow the system to extend forwarding path processing for pre-defined applications, for example, MPLS over PW.

When this procedure is completed, an internal spoke SDP is automatically created.

76.56.2 Steps

1

Perform one of the following:

a. To create an FPE bound to a PXC path on a single port, go to step Step 2.

b. To create an FPE bound to a PXC path on a LAG, go to step Step 4 .

2

Create a PXC path:

1. Create a PXC port, see 16.59 “To configure PXC loopback ports” (p. 652).
2. On the PXC port, right-click on subport b and choose Properties. The Port Cross Connect SubPort (Edit) form opens.
3. Choose the Egress Scheduling Virtual Port tab.
4. Click Create and create an egress scheduling virtual port with the IP address of the NE.
5. Complete the changes and close the form.

3

Create an FPE on the NE, with PW Port enabled. In the Path panel, enter the PXC ID configured in the previous step. See 12.41 “To create an FPE” (p. 374). Go to step Step 6.

4

Create a LAG path:

1. Create two PXC ports, see 16.59 “To configure PXC loopback ports” (p. 652).
2. Create two LAGs. The LAGs must include the PXC subports of the PXCs created in the previous step, and the subports in each LAG must have the same direction (a or b). For example, LAG 1 can contain the a subports of the two PXCs and LAG 2 can contain the b subports. See 13.16 “To create a LAG” (p. 431)

5

Create an FPE on the NE, with PW Port enabled. In the Path panel, enter the LAG IDs configured in the previous step. See 12.41 “To create an FPE” (p. 374).

Note: The LAG entered as the FPE Xa LAG is not required to be the LAG including the direction a subports.

6

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

7

Choose a VLL service and click Properties. The Epipe Service (Edit) form opens.

8

On the navigation tree, right-click on Epipe Service and choose Create Epipe Site, or right-click on a site and choose Properties. The Epipe Site (Create|Edit) form opens.

9

Click on the PW Port FPE tab.

10

Enable PW Port FPE, and add all applicable configurations.

11

Complete the configuration and close the form.

The PW Port association appears in the PW Port FPE tab of the FPE properties.

END OF STEPS

77 VPLS management

77.1 Overview

77.1.1 Purpose

VPLS is a class of virtual private network multipoint L2 service that allows multiple customer sites to be connected in a single bridged domain contained within the service provider-managed IP/MPLS network. Customer sites in the VPLS appear to be on the same LAN, even if the sites are geographically dispersed.

VPLS offers the following advantages:

- Ethernet interfaces on the host access side simplify provisioning.
- All routers in the VPLS are part of the same LAN, which simplifies IP addressing and allows customers to control and simplify their routing strategies.
- VPLS is protocol independent, which means there is no L2 protocol conversion between LAN and WAN technologies.

You can use HVPLS to eliminate the need for a full mesh of virtual circuits between devices in the VPLS. See 77.2.1 “HVPLS” (p. 2210) in this section for more information.

A VPLS can span a single site or multiple sites. A VPLS that spans a single site is called a local VPLS. In a local VPLS, customer data enters the service through multiple access interfaces on a single PE device. No circuit provisioning is required for the local VPLS.

A VPLS that spans multiple sites is called a distributed VPLS. In a distributed VPLS, customer data enters the service using two or more interfaces on different PE devices. The VPLS is transported by service circuits over an IP/MPLS provider core network carried by service tunnels. Service tunnels are created using GRE or MPLS LSPs.

The NFM-P supports end-to-end VPLS configuration using tabbed configuration forms with an embedded navigation tree.

The General tab of the NFM-P service management form displays useful information about the operational state of the service and its sites through the Aggregated Operational State and State Cause indicators.

The Aggregated Operational State indicator has four possible values: Up, Down, Partially Down, and Unknown. The value is derived from the operational states of the sites that are part of the service, as follows:

- Up—all sites are operationally up
- Partially Down—at least one site is operationally down
- Down—all sites are operationally down
- Unknown—the service has no provisioned sites

When the Aggregated Service Site Operational State is Partially Down or Down, a check mark appears beside the appropriate State Cause indicator to identify the type of fault to the NFM-P operator. Alarms can be viewed on the Faults page.

When you use the NFM-P to create or discover a service, the NFM-P assigns a default tier value to the service. The Service Tier parameter value is relevant only in the context of composite service topology map views. See Chapter 85, “Composite service management” for more information about the hierarchical organization of composite services.

Common to all services, such as VPLS, are policies that are assigned to the service. Policies are defined at a global level and can then be applied to components of the service, such as interfaces and circuits, when the service is configured or modified.

The following policies are common to all services:

- QoS policies to define ingress classification, policing, shaping, and marking on the ingress side of the interface. QoS policies are configured using the Access Ingress Policy Manager and the Access Egress Policy Manager.
- Policer control policies to control access ingress policers and access egress policers under a common hierarchy. Policer control policies are configured using the Policer Control Policy Manager.
- Scheduling policies to define hierarchical rate limiting and scheduling to govern the scheduling of queues. Scheduler policies are configured using the Scheduler Policy Manager.
- Port scheduler policies define hierarchical bandwidth allocation and scheduling at the egress port level. Port scheduler policies are configured using the Port Scheduler Policy and HSMDA Scheduler Policy forms.
- Filter policies to control network traffic into or out of an interface or circuit based on IP or MAC matching criteria. Filter policies are configured using the ACL IP Filter Manager and the ACL MAC Filter Manager.
- Accounting policies to count the traffic on a service to ensure proper billing and enforcement of SLAs. Accounting policies are configured using the Accounting Policy Manager.
- ANCP policies provide status and control information based on port-up and port-down messages and current line rate changes between the edge device and the access node. ANCP policies are configured using the Manage Subscriber Policies form.
- Time of day suites specify time and day restriction policies that are assigned to QoS policies and schedulers, ACL filters, and aggregation schedulers. Time of day suites and time range policies are configured using the Time of Day Suite form and Time Range form, respectively.

See Chapter 49, “Policies overview” for more information about policies.

Packets that arrive at an edge device are associated with a VPLS based on the access interface on which they arrive. An access interface is uniquely identified using the following parameters:

- physical Ethernet port or POS port and channel
- encapsulation type
- encapsulation identifier (if required)

If there are service issues, the service provider can use OAM tools to troubleshoot service and network transport issues, and ensure problems are handled properly through the physical and logical network.

To provide a VPLS over an MPLS infrastructure, the device is configured to provide bridging and replication for each VPLS. The routers that are part of the VPLS are connected by MPLS LSPs. Multiple VPLS can use the same set of service tunnels. Multiple service tunnels can rely on multiple LSPs. The signaling is specified in sets of ingress and egress VC labels for each VPLS.

The following additional features are configured for the VPLS:

- MAC learning for the access ports and tunnels, including filtering based on MAC addresses on a per SAP basis
- MAC learning protection on SAPs to prevent DoS attacks from sourcing
- rate limiting of broadcast, destination unknown, and multicast traffic on a per access port basis
- FIB for each VPLS, including FIB size limits, static MAC addresses, alarms, and discarding unknown locations
- optional support for spanning tree for loop detection
- GSMP for each VPLS
- L2 management interfaces for each VPLS

You can run an OAM Validation test suite for the service by clicking on the Validate button. If the Validate button is not visible, click on More Actions and choose Validate. Alternatively, you can also perform a One Time Validation. If a check mark appears beside the OAM Validation Failed state cause indicator, the test has failed. In addition, the Tested Entity Result tab on the Tests tab displays detailed information about the OAM test result. OAM validation tests are not supported for HVPLS.

77.1.2 Contents

VPLS management overview

77.2 VPLS management overview

77.2.1 HVPLS

A hierarchical VPLS is created by enhancing the VPLS core mesh with a spoke SDP binding that is connected to another site in the same VPLS, a site in another VPLS, or a VLL site.

HVPLS offers the following advantages:

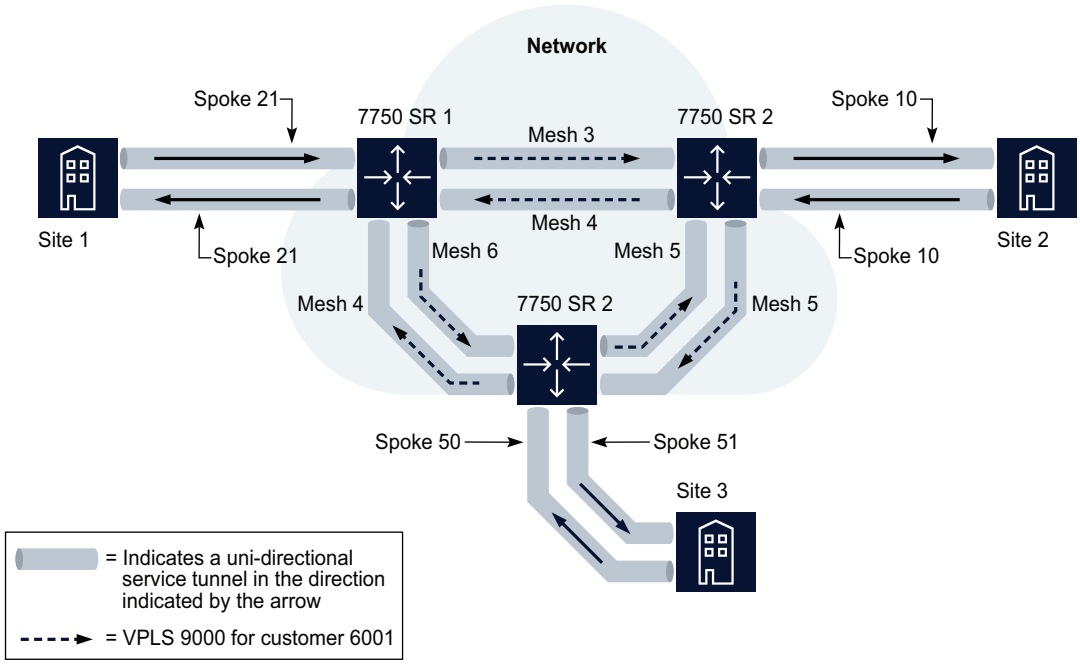
- reduces the complexity of mesh configuration
- decreases the amount of signaling of routes between devices

When traffic arrives at an access-spoke circuit, it acts like a bridge port where flooded traffic received on the access spoke is replicated to all other spokes, meshes, or SAPs but it is not transmitted on the port where it is received.

Sample configuration

The following figure shows a sample HVPLS with a mesh and spoke configuration. Spokes 50 and 51 are unidirectional access-spoke circuits bound to service tunnels. The access-spoke circuits exist within the context of a VLL service or VPLS that is interconnected to the original, fully meshed VPLS. Alternatively, the access-spoke circuit can provide interconnectivity to a service site.

Figure 77-1 HVPLS configuration



17438

The NFM-P supports the following HVPLS interconnectivity using spoke SDPs:

- VPLS to VPLS
- intra-VPLS
- VPLS to VLL

77.2.2 MVPLS

VPLS topology loops can occur if either of the following is true:

- Two VPLS are connected by redundant spoke SDPs.
- A CE NE is connected to a VPLS with redundant L2 access interfaces.

To remove topology loops, RSTP must be enabled on the redundant spoke SDPs or L2 access interfaces to block some of them from passing traffic. This requires the creation of an MVPLS.

MSTP is an extension of RSTP which allows VLANs to be grouped into spanning tree instances. Each instance has an independent spanning tree topology. MSTP can be run in an MVPLS to provide multiple forwarding paths for data traffic, which allows load balancing and reduces the number of spanning tree instances required to support a large number of VLANs. An MST region comprises a set of interconnected switches that have the same MST configuration. Each region can be configured with up to 16 MST instances. The instance with ID 0 is an internal spanning tree that runs an MST region and sends and receives BPDUs. All other spanning tree instance information is encapsulated within MSTP BPDUs.

An MVPLS is created to run RSTP or MSTP and manage traffic on the associated VPLS. An MVPLS contains sites, spoke SDP bindings, mesh SDP bindings, and L2 access interfaces. The MVPLS spoke SDP bindings and L2 access interfaces are configured to manage the associated VPLS spoke SDP bindings and L2 access interfaces.

In the case of spoke redundancy, the MVPLS runs RSTP on the redundant spoke SDPs and associates the resultant traffic-blocking actions with all VPLS that use the same spoke SDPs.

MVPLS traffic blocking can also be used on the access side to manage redundant L2 access interface connections. A VLAN ID range is specified for each MVPLS L2 access interface which identifies the VC IDs of the managed VPLS L2 access interfaces.

RSTP is enabled by default on an MVPLS. When the Admin state of an MVPLS is down, all managed L2 access interfaces and spoke SDPs in the associated VPLS are disabled. However, if the Admin state of individual L2 access interfaces or spoke SDPs of an MVPLS are down, then the managed VPLS L2 access interfaces or spoke SDPs are not affected by traffic blocking.

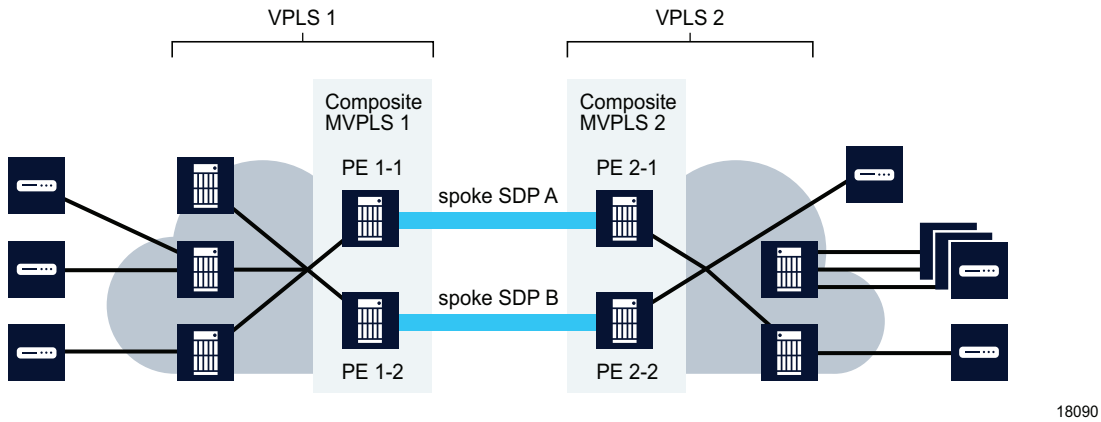
A common MVPLS situation occurs when two VPLS are connected by redundant spoke SDPs. If traffic is not blocked on one of the redundant spoke SDPs, then a loop results. To remove the loop, RSTP must be run on the spoke SDPs that form the loop to block one of the redundant spoke SDPs. Blocking is accomplished by creating an MVPLS on each side of the redundant spoke SDPs and creating a composite MVPLS to connect the MVPLS.

Another common MVPLS situation occurs when an access switch with many VLANs is redundantly connected to two other bridges, on which each uplink carries half the VLANs. MSTP allows you to

build multiple spanning trees over VLAN trunks and to group and associate the VLANs to spanning tree instances, each with a different port instance cost and port instance priority.

The following figure shows an example of a composite MVPLS that is composed of MVPLS 1, MVPLS 2, and spoke SDPs.

Figure 77-2 Composite MVPLS



Another scenario occurs when multiple L2 access interfaces from a VPLS are connected to the same customer edge equipment. In this case, a single MVPLS must be created with L2 access interfaces defined to manage the traffic on the associated VPLS redundant L2 access interfaces.

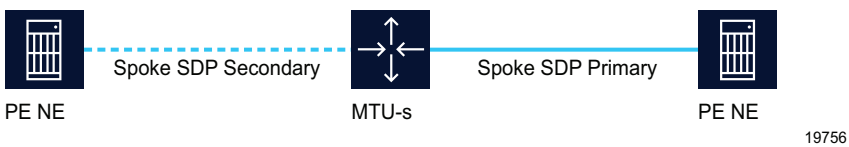
77.2.3 Dual homing for VPLS

A VPLS can be configured for dual homing through the use of redundant spoke SDPs. NFM-P handles the redundant spoke SDPs by grouping them together to form an endpoint object. The redundant spoke SDPs provide active and standby pseudowires for the service. This spoke SDP access arrangement allows data flow control and management support without requiring STP, which cannot be enabled on a spoke SDP binding that is under an endpoint. For VPLS, you can associate only spoke SDP bindings with an endpoint, and each endpoint can be associated with a maximum of two spoke SDP bindings.

Sample configurations

The following figure shows a simple dual homing configuration.

Figure 77-3 MTU redundant access to VPLS



VPLS dual homing provides the ability to have an NE deployed as an MTU-s with links to multiple PE NEs without requiring an MVPLS.

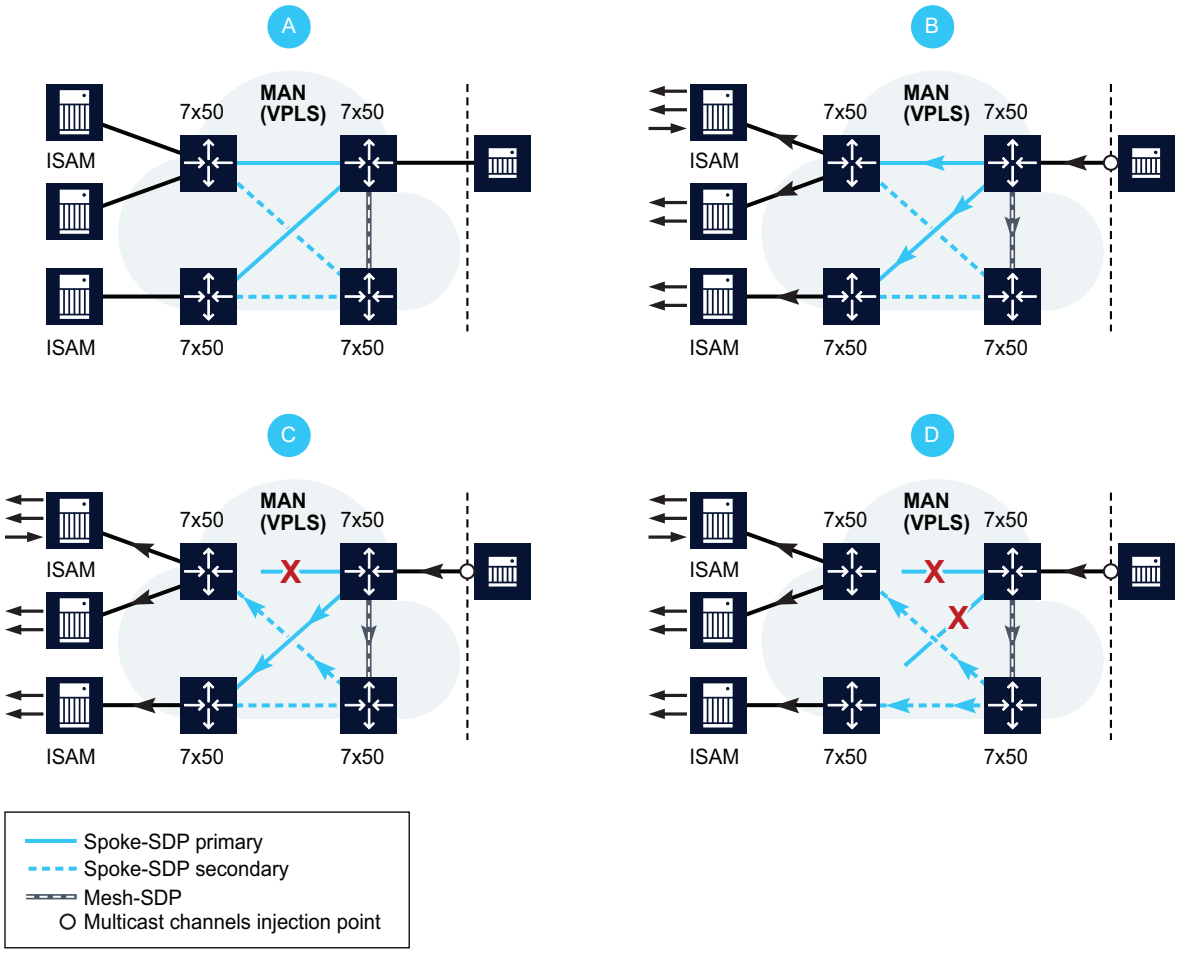
Note: You cannot create a VPLS endpoint on a site that has an active or inactive MC ring SAP. See Chapter 45, “MC ring groups” for more information.

You cannot create an endpoint in an MVPLS.

In this example, the MTU-s has spoke SDPs to two PE devices. One is designated as the primary spoke and the other as the secondary, or standby spoke, based on a precedence value specified for each spoke. The standby spoke is in a blocking state when the primary spoke is available. If the primary spoke becomes unavailable, the MTU-s immediately switches the traffic to the standby spoke. You can configure the service to revert back to the original configuration, after a specified delay, when the primary spoke is again available. Forced manual switchover is also supported.

You can configure a MAC flush to speed the convergence during a switchover. The PE devices that receive the MAC flush remove each MAC address that is associated with the affected VPLS instance and forward the MAC flush to the other PE devices in the VPLS. The following figure shows a dual-homed VPLS for BTV distribution.

Figure 77-4 BTV distribution in redundant VPLS architecture

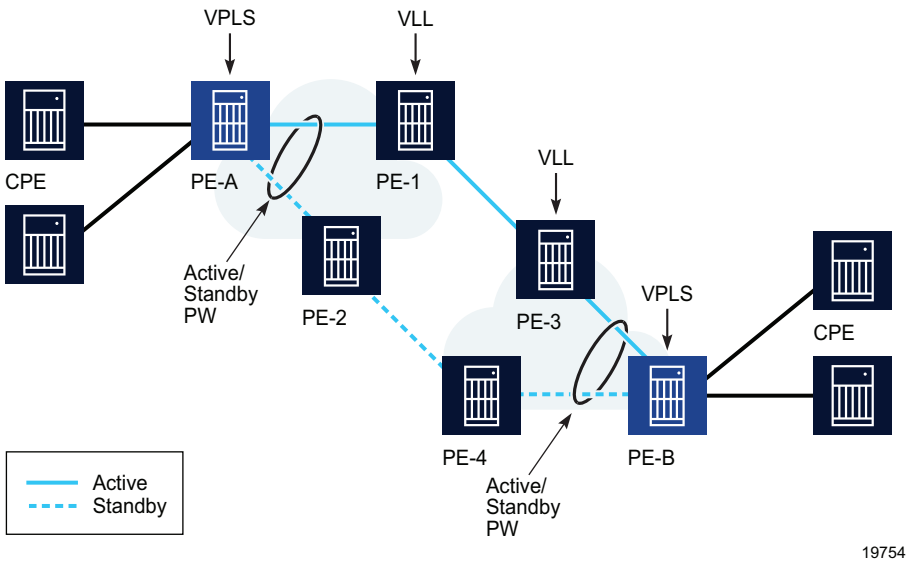


In the nominal operating mode shown in panel A, the edge router (grey icon) has been configured to statically join all multicast channels and inject them into the aggregation network. The access layer 7x50 unit (directly connected to ISAM) is dual-homed into two aggregation layer 7x50s edge routers (larger icons) using primary and secondary spoke SDPs. A mesh SDP interconnects both aggregation nodes. Injected BTV traffic from the edge router is broadcast on the primary spoke SDPs to the connected MTU devices (panel B).

A copy of the channels is also sent on the mesh SDP to the peer aggregation node, which also replicates the traffic to the connected spoke SDPs (aggregation layer nodes are not aware of primary/secondary spoke selection done by the MTU layer devices). The MTUs only receive traffic from the primary spoke SDP. Traffic received on the secondary spoke SDP is blocked. In the event of a link failure (panel C) or MDA failure (panel D), the MTU switches over to the secondary spoke SDP and immediately start receiving traffic from it instead of the primary spoke SDP.

Composite services also support VPLS with redundant spoke SDP bindings to VLL services. The following figure shows a VPLS and VLL combination example that provides an E2E redundant path.

Figure 77-5 VPLS and VLL combination to provide E2E redundant path



77.2.4 Provider Backbone Bridging in VPLS

Provider Backbone Bridging (PBB) is a technology configuration employed in next-generation networks that utilize carrier-grade Ethernet as the transport architecture. It addresses the potentially enormous increase in MAC addresses stored in the router lookup databases by encapsulating the customer frame in a Provider Ethernet header. The Customer MAC address (C-MAC) is then only dealt with by lower tier (or satellite) H-VPLS PEs. The core H-VPLS PEs only need to handle the MAC addresses (B-MAC) of the backbone provider, which are substantially less in number. For this reason, the technique is also referred to as MAC-in-MAC encapsulation.

IEEE 802.1ah defines an architecture and bridge protocols for interconnection of multiple Provider Bridge Networks (PBNs). PBB is defined in IEEE as a connectionless technology based on multipoint VLAN tunnels. MSTP is used as the core control plane for loop avoidance and load balancing. As a result, the coverage of the solution is limited by STP scale in the core of large service provider networks.

A Provider Backbone Bridged Network is a Virtual Bridged Local Area Network that comprises Backbone Edge Bridges (BEBs) and Backbone Core Bridges (BCBs) under the administrative control of a single backbone provider. Each BEB provides interfaces that encapsulate or verify the encapsulation of customer frames, and then relay those frames across the backbone. The term may also mean a provider who is purchasing a service from another provider and using either a PBN or PBBN internally.

Backbone VLANs are used to create multipoint trunks in the backbone. The B-VLAN determines the route the frames take and limits broadcasting within the backbone. The B-TAG is added to the

frame at the Customer Backbone Port (CBP). The selection of B-VLAN used to form the B-TAG is determined by the configuration of the CBP service instance table. This table maps ISIDs to B-VIDs and is created as part of service provisioning.

Backbone VLAN Connectivity

The backbone provider can use and configure MSTP to provide a number of independent spanning tree active topologies and can assign each B-VLAN to one of these active topologies to best use the resources in the network. MVRP, running in the context of each spanning tree active topology, configures the extent of each B-VLAN to the subset of that active topology necessary to support connectivity between the customer points of attachment to the instance of MAC service provided, and can reconfigure that connectivity as required if the spanning tree active topology changes. The operation of MSTP within a backbone provider's network is independent of the operation of any spanning tree protocol within attached provider or customer networks. This is achieved by removing all MSTP BPDUs received or to be transmitted at the service access interfaces. The operation of MVRP within a PBBN is independent of the operation of any configuration protocol within attached customer networks.

SR PBB implementation

The IEEE PBB model is organized around a B-component handling the provider backbone layer and an I-component concerned with the mapping of Customer/Provider Bridge (QinQ) domain (that is, MACs, and VLANs) to the provider backbone (that is, B-MACs, and B-VLANs). The I-component contains the boundary between the customer and backbone MAC domains. PBB encapsulates the customer payload in a provider backbone Ethernet header, which allows the C-MACs to be hidden from the core PEs. A special Group MAC is used for the Backbone Destination MAC when the customer frame type is either unicast, multicast, broadcast, or unknown.

The SR PBB solution can be summarized as follows:

- Two VPLS variants are employed, namely B-VPLS and I-VPLS, functioning as the B-type BEB, and the I-type BEB respectively. A B-VPLS instance (a service instance within a service router) and its corresponding I-VPLS instances must be co-located in a service router. From a network-wide perspective, a B-VPLS comprises multiple Backbone Virtual Switch Instances (B-VSIs).

  Note:

  For the description in this section and in the procedures in this chapter, B-VSI is used for a single B-type BEB instance, and is referred to as a B-Site. Similarly, I-VSI is used for a single I-type BEB instance, and is referred to as an I-Site.
- mB-VPLS and mI-VPLS are also available to provide loop avoidance for B- and I-VPLS in the same way as m-VPLS and regular VPLSs operate.
- An NFM-P VPLS can include regular sites and either B-Sites or I-Sites. The service should not contain both B-Sites and I-Sites. When a VPLS has at least one B-Site it becomes a B-VPLS. When a VPLS has at least one I-Site, it becomes an I-VPLS.

  Note:

  Regular sites, B-Sites, and I-Sites cannot change their type after they are created.
- An I-Site can be bound to one B-Site, but a B-Site can be used by multiple I-VPLSs.

B-VPLS and I-VPLS instances

PBB processing may be seen as a chain of two linked VPLS contexts, namely B-VPLS and I-VPLS.

Their characteristics are summarized in the sections that follow.

I-VPLS

I-VPLS is the abbreviated form for Service Instance ID (ISID) VPLS. An I-VPLS instance on a service site is referred to as an I-Site.

The following are I-VPLS and I-Site characteristics:

- An I-Site operates using customer addressing and maps the C-MACs to B-MACs.
- You can select one B-Site to associate with an I-Site; the B-Site must be on the same PE NE as the I-Site.
- I-Sites support only spoke SDP bindings and not mesh SDP bindings.
- An I-Site L2 access interface, or I-SAP, can co-exist on a port with regular L2 access interfaces or subscriber management M-L2 access interfaces. The existing port encapsulation is supported. An encapsulation tag that is used for service selection on an I-SAP is removed before the PBB encapsulation is added. The appropriate encapsulation tags are added at the remote PBB PE when sending the packet out on the egress access interface.
- An I-Site can be connected to one or more regular VPLS sites. A regular (network level) VPLS can have a mix of regular sites and I-Sites. The I-Sites of such services are responsible for the mapping of C-MACs to B-MACs. The regular sites of the service function as normal (bridge).
- ISID is a 24-bit field that carries the service instance identifier associated with this frame. It is used at the destination PE as a demultiplexer field, a function similar to a VC label. Default to service ID only works if the service ID is within the ISID range. For a service with service ID larger than 16 777 215, the ISID value must be specified.
- The ISID must be unique on one router.
- The Provider MSTP support in an M-VPLS is in the I-VPLS space.
- The I-Site MTU must be at least 18 bytes smaller than the B-Site MTU to which it is bound.
- If a VPLS has an attached I-Site, the Include I-Site(s) indicator on the General tab of the VPLS configuration form is selected.
- IGMP snooping can be configured for I-Sites and I-L2 Access Interfaces, except on routed I-VPLS services.
- PIM snooping can be configured for I-Sites and SAP and Spoke SDP bindings of I-VPLS services.

Backbone-VPLS (B-VPLS)

Multiple L2 services can use a single B-VPLS. Ordinarily, a pair of SDP bindings (in opposite directions) provide either point-to-point connection between two sites of a service (as SDP bindings) or between different services (as a service connector). However, a B-VPLS provides a multipoint connection between sites of a service or for multiple services.

The following are properties and characteristics of a B-VPLS and B-Sites:

- The B-VPLS operates using the provider or backbone addressing (B-MACs).
- The B-VPLS provides backbone tunneling for one or multiple I-VPLSs.

- The B-VPLS accepts mesh or spoke SDP bindings, thereby providing both routing and MAC hiding using PBB/PW encapsulation.
- The B-VPLS accepts access interfaces using PBB encapsulation for tunneling through an Ethernet-only network.
- A regular (network level) VPLS can have a mix of regular sites and B-Sites to function as a B-VPLS (that is, operating using B-MACs).
- The backbone's Source MAC address can be configured on a B-Site. All the I-Sites provisioned under this B-Site shares the provisioned values. By default, this is a loopback chassis MAC address. It must be a unicast MAC address.
- A B-Site site can not be deleted until all its I-Site associations are removed.
- A B-Site can have both spoke and mesh SDP bindings and only an MPLS type of tunnel can be used (including LDP SDP). This also applies for a regular pseudowire, where the outgoing PBB frame on a B-SDP (that is, a B-PW) contains a B-VID qtag only if the PW type is Ethernet VLAN. Alternatively, if the pseudowire type is Ethernet, the B-VID qtag is stripped before the frame goes out.
- Only Null, dot1q, and QinQ encapsulation types can be used by a B-Site L2 access interface. These access interfaces must use PBB encapsulation and have the following properties:
  - Ethernet dot1q is applicable to the bulk of PBB use cases, such as one B-VID.
  - Ethernet Null is supported for direct connection between neighboring I-VPLS, for example, when no B-VID is required and all traffic is sent to or from local I-VPLS.
  - There is no requirement for a PBB SAP type for PBB on the B-VPLS SAPs. Only the B-VID is used for tunnel delimitation on the port.
  - The default access interface type is blocked for the B-L2 access interface.
  - The following rules apply to the SAP processing of PBB frames:

    > For transit frames (frames not destined to a local MAC), there is no need to process the I-tag component of the PBB frames. Regular Ethernet SAP processing is applied to the backbone header (B-MACs and B-VID).

    > If a local I-VPLS instance is associated with the B-VPLS, then local frames (frames originated or terminated on local I-VPLSs) are PBB encapsulated and de-encapsulated using the pbb-etype provisioned under:

    related port->I-VPLS->root pbb component

    (listed in decreasing order of precedence, where the related port is highest in the order).
- If a VPLS has an attached B-Site, the Include B-Site(s) indicator on the General tab of the VPLS configuration form is selected

Service topology map views

Service and composite service topology maps support PBB.

The service map shows different types of sites with various icons for I-Sites, B-Sites, and Epipe PBB sites. With an I-VPLS bound to B-VPLS, the map shows the PBB backbone network as a cloud. The bindings between I-VPLS and B-VPLS are shown as a binding link.

MRP and MMRP support

The Multiple Registration Protocol allows participants in an MRP application to register Group MAC addresses with other participants in a Bridged LAN. An MRP participant may transmit and receive

MRP PDUs. For the PBB implementation, the MRP parameters can be configured at the service site level, on the access interface, or the SDP binding.

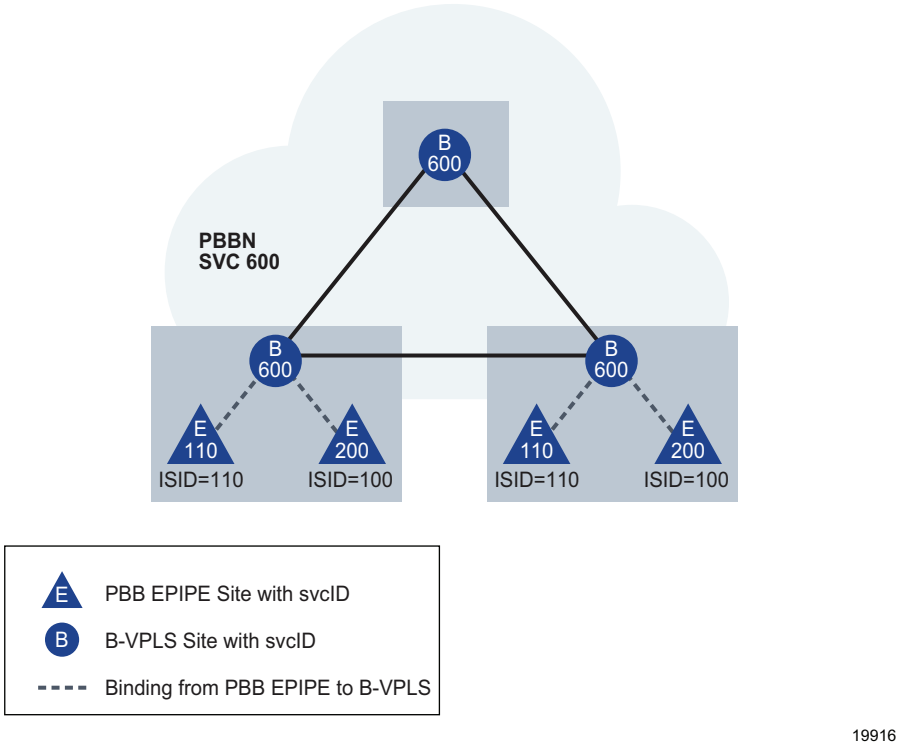
If MRP is enabled on the NE, the NFM-P MMRP application automatically advertises the presence of the Group B-MAC address on the active B-VPLS virtual links—that is, on the B-Site spoke bindings or the B-L2 access interfaces. You can view the MMRP entries advertised and/or received on the Forwarding Control→MMRP Entries tabs of the B-Site spoke bindings or the B-L2 access interfaces. All of the MMRP entries may also be viewed together at the I-Site level.

Epipe service with PBB

A PBB tunnel may be linked to an Epipe and to a B-VPLS. MAC switching and learning is not required for the point-to-point service, since all packets ingressing the Epipe access interface are PBB encapsulated and then forwarded to the PBB tunnel for the backbone destination MAC address. Similarly, all the packets ingressing the B-VPLS and destined for the ISID are PBB de-encapsulated and then forwarded to the Epipe access interface. A fully-specified backbone destination address must be provisioned for each PBB Epipe instance to be used for each incoming frame on the related Epipe L2 access interface. If the backbone destination address is not found in the B-VPLS forwarding database, then packets may be flooded through the B-VPLSs.

To enable an Epipe service with PBB, the Epipe site is configured as a PBB site and functions similarly to a VPLS I-Site. This can only be specified during the site's creation. On the Epipe PBB site, you select a B-Site that acts as the tunnel for the Epipe. You also specify the destination B-MAC address of the remote PE where the other site is located. The following figure shows a simplified view of this configuration.

Figure 77-6 Epipe service link to a B-VPLS



See the *7750 SR OS Services Guide* for more information about PBB.

77.2.5 EVPN

The VPLS solution has some limitations: MAC address learning is limited in the data plane, and active-active multi-homing is not available. Ethernet VPN addresses these limitations.

EVPNs are used to connect data centres. An EVPN is a network of PE and CE devices, connected using a layer 2 overlay over a layer 3 network. An EVPN instance is configured on a PE router. The PE router can be the VPLS interface of a VPRN.

In an EVPN, MAC learning between PEs occurs in the control plane. The control plane for advertising MAC reachability information is Multiprotocol BGP (MP-BGP). PEs learn MAC addresses from the CEs that are connected to them and advertise them to other PEs in the control plane using MP-BGP. Control plane learning allows EVPN to support different data plane encapsulation technologies between PEs. The PEs may be connected to each other by an MPLS LSP infrastructure or an IP infrastructure. If an IP or MPLS infrastructure is in use, IP/GRE or MPLS tunneling can be used between the PE devices.

In addition to MAC learning within the control plane, BGP-EVPN is capable of efficient multi-destination traffic delivery and active-active multi-homing.

The data plane is configured in VPLS and Epipe. The following data planes are supported:

- EVPN-VXLAN:

  With EVPN-VXLAN integration the VPLS site performs data plane learning on the traffic received from the VXLAN and implements EVPN to distribute the client MAC addresses learned into BGP. VXLAN or Ethernet frames are encapsulated with MPLS when sending the packets over the MPLS core and with the VXLAN tunnel header when sending the packets over the VXLAN network.

  Depending on the NE and release, up to two VXLAN instances can be created on a VPLS. If two instances are created, one sends data to the DC LAN and one toward the WAN.

  EVPN tunneling with EVPN-VXLAN:

  Each VXLAN can be identified using a VNI in the VPLS. The VNI needs to be the same for the VPLS to communicate. Each VPLS is associated with a VPRN for L3 connectivity. If an EVPN tunnel is configured in an IRB backhaul R-VPLS, there is no need to provision the IRB IPv4 addresses on the VPRN.

- EVPN-MPLS:

  MPLS edge switches (MES) can be PEs in an EVPN. The MES devices are interconnected using LSPs. EVPN-MPLS integration allows the use of MPLS functionality for routing with EVPN control plane learning.

- EVPN-VPWS:

  EVPN with VPWS offers the benefits of EVPN in a point-to-point implementation. An EVPN-VPWS network offers single-active or active-active multihoming.

- PBB-EVPN:

  With PBB-EVPN, instead of sending the customer MAC addresses as control plane learning, the backbone MAC addresses are distributed in the EVPN. This simplifies control plane learning in the EVPN and allows for increased efficiency in a large network.

- ETree:

  An ETree service is a type of Ethernet service that is based on a rooted-multipoint Ethernet virtual connection. In an ETree, each attachment circuit is designated as either a root or a leaf AC. A leaf AC can send or receive traffic only from a root. A root can send traffic to another root or to a leaf. If a root or leaf tag specified in a SAP, it will replace the outer VLAN tag for data routing.

Ethernet segments

An ES is a group of ports on an NE that are part of the same redundancy group, and are identified by a unique Ethernet Segment Identifier. They can be associated with ports, LAGs, SDPs, or VXLANs. To support multi-homing, the ESI should be the same between two PEs.

The use of an ES composed of physical links satisfies the redundancy requirements for CEs that are directly connected to the ES PEs by a port, LAG, or SDP, however it does not work when there is an aggregation network between the CEs and the ES PEs, and different ESs must be defined in the same port or LAG.

The concept of the physical links in an ES is extended to Ethernet Virtual Circuits where many of such EVCs can be aggregated on a single physical External Network-to-Network Interface (ENNI).

An ES that consists of a set of EVCs is referred to as a virtual ES (vES).

A vES can be associated with:

- Qtag-ranges on dot1q ports or LAGs
- S-tag-ranges on QinQ ports or LAGs
- C-tag-ranges per S-tag on QinQ ports or LAGs
- VC-ID ranges on SDPs
- Service ranges on VXLANs
  For service ranges to be created, the Network Interconnect VXLAN must be set to 1.

Interconnect Ethernet segments

An I-ES is a virtual ES, that is, an ES that consists of a set of Ethernet Virtual Circuits instead of a set of physical links. An I-ES allows DC GWs with two BGP instances to handle VXLAN access networks. I-ESs support the multi-homing functions of BGP MPLS EVPN.

An I-ES is used to connect a VXLAN to MPLS. Both services will be up at the same time with two different BGP instances.

77.2.6 SPB in VPLS

SPB simplifies network creation and configuration because service provisioning is required only at the network edge. SPB uses IS-IS to dynamically build the topology between NEs. The NFM-P supports SPB on B-VPLS services.

SPB allows shortest path forwarding in a mesh network by using multiple equal cost paths. In addition, SPB supports a link state spanning tree. SPB is appropriate for larger layer 2 topologies, with faster convergence than STP variant protocols for the same size networks, and improved use of the mesh topology.

The main components of B-VPLS SPB are:

- control B-VPLS
- user B-VPLS

The control B-VPLS defines the SPB IS-IS instance and is associated with an ECT algorithm and a set of SAPs or spoke SDPs for link connectivity. The user B-VPLS is a logical B-VPLS subset of the control B-VPLS. User B-VPLSs are associated with the forwarding ID, which is a logical backbone VLAN ID, that you define in the control B-VPLS. The user B-VPLS forwarding ID does not have to match the control B-VPLS forwarding ID. The user B-VPLS must be a subset of the control B-VPLS, or else a black hole can occur.

You can perform the following OAM diagnostic tests on SPB-enabled B-VPLSs:

- CFM link trace
- CFM loopback

Note: SPB does not support MEPs on SAPs and spoke SDP bindings. You cannot create an SPB instance on a control or user B-VPLS if any MEPs or MIPs are enabled on a SAP or

spoke SDP binding. Virtual MEPs are supported. You cannot configure MIPs on SPB-enabled SAP and spoke SDP bindings.

Static B-MACs and ISIDs

An SPB interface on a SAP or SDP can have static B-MACs and static ISIDs that are not part of the SPB network or region. Static B-MACs and ISIDs allow SPB networks to interface with other PBB networks that use other control planes. Static B-MACs allow remote PBB Epipes to connect to SPB managed networks. Static ISIDs allow I-VPLS services to connect to non-SPB I-VPLS services. You can define an ISID policy to use the default multicast tree and to suppress the advertisement of ISIDs in SPB when I-VPLS or static ISIDs are used for unicast services. See 77.27 “To create a static ISID range on a VPLS B-L2 access interface or spoke SDP binding” (p. 2288), 77.65 “To create a static B-MAC on a B-VPLS site” (p. 2329), and 77.66 “To create an ISID policy on a control or user B-VPLS site” (p. 2330) for more information.

SPB B-VPLS audit

You can perform an RCA audit on an SPB-enabled B-VPLS to verify whether:

- all user B-VPLS SAPs and spoke SDP bindings are fate-shared with a control B-VPLS. The following are the fate-sharing rules:
  - a user B-VPLS Dot1Q SAP fate-shares with the control B-VPLS SAP if they are in the same physical port
  - a user B-VPLS QinQ SAP fate-shares with a control B-VPLS SAP if they are in the same physical port and have the same top tag
  - a user B-VPLS spoke SDP binding fate-shares with a control B-VPLS spoke SDP binding if they are in the same SDP
- user B-VPLS instances belonging to the same service on different sites must have same forwarding ID
- the ECT-to-forwarding ID mapping is consistent on all the sites for the active B-VPLS services
- the ISID policy (Control/User) of all sites in the B-VPLS is consistent. All sites in this service must have the same ISID configuration if the Use Default Multicast Tree and No Advertise Local parameters are enabled.
- the ISID policy (Control/User) of all sites in the B-VPLS is configured. ISID ranges that are defined by one service site are be defined by all service sites of this service.

77.2.7 BGP Auto Discovery

BGP Auto Discovery enables a VPLS PE router to discover other PE routers that are part of the same VPLS domain. This allows each PE's configuration to consist only of the identity of the VPLS instance established on a specific PE, and not the identity of every other PE in that VPLS instance. If you need to change the VPLS topology, only the affected PE's configuration needs to change. Other PEs automatically discover the change using MP-BGP and adapt themselves accordingly. In contrast, if the BGP AD functionality is not used, you must then explicitly configure each PE router with the identities of all the other PEs in a specific VPLS.

You must assign a single, globally unique VPLS-ID to each VPLS (that is, the same value for all sites to the same VPLS across the entire network). The VPLS-ID eliminates the possibility of a collision between VPLSs belonging to different service providers.

There is also a globally unique Route Distinguisher (RD) ID associated with a VPLS. Each site also needs a unique ID that is a BGP NLRI. The PE address does not have to be globally routable, but it must be unique within the VPLS. The PE ID can be the PE router ID, for operational convenience.

Each site must also be associated with one or more RT Extended Communities, and the RTs control the distribution of NLRIs.

Each PE distributes the NLRI for each of its sites, with itself as the BGP next hop, and with the appropriate RT for each NLRI. A PE with a specific RT imports all NLRIs that have that same RT (and learns the other PEs addresses through their next hops). H-VPLS can be configured by using multiple RTs.

In summary, the BGP advertisement for a specific site in a PE includes:

- An NLRI. This is the VSI-ID.
- A BGP next hop equal to the loopback address of the PE.
- An extended community attribute containing the VPLS-ID.
- An extended community attribute containing one or more RTs.

Targeted-LDP [(T-)LDP] signaling is set up for the point-to-point PWs between sites using the selected (T-)LDP sessions corresponding to the remote PE(s) that have been recently added to their list.

To auto-create a spoke SDP binding, you must create a PW template policy and distribute the policy to the NEs. The NFM-P policy distribution mechanism is used to send out the template and maintain consistency in the network. The template selection is at the PE level, not at the service level, because not all PEs are capable of supporting BGP AD and some VPLS sites may not support BGP discovery.

Consider the following with regard to tunnel creation:

- If you plan to use BGP AD for all or part of the VPLS, you must not enable automatic mesh SDP binding creation.
- A provisioned PW to a specific remote PE takes precedence over one that is auto-discovered using BGP AD. In other words, if there is an existing SDP binding available, the router selects this existing binding and does not automatically create a new one.
- When the NFM-P auto-tunnel creation function is being used for non-BGP AD VPLSs, the automatically-created components are excluded from discovery. Also, you cannot select an automatically-created SDP or SDP binding when you create a service tunnel that is to be used as part of a BGP AD VPLS.

An NFM-P-managed VPLS or H-VPLS may consist of various site types located on different PEs, and which in turn, may be of differing versions. Due to these possibilities, some restrictions apply in terms of using Auto Discovery. For example, an M-VPLS site cannot be in the same service with a regular site. However, BGP AD-enabled sites and regular sites can be components of the same VPLS.

77.2.8 BGP VPLS

BGP VPLS is an extension of the VPLS concept. When configured as a BGP VPLS, such a service can interconnect with another BGP VPLS across different VPLS domains.

The control plane of the BGP VPLS provides auto-discovery and signaling capability. In this context, auto-discovery is a means for a PE router to discover other remote PE routers that are members of a given VPLS. The signaling function enables a PE router to know which pseudowire label a given remote PE router will use when sending the data to the local PE router. The BGP VPLS control plane carries sufficient information to provide the auto-discovery and signaling functions concurrently.

Some of the major features of the Nokia BGP VPLS solution include:

- The data plane is identical with the BGP AD (LDP VPLS) solution. For example, VPLS instances are interconnected via a pseudowire mesh. Split horizon groups may be used for loop avoidance between the pseudowires.
- Addressing is based on a two-byte VE ID assigned to the VPLS instance.
- The target VPLS instance is identified by the Route Target (RT) contained in the MP-BGP advertisement (extended community attribute).
- Auto-discovery is MP-BGP based.
- Pseudowire label signaling is MP-BGP based. As a result, the BGP NLRI content also includes label related information such as block offset, block size, label base, and so forth,

The Nokia BGP VPLS solution is compliant with RFC 4761.

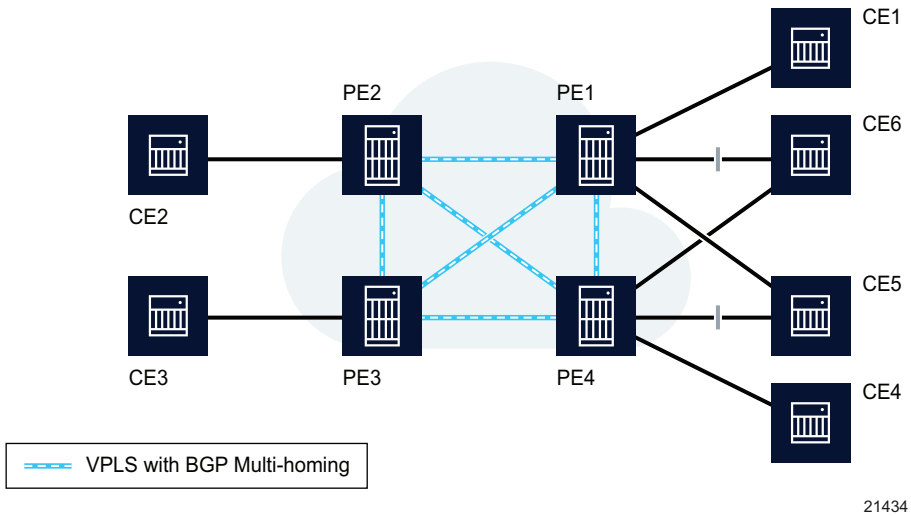
See the *7750 SR OS Services Guide* for more information regarding BGP VPLS.

77.2.9 BGP VPLS Multi-homing

The NFM-P allows BGP VPLS multi-homing to be established for CEs and access PEs by first configuring the multi-homing VPLS sites and then assigning the same multi-homing site ID to each.

The following figure shows an example of this approach, where a VPLS contains certain CEs that are multi-homed to pairs of VPLS PEs.

Figure 77-7 CE Multi-homing in VPLS



The BGP/LDP-signaled PW infrastructure (shown as the cloud at the center) is used to interconnect the VSIs between PEs. In this example, CE5 and CE6 are dual-homed to PE1 and PE4. To avoid loops, only one SAP must be active at any point in time between any multi-homed CE (such as CE5 or CE6) and its pair of connected PEs (such as PE1 and PE4). The others are blocked. Service providers use their MP-BGP on PE1 and PE4 to control the activation of the SAPs connected to the same customer site.

Other CE topologies (for instance, square connectivity) where, for example, CE1 and CE4 are part of the same customer site (and are themselves interconnected) are also supported.

When multi-homing a VPLS site using BGP (potentially into different autonomous systems), the PE routers (for example, PE1 and PE4) that are connected to the same customer site (for example, CE5) are configured with the same multi-homing ID. In this way, a loop-free topology is constructed using a routing mechanism such as BGP path selection. When a BGP speaker receives two equivalent NLRIs, it applies standard path selection criteria such as local preference and AS path length to determine which NLRI to choose.

Two VPLS NLRIs are considered equivalent from a path selection perspective if the following are identical:

- Route distinguisher
- Multi-homing ID

77.2.10 MVR on VPLS

MVR on VPLS is a bandwidth optimization method for applications on a broadband services network. At the port level, MVR allows a VPLS end user to subscribe or unsubscribe to a multicast stream on one or more network-wide multicast VPLS instances without requiring that the stream be part of the customer VPLS.

MVR on VPLS is a mechanism through which the supporting devices are able to participate in a multicast distribution system. Separate, dedicated VLANs must be constructed specifically for multicast traffic distribution.

MVR assumes that hosts join and leave multicast streams by sending IGMP join and leave messages. The IGMP join and leave messages are sent inside the VPLS to which the host port is assigned. The multicast VPLS is shared in the network while the hosts remain in separate VLANs. For example, two user VPLS that are bound to the same MVR VPLS cannot exchange any information, but the same multicast service can still be provided to them.

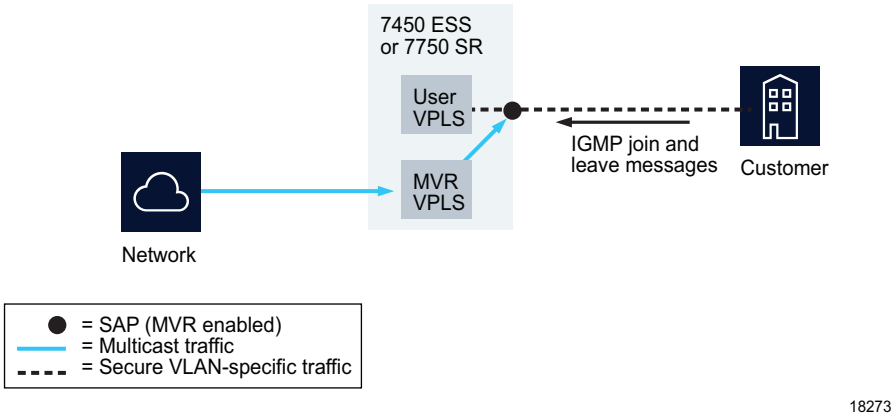
An MVR VPLS is a VPLS that is responsible for sending multicast traffic through the network. An MVR VPLS is associated with a multicast package policy and has MVR-enabled sites. The MVR VPLS is configured to distribute certain multicast streams. An MVR VPLS can also be configured as a user VPLS to receive multicast traffic.

A user VPLS is a VPLS that contains SAPs that can receive multicast traffic from an MVR VPLS. Each SAP must be configured individually to use a specific MVR VPLS. Any VPLS, including an MVR VPLS, can be used as a multicast receiver for an MVR VPLS. IGMP and/or MLD snooping must be enabled on each site.

The following figure shows an example of MVR on VPLS. MVR reacts only to join and leave IGMP messages from the multicast groups configured for the MVR VPLS with which the user VPLS is

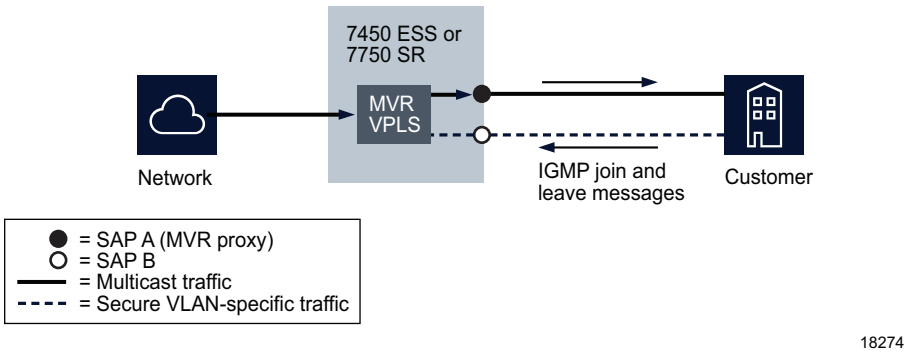
associated. Join and leave messages from all other multicast groups are managed by IGMP and/or MLD snooping. Therefore, several MVR VPLS instances can be configured, each with its own set of multicast channels.

Figure 77-8 MVR on VPLS



In some situations, such as when a host is connected to a 7301 ASAM, the multicast traffic cannot be sent from the MVR VPLS to the VLAN on which the IGMP message was received (standard MVR behavior) but to another VLAN. This configuration is known as MVR by proxy. The 7450 ESS, 7750 SR, and 7950 XRS allow multicast traffic to be sent to a SAP other than the SAP from which the IGMP message originated. When configuring MVR by proxy, you must indicate the MVR VPLS on which the multicast channel is available and the SAP to which the multicast traffic must be copied. The following figure shows an example of MVR by proxy.

Figure 77-9 MVR by proxy



Configuring MVR on VPLS using the NFM-P involves the following steps.

1. Configure PIM before configuring MVR. See Chapter 28, “Routing protocol configuration” for more information.

2. Create a multicast package policy for all supporting NEs in an MVR VPLS. See Chapter 52, “Multicast policies” for more information.

   Alternatively, you can configure NEs individually in an MVR VPLS using a routing policy statement. See 54.5 “To configure a routing policy statement” (p. 1745) for more information.

3. Create the MVR VPLS. See 77.48 “To configure MVR for a VPLS site” (p. 2308) for more information.
   - Associate the multicast package policy with the service, which indicates that a VPLS is an MVR VPLS.
   - Specify the VPLS sites that are the sources of the multicast groups. MVR must be enabled on each site.
   - Configure SAPs only if you are configuring the MVR VPLS to be a user VPLS as well. See 77.5 “To create a VPLS” (p. 2249) for more information about configuring a user VPLS.

4. Create the user VPLS. See 77.5 “To create a VPLS” (p. 2249) for more information.
   - The SAPs are standard host access points.
   - Configure IGMP and/or MLD snooping and MVR on each site.
   - Associate the MVR VPLS with each SAP for which access to multicast traffic is needed. This association means that IGMP requests received at that SAP for a multicast group are fulfilled as long as the multicast group being requested is included in the multicast package policy of the MVR VPLS. After the SAPs in a user VPLS have been associated with a specific MVR VPLS, the SAP becomes known to the MVR VPLS.

5. If using MVR by proxy, configure a VPLS SAP that is to act as the MVR proxy. See 77.48 “To configure MVR for a VPLS site” (p. 2308) for more information.

In a situation in which an MVR VPLS has VPLS sites that do not support MVR, the following conditions apply:

- The ability to configure MVR is not available for the VPLS sites and SAPs of a device that does not support MVR.
- Multicast package policies are not distributed to the devices that do not support MVR.

77.2.11 GSMP group on VPLS

The edge devices determine the circuit that opens an ANCP session. ANCP provides status and control information such as current line rate and port-up and port-down messages to the edge devices. The edge devices perform the following functions:

- adjust the H-QoS subscriber scheduler with the correct rate
- raise an alarm when the rate goes below a set threshold
- send DSL line OAM commands to complete OAM tests

A GSMP group is created under the GSMP tab of the VPLS site form. Multiple groups can be defined and different ANCP capabilities can be associated with different groups. A neighbor can be defined in a GSMP group. Multiple neighbors can be configured for each group.

Note: A GSMP group must be configured on VPLS, MVPLS or VPRN for an ANCP session to open.

77.2.12 L2 management interfaces on VPLS

L2 management interfaces act as a host. L2 management interfaces are created the same way out-of-band interfaces are created on VPLS. L2 management interfaces are used for CPM protocols such as telnet, SSH, SNMP, ping, and ANCP.

CPM filtering is used to limit access to L2 management interfaces.

77.2.13 Routed VPLS

A routed VPLS connector joins an L3 access interface within an IES or VPRN service context to a VPLS service on the same site. When an IES or VPRN IP interface is bound to a VPLS site name, the site name cannot be bound to another IP interface. While an IES or VPRN IP interface can only be bound to a single VPLS site, the service context containing the IP interface can have other IP interfaces bound to other VPLS sites. Both the IES or VPRN IP interface and VPLS site must be located on the same NE.

If a VPLS site name does not exist within the system, the binding between the IP interface and the VPLS site remains operationally down until a VPLS site name is assigned to the VPLS site. When an IP interface is bound to a VPLS site, the operational state of the RVPLS binding is dependent upon the operational state of the VPLS site, and whether the IP interface binding is enabled on the VPLS site.

This functionality is limited to supporting devices.

Note: You can create and manage a routed VPLS connector from the navigation tree on the Composite Service (Edit) form or from an IES or VPRN access interface form, routed VPLS path.

The routed VPLS binding will not be operationally up until the Enable IP interface binding parameter is set to true and the VPLS site is operationally up. See 77.33 “To configure a VPLS site” (p. 2294) for more information.

You can add a routed VPLS L3 access interface to an IGMP interface on an IES or VPRN service.

For supported 7210 SAS-K nodes, RVPLS uses an IES, VPRN L3 access interface, or spoke SDP binding on the same NE as the RVPLS connector.

77.2.14 FIBs

The FIB is the set of information that represents the best forwarding information for a destination. A FIB entry is analogous to a static MAC address, and every computer and network node has a MAC address that is hardware-encoded. In NFM-P, static MAC addresses can be also created on VPLS endpoint objects, access interfaces, and service circuits.

The edge devices perform the packet replication required for broadcast and multicast traffic across the bridged domain. Devices perform MAC-address learning to reduce the amount of unknown destination MAC address flooding. The edge devices learn the source MAC addresses of the traffic arriving on their access and network ports. You can also specify and manage static MAC addresses using the FIB entries table.

Each device maintains a FIB for each VPLS instance. Learned MAC addresses are populated in the FIB table of the service. All traffic is switched based on MAC addresses and forwarded between all participating sites using the service. Unknown destination packets (i.e., the destination MAC

address has not been learned) are forwarded on all LSPs to the participating devices for that service until the router responds and the MAC address is learned by the device associated with that service.

Note: Each VPLS FIB entry consumes system resources. The devices allow you to set the maximum number of MAC entries allowed in a VPLS instance to prevent a VPLS instance from consuming a disproportionate amount of resources.

The size of the VPLS FIB can be configured with a low watermark and a high watermark expressed as a percentage of the total FIB size limit. If the actual FIB size grows above the configured high watermark percentage, an alarm is generated. If the FIB size falls below the configured low watermark percentage, the alarm is cleared.

77.2.15 MAC learning

Like an L2 device, learned MACs within a VPLS instance can be aged out if no packets are sourced from the MAC address for a specified period of time (the aging time). In each VPLS, there are independent aging timers for locally learned MAC and remotely learned MAC entries in the FIB. A local MAC address is a MAC address associated with an access interface, because it ingressed on a SAP. A remote MAC address is a MAC address received using a service tunnel from another device that is part of the VPLS.

Unknown MAC discard is a feature which discards all packets ingressing the service where the destination MAC address is not in the FIB. The normal behavior is to flood these packets to all end points in the service.

MAC learning can also occur for Split Horizon Groups (SHG) but with accompanying risks. For example, in an L2 environment of an SHG, hosts (among whom mutual communication is disallowed) can launch DoS attacks by sending a flood of packets that source an uplink MAC address to unprotected customer SAPs.

This situation can be managed by controlling MAC learning on SAPs and SDPs. When a frame arrives at a protected SAP or SDP, the MAC is applied to its learning table; when a frame arrives at an unprotected customer SAP or SAP containing the address of a protected source MAC address, the system can be configured to take one of the following actions:

- The frame is immediately dropped and not learned by the unprotected SAP. As a result, the unprotected SAP does not know the MAC address of the uplink and, therefore, cannot use it to flood packets to other SAPs in the SHG.
- The frame is not dropped, but an alarm is generated.
- The SAP is placed in an operational Down state.

In addition, you can specify automatic population of the MAC protect list with source MAC addresses learned on the SAP or SDP.

Auto Learn Mac Protect and Restrict Protected Source functionalities are supported on SAPs, spoke and mesh SDP bindings, split horizon groups, and endpoints under a VPLS service. The functionality is also supported on Service PW-Template policies, in order to allow its use with BGP auto discovery for spoke SDP bindings and split horizon groups.

77.2.16 MAC move

A sustained high MAC re-learn rate can be a sign of a loop somewhere in the VPLS topology. Typically, STP detects loops in the topology, but for those networks that do not run STP, the MAC move feature is an alternative way to protect the network against loops.

When enabled on a VPLS, MAC move monitors the re-learn rate of each MAC. If the rate exceeds the configured allowed limit, it disables the SAP on which the source MAC last arrived. The SAP can be disabled permanently or for a length of time that grows linearly with the number of times the SAP is disabled.

There is also the option of marking a SAP as non-blockable, which means that when the re-learn rate exceeds the limit, another SAP—one that is blockable—is disabled instead. When the MAC move parameter is set to blockable, ports can be blocked in a specific order depending on the number of times the re-learn rate exceeds the configured threshold period.

MAC move is configurable on VPLS SAPs and VPLS spoke SDPs. Blocking information for an object is displayed on the MAC move configuration form for the object. This information includes:

- the number of MAC learning retries that remain before blocking occurs
- the time that remains before the blocked object is unblocked
- the order of blocking, starting with tertiary, secondary and primary

77.2.17 MAC rewrite

With Layer 2 policy-based redirects, packets may be discarded by the far-end router when the packets arrive. This can occur if the far-end IP interface has a different MAC address than the IP interface that is reachable via normal forwarding.

To avoid the discards, you can specify a destination MAC overwrite address for VPLS and MPLS SAPs to override the address specified in the device routing table. When enabled, all Unicast packets have their destination MAC rewritten to an operator-configured value that is expected to be that of the far-end IP interface. Multicast and broadcast packets are unaffected. This feature is not supported on B-VPLS, I-VPLS, Capture SAP, or Routed VPLS. See 77.69 “To assign QoS policies or to enable a MAC override address to a VPLS or MVPLS L2 access interface” (p. 2340)

77.2.18 Flooding

Traffic that is normally flooded throughout the VPLS can be rate limited on SAP ingress through the use of Service Ingress QoS Policies. In a Service Ingress QoS Policy, individual queues can be defined per forwarding class to provide shaping of broadcast traffic, MAC multicast traffic and unknown destination MAC traffic. You can also specify how to classify frames.

Multiple services and service types can be configured on a port. VPLS spanning tree protocols are configured on a per-service site basis, not a per-port basis, thus, multiple instances of STP per site are supported. Unknown destinations, broadcasts, and multicasts are flooded to all other SAPs in the service.

The flooding mechanism and the way that the Interior Gateway Protocol (IGP) operates ensure that no packets are duplicated on any interface. If SAPs are connected together, either through misconfiguration or for redundancy purposes, loops can form and duplicate packets can traverse the network. The STP is designed to prevent multiple SAPs from forwarding a packet into the VPLS

77.2.19 Spanning tree protocols

The NFM-P supports RSTP for VPLS instances and maintains support for legacy STP implementations. STP on the 7750 SR and 7950 XRS incorporates an optimized and compatible implementation of IEEE 802.1D which attempts to eliminate STP blocking of links in the core of the VPLS. STP on the 7210 SAS and 7450 ESS is used to guarantee that service tunnels are not blocked in any circumstance while not imposing artificial restrictions on the placement of the root bridge in the network. To provide this support, all mesh service tunnels are configured as root ports or designated ports.

RSTP, which is the default STP mode managed by the NFM-P, is compliant with IEEE standard 802.1D-2004. Other available STP types include an RSTP variant with 802.1w-2001 backward compatibility, an STP variant that is compliant with 802.1w-2001, and MSTP, an STP variant that is compliant with 802.1s-2002.

The NFM-P verifies STP parameters that are configured within each VPLS instance. However, it does not check the compatibility of STP configurations between interconnected VPLS instances.

77.2.20 IGMP snooping

IGMP snooping allows a device to snoop packets sent between IP multicast devices and IP multicast hosts to learn the IP multicast group membership. The device checks the IGMP packets for the group registration information, and configures multicasting accordingly.

Without IGMP snooping, multicast traffic is forwarded to all ports, which is the same as broadcast traffic. IGMP snooping ensures that multicast traffic is forwarded only to ports that are members of a specific multicast group to reduce the amount of multicast traffic that passes through the device.

You can enable IGMP snooping for VPLS sites, access interfaces, and spoke SDPs.

Note: IGMP snooping is not supported when MAC subnetting is enabled.

77.2.21 MLD snooping

Multicast Listener Discovery snooping is essentially the IPv6 version of IGMP snooping. The guidelines and procedures are very similar to IGMP snooping.

When MLD snooping is not enabled, L2 switches treat multicast traffic like an unknown MAC address or broadcast frame, that is, the frame is flooded out on every port of a VLAN. When MLD snooping is enabled, switches snoop the frame's L3 header for more efficient switching. In the context of IP multicast, only hosts that have expressed interest in receiving packets for the multicast groups have the frames forwarded to them.

The 7x50 router allows the enabling of MLD snooping for VPLS. A database of group members (per VPLS instance) is built by listening to MLD queries and reports from each SAP and SDP of the instance. These reports are forwarded to the multicast routers, if any are present.

MLD snooping is not supported when MAC subnetting is enabled.

Consider the following:

- Multicast groups can be learned (using the destination IP addresses of multicast packets) through MLD snooping or by static configuration at the port.
- The Fast leave feature modifies the membership leave mechanism by terminating the session

immediately, rather than issuing a group-specific query to check if other members are still present on the network. Therefore, if a port (SAP or SDP) is configured for Fast leave, the session is terminated immediately without checking if the port also has other hosts subscribed to that same multicast group.

- A multicast router retains a list of multicast group memberships for each attached network. Therefore, a multicast router can assume the role of querier or listener. However, there can be only one querier per physical network.
- MLD snooping statistics are collected for each NE port, SAP, or SDP binding, and are viewable from the Statistics tab of a VPLS site properties form.
- The NFM-P supports MLDv1 and MLDv2.
- The NFM-P supports MVR.
- MLD snooping can co-exist with IGMP snooping and PIM snooping.
- MAC-based forwarding entries can be built using MLD snooping results.

77.2.22 PIM snooping

Protocol Independent Multicast snooping for VPLS allows a VPLS PE router to build multicast states by snooping PIM protocol packets that are sent over the VPLS. The VPLS PE then forwards multicast traffic based on the multicast states.

When all receivers in a VPLS are IP multicast routers running PIM, multicast forwarding in the VPLS can be efficient when PIM snooping for VPLS is enabled. After PIM snooping is turned up at the service level, all sites have PIM snooping configured and are set to the down state, by default. If any site does not support this feature, the NFM-P treats it as having PIM snooping turned off.

Since PIM snooping operates on PIM Hello packets as well as Join/Prune packets, PIM neighbors of the current router are learned by snooping on Hello packets. Therefore, in a meshed VPLS, every node learns from every other node's Hello packet and considers that node as a neighbor.

VPLS PE routers only snoop on PIM Hello and Join/Prune packets; they do not generate PIM messages on their own. Therefore, when PIM snooping is configured at the service level, all CE routers must have Join/Prune suppression disabled. If a VPLS PE router detects a condition where Join/Prune suppression is not disabled on one or more CE routers, the PE router puts PIM snooping into a non-operational state for the entire service. A trap on the PE is generated to report this condition and an alarm is raised to the NFM-P operator. To bring PIM snooping back to the operational state, PIM snooping must be disabled and then re-enabled.

Since PIM uses state refreshes, VPLS PE routers may not learn multicast states from all the CE routers, if PIM snooping was just enabled or the all snooping state was just cleared, until the next refresh.

To avoid traffic interruption, PIM snooping should hold up its operations for a period of time (60 seconds, if default timer is used). During this period of time, multicast traffic is flooded in the VPLS just like snooping was not enabled. The NFM-P should have this hold-up timer configurable on VPLS properties panel having range 0-120 with 60 secs as default.

A variety of statistics are gathered for PIM snooping operation and are available for viewing and analysis in the PIM Snooping tab of a VPLS configuration form under the Multicast tab.

PIM snooping is not supported when MAC subnetting is enabled.

77.2.23 Split horizon groups

SHGs control traffic that flows through SAPs or spoke SDPs for a VPLS site. SHGs prevent a packet received on a SAP within the group from being propagated to other members of the group.

SHGs are defined when you create or modify a VPLS site. You can create multiple SHGs for a VPLS site. SHGs can support a mix of spoke SDPs and SAPs. When you create SAPs or spoke SDPs they can be associated with an SHG.

Users can:

- configure, modify, or delete SHGs on a VPLS site
- associate SAPs or spoke SDPs with SHGs

77.2.24 Residential split horizon groups

RSHGs are SHGs with the Residential parameter enabled. SAPs that are associated with RSHGs are called lightweight SAPs. RSHGs use dual-pass queue optimization and do not support downstream broadcast or multicast traffic.

Users can:

- configure, modify, or delete RSHGs on a VPLS site
- associate SAPs or spoke SDPs with RSHGs

Note: If a SAP or spoke SDP is associated with an RSHG, then the following apply:

- MAC pinning is enabled by default and cannot be disabled for the interface
- IGMP snooping, MLD snooping, and MVR are not configurable for the interface

77.2.25 QTag Manipulation

The NFM-P supports QTag Manipulation on supporting NEs. QTag Manipulation allows you to define actions for inner and outer VLAN IDs, and assign tag values where required. For example, you can configure QinQ Tunneling, VLAN Translation, or other manipulations for L2 traffic that ingresses and egresses the interface. QTag Manipulation is configured on the Port tab of the L2 Access Interface properties form. See the NE documentation for more information about QTag Manipulation actions.

77.2.26 Default SAPs

The NFM-P allows you to create default SAPs that you can use in an L2-based service to perform management tasks or to deliver a specific class of end-user service. One default SAP can be defined on any dot1q encapsulated Ethernet port. Up to four default SAPs can be defined on any Q in Q encapsulated Ethernet port.

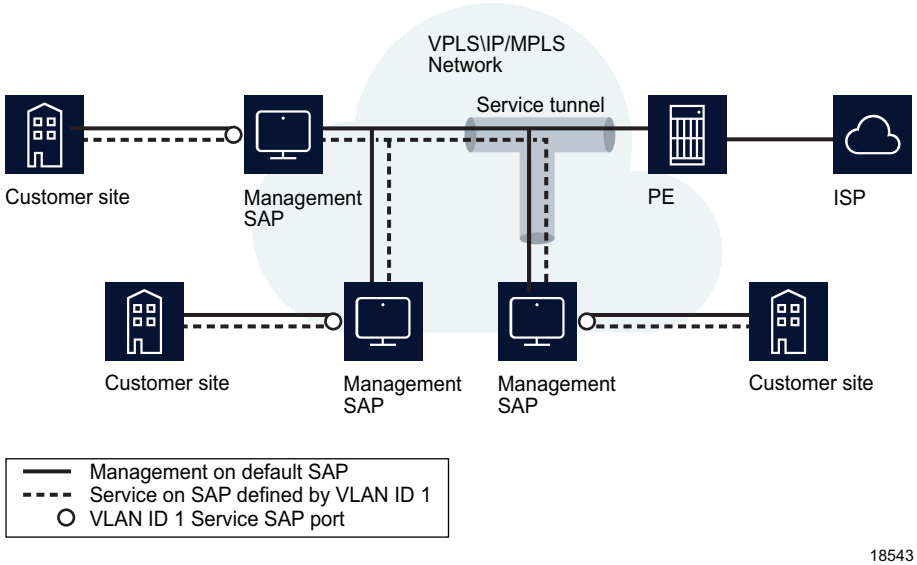
You can create a default SAP by specifying an outer encapsulation value of 4095 or *. If the XML API is used, the outer encapsulation value is always 4095. You can also enable the Enable Q in Q Untagged Sap parameter on an NE which allows the creation of the following default SAPs for a Q in Q Ethernet port:

- The SAP type *.null functions as a default SAP for single-tagged frames on a Q in Q port. This SAP accepts single tags in the range 0 to 4095 as well as untagged traffic.

- The SAP type *.* functions as a default SAP for double-tagged frames on a Q in Q port. This SAP accepts untagged, single-tagged, and double-tagged frames with tags in the range 0 to 4095.

The following figure shows a default SAP used as a dedicated management port.

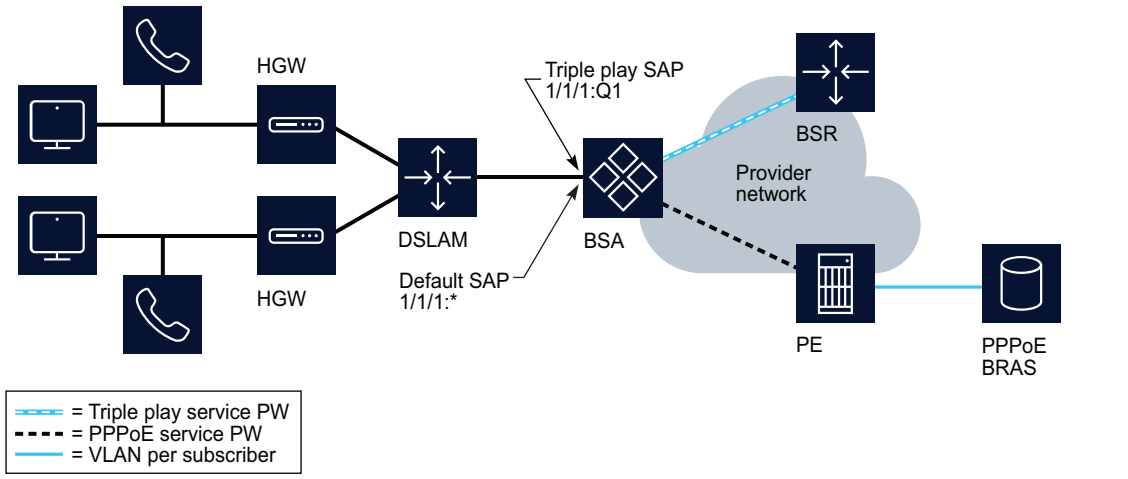
Figure 77-10 Default SAP as a dedicated management port



The dotted line shows that a business customer uses an entire port to access an L2 service using a VLAN tag ID 1, which is transparent to the network service provider. The service provider has assigned a default SAP for management of the customer network, as shown by the solid line. The customer uses one SAP for service delivery, and the service provider uses the default SAP to manage the customer network.

Default SAPs can also be used to differentiate one class of service from another on a single port. In the following figure the service provider can deliver aggregated high-speed Internet services on a single default SAP for multiple hosts while applying tags that assign one VLAN per host. At the same time, each of the remaining SAPs on the same port can be deployed for higher-level services, such as triple play delivery, in which multiple or individual hosts are assigned to a single SAP. Using such differentiated SAPs is efficient and significantly increases network scalability, because of the reduced number of SAPs allocated to various customers.

Figure 77-11 Default SAP to differentiate subscriber services



77.2.27 Layer 2 protocol tunneling termination

L2PT allows service providers to preserve the VLAN and Layer 2 protocol configurations of individual customers without impacting the traffic of other customers across the core network. L2PT termination allows Layer 2 PDUs to be transparently tunneled across the core network, avoiding interaction between the network provider and customer protocols.

Transparent L2PT is performed on the ingress side of every SAP or spoke SDP of the PE routers configured with L2PT termination. L2PT tunnels PDUs by overwriting the destination MAC address in an Ethernet frame using the multicast MAC address 01-00-0c-cd-cd-d0. The Ethernet frame is then transparently tunneled over the core network to a peer PE router. The peer PE router at the egress side of the tunnel restores the MAC address and the L2 protocol so that packets are forwarded to all ports in the same VLAN.

L2PT termination can only be enabled if STP is disabled on the VPLS.

77.2.28 BPDU translation

VPLS networks typically interconnect customer sites that use different access technologies, such as Ethernet and bridge-encapsulated ATM PVCs. Because of this, BPDU translation may be necessary to provide end-to-end interconnectivity.

If BPDU translation is enabled on a SAP or spoke SDP, the device intercepts all BPDUs and performs the required translation.

BPDU translation can be enabled only on a SAP or spoke SDP binding if STP is disabled on the VPLS.

77.2.29 DoS protection

To protect a VPLS from a high incoming packet rate that characterizes a DoS attack, you can use the NFM-P to create DoS protection policies for the VPLS L2 access interfaces. A DoS protection policy limits the number of control-plane packets that an interface receives each second, and optionally logs a violation notification if a policy limit is exceeded. You can use the NE System Security form to view the violations for a specific NE.

You can configure a DoS protection policy to control the following on a VPLS L2 access interface:

- the control-plane packet arrival rate per subscriber host on the interface
- the overall control-plane packet arrival rate for the interface
- whether an NE sends a notification trap if a policy limit is exceeded

Each VPLS L2 access interface on an NE that supports DoS protection is automatically assigned a default DoS protection policy. The default policy limits only the overall packet arrival rate for the interface, and cannot be deleted or modified. See the procedure to configure an NE DoS protection policy in the *NSP System Administrator Guide* for information about creating a DoS protection policy.

77.2.30 DDoS protection on access interfaces

You can configure a DDoS protection policy on a VPLS L2 access interface, I-VPLS I-L2 access interface, MVPLS L2 access interface, or I-MVPLS I-L2 access interface. See the procedure to configure an NE DDoS protection policy in the *NSP System Administrator Guide* for more information.

77.2.31 Copying and moving SAPs between ports

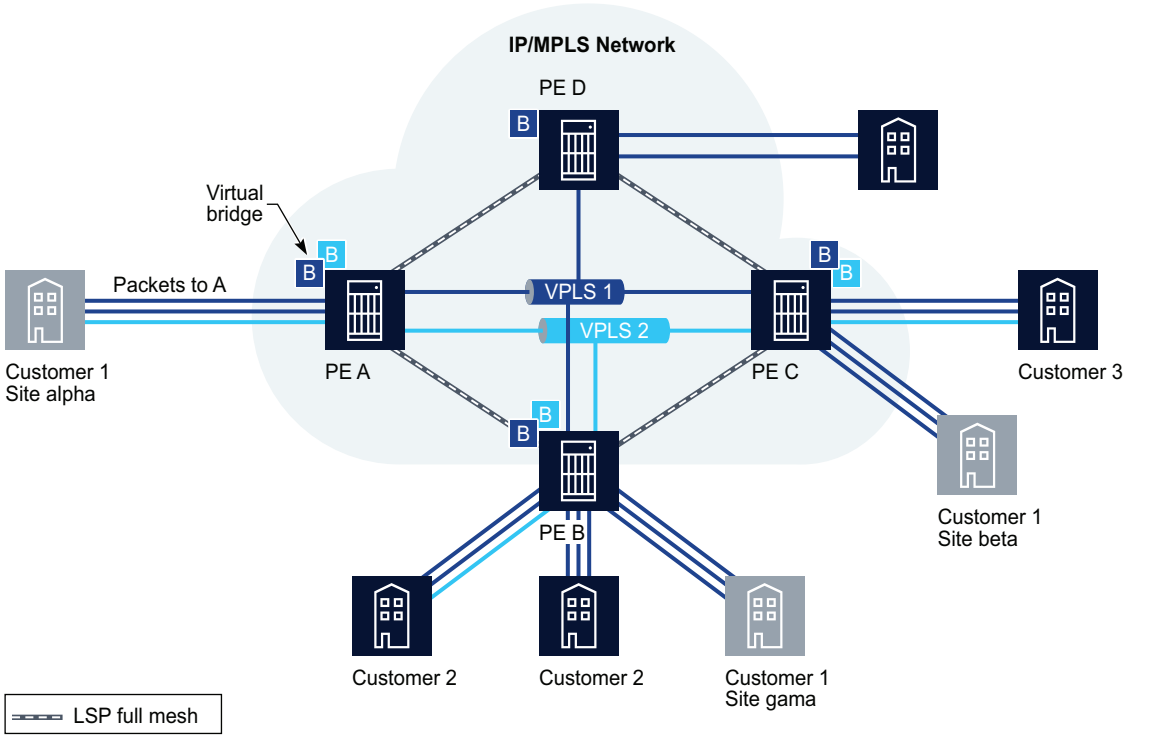
You can copy and move SAPs between ports. See 16.6 “Copying and moving SAPs” (p. 574) in Chapter 16, “Port and channel object configuration” for more information.

77.3 Sample VPLS configuration

77.3.1 Sample VPLS

The following figure shows a sample VPLS configuration.

Figure 77-12 Sample VPLS



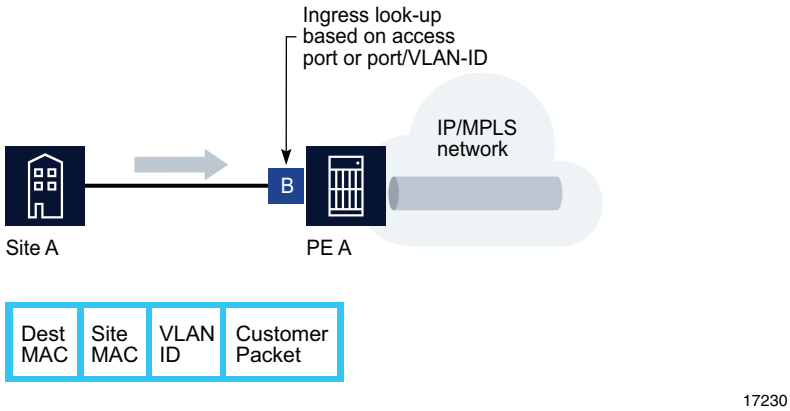
VPLS 1 is a distributed service, which consists of customer 1 connected to PE A, PE B, and PE C, at sites alpha, gamma, and beta, respectively. All three customer sites belong to VPLS 1.

In the following example, Customer 1 wants to send data from site alpha to site beta.

Customer 1 packets arriving at PE A are associated to the appropriate VPLS 1 for that customer, based on the combination of the access port and the dot1q (VLAN ID) in the packet. PE A learns the source MAC address in the packet and creates an entry in the FIB table that associates the MAC address to the access port on which it was received.

PE A is sending the packets to PE C. The destination MAC address in the packet is looked up in the FIB table of PE A for the VPLS instance, as shown in the following figure.

Figure 77-13 Packet forwarding by ingress router PE A



The destination MAC address in the FIB table has one of two values:

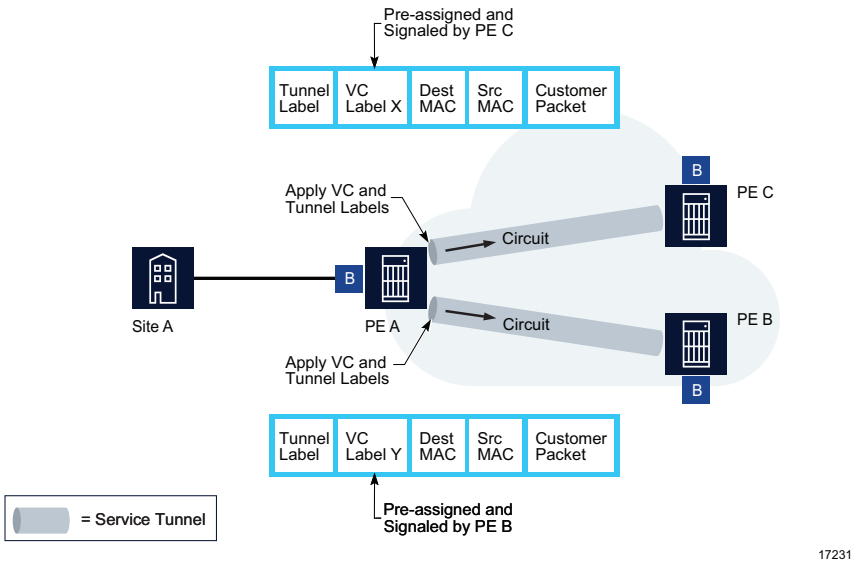
- known
- unknown

If the destination MAC address is known by PE A, an existing entry in the FIB table identifies the far-end PE C and the service VC label (VLAN ID) used to send the packets from PE A to PE C. PE A chooses a transport LSP to send the packets to PE C. The packets from the customer 1 site alpha to site beta are sent on the LSP after the VC label is removed and the transport label is added to the packet, as shown in Figure 77-13, “Packet forwarding by ingress router PE A” (p. 2239) .

If the destination MAC address is not known by PE A, PE A floods packets to both PE B and PE C, which are both part of VPLS 1. PE A uses the VC labels (VLAN IDs) that PE B and PE C previously signaled for this VPLS 1.

As shown in the following figure , the packets from PE A are transported across the core IP/MPLS network.

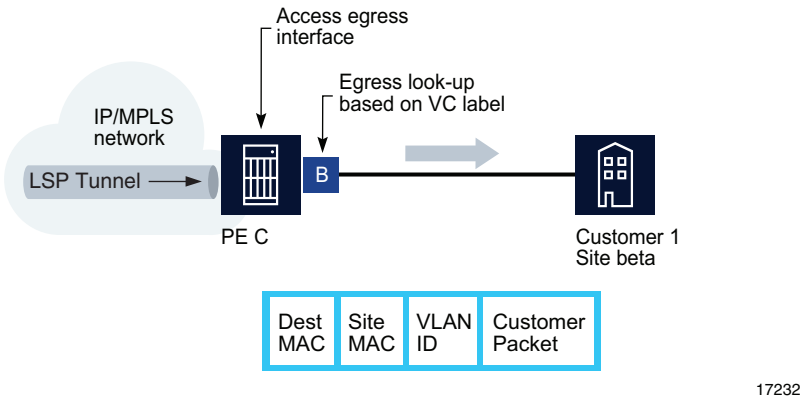
Figure 77-14 Packet forwarding from PE A across the core IP/MPLS network



The core routers are LSRs that switch the packets towards their destination based on the tunnel label, also called a transport label. The core routers are not aware that the packets belong to a VPLS.

When the packets from PE A arrive at PE C, PE C removes the tunnel label to reveal the VC label that associates the packets with VPLS 1, as shown in the following figure.

Figure 77-15 Packet forwarding by egress router PE C



PE C learns the source MAC address of PE A and creates an entry in its FIB table that associates the MAC address and the VC label with PE A. The destination MAC address is looked up in the FIB table. It has one of two values:

- known
- unknown

If the destination MAC address is known by PE C, an existing entry in the FIB table identifies the local access (egress SAP) port used by VPLS 1 site beta and the service VC label (VLAN ID) that needs to be added to send the packets from PE C to customer 1.

If the destination MAC address is not known by PE C, PE C floods packets to all local access ports that belong to VPLS 1.

77.3.2 Configuration steps

Assuming the core IP/MPLS network has already been configured, the following high-level tasks are required to configure this sample VPLS.

1

Configure policies as required, for example, access ingress and access egress, Scheduler, ACL MAC, Accounting, ANCP, DoS protection, and DDoS protection.

2

Configure ports as access ports for use in the service.

3

Configure service tunnels, as required.

4

Create and configure Customer 1.

5

Create and configure VPLS 1.

6

Create, update, or configure additional sites or L2 access interfaces for the VPLS.

7

For an HVPLS, use spoke SDP bindings to connect VPLS sites to other sites in the same VPLS, to sites in a different VPLS, or to VLL service sites.

8

Create a single MVPLS.

9

Create a composite MVPLS to manage traffic blocking for multiple VPLS.

VPLS management procedures

77.4 Workflow to create a VPLS

77.4.1 Overview

The following workflow lists the high-level steps required to create a VPLS. As a prerequisite for creating a VPLS, this workflow assumes the following:

- a group or customer with the required user access privileges has been set up.
- the IP or IP/MPLS core network exists.
- any required service tunnels are created including the static, dynamic or SR-TE LSP required to create the service tunnel. See 33.9 “To create an IP/MPLS service tunnel” (p. 1190) .
- the access ports for the service are created. See Chapter 16, “Port and channel object configuration” for more information.
- any required pre-defined routing, QoS, scheduling, filter, accounting, and time of day suite policies are created. See Chapter 49, “Policies overview” for more information. You do not have to create pre-defined policies if policies are created on a per-service basis.
- any required MP-BGP for PE-to-PE routing is configured. See Chapter 28, “Routing protocol configuration” for more information about protocol configuration.

77.4.2 Stages

1

Create and configure a VPLS. See 77.5 “To create a VPLS” (p. 2249) .

1. Define the service type as VPLS.
2. Ensure the LSP network is configured when the transport mechanism is MPLS.
3. Configure HVPLS spoke redundancy.

2

Specify the sites for the service. See 77.33 “To configure a VPLS site” (p. 2294) .

1. As required, perform the following for the VPLS site. See 77.35 “To configure MFIB, STP, FIB, and MAC learning protection for a VPLS site” (p. 2296) .
   - specify STP parameters
   - create MSTP instances and associate VLANs
   - specify protected MAC addresses
2. Configure a default gateway for the site. See 77.37 “To configure a default gateway for a VPLS site” (p. 2299) .
3. Configure ingress multicast forwarding for the site. See 77.38 “To configure ingress multicast forwarding on a VPLS site” (p. 2299) .
4. Configure a provider tunnel for the site. See 77.39 “To configure a provider tunnel for a VPLS site” (p. 2300) .

5. Specify the service tunnel required bandwidth for the site. See 77.40 “To configure service tunnel required bandwidth for a VPLS site” (p. 2301) .
6. Configure IGMP snooping on the site. See 77.41 “To configure IGMP snooping on a VPLS site” (p. 2302) .
7. Configure PIM snooping on the site. See 77.42 “To configure PIM snooping on a VPLS site” (p. 2303) .
8. Configure the split horizon group parameters. See 77.44 “To configure an SHG on a VPLS site” (p. 2304) .
9. Configure the EVPN gateway parameters. See 77.45 “To configure an EVPN gateway on a VPLS site” (p. 2305) .
10. Configure MVR. See 77.48 “To configure MVR for a VPLS site” (p. 2308) .
11. Configure GSMP group and GSMP group neighbor parameters. See 77.49 “To configure a GSMP group on a VPLS site” (p. 2309) .
12. Create L2 management interfaces on the site. See 77.50 “To configure L2 management interfaces on a VPLS site” (p. 2310) .
13. Configure MLD snooping on the site. See 77.51 “To configure MLD snooping on a VPLS site” (p. 2311) .
14. Associate a virtual MEP to the site. See 77.52 “To create a Virtual MEP on a VPLS site” (p. 2312) .
15. Configure MVR for MLD on the site. See 77.53 “To configure MVR for MLD on a VPLS site” (p. 2313) .
16. Configure IGMP host tracking on the site. See 77.54 “To configure IGMP host tracking on a VPLS site” (p. 2314) .
17. Configure WLAN GW L2 wholesale forwarding on a site. See 77.55 “To configure WLAN GW L2 wholesale forwarding on a VPLS site” (p. 2315) .
18. Configure a non-system IP termination for VXLAN. See 77.56 “To configure a non-system IP address VXLAN termination” (p. 2316).
19. Configure EVPN VXLAN on a site. See 77.57 “To configure EVPN on a VPLS site” (p. 2317) .
20. Configure PBB-EVPN on the site. See 77.59 “To configure PBB-EVPN on a VPLS site” (p. 2320) .
21. Configure a black hole MAC address on the site. See 77.60 “To configure a black hole MAC address on a VPLS site” (p. 2321) .
22. Enable SPB on a control B-VPLS site. See 77.61 “To enable SPB on a control B-VPLS site” (p. 2323) .
23. Connect an Ethernet ring to the service. See 77.22 “To connect a G.8032 Ethernet ring to a VPLS” (p. 2280) .

3

Create L2 access interfaces for the VPLS sites, as required. See 77.67 “To create a VPLS or MVPLS L2 access interface” (p. 2332) .

1. Specify aggregation on a service basis, or across a card or port.
2. Configure MSAP policies. Create an MSAP Policy to control how the parameters are applied to an MSAP when it is automatically created. See 64.10 “To configure an MSAP policy” (p. 1852) for more information.
3. Configure the SAP Sub Type as Regular or Capture, as required. Regular is the default value used for the creation of a SAP and Capture is the value used to enable the automatic creation of an MSAP. That is, you create a Capture SAP to enable the creation of an MSAP. See 74.26 “To configure a capture SAP” (p. 2049) for more information about creating a Capture SAP.
4. Assign QoS, scheduling, accounting, and filter policies. See 77.67 “To create a VPLS or MVPLS L2 access interface” (p. 2332) .
5. Specify MAC ACL filters. See 77.67 “To create a VPLS or MVPLS L2 access interface” (p. 2332) .
6. Assign a time of day suite. See 77.67 “To create a VPLS or MVPLS L2 access interface” (p. 2332) .
7. Configure queue override parameters. See 77.67 “To create a VPLS or MVPLS L2 access interface” (p. 2332) .
8. Configure the BPDU Termination, STP, and FIB parameters. See 77.72 “To configure BPDU Termination, STP, and FIB parameters for the VPLS L2 access interface” (p. 2348) .
9. Assign a DoS protection policy or DDoS protection policy. See 77.73 “To assign a DoS protection policy or DDoS protection policy to the VPLS L2 access interface” (p. 2350) .
10. Configure subscriber management. See 77.74 “To configure residential subscriber management for the VPLS L2 access interface” (p. 2351) .
11. Configure Ethernet tunnels. See 77.75 “To configure an Ethernet tunnel on a VPLS L2 access interface” (p. 2352) .
12. Configure a redundant VLAN range. See 77.76 “To configure a redundant VLAN range on a VPLS L2 access interface” (p. 2353) .
13. Configure IGMP snooping parameters. See 77.77 “To configure IGMP snooping for a VPLS L2 access interface” (p. 2354) .
14. Configure ARP hosts. See 77.78 “To configure the ARP host for the VPLS L2 access interface” (p. 2355) .
15. Configure DHCP relay parameters. See 77.79 “To configure DHCP for the VPLS L2 access interface” (p. 2356) .
16. Configure MVR. See 77.80 “To configure MVR for a VPLS L2 access interface” (p. 2357) .
17. Configure anti-spoofing parameters. See 77.81 “To configure anti-spoofing filters for a VPLS L2 access interface” (p. 2358) .
18. Configure DHCPv6 snooping parameters. See 77.90 “To configure DHCPv6 snooping for a VPLS or MVPLS L2 access interface” (p. 2381) .

19. Create a MIP and a MEP on the interface. See 77.82 “To create MIPs and MEPs on a VPLS L2 access interface” (p. 2360) .
20. Assign an ANCP policy. See 77.83 “To assign an ANCP policy to a VPLS L2 access interface” (p. 2362) .
21. Configure PIM snooping parameters. See 77.84 “To configure PIM snooping on a VPLS L2 access interface” (p. 2363) .
22. Configure MLD snooping parameters. See 77.85 “To configure MLD snooping for a VPLS L2 access interface” (p. 2364) .
23. Configure MVR for MLD. See 77.86 “To configure MVR (MLD) for a VPLS L2 access interface” (p. 2365) .
24. Configure custom object attributes for AA reporting. See 77.23 “To configure custom object attributes for AA reporting” (p. 2282) .

4

Create endpoints on the site for redundant configuration. See 77.43 “To create an endpoint for redundancy (dual homing) on a VPLS site” (p. 2303) .

5

Create a spoke SDP binding under any endpoints you created on the site. See 77.92 “To create a VPLS or MVPLS spoke SDP binding” (p. 2386) .

6

Create a mesh SDP binding for the VPLS site. See 77.91 “To create a VPLS or MVPLS mesh SDP binding” (p. 2382) .

7

Create a spoke SDP binding for the VPLS site. See 77.92 “To create a VPLS or MVPLS spoke SDP binding” (p. 2386) .

8

Configure the following on the SDP binding, as required.

1. Assign a DoS protection policy. See 77.94 “To assign a DoS protection policy to a VPLS SDP binding” (p. 2393) .
2. Configure the MFIB, STP, and FIB parameters. See 77.105 “To configure learning protection parameters on a VPLS SDP binding” (p. 2403) .
3. Configure DHCP for the SDB binding. See 77.95 “To configure DHCP for the VPLS SDP binding” (p. 2394) .
4. Configure IGMP snooping parameters. See 77.96 “To configure IGMP snooping for the VPLS SDP binding” (p. 2395) .
5. Configure DHCPv6 snooping parameters. See 77.108 “To configure DHCPv6 snooping for the VPLS or MVPLS SDP binding” (p. 2407) .

6. Create a MIP on the SDP binding. See 77.98 “To create a MIP on a VPLS SDP binding” (p. 2396) .
7. Create a MEP on the SDP binding. See 77.99 “To create a MEP on a VPLS SDP binding” (p. 2398) .
8. Configure MLD snooping parameters. See 77.100 “To configure MLD Snooping for the VPLS SDP binding” (p. 2399) .
9. Configure PIM snooping parameters. See 77.104 “To configure PIM snooping for a VPLS spoke SDP binding” (p. 2403) .
10. Configure custom object attributes for AA reporting. See 77.106 “To configure custom object attributes for AA reporting for a spoke SDP binding” (p. 2405) .

9

Configure a site for BGP AD or BGP VPLS, as required. See 77.110 “To configure a site for BGP AD or BGP VPLS” (p. 2408) .

1. Create a routing policy statement to define the required community members. See 54.5 “To configure a routing policy statement” (p. 1745) .
2. Enable BGP on the routing instance of each NE in the VPLS or BGP VPLS. See 28.29 “To enable BGP on a routing instance” (p. 916) .
3. Configure global-level BGP on each NE in the VPLS or BGP VPLS. See 28.31 “To configure global-level BGP” (p. 918) .
4. Create a PW template policy. See Chapter 83, “Service PW template policies” for information about PW template policies.
5. Distribute the PW template policy to each NE that is or will be a component of the VPLS or BGP VPLS.
6. Configure a site for BGP VPLS Multi-homing, as required. See 77.111 “To configure a site for BGP VPLS Multi-homing” (p. 2412) .
7. Configure a site for EVPN VXLAN, as required. See 77.57 “To configure EVPN on a VPLS site” (p. 2317)
8. Configure a site for PBB-EVPN, as required. See 77.59 “To configure PBB-EVPN on a VPLS site” (p. 2320) .
9. Configure ethernet segments for a PBB-EVPN, as required. See 77.17 “To configure an Ethernet segment” (p. 2275) .
10. Create SDPs for the BGP VPLS Multi-homing site(s), if manually-provisioned service tunnels are required. See 33.9 “To create an IP/MPLS service tunnel” (p. 1190) .
11. Re-evaluate the PW template policies associated with a BGP AD or BGP VPLS site when a policy is modified. See 77.112 “To re-evaluate the PW Templates associated with a BGP AD or BGP VPLS” (p. 2416) and 83.5 “To reevaluate a PW template policy on a local definition after a configuration change” (p. 2747) .

10

Perform one or more of the following.

a. Create an HVPLS. See 77.6 “To create an HVPLS” (p. 2249) .

b. Create an MVPLS. See 77.7 “To create an MVPLS” (p. 2251) .

c. Create a B-site for VPLS or MVPLS. See 77.24 “To create a B-site for VPLS or MVPLS” (p. 2283) .

d. Create an I-VPLS. See 77.8 “To create an I-VPLS” (p. 2253) .

e. Create a VPLS or MVPLS B-L2 access interface. See 77.87 “To create a VPLS or MVPLS B-L2 access interface” (p. 2366) .

f. Create a VPLS I-L2 access interface. See 77.88 “To create a VPLS I-L2 access interface” (p. 2372) .

g. Configure a GNE site on a VPLS service. See 77.34 “To configure a GNE site on a VPLS service” (p. 2295) .

h. Force a switchover to a redundant spoke SDP binding. See 77.107 “To force a switchover to a redundant spoke SDP binding” (p. 2406) .

i. Run an OAM validation test for a VPLS. See 77.28 “To run a VPLS service OAM validation test” (p. 2289) .

11

As required, modify the FIB entries associated with a VPLS:

a. Add or modify FIB entries. See 77.29 “To add or modify FIB entries associated with a VPLS” (p. 2290) .

b. List FIB entries. See 77.30 “To list FIB entries associated with a VPLS” (p. 2291) .

12

As required, view VPLS information:

a. View the service topology map associated with a VPLS. See 77.12 “To view the service topology associated with a VPLS ” (p. 2269) .

b. View the VPLS operational status. See 77.15 “To view the VPLS operational status” (p. 2274) .

c. View IGMP snooping queriers. See 77.31 “To view IGMP snooping queriers” (p. 2292) .

d. View MLD snooping queriers. See 77.32 “To view MLD snooping queriers” (p. 2292) .

13

As required, modify a VPLS:

a. Using the Show Info form. See 77.10 “To view VPLS contents” (p. 2260) .

b. Using the Manage Services form. See 77.9 “To modify a VPLS” (p. 2259) .

c. Using the topology view. See 77.11 “To modify a VLPS using the topology view” (p. 2262) .

14

As required, delete a VPLS. See 77.13 “To delete a VPLS” (p. 2269) .

77.5 To create a VPLS

77.5.1 Steps

1

Choose Create→Service→VPLS from the NFM-P main menu. The VPLS Service (Create) form opens.

2

Select a customer to associate with the VPLS in the Customer panel.

3

Configure the required general service parameters.

The Service ID and SVC Mgr Service ID parameters are configurable when the Auto-Assign ID parameter is disabled.

The Default Mesh VC ID parameter is configurable when the Inherit Service ID Value parameter is disabled.

4

If you enabled the Automatic Mesh SDP Binding Creation parameter in Step 3 , select a tunnel selection profile in the Automatic Mesh SDP Binding Creation Preferences panel.

5

Save the changes and close the form.

END OF STEPS

77.6 To create an HVPLS

77.6.1 Overview

An HVPLS consists of a VPLS in which one or more sites connect to other sites in the same VPLS, different VPLS, or to VLL services.

Note: One VPLS site in an HVPLS must be configured with an SHG. See 77.2.23 “Split horizon groups” (p. 2234) in this chapter for more information.

77.6.2 Steps

1

CAUTION

Service Disruption

If you are creating an HVPLS that includes two sites in the same VPLS connected by spoke SDPs, do not create mesh SDP bindings between the sites. Mesh SDP binding functionality is available in the spoke SDP bindings between the sites.

Add a VPLS to the HVPLS.

a. Create a new VPLS.

1. Perform 77.5 “To create a VPLS” (p. 2249) .
2. Go to Step 2 .

b. Use an existing VPLS. Go to Step 3 .

2

Create another service for inclusion in the HVPLS.

a. Create a VPLS.

1. Perform 77.5 “To create a VPLS” (p. 2249) .
2. Go to Step 3 .

b. Create a VLL.

1. Perform the appropriate VLL creation procedure in Chapter 76, “VLL service management” .
2. Go to Step 3.

3

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

4

Choose a VPLS that you want to include in the HVPLS and click OK. The VPLS Service (Edit) form opens.

5

On the service tree, expand Sites→site and right-click on Spoke SDP Bindings below the site and choose Create Spoke SDP Bindings. The Spoke SDP Binding (Create) form opens.

6

Perform Step 8 to Step 34 77.92 “To create a VPLS or MVPLS spoke SDP binding” (p. 2386). Choose the destination NE for the site that you want to include in the HVPLS as the Tunnel Termination Site.

7

Perform 77.33 “To configure a VPLS site” (p. 2294) to add sites to the HVPLS.

END OF STEPS

77.7 To create an MVPLS

77.7.1 Purpose

An MVPLS runs RSTP or MSTP to manage traffic blocking on the associated VPLS. Perform this procedure to create an MVPLS to run MSTP, or to run RSTP and manage traffic on the associated VPLS SAPs or redundant spoke SDPs. The procedure also applies to the I-Sites and B-Sites used in PBB.

77.7.2 Steps

1

Choose Create→Service→MVPLS from the NFM-P main menu. The MVPLS service (Create) form opens.

2

Select a customer to associate with the MVPLS.

3

Configure the required parameters.

4

To configure service tunnel required bandwidth for the service:

Note: To configure service tunnel required bandwidth, you must enable the Multi-Segment Tunnel Selection and Service Bandwidth Management checkboxes on the Services tab on the NFM-P System Preferences form. For more information, see the procedure to configure NFM-P system preferences in the *NSP System Administrator Guide*.

1. Click on the Bandwidth tab.
2. Configure the Bandwidth Method parameter.
3. If the Bandwidth Method parameter is set to Manual or Calculate, configure LSP Path Booking parameter.
4. If the Bandwidth Method parameter is set to Manual, enter a required bandwidth value for each CoS (see CoS 0 Bandwidth - CoS 7 Bandwidth).

5

On the service tree, right-click on Sites under MVPLS and choose one of the following:

- Create MVPLS B-Site
- Create MVPLS I-Site
- Create MVPLS Site

6

Select a site. Depending on your selection in Step 5 , the MVPLS B-Site (Create), MVPLS I-Site (Create), or MVPLS Site (Create) form opens.

7

Perform one of the following:

a. Create an RSTP site for the MVPLS.

1. For regular VPLS sites, perform Step 4 to Step 5 of 77.33 “To configure a VPLS site” (p. 2294) . Specify RSTP as the value for the STP Mode parameter in Step 6 of 77.35 “To configure MFIB, STP, FIB, and MAC learning protection for a VPLS site” (p. 2296) . Go to 4 when completed.
2. For B-Sites, perform Step 5 to Step 20 of 77.24 “To create a B-site for VPLS or MVPLS” (p. 2283) . Specify RSTP as the value for the STP Mode parameter in Step 8 4 . Go to 4 when completed.
3. For I-Sites, perform Step 8 to Step 25 of 77.8 “To create an I-VPLS” (p. 2253) . Specify RSTP as the value for the STP Mode parameter in Step 14 4 . Go to 4 when completed.
4. Repeat 1 , 2 , or 3 , as required, for each site that you want to create in the MVPLS.

b. Create an MSTP site for the MVPLS.

1. For regular VPLS sites, perform Step 4 to Step 5 of 77.33 “To configure a VPLS site” (p. 2294) . Specify MSTP as the value for the STP Mode parameter in Step 6 of 77.35 “To configure MFIB, STP, FIB, and MAC learning protection for a VPLS site” (p. 2296) . Go to 4 when completed.
2. For B-Sites, perform Step 5 to Step 20 of 77.24 “To create a B-site for VPLS or MVPLS” (p. 2283) . Specify MSTP as the value for the STP Mode parameter in Step 8 4 . Go to 4 when completed.
3. For I-Sites, perform Step 8 to Step 25 of 77.8 “To create an I-VPLS” (p. 2253) . Specify MSTP as the value for the STP Mode parameter in Step 14 4 . Go to 4 when completed.
4. Repeat 1 , 2 , or 3 , as required, for each site that you want to create in the MVPLS.

8

Save the changes and close the forms.

9

If the MVPLS site is to manage traffic on associated VPLS SAPs, create a SAP for the MVPLS with a defined redundant VLAN range.

Note: If an MVPLS site has SAPs that manage traffic on the associated VPLS SAPs, you must define a redundant VLAN range during SAP creation in the MVPLS.

1. For regular VPLS sites, perform Step 4 to Step 29 of 77.67 “To create a VPLS or MVPLS L2 access interface” (p. 2332) . Ensure that you perform 77.76 “To configure a redundant VLAN range on a VPLS L2 access interface” (p. 2353) to specify a redundant VLAN range. Go to 4 when completed.
2. For B-Sites, perform Step 4 to Step 25 of 77.87 “To create a VPLS or MVPLS B-L2 access interface” (p. 2366) . Ensure that you perform Step 20 to specify a redundant VLAN range. Go to 4 when completed.
3. For I-Sites, perform Step 4 to Step 30 of 77.88 “To create a VPLS I-L2 access interface” (p. 2372) . Ensure that you perform Step 23 to specify a redundant VLAN range. Go to 4 when completed.
4. Save the changes and close the form.The MVPLS service (Edit) form reappears.

10

Save the changes and close the forms.

END OF STEPS

77.8 To create an I-VPLS

77.8.1 Steps

1

Choose Create→Service→VPLS from the NFM-P main menu. The VPLS Service (Create) form opens.

2

Select a customer to associate with the VPLS in the Customer panel.

3

Configure the required parameters.

4

To configure service tunnel required bandwidth for the service:

Note: To configure service tunnel required bandwidth, you must enable the Multi-Segment Tunnel Selection and Service Bandwidth Management checkboxes on the Services tab on the NFM-P System Preferences form. For more information, see the procedure to configure NFM-P system preferences in the *NSP System Administrator Guide*.

1. Click on the Bandwidth tab.
2. Configure the Bandwidth Method parameter.
3. If the Bandwidth Method parameter is set to Manual or Calculate, configure LSP Path Booking parameter.

4. If the Bandwidth Method parameter is set to Manual, enter a required bandwidth value for each CoS (see Override Service Configuration).

5

Perform one of the following.

a. Create an I-site for the VPLS. Go to Step 6 .

b. Complete service creation if I-sites, I-L2 access interfaces, and SDP bindings for the VPLS are to be created later. Go to Step 30 .

6

On the service tree, right-click on Sites and choose Create VPLS I-Site.

7

Select a site. The I-Site (Create) form opens.

8

Configure the general parameters.

9

Configure the parameters in the Routed VPLS panel.

10

Configure the parameters in the Load Balancing panel.

11

Click on the Backbone tab.

12

Select the Backbone VPLS site.

Note: The selection of the B-site in this step must be repeated for each I-site you create, since you must select the B-VPLS site that is within the same site as the I-site.

13

Configure the required parameters.

The Force Q Tag Forwarding parameter is only displayed if the NE for this site is in chassis mode D or higher or Sparrow.

14

To configure MFib, STP, FIB, and MAC Protection parameters for the I-site:

1. Click on the Forwarding Control tab.

2. Configure the required parameters.
3. Click on the STP tab to configure STP parameters for the I-site.
4. Configure the bridge-level STP parameters for the I-site.

   Nokia STP in a VPLS interoperates with customer STP implementations as a mechanism for loop detection and prevention. The bridge-level parameters balance the STP resiliency and speed of convergence.

   Modifying the bridge-level parameters must be done within the constraints of the following formulas:

   - 2 (Bridge Forward Delay – 1.0 s) >= Bridge Max Age
   - Bridge Max Age >= 2 (Bridge Hello Time + 1.0 s)

   Note:

   If you are configuring an MVPLS I-site, set the STP Mode parameter to RSTP or MSTP, depending on the MVPLS type. The MSTP option is available only if you are creating an MVPLS. See 77.7 “To create an MVPLS” (p. 2251) for more information about creating an MVPLS.

   MSTP is configurable only on the 7450 ESS, 7750 SR, and 7950 XRS.
5. Click on the FIB tab to configure FIB parameters for the I-site.
6. Configure the required parameters.
7. Configure the required MAC move parameters in the Mac Move panel.
8. Click on the MAC Protection tab to configure the list of protected MAC addresses.
9. Click Create. The MAC Protection (Create) form opens.
10. Configure the Protected Mac Address parameter.
11. Save the changes and close the form.
12. To configure an MVPLS I-site that requires MSTP, click on the MSTP tab.
13. Configure the required parameters.
14. Click on the MST Instances tab.
15. Click Create. The MST Instance (Create) form opens.
16. Configure the required parameters.
17. Click on the VLAN Ranges tab. Click Create. The MST Instance Managed VLAN range (Create) form opens.
18. Configure the required parameters.
19. Save the changes and close the forms.

15

To configure ingress multicast forwarding:

Note: An Operational Channels tab appears when you access the VPLS I-Site form in the Edit mode. It displays data for the operational channels when traffic from a specific multicast source for a specific multicast group passes through the service. You must click Search to refresh the data. See Chapter 49, “Policies overview” for information about listing the operational channel parameters.

1. Click on the Multicast tab, then on the Mcast Path Mgmt tab.
2. Select an ingress multicast info policy.

16

To assign test generation options to the site:

1. Click on the OAM tab, then the Configuration tab.
2. Configure the required Test Generation Options parameters.

17

To configure service tunnel required bandwidth for the site:

Note: To configure service tunnel required bandwidth, you must enable the Multi-Segment Tunnel Selection and Service Bandwidth Management checkboxes on the Services tab on the NFM-P System Preferences form. For more information, see the procedure to configure NFM-P system preferences in the *NSP System Administrator Guide*.

1. Click on the Bandwidth tab.
2. Enable the Override Service Configuration parameter.
3. Configure the Bandwidth Method parameter.
4. If the Bandwidth Method parameter is set to Manual, enter a required bandwidth value for each CoS (see CoS 0 Bandwidth - CoS 7 Bandwidth).

18

Configure IGMP snooping for the site.

1. Click on the Multicast tab.
2. Click on the IGMP Snooping tab.
3. Configure the required parameters.

   The Query source address parameter is configurable when the Use query source address parameter is enabled.

19

Configure MLD snooping for the site.

1. Click on the Multicast tab.
2. Click on the MLD Snooping tab.
3. Click on the General tab and configure the required parameters.
4. Click on the MRouters tab to view a list of multicast routers.

20

If you are configuring an MVPLS I-site, go to Step 22 .

21

To configure an SHG on the site:

Note: You must configure an SHG or RSHG if you plan to create a spoke circuit from this VPLS I-site to a VLL or to another VPLS.

1. Click on the Split Horizon Groups tab.
2. Click Create. The Site, New Split Horizon Group (Create) form opens.
3. Configure the required parameters.
4. Save the changes and close the form.

22

To create an I-L2 access interface for the I-site, perform Step 3 to Step 30 of 77.88 “To create a VPLS I-L2 access interface” (p. 2372) .

23

To create a virtual MEP on the site, perform Step 3 to Step 12 of 77.52 “To create a Virtual MEP on a VPLS site” (p. 2312) .

24

To create a spoke SDP binding between the I-site and regular VPLS sites, click on the Components tab and perform Step 7 to Step 34 of 77.92 “To create a VPLS or MVPLS spoke SDP binding” (p. 2386) , as required. I-sites can only use spoke SDP bindings.

Note: You cannot create a spoke SDP binding on an MVPLS site that runs MSTP, or enable MSTP on a site that has a spoke SDP binding.
You cannot enable MSTP on an access interface that has a non-zero encapsulation value.

25

Save the changes and close the form.The I-Site (Create) form closes, and a dialog box appears.

26

Save the changes and close the form.The VPLS Service (Create) form displays the new I-site on the navigation tree under VPLS.

27

Repeat Step 6 to Step 26 to create additional I-sites for the I-VPLS.

28

To add protected MAC addresses at the service level:

1. Click on the Forwarding Control tab.
2. Click on the MAC Protection tab.

3. Click Create. The MAC Protection (Create) form opens.
4. Configure the Protected Mac Address parameter.
5. Save the changes and close the form. Protected MAC addresses that you add on the site level, as performed in Step 14 , are automatically added to the service-level MAC protection list.

29

To configure bandwidth for the service if required, click on the Bandwidth tab:

Note: The Bandwidth tab is only available if service CAC is configured. See the procedure to configure NFM-P system preferences in the *NSP System Administrator Guide* for information about enabling and disabling service CAC.

The ability to configure required bandwidth is only applicable to I-sites.

1. For each CoS, configure the CoS Bandwidth (Mbps) parameter.
2. Click on the General tab to determine the CAC status.

   If the Verify CAC button is enabled, the CAC has not been verified. The Probable Cause and CAC Status fields provide details.

The CAC Status field describes the current CAC status of the service. CAC statuses are as follows.

- CAC Verified indicates that all tunnels have sufficient bandwidth to admit service and that requested bandwidth for the service is booked on the appropriate physical links.
- CAC Failed indicates that the attempt made to admit service into the network was unsuccessful. The most likely cause for this is insufficient bandwidth. See the Probable Cause field for more specific information.
- BW Defined, No CAC Request indicates that the required bandwidth is defined on the service; however, a CAC request has not occurred.
- CAC To be Verified indicates that a tunnel has been configured on the service either manually or through the CLI; however, the required bandwidth has not been verified in the network.

The Probable Cause field describes possible reasons for the current CAC state. Probable causes are as follows.

- No Candidate Tunnels Found indicates that the autobind tunnel function was found, but no suitable tunnels were found.
- Different PBB Tunnels Applied to Service indicates that two or more different PBB tunnels are configured on this service.
- Not Enough Bandwidth on any Candidate Tunnels indicates that one or more candidate tunnels were found, but the available bandwidth was insufficient to admit the service.
- Automatic PBB Tunnel Selection Failed indicates that a suitable PBB tunnel was found, but there were errors when attempting to assign the tunnel to the service. A dialog box will provide more details.
- Site Missing Tunnel indicates that at least one selected site is not configured with a PBB tunnel.

- All PBB Tunnels have not been Verified indicates that all sites within the service have a tunnel configured, but the available bandwidth has not been booked or verified in the network.

3. To manually verify the CAC, click on the Verify CAC button if it is enabled. The NFM-P will attempt to find the most appropriate PBB tunnel for the service based on available bandwidth, and to automatically bind the tunnel to the service if one has not already been assigned.

30

Save the changes and close the forms.

END OF STEPS

77.9 To modify a VPLS

CAUTION

Service Disruption

Modifying parameters can be service-affecting.

77.9.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

The following tabs contain parameter information for the service:

- General tab—displays the general service properties
- MVR tab—displays multicast package policy information for the service
- Bandwidth tab — displays service tunnel bandwidth booking information for the service.
- OAM tab—allows the creation and execution of service-specific diagnostic tests
- Forwarding Control tab—lists the FIB and STP instances
- Sites tab—lists the sites that belong to the service
- L2 Access Interfaces tab—lists the L2 access interfaces that belong to the service
- L2 Management Interfaces tab—lists the L2 management interfaces that belong to the service
- Mesh SDP Bindings tab—displays the mesh SDP bindings that belong to the service
- Spoke SDP Bindings tab—displays the spoke SDP bindings that belong to the service, including active and backup SDP bindings associated with endpoints.

- Endpoints tab—displays the endpoints associated with the service
- Faults tab—displays the faults associated with the service
- Schedulers tab—configures the rate type and displays the egress aggregate rate limit
- QoS tab

3

Navigate to related components for the service using the navigation tree, as required.

Certain service components have related objects that can be easily examined using the navigation tree. For such objects, right-clicking them in the navigation tree offers a “Navigate to...” option in the contextual menu. If you select this option, the properties form for the related object is displayed. This can be very convenient, especially for complex services containing many sites and components.

The VPLS components for which you can navigate to such related objects include:

- I-Sites: you can navigate to the associated B-VPLS or B-(M)VPLS
- L2 Access Interfaces: you can navigate to the opposite SAP in a VLAN Uplink configuration
- Redundant L2 Access Interfaces: you can navigate to the opposite SAP.
- Mesh SDP Bindings: you can navigate to the opposite (return) mesh SDP
- Spoke SDP Bindings: you can navigate to the opposite (return) spoke SDP

4

Modify the components and parameters for the service, as required.

5

Save the changes and close the forms.

END OF STEPS

77.10 To view VPLS contents

77.10.1 Purpose

Use this procedure to view various contents of a VPLS and any modifications you make to it before deploying the changes.

Note: The procedure also provides information on the following policy types associated with the service:

- QoS SAP ingress and QoS SAP egress polices
- ACL IP/IPv6 filters and ACL MAC filter policies

Two information views are available. The Committed info view displays the current contents of a service, and the Committed menu item is always enabled. The Modified info view allows you to review any changes you make to a service before committing them. Modified, created, and deleted attributes and objects are displayed.

77.10.2 Steps

1

Choose Manage Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Click Search and select the service that you want to view or modify.

3

On the service navigation tree, expand the Sites icon and click on the required site. The site properties form is displayed.

4

Perform one of the following:

a. To view the currently committed service contents, go to Step 5 .

b. To view modified service contents before committing any changes, go to Step 6 .

5

Click on the Show Info and choose the Committed menu item. A Committed Values form is displayed and shows various policy attributes that have been previously configured and saved in the local policy. The information displayed in the form is similar to the information retrieved in CLI by running the “config>service>*Service Type#* info” command, where *Service Type#* is the type of service (followed by its Service ID, for example: vpls42) that you want to query.

6

Modify any service parameters or objects, as required. Otherwise go to Step 9 .

7

Click on the Show Info and choose the Modified menu item. A Modified Values form is displayed. The table lists modified, created, and deleted actions, as well as specific attributes and objects, along with their old value, new value, and tab location. The Attribute Title corresponds to the attribute or object name acted upon by your current modifications. For created objects, the values of mandatory attributes are shown in comma-separated format.

8

Select an item in the Modified Values form and then click Show on Form. The service form tab containing the changed item is displayed and the modified attribute is highlighted in blue.

9

Save your changes if required, and close the form.

END OF STEPS

77.11 To modify a VLPS using the topology view

77.11.1 Purpose

The topology view for a service provides a graphical representation of the various components and their interconnections. You can also use this view to add, modify, or just navigate to service components. This provides an alternative approach to performing these functions from the navigation tree view.

Working from the topology view can expedite the creation of the components, since many of the fields you would ordinarily have to set in the configuration forms will be automatically populated using this approach. OAM components can also be configured in this way. The configuration forms can also be accessed directly at any time from this view by right-clicking a component. This allows quick access to conduct more detailed component configuration.

77.11.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click on the Topology View button. The Service Topology map opens.

The remainder of this procedure contains a number of sub-procedures describing the various components that can be created and modified from the topology view. These include:

- Creating a new site. Go to Step 3 .
- Creating site components. Go to Step 9 .
- Creating SDP bindings. Go to Step 22 .

Adding a new site

3

Right-click on any blank space in the service topology map. A contextual menu is displayed. You can choose to create one of the following:

- VPLS Site
- VPLS B-Site
- VPLS I-Site

4

Select the required option. The Select Network Elements form appears.

5

Select one or more sites to add to the service and click OK. The VPLS Site (Create), VPLS I-Site (Create), or VPLS B-Site (Create) form is displayed, depending on your menu item selection. If you selected more than one site, the VPLS Site (Multiple Instances) (Create), VPLS I-Site (Multiple Instances) (Create), or VPLS B-Site (Multiple Instances) (Create) form is displayed, depending on your menu item selection.

6

Save the changes and close the form.The VPLS Site (Create) (or VPLS Site (Multiple Instances) (Create)) form closes and the new site (or sites) is displayed on the map.

7

If you want to perform detailed configuration of site properties for the new site, right-click on the site icon and select Properties. The VPLS Site (Edit) form opens. See 77.5 “To create a VPLS” (p. 2249) for detailed site configuration information.

8

Return to Step 2 for a list of other functions you can perform from the topology view or go to Step 50 to finish.

Creating site components

9

Right-click on any site icon in the service topology map. A contextual menu is displayed. You can choose to create one of the following:

- VPLS L2 Access Interface (this choice will actually display as either a regular L2 Access Interface, or a B-L2 or I-L2 variant, depending on the site you select). Go to Step 10 .
- VPLS L2 Management Interface. Go to Step 14 .
- VPLS Endpoint. Go to Step 18 .

10

If you choose to create a VPLS L2 Access Interface, then the VPLS L2 Access Interface (Create) form is displayed. If the selected site is a B-Site or I-Site, then the B-L2 or I-L2 Access Interface (Create) form is displayed accordingly.

11

Click on the Port tab and assign a port to the interface.

See 77.67 “To create a VPLS or MVPLS L2 access interface” (p. 2332) (or 77.87 “To create a VPLS or MVPLS B-L2 access interface” (p. 2366) or 77.88 “To create a VPLS I-L2 access interface” (p. 2372) for B-L2 or I-L2 Access Interfaces respectively) for detailed information on further configuring the interface.

12

Save the changes and close the form.The VPLS L2 Access Interface (Create) form closes.

13

Go to Step 21 .

14

If you choose to create a VPLS L2 Management Interface, then the VPLS L2 Management Interface (Create) form is displayed.

15

Click on the Port tab and assign a port to the interface.

See 77.67 “To create a VPLS or MVPLS L2 access interface” (p. 2332) for detailed information on further configuring the interface.

16

Save the changes and close the form.The VPLS L2 Management Interface (Create) form closes.

17

Go to Step 21 .

18

If you choose to create a VPLS Endpoint, then the Endpoint (Create) form is displayed.

19

Configure the Name parameter for the endpoint.

See 77.5 “To create a VPLS” (p. 2249) (or 77.24 “To create a B-site for VPLS or MVPLS” (p. 2283) for B-Sites) for detailed information on further configuring the endpoint.

20

Save the changes and close the form.The Endpoint (Create) form closes and the new endpoint is displayed in the topology view.

21

Return to Step 2 for a list of other functions you can perform from the topology view or go to Step 50 to finish.

Creating SDP bindings

22

Select the sites you want to connect in the service topology map and right-click on any one of them. A contextual menu is displayed.

Note: If you intend to create either a spoke or a mesh binding between two sites, the order in which you select them is important. The first site you select will become the source site and the second site will become the destination site. Therefore, it is not recommended that you do a marquee-select in the topology view, since you will not be sure of this hierarchy. Instead, select the sites individually, and hold down the Shift or Ctrl key after your first selection.
If you intend to create a full mesh between sites, then the order in which you select the sites is not important.
If you intend to add a service site to an existing mesh of sites, then the first site you select must be the one that is not currently a part of the mesh. The second site you select can be any member of the existing mesh.

23

Select Connect. Depending on the sites you selected, one or more of the following options are available:

- Create Spoke SDP Binding. Go to Step 24 .
- Create Mesh SDP Binding. Go to Step 31 .
- Create Full Mesh. Go to Step 38 .
- Add To Existing Mesh. Go to Step 44 .

24

If you choose the Create Spoke SDP Binding option, then the Spoke SDP Binding (Create) form is displayed.

Note: For this function, it is assumed that you clicked on the source site first and then held down the Shift or Ctrl key while right-clicking on the destination site to display the contextual menu.
You can also create a spoke SDP binding between a site icon and an endpoint icon, or between two endpoint icons in the topology view. Appropriate endpoints must first exist or be created to enable this.

25

Enable the Auto-Select Transport Tunnel parameter.

26

You can manually configure other parameters here if required, or just click OK. One of the following will result:

- If an available transport tunnel exists between the two sites, then the Spoke SDP Binding (Create) form closes and the new binding between the two sites is displayed in the topology view. See 77.92 “To create a VPLS or MVPLS spoke SDP binding” (p. 2386) for more detailed information on creating and configuring spoke SDP bindings.
- If an available transport tunnel does not exist between the two sites, then an error message is displayed to that affect. See Chapter 33, “Service tunnels” for information on how to create the required tunnel. Once the tunnel is created, you can repeat this sub-procedure.

27

Assuming that the spoke SDP binding was successfully created in Step 26 , select the same two sites again in the topology view, although this time do so in the opposite order that you originally selected them. This will allow you to create a spoke binding for the return tunnel.

28

Right-click on the second site you selected and choose the Create Spoke SDP Binding ... option. The Spoke SDP Binding (Create) form is displayed.

29

You can manually configure other parameters here if required, or just click OK. One of the following will result:

- If an available transport tunnel exists between the two sites, then the Spoke SDP Binding (Create) form closes and the new return binding between the two sites is displayed in the topology view.
- If an available transport tunnel does not exist between the two sites, then an error message is displayed to that affect. See Chapter 33, “Service tunnels” for information on how to create the required tunnel. Once the tunnel is created, you can repeat this sub-procedure.

30

Return to Step 2 for a list of other functions you can perform from the topology view or go to Step 50 to finish.

31

If you choose the Create Mesh SDP Binding option, then the Mesh SDP Binding (Create) form is displayed.

Note: For this function, it is assumed that you clicked on the source site first and then held down the Shift or Ctrl key while right-clicking on the destination site to display the contextual menu.

32

Enable the Auto-Select Transport Tunnel parameter.

33

You can manually configure other parameters here if required, or just click OK. One of the following will result:

- If an available transport tunnel exists between the two sites, then the Mesh SDP Binding (Create) form closes and the new binding between the two sites is displayed in the topology view. See 77.91 “To create a VPLS or MVPLS mesh SDP binding” (p. 2382) for more detailed information on creating and configuring mesh bindings.
- If an available transport tunnel does not exist between the two sites, then an error message

is displayed to that affect. See Chapter 33, “Service tunnels” for information on how to create the required tunnel. Once the tunnel is created, you can repeat this sub-procedure.

34

Assuming that the mesh SDP binding was successfully created in Step 33 , select the same two sites again in the topology view, although this time do so in the opposite order that you originally selected them. This will allow you to create a mesh binding for the return tunnel.

35

Right-click on the second site you selected and choose the Create Mesh SDP Binding ... option. The Mesh SDP Binding (Create) form is displayed.

36

You can manually configure other parameters here if required, or just click OK. One of the following will result:

- If an available transport tunnel exists between the two sites, then the Mesh SDP Binding (Create) form closes and the new return binding between the two sites is displayed in the topology view.
- If an available transport tunnel does not exist between the two sites, then an error message is displayed to that affect. See Chapter 33, “Service tunnels” for information on how to create the required tunnel. Once the tunnel is created, you can repeat this sub-procedure.

37

Return to Step 2 for a list of other functions you can perform from the topology view or go to Step 50 to finish.

38

If you choose the Create Full Mesh option, the Complete Vpls Mesh for Service Component form is displayed.

39

Click Select to display the Tunnel Selection Profiles form.

40

Click Search to display a list of available Tunnel Selection Profiles.

41

Click on the desired profile entry and click OK. The Tunnel Selection Profiles form closes and your selection is displayed in the Complete Vpls Mesh for Service Component form.

42

Click OK to accept your selection and close the Complete Vpls Mesh for Service Component form. One of the following will result:

- If available transport tunnels exist between the selected sites, then the new mesh bindings between the sites are created and displayed in the topology view. See 77.91 “To create a VPLS or MVPLS mesh SDP binding” (p. 2382) for more detailed information on creating and configuring mesh bindings.
- If available transport tunnels do not exist between all the sites, then the new bindings that can be created are displayed, and an error message is also displayed informing you that the full mesh could not be completed. See Chapter 33, “Service tunnels” for information on how to create the required tunnels. Once the tunnels are created, you can repeat this sub-procedure.

43

Return to Step 2 for a list of other functions you can perform from the topology view or go to Step 50 to finish.

44

If you choose the Add To Existing Mesh option, the Complete Vpls Mesh for Service Component form is displayed.

45

Click Select to display the Tunnel Selection Profiles form.

46

Click Search to display a list of available Tunnel Selection Profiles.

47

Click on the desired profile entry and click OK. The Tunnel Selection Profiles form closes and your selection is displayed in the Complete Vpls Mesh for Service Component form.

48

Click OK to accept your selection and close the Complete Vpls Mesh for Service Component form. One of the following will result:

- If available transport tunnels exist between the selected sites, then the new mesh bindings between the sites are created and displayed in the topology view. See 77.91 “To create a VPLS or MVPLS mesh SDP binding” (p. 2382) for more detailed information on creating and configuring mesh bindings.
- If available transport tunnels do not exist between the selected sites, then an error message is displayed to that affect. See Chapter 33, “Service tunnels” for information on how to create the required tunnels. Once the tunnels are created, you can repeat this sub-procedure.

49

Return to Step 2 for a list of other functions you can perform from the topology view or go to Step 50 to finish.

50

Close the forms.

END OF STEPS

77.12 To view the service topology associated with a VPLS

77.12.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Topology View. The Service Topology map opens.

See Chapter 4, “Topology map management” more information about service topology views.

Note: In the VPLS topology map view, a redundant spoke SDP binding under an endpoint displays differing colors, depending on whether it is in the active or backup state. Backup spoke SDP bindings are shown in purple.

3

Close the Service Topology form.

4

Close the Manage Services form.

END OF STEPS

77.13 To delete a VPLS

CAUTION

Service disruption

Deleting a service may result in a service disruption for customers.

Consider the implication of deleting the service before proceeding.

Note: A VPLS cannot be deleted if the L2 access interface has MSAPs that are in an active state. See Chapter 74, “Residential subscriber management” for more information about MSAPs.

77.13.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a service or a range of services.

3

Click on Delete. A warning form appears. This form is dynamic based on the priority of the service. Perform one of the following:

a. For services with a low priority, go to Step 4 .

b. For services with a medium priority, configure the “Enter the highest priority of the service being deleted” text field by typing: Medium. Go to Step 4 .

c. For services with a high priority, configure the “Enter the highest priority of the service being deleted” text field by typing: High. Go to Step 4 .

4

For all services, regardless of the priority configuration, acknowledge the check box that prompts you to confirm that you understand the implications of deleting the service.

Note: If you select multiple services with different priorities, you must enter the highest priority level of selected services before you can delete the services.

5

Click Yes to confirm the action. The service is deleted and removed from the list.

6

Close the Manage Services form.

END OF STEPS

77.14 To copy or move a VPLS

77.14.1 Purpose

Perform this procedure to copy or move a VPLS from one NE to another NE. The VPLS service site and all of the children objects, including SAPs, SDP bindings, MEPs on the SAPs and related CFM tests, are moved to the destination site. MEPs and associated CFM tests are included in VPLS

copy/move operations for B-sites, L2 SAPs and SDP bindings (including return SDP bindings). Return SDP bindings (from remote site to the source site) for SDP bindings from the source site to a remote site are copied or moved. Ingress and egress, scheduler, policer, accounting, and IP/MAC filters (ACLs) policies are copied and distributed to the destination NE.

If there are SAPs on different ports within a VPLS, you must move the service port by port. When the service does not already exist on the destination NE—that is, before an move operation—the service site and children objects are moved to the destination NE. Only SAPs on the specified port are moved to the destination site. After an initial move, moving the remaining SAPs on other ports is a SAP move operation. See 16.32 “To copy or move L2 SAPs between ports” (p. 614) .

Note: Consider the following site limitations when you copy or move a service:

- Copying and moving VPLS services is only supported on 7750 SR, 7450 ESS, and 7950 XRS NEs.
- The NE type and major software release of the source and destination NEs must be the same.
- The chassis mode of the destination NE must be the same or higher than the chassis mode of the source NE.
- The NFM-P copies the source site and children objects and creates them on the destination NE.
- You cannot move sites that are used in a backbone configuration.
- You cannot move sites for which RVPLS is enabled.
- You cannot move sites created by a RADIUS script for dynamic service.

Consider the following SAP limitations when you copy or move a service:

- The source and destination ports must be compatible, for example, have the same encapsulation type, be HSMDA ports or not, or both be access or hybrid.
- You cannot move or copy SAPs that are configured on PW ports and Ethernet tunnel endpoints.
- SAPs with connection profiles (ATM/VLAN) can be copied or moved when there is at least one SAP configured on the source port with the encap value in the specified range on the source service site.
- If the source site only contains SAPs with connection profiles, the site will not be copied or moved.
- If the source site contains SAPs associated with connection profiles on the specified port, and SAPs on a different port, or SAPs on the specified source port but with encap values out of the range, the site will not be copied or moved.
- Connection profiles on source SAPs must not overlap with the encap values of SAPs on the destination port or fall in a range where a SAP on the destination port may exist.

  The encap range specified in the service copy or move procedure does not apply to connection profiles.
- If there is a Ethernet Ring Path Endpoint associated with the source SAP, the association is not be copied to destination SAP.

Take into account the following service tunnel considerations when you move a service:

- If the spoke SDP bindings on the source NE use an SR-ISIS or SR-OSPF service tunnel,

the NFM-P looks for a matching tunnel on the destination NE. If no matching tunnel exist, then the NFM-P creates one.

- If the spoke SDP bindings on the source NE use an MPLS-TP service tunnel, the copy/move operation is allowed, but an MPLS-TP service tunnel must exist on the destination NE.
- You cannot move SDP bindings that use L2TPv3 service tunnels.
- You cannot move spoke SDP bindings if they are not manually created.

77.14.2 Steps

1

Choose Tools→Copy/Move→Service from the NFM-P main menu. The Service Copy/Move form opens.

2

Configure the Action Type parameter.

3

Set the Service Type parameter to VPLS or VPLS+VLL.

Note: Only VPLS is supported for the action type Copy.

4

In the Source panel, choose the NE from which you want to copy or move the service.

5

In the Source Port panel, choose the source port from which you want to copy or move the service.

6

Configure required parameters in the Source panel.

7

In the Destination panel, choose the NE to which you want to copy or move the service.

8

In the Destination Port panel, choose the port to which you want to copy or move the service.

9

Configure the required parameters in the Execution Details panel.

The NFM-P creates SAPs on the destination port with the same encapsulation values as the source SAP if you set the Outer Encap Value Offset and Inner Encap Value Offset parameters

to 0. Otherwise, the NFM-P creates SAPs on the destination port encapsulation values equal to the source encapsulation value plus the Outer Encap Value Offset or Inner Encap Value Offset parameter.

10

Click Result Export Path and specify the file name and location in which to save a text file that contains the results of service copy/move operation.

11

Click Execute.

12

Click on the Results tab to view the results of the copy or move action.

END OF STEPS

Note:

For a VPLS move, if the new site is created successfully with all children copied from the source site, the source site is deleted.

A service move searches for all of the SAPs with specified service type on the source NE, within the encapsulation value range that you specified in Step 6 on the specified port. The NFM-P creates the associated service sites on the destination NE with the corresponding SAPs on the destination port, including all children objects, such as SDP bindings, that existed on the source site.

The source site is not deleted if the new site is created successfully with only some of the SAPs from source site, for instance, there are SAPs remaining on the source site on different ports or with outer or inner encapsulation values out of the specified range. The SAPs that are within the specified encapsulation range that you specified in Step 6 will be deleted from the source port after the move, along with all corresponding SDP bindings.

If the corresponding service site exists on the destination NE, only the SAPs within the specified encapsulation range are copied/moved to the destination site. All other children objects, such as SDP bindings, under the source site are not copied or moved to the destination site. In this case, the source site will be deleted along with all other children objects when the last SAP is moved.

If a SAP exists on the destination site with same encapsulation values as the source SAP (the source SAP encapsulation values plus the Outer Encap Value Offset or Inner Encap Value Offset parameters that you specified in Step 9), the move action fails.

If there is a failure when moving a site or any of the child objects, the move action for this site fails and nothing from this site is moved to the destination NE.

If there are multiple service sites being copied or moved along with the SAPs as specified by source port and encapsulation range, the copy or move action continues to the next site if there is an individual failure.

The NFM-P reports that the copy or move action is finished when the NFM-P database transaction has completed; deployment operations on the node may continue after the database transaction is complete.

77.15 To view the VPLS operational status

77.15.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

View the Aggregated Operational State and State Cause indicators. When the Aggregated Operational State is Down or Partially Down, a check mark beside the appropriate State Cause indicator identifies the type of associated service fault.

4

Click on the appropriate tab to view or edit an object that is identified as faulty by a State Cause indicator.

5

Click on the Faults tab to view the alarms for the object. The Object Alarms tab is displayed.

6

Click on the Aggregated Alarms tab to view the aggregated alarms for the object.

7

Click on the Tests tab if the OAM Validation Failed indicator is enabled. You can view the OAM validation test suite results by clicking on the Tested Entity Result tab.

Note: You can run the OAM Validation test suite for this service from this form by clicking on the Validate button. If the Validate button is not visible, click on the More Actions button and choose Validate.
As an alternative, you can also run an OAM validation test on the service by performing a One Time Validation.

8

Save the changes and close the forms.

END OF STEPS

77.16 To configure a VPLS for AA reporting

77.16.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

Click on the Application Assurance tab. The NSP Analytics Parameters tab is displayed.

4

Configure the required parameters.

5

To configure one or more custom DCP groups, see the custom DCP group configuration procedure in Chapter 87, “Application assurance” .

6

To specify one or more application or application groups for IP detail reporting:

1. Click on the IP Detail Application or IP Detail Application Group tab and click Create. The IP Detail Application or IP Detail Application Group (Create) form opens.
2. Configure the required parameters.

   You can specify up to 10 applications and up to 10 application groups.

7

Save the changes and close the forms.

END OF STEPS

77.17 To configure an Ethernet segment

77.17.1 Purpose

Ethernet segments are used by EVPNs. An Ethernet segment is a group of ports on an NE that are part of the same redundancy group, and are identified by a unique Ethernet Segment Identifier.

77.17.2 Steps

1

Navigate to the NE where you want to configure an Ethernet segment.

2

Right-click on the NE and choose Properties. The Network Element form opens.

3

Click on the Globals tab, and then on the BGP tab. In the Ethernet Segment panel, click Create. The BGP EVPN Ethernet Segment form opens.

4

Configure the required parameters.

5

Save your changes and close the form.

END OF STEPS

77.18 To configure a BGP EVPN

77.18.1 Steps

A 7750 SR, 7450 ESS, 7250 IXR, or 7950 XRS can generate Ethernet auto-discovery routes. When BGP EVPN is configured, a single AD per-ES route with the associated RD and a set of EVI route-targets is advertised.

1

On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, and then on the Service tab.

3

Click on the BGP tab, and then on the EVPN tab.

4

Configure the required BGP EVPN parameters. The following considerations apply:

- The default Route Distinguisher Type is None. In this case, the RD is automatically built using the BGP-AD VPLS ID configured under the VPLS Site BGP tab. If you set the Route Distinguisher Type to Configured, then you need to provide an RD IP address.

- The default AD per-ES routes advertisement type is EVI-RT, which specifies the option to advertise a separate AD per-ES route per service.

  The EVI-RT Set advertisement type specifies the option to advertise a set of AD per-ES routes aggregating the route targets for all the services in the Ethernet segment. If you choose EVI-RT Set, then you need to specify the IP address part of the RD that is being used in the EVI-RT Set option.
- To allow for both EVPN VXLAN and EVPN MPLS to be in an Admin Up state on the same VPLS, different BGP IDs should be assigned to VXLAN and MPLS.
- If two EVPN VXLAN instances are created on the same VPLS, different BGP IDs should be assigned to each VXLAN.
- To allow propagation of attributes to other owners in VPRN, enable the Attribute Uniform Propagation parameter.
- To allow new BGP based selection for RT5 routes, enable BGP Path Selection parameter.
- To ignore the D-PATH domain segment length, enable the D-Path Length Ignore parameter.

5

Save the changes and close the form.

END OF STEPS

77.19 To assign a multicast package policy to a VPLS

77.19.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

Click on the Multicast tab.

4

Click on the MVR tab.

5

Select a multicast package policy. The Select Multicast Package Policy - VPLS Service - Subscriber form opens.

6

Choose a multicast package policy and click OK. The Select Multicast Package Policy - VPLS Service - Subscriber form closes, and the VPLS Service (Create) form refreshes with the multicast package policy name.

After the multicast package policy is applied to the VPLS, the policy is distributed as the routing policy to all MVR-capable VPLS sites. If you apply another package policy to the site, the new policy is distributed to the site. The previously distributed policy remains on the site.

7

Save the changes and close the forms.

8

Close the Manage Services form.

END OF STEPS

77.20 To configure bandwidth management for a VPLS

Note: In order to configure required bandwidth, you must enable the Multi-Segment Tunnel Selection and Service Bandwidth Management checkboxes on the Services tab on the NFM-P System Preferences form. For more information, see the procedure to configure NFM-P system preferences in the *NSP System Administrator Guide*.

77.20.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

Click on the Bandwidth button.

4

Click on the Required Bandwidth tab to configure service tunnel required bandwidth for the service.

5

Configure the Bandwidth Method parameter.

6

If you set the Bandwidth Method parameter to Input Manually or Calculate From SAPs,

configure LSP Path Booking parameter.

7

If you the Bandwidth Method parameter to Input Manually, enter a required bandwidth value for each CoS (see CoS 0 Bandwidth - CoS 7 Bandwidth).

8

Click on the Bandwidth Reserved Tunnel tab to reserve PBB tunnel bandwidths.

9

For each CoS, enter a value for the CoS Reserved Bandwidth (Mbps) to specify how much bandwidth this tunnel will reserve in the network.

10

Click on the Reserve Bandwidth button. This action checks to ensure that all the active links in the B-VPLS have enough bandwidth to admit the tunnel into the network and book the bandwidth. The tunnel status will be updated appropriately, based on the outcome of the action. Once the bandwidth is reserved, the BW Utilization tab on the applicable Physical Link properties form will also show this tunnel and the bandwidth information.

Note: The reserved bandwidth of the tunnel can be changed at any time after the service creation. However, if a change to the reserved bandwidth causes the used bandwidth to be greater than the requested change, or if there is insufficient bandwidth in the network to facilitate this change, then it will be denied and an appropriate message is displayed.
Once bandwidth is reserved on the tunnel, any changes to the topology of the B-VPLS (for example, uplinks added, STP state changes, and so forth) will be updated automatically with the correct bandwidth information on the underlying physical links. If there is insufficient bandwidth available when the changes happen, the bandwidth will still be booked on the physical links and the appropriate alarms will be raised.
To unreserve bandwidth of the tunnel after the service creation, you can set all of the configured Cos Reserved Bandwidth parameters back to 0. However, this can only be done when there are no longer any i-services riding on this PBB Tunnel.
After the service has been created, the Tunnel Usage tab shows all the i-services currently using this tunnel and the specific bandwidth usage per service.

11

Save the changes and close the forms.

END OF STEPS

77.21 To add protected MAC addresses to a VPLS

77.21.1 Purpose

Protected MAC addresses that you add at the VPLS site level are automatically added at the service level. See Step 8 of 77.33 “To configure a VPLS site” (p. 2294) for more information about adding protected MAC addresses at the site level.

77.21.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

Click on the Forwarding Control tab, then the MAC Protection tab.

4

Click Create. The MAC Protection (Create) form opens.

5

Configure the Protected Mac Address parameter.

6

Save the changes and close the forms.

END OF STEPS

77.22 To connect a G.8032 Ethernet ring to a VPLS

77.22.1 Purpose

Perform the following procedure to connect an existing G.8032 Ethernet ring to a VPLS. See 33.5 “Ethernet G.8032 rings” (p. 1183) for information about using the NFM-P to automatically create G.8032 Ethernet rings. See 33.18 “To create an Ethernet G.8032 ring” (p. 1212) to create G.8032 Ethernet rings using the NFM-P GUI.

Connecting an Ethernet ring adds the sites in the ring to the VPLS, then creates SAPs and paths for the ring.

77.22.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

Perform the following bandwidth management configuration as required:

a. To configure service-level bandwidth management parameters for the service, see 77.20 “To configure bandwidth management for a VPLS” (p. 2278) .

b. To configure service tunnel required bandwidth for a VPLS site, see 77.40 “To configure service tunnel required bandwidth for a VPLS site” (p. 2301) .

4

Select one or more sites in the navigation tree and right-click and choose Connect to Ethernet Ring. The sites must be part of the same Ethernet ring. The Connect to Ethernet Ring form opens.

5

Select an Ethernet ring:

a. Click Select to manually select an Ethernet ring.

b. Enable the Automatic Ring Selection parameter to automatically select an Ethernet ring and select a Tunnel Selection Profile.

Note: To use a Tunnel Selection Profile, the Multi-Segment Tunnel Selection system preference must be enabled. For information, see the procedure to configure NFM-P system preferences in the *NSP System Administrator Guide*.

6

Configure the required parameters.

Note: If you are connecting a G.8032 Ethernet ring to a VPLS using a Dot1q SAP, only configure the Data Service Outer Encap parameter. For QinQ SAPs, configure both the Data Service Outer/Inner Encap parameters.

7

As required, repeat Step 3 to perform additional bandwidth management configuration on customer SAPs. If you modify the bandwidth parameters, choose Audit CAC to recalculate service tunnel bandwidth booking.

8

Save the changes and close the forms. All sites in the ring are created in the service, if they were not already present.

END OF STEPS

77.23 To configure custom object attributes for AA reporting

77.23.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→site→L2 Access Interfaces.

4

Right-click the L2 access interface and choose Properties. The VPLS L2 Access Interface (Edit) form opens.

5

On the General tab, choose an Application Profile for the applicable Group and Partition.

6

Click on the Application Assurance tab, then the NSP Analytics Parameters sub-tab.

7

Click on the Reporting tab and click Create. The AA Reporting (Create) form opens.

8

Configure the required parameters.

9

Save the changes and close the forms.

END OF STEPS

77.24 To create a B-site for VPLS or MVPLS

77.24.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose the required VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, right-click on the Sites icon and choose Create VPLS B-Site.

4

Select a site. The B-Site (Create) form opens.

5

Configure the required parameters.

6

Click on the Backbone tab.

7

Configure the backbone parameters.

The Source MAC Address should not be duplicated for other B-sites within the same B-VPLS.

The Source MAC Address parameter is the only applicable parameter when configuring PBB on a 7210 SAS-M, 7210 SAS-T, or 7210 SAS-X.

The Use SAP Backbone MAC Address parameter is configurable only on the 7750 SR, 7750 SR-c12, 7750 SR-12E, 7450 ESS, or 7950 XRS. The NE must also be configured with an IOM 3 MDA or an XMA.

8

To configure MFIB, STP, FIB, and MRP parameters for the B-site:

1. Click on the Forwarding Control tab.
2. Configure the required parameters.
3. Click on the STP tab to configure STP parameters for the B-site. Otherwise, go to 5 .
4. Configure the bridge-level STP parameters for the B-site.

Nokia STP in a VPLS interoperates with customer STP implementations as a mechanism for loop detection and prevention. The bridge-level parameters balance the STP resiliency and speed of convergence.

Modifying the bridge-level parameters must be done within the constraints of the following formulas:

- 2 (Bridge Forward Delay – 1.0 s) >= Bridge Max Age
- Bridge Max Age >= 2 (Bridge Hello Time + 1.0 s)

Note:

If you are configuring an MVPLS B-site, set the STP Mode parameter to RSTP or MSTP, depending on the MVPLS type. The MSTP option is available only if you are creating an MVPLS. See 77.7 “To create an MVPLS” (p. 2251) for more information about creating an MVPLS.

MSTP is configurable only on the 7450 ESS, 7750 SR, and 7950 XRS.

5. To configure FIB parameters for the B-site, click on the FIB tab.
6. Configure the required parameters.
7. Configure the MAC move parameters in the Mac Move panel.
8. If you are configuring an MVPLS B-site that requires MSTP, click on the MSTP tab.
9. Configure the required parameters.
10. Click on the MST Instances tab and click Create. The MST Instance (Create) form opens.
11. Configure the required parameters.
12. Click on the VLAN Ranges tab. Click Create. The MST Instance Managed VLAN range (Create) form opens.
13. Configure the required parameters.
14. Save the changes and close the forms.
15. Click on the MRP tab and configure the required parameters.

    Note:

    You can view information regarding MMRP Entries for the access interface and/or SDP Binding by clicking on the MMRP Entries tab.

9

To assign test generation options to the site:

1. Click on the OAM tab, then the Configuration tab.
2. Configure the required Test Generation Options parameters.

10

To configure service tunnel required bandwidth for the site:

Note: To configure service tunnel required bandwidth, you must enable the Multi-Segment Tunnel Selection and Service Bandwidth Management checkboxes on the Services tab on the NFM-P System Preferences form. For more information, see the procedure to configure NFM-P system preferences in the *NSP System Administrator Guide*.

1. Click on the Bandwidth tab.
2. Enable the Override Service Configuration parameter.
3. Configure the Bandwidth Method parameter.
4. If the Bandwidth Method parameter is set to Manual, enter a required bandwidth value for each CoS (see CoS 0 Bandwidth - CoS 7 Bandwidth).

11

To configure a provider tunnel for the site:

When you configure an inclusive Provider Tunnel, multicast and broadcast Ethernet frames are always forwarded over a P2MP LSP, defined as the Inclusive Provider Multicast Service Interface (I-PMSI). When a Provider Tunnel is not configured, these frames are replicated at the ingress PE and a copy of each frame is forwarded over the P2P PW to each destination PE participating in the VPLS instance. Provider Tunnels can be configured on VPLS and B-VPLS sites.

Note: Provider tunnels are supported on the 7750 SR-7, 7750 SR-12, 7750 SR-c4, 7750 SR-c12, 7750 SR-12E, and 7450 ESS NEs in all chassis modes, as well as on the 7540 ESS, provided all network IP interfaces are on IOM3/IMM ports (chassis mode D).

1. Click on the Provider Tunnel tab.
2. Enable the Enable Provider Tunnel parameter.
3. Configure the required parameters.

   The Administrative State parameter is only configurable when the Enable BGP AD parameter has been enabled for the site.

   The LSP Template parameter is only configurable when the Type parameter is set to RSVP.

12

To create an endpoint for redundancy (dual homing) on the B-site:

1. Click on the Endpoints tab.
2. Click Create. The Endpoint (Create) form opens.
3. Configure the required parameters.
4. Save the changes and close the forms.

13

If you are configuring an MVPLS B-site, go to Step 17 .

14

To configure an SHG on the site:

Note: You must configure an SHG or RSHG if you plan to create a spoke circuit from this VPLS B-site to a VLL or to another VPLS.

1. Click on the Split Horizon Groups tab.

2. Click Create. The Site, New Split Horizon Group (Create) form opens.
3. Configure the required parameters.
4. Save the changes and close the form.

   Note:

   You can view information about the I-Sites and Epipe sites associated with the B-Site by clicking on the Associated Sites tab.

15

To create a B-L2 access interface for the site, perform Step 4 to Step 30 of 77.87 “To create a VPLS or MVPLS B-L2 access interface” (p. 2366) .

16

To create a mesh SDP binding for the site, perform Step 4 to Step 21 of 77.91 “To create a VPLS or MVPLS mesh SDP binding” (p. 2382) .

17

To create a redundant spoke SDP binding under an endpoint, perform Step 3 to Step 34 of 77.92 “To create a VPLS or MVPLS spoke SDP binding” (p. 2386) .

18

To create a spoke SDP binding for the site, perform Step 5 to Step 34 of 77.92 “To create a VPLS or MVPLS spoke SDP binding” (p. 2386) .

Note: You cannot create a spoke SDP binding on an MVPLS site that runs MSTP, or enable MSTP on a site that has a spoke SDP binding.
You cannot enable MSTP on a SAP that has a non-zero encapsulation value.

19

To create a virtual MEP on the site, perform Step 3 to Step 12 of 77.52 “To create a Virtual MEP on a VPLS site” (p. 2312) .

20

Save the changes and close the forms.

END OF STEPS

77.25 To view SPB fate-shared objects

77.25.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose the required VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, right-click on the B-site and choose Properties. The VPLS Site (Edit) form opens.

4

Click on the SBP Fate Sharing tab. The SAPs tab is displayed with a list of fate-shared SAPs within the SPB B-VPLS.

5

Click on the Spoke SDPs tab. A list of fate-shared spoke SDP bindings within the SPB B-VPLS is displayed.

6

Click on the SPB User Sites tab. A list of SPB user B-VPLS sites associated with the control B-VPLS is displayed.

7

Close the forms.

END OF STEPS

77.26 To list the SPB instances on an NE

77.26.1 Steps

1

Right-click on an NE in the Equipment navigation tree and choose Properties. The Network Element (Edit) form opens.

2

Click on the Globals tab, then on the Service tab.

3

Click on the SPB Control Instances tab. A list of all SPB instances configured on the NE is displayed.

4

Close the Network Element (Edit) form.

END OF STEPS

77.27 To create a static ISID range on a VPLS B-L2 access interface or spoke SDP binding

77.27.1 Purpose

Perform the following procedure to create a static ISID range to allow I-VPLS services to connect to non-SPB I-VPLS services. You can create one or more static ISID ranges on a B-L2 access interface or spoke SDP binding on a control or user B-VPLS site. See 77.61 “To enable SPB on a control B-VPLS site” (p. 2323) and 77.62 “To enable SPB on a user B-VPLS site” (p. 2326) for information about how to enable SPB on a control or user site.

77.27.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand the B-VPLS site.

4

Perform one of the following:

a. To add a static ISID range on a B-L2 access interface, expand the L2 Access Interfaces icon, and click on the B-L2 access interface. The Port (Edit) form opens.

b. To add a static ISID range on an SDP binding, expand the Spoke SDP Bindings icon and click on the SDP binding. The Spoke SDP Binding (Edit) form opens.

5

Click on the Static ISID tab.

6

Click Create. The Static ISID Range Entry (Create) form opens.

7

Configure the required parameters.

8

Save the changes and close the form.

9

To view the status information about the configured static ISIDs, click on the Static ISID Ranges tab.

10

Save the changes and close the forms.

END OF STEPS

77.28 To run a VPLS service OAM validation test

77.28.1 Prerequisites

An OAM validator test suite must be created for the tested entity.

Note: As an alternative, you can also run an OAM validation test on the service by performing a One Time Validation.

OAM validation tests are not supported for HVPLS.

77.28.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

Click Validate. If an OAM validator test suite is not associated to the service, a dialog box appears:

1. Click OK to associate the service with an existing OAM validator test suite. The Choose Validator Test Suite form opens.
2. Select an OAM validator test suite.

4

View the State Cause indicators. When the validation test fails, a check mark appears beside the OAM Validation Failed indicator.

5

Click on the Tests tab, then on the Tested Entity Result tab.

6

Choose an entry and click Properties. The Tested Entity Result (Edit) form opens.

7

Click on the Results tab to display the validation test results.

8

If you need to compare two test results from the same type of test, choose the two test results and click Compare; the Difference form opens. Otherwise go to Step 11 .

9

Compare the test results.

10

Close the Difference form.

11

Close the Tested Entity Result form.

12

Save the changes and close the forms.

END OF STEPS

77.29 To add or modify FIB entries associated with a VPLS

77.29.1 Steps

1

Choose Manage→Service→FIB Entries from the NFM-P main menu.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

Click on the Forwarding Control tab, then on the FIB Entries tab.

4

Click Search. A list of FIB entries appears.

5

Add or modify FIB entries:

a. To add a FIB entry:
   1. Click Create. The FIB Entry (Create) form opens.
   2. Configure the required parameters.
   3. Select an interface, service circuit, or endpoint from the list on the L2 Interfaces, Service Circuits, or Endpoints tab.
   4. Save the changes and close the form.

b. To modify FIB entries:
   1. Choose a FIB entry from the list and click Properties. The FIB Entry (Edit) form opens.
   2. Configure the parameters and view the information as required.
   3. Save the changes and close the form.

END OF STEPS

77.30 To list FIB entries associated with a VPLS

77.30.1 Steps

1

Choose Manage→Service→FIB Entries from the NFM-P main menu.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

Click on the Sites tab, then on the VPLS, B-VPLS, or I-VPLS tabs.

4

Select the site can click Properties. The VPLS Site (Edit) form opens.

5

Click on the Forwarding Control tab, then on the FIB Entries tab.

6

Click Resync for the FIB entries on the right side of the form. Resync on the bottom of the form is for re-synchronizing the entire VPLS site.

7

Click Find. A list of FIB entries appears.

END OF STEPS

77.31 To view IGMP snooping queriers

77.31.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, click on a site. The VPLS Site (Edit) form opens.

4

Click on the Multicast tab, then on the IGMP Snooping tab.

5

Click on the MRouters tab. The MRouters table displays a list of IGMP snooping queriers and their properties.

6

Click Refresh to view periodic updates to the Mrouters table.

7

Close the forms.

END OF STEPS

77.32 To view MLD snooping queriers

77.32.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expands Sites and click on a site. The VPLS Site (Edit) form opens.

4

Click on the Multicast tab, then the MLD Snooping tab.

5

Click on the MRouters tab. The MRouters table displays a list of MLD snooping queriers and their properties.

6

Click Refresh to view periodic updates to the Mrouters table.

7

Close the forms.

END OF STEPS

VPLS site management procedures

77.33 To configure a VPLS site

77.33.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, right-click on the Site icon and choose Create VPLS Site and select a site, or expand the Site icon and choose Properties. The VPLS Site (Create|Edit) form opens.

Note: The options to create either a B-Site or an I-Site are used when you are configuring a VPLS that utilizes Provider Backbone Bridging. See 77.2.4 “Provider Backbone Bridging in VPLS” (p. 2215) in “VPLS management overview” (p. 2210) for more information.

4

Configure the required general parameters.

The following considerations apply:

- To configure the Enable IP Interface Binding parameter on the 7450 ESS, you must enable mixed mode on the NE.
- For 7210 SAS NEs that support RVPLS, the Enable IP Interface Binding parameter is configurable when the RVPLS parameter is selected. To bind the site to an IES, see 78.30 “To bind an IES L3 access interface to a VPLS site or VPLS I-site” (p. 2475). To bind the site to a VPRN, see 79.98 “To bind a VPRN L3 access interface to a VPLS site or VPLS I-site” (p. 2673).
- Tunnel Fault Notification is configurable on sites where the device has ports configured in access or hybrid mode with QinQ encapsulation.
- If you are configuring a tunnel facility MEP, Tunnel Fault Notification must be set to Accept, in order to accept the fault propagation from the tunnel facility MEP.
- The Customer VID parameter is configurable only when the SAP Type parameter is set to dot1q-preserve.
- You can configure a VLAN range SAP only when the SAP Type parameter is set to dot1q-range.
- For MVPLS sites, the Allow L2Pt Xstp BPDU parameter is read-only.
- The Enable VXLAN ECMP parameter can only be configured if all cards in the chassis are FP3 or higher.

5

Configure the parameters in the GSMP panel.

6

Configure the parameters in the ETree panel.

You must enable the Etree Enabled parameter before you can configure ETree tags at the SAP or SDP spoke levels.

7

Configure the parameters in the Pim Snooping panel.

You must enable the PIM Snooping Enabled parameter before you can configure PIM snooping parameters on the Multicast tab and at the SAP and SDP spoke levels.

8

Configure the parameters in the Routed VPLS panel.

9

Configure the parameters in the Load Balancing Panel.

10

Save the changes and close the forms.

END OF STEPS

77.34 To configure a GNE site on a VPLS service

77.34.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS service and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, right-click on VPLS Service and choose Create GNE Site.

4

Select a site. The GNE Site (Create) form opens.

5

Configure the required parameters.

6

Click Apply.

7

To configure an interface for the GNE site:

1. Click on the GNE Service Interfaces tab and then click on Create. The GNE Service Interface (Create) form opens.
2. Configure the required parameters.
3. Click on the Ports tab and select a Generic NE interface.
4. Configure the required parameters.
5. Save the changes and close the form.

8

Save the changes and close the forms.

You can use the topology maps to view the service. See Chapter 4, “Topology map management” for more information about service topology maps.

END OF STEPS

77.35 To configure MFIB, STP, FIB, and MAC learning protection for a VPLS site

77.35.1 Purpose

Configure MFIB, STP, FIB, and MAC learning protection parameters for a VPLS site.

77.35.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand the site on which you want to configure MFIB, STP, FIB, and MAC learning protection parameters and click Properties. The VPLS Site (Edit) form opens.

4

Click on the Forwarding Control tab. The MFIB tab is displayed.

5

Configure the required MFIB parameters.

6

Click on the STP tab to configure the required STP parameters.

Note: Nokia STP in a VPLS interoperates with customer STP implementations as a mechanism for loop detection and prevention. The bridge-level parameters balance the STP resiliency and speed of convergence. Modifying the bridge-level parameters must be done within the constraints of the following formulas:

- 2 (Bridge Forward Delay – 1.0 s) >= Bridge Max Age
- Bridge Max Age >= 2 (Bridge Hello Time + 1.0 s)
  If you are configuring an MVPLS site, set the STP Mode parameter to RSTP or MSTP, depending on the MVPLS type. The MSTP option is available only if you are creating an MVPLS. See 77.7 “To create an MVPLS” (p. 2251) for more information about creating an MVPLS.
  MSTP is configurable only on the 7450 ESS, 7750 SR, and 7950 XRS.

7

To configure FIB parameters:

1. Click on the FIB tab.
2. Configure the required parameters.

8

To configure the list of protected MAC addresses:

1. Click on the MAC Protection tab and click Create. The MAC Protection (Create) form opens.
2. Configure the Protected Mac Address parameter.
3. Save the changes and close the form.

9

If you are configuring an MVPLS site that requires MSTP:

MSTP is configurable only on the 7450 ESS, 7750 SR, and 7950 XRS.

1. Click on the MSTP tab.
2. Configure the required parameters.
3. Click on the MST Instances tab and click Create. The MST Instance (Create) form opens.
4. Configure the required parameters.

5. Click on the VLAN Ranges tab. Click Create. The MST Instance Managed VLAN range (Create) form opens.
6. Configure the required parameters.
   - Min. VLAN Tag
   - Max. VLAN Tag
7. Save the changes and close the forms.

10

Save the changes and close the forms.

END OF STEPS

77.36 To configure SHCV for a VPLS site

77.36.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand the site on which you want to configure SHCV and click Properties. The VPLS Site (Edit) form opens.

4

Click on the Subscriber Management tab.

5

Select the SHCV Enabled parameter to enable SHCV.

6

Configure the required parameters.

7

Save the changes and close the forms.

END OF STEPS

77.37 To configure a default gateway for a VPLS site

77.37.1 Purpose

Configure a default gateway for the site.

77.37.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Configure the filter criteria and click Search. A list of services appears.

3

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

4

On the service tree, expand the site on which you want to configure the default gateway and click Properties. The VPLS Site (Edit) form opens.

5

Click on the Default Gateway tab.

6

Configure the required parameters.

7

Save the changes and close the forms.

END OF STEPS

77.38 To configure ingress multicast forwarding on a VPLS site

77.38.1 Purpose

Configure ingress multicast forwarding.

Note: An Operational Channels tab appears when you access the VPLS Site form in the Edit mode. It displays data for the operational channels when traffic from a specific multicast source for a specific multicast group passes through the service. You must click Search to refresh the data. See Chapter 49, “Policies overview” for information about listing the operational channel parameters.

77.38.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand the site on which you want to configure ingress multicast forwarding and click Properties. The VPLS Site (Edit) form opens.

4

Click on the Multicast tab, then on the Mcast Path Mgmt tab.

5

Select a multicast info policy.

6

Save the changes and close the forms.

END OF STEPS

77.39 To configure a provider tunnel for a VPLS site

77.39.1 Purpose

When you configure an inclusive provider tunnel, multicast and broadcast Ethernet frames are always forwarded over a P2MP LSP, defined as the Inclusive Provider Multicast Service Interface (I-PMSI). When a provider tunnel is not configured, these frames are replicated at the ingress PE and a copy of each frame is forwarded over the P2P PW to each destination PE participating in the VPLS instance. Provider tunnels can be configured on VPLS and B-VPLS sites.

Note: Provider tunnels are supported on the 7750 SR-7, 7750 SR-12, 7750 SR-c4, 7750 SR-c12, 7750 SR-12E, and 7450 ESS NEs in all chassis modes, as well as on the 7540 ESS, provided all network IP interfaces are on IOM3/IMM ports (chassis mode D).

77.39.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand the site on which you want to configure a provider tunnel and click Properties. The VPLS Site (Edit) form opens.

4

Click on the Provider Tunnel tab and enable the Enable Provider Tunnel parameter.

5

Configure the required parameters.

The LSP Template parameter is only configurable when the Type parameter is set to RSVP.

The Administrative State parameter is configurable only when the LSP Template parameter has been configured.

6

Save the changes and close the forms.

END OF STEPS

77.40 To configure service tunnel required bandwidth for a VPLS site

77.40.1 Purpose

To configure service tunnel required bandwidth, you must enable the Multi-Segment Tunnel Selection and Service Bandwidth Management check boxes on the Services tab on the NFM-P System Preferences form. For more information, see the procedure to configure NFM-P system preferences in the *NSP System Administrator Guide*.

77.40.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand the site on which you want to configure service tunnel required bandwidth and click Properties. The VPLS Site (Edit) form opens.

4

Click on the Bandwidth tab.

5

Enable the Override Service Configuration parameter.

6

Configure the required parameters.

If the Bandwidth Method parameter is set to Input Manually, enter a required bandwidth value for each CoS (see CoS 0 Bandwidth - CoS 7 Bandwidth).

7

Save the changes and close the forms.

END OF STEPS

77.41 To configure IGMP snooping on a VPLS site

77.41.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand the site on which you want to configure IGMP snooping and click Properties. The VPLS Site (Edit) form opens.

4

Click on the Multicast tab, then on the IGMP Snooping tab.

5

Configure the required parameters.

If the Administrative State is down, packets will be forwarded along the P2P PWs, otherwise they will be forwarded along the P2MP LSP instance.

6

Save the changes and close the forms.

END OF STEPS

77.42 To configure PIM snooping on a VPLS site

77.42.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand the site on which you want to configure PIM snooping and click Properties. The VPLS Site (Edit) form opens.

4

Click on the Multicast tab, then on the PIM Snooping tab.

5

Configure the required parameters.

If the node has associated Neighbour and (S,G) Entries, then the same is displayed under EVPN MPLS sub-tab.

6

Save the changes and close the forms.

END OF STEPS

77.43 To create an endpoint for redundancy (dual homing) on a VPLS site

77.43.1 Note

You cannot create a VPLS endpoint on a site that has an active or inactive MC ring SAP. See Chapter 45, “MC ring groups” for more information.

77.43.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand the site on which you want to create an endpoint for redundancy and click Properties. The VPLS Site (Edit) form opens.

4

Click on the Endpoints tab and click Create. The VPLS Endpoint (Create) form opens.

5

Configure the required parameters.

The EndPoint ID parameter is configurable only if you set the Endpoint Type parameter to Multi Chassis.

The Restrict Protected Source Action parameter is configurable only if you enable the Restrict Protected Source parameter.

6

Save the changes and close the forms.

END OF STEPS

77.44 To configure an SHG on a VPLS site

77.44.1 Purpose

You must configure an SHG or RSHG if you plan to create a spoke circuit from this VPLS site to a VLL or to another VPLS.

77.44.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand the site on which you want to configure SHG and click Properties. The VPLS Site (Edit) form opens.

4

Click on the Split Horizon Groups tab and click Create. The Site, New Split Horizon Group (Create) form opens.

5

Configure the required parameters.

The Restrict Protected Source Action parameter is configurable only if you enable the Restrict Protected Source parameter.

6

Save the changes and close the forms.

END OF STEPS

77.45 To configure an EVPN gateway on a VPLS site

77.45.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand the site on which you want to configure gateway and click Properties. The VPLS Site (Edit) form opens.

4

Click on the EVPN MCast Gateway tab and click Create. The EVPN Gateway (Create) form opens.

5

Configure the required parameters.

6

Save the changes and close the forms.

END OF STEPS

77.46 To configure proxy ARP for a VPLS site

77.46.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand the site on which you want to configure Proxy ARP and click Properties. The VPLS Site (Edit) form opens.

4

Enable the Enable Proxy ARP parameter.

5

Click on the Proxy ARP tab.

6

Configure the required general parameters.

Note: The Administrative State parameter is not configurable on the 7210 SAS-Mxp as it is automatically updated based on the state of global System EVPN Proxy ARP ND parameter. See 12.45 “To configure the global EVPN proxy ARP and node discovery on an NE” (p. 377) for more information.

7

Configure the parameters in the Duplicate Detect panel.

8

To configure a static proxy ARP entry:

1. Click on the Static tab.
2. Click Create. The Static Proxy ARP (Create) form opens.
3. Configure the IP Address and IEEE Address parameters.
4. Save the changes and close the form.

9

Before a dynamic proxy ARP entry can be configured, a MAC List must be configured on the NE; see 12.15 “To configure proxy ARP and proxy node discovery for an NE” (p. 351)

To configure a dynamic proxy ARP entry:

1. Click on the Dynamic tab.
2. Click Create. The Dynamic Proxy ARP (Create) form opens.
3. Configure the IP Address and MAC List parameters.
4. Save the changes and close the form.

10

Save the changes and close the forms.

END OF STEPS

77.47 To configure proxy node discovery for a VPLS site

77.47.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand the site on which you want to configure MVR and click Properties. The VPLS Site (Edit) form opens.

4

Enable the Enable Proxy Node Discovery parameter.

5

Click on the Proxy ND tab.

6

Configure the required general parameters.

Note: The Administrative State parameter is not configurable on the 7210 SAS-Mxp as it is automatically updated based on the state of global System EVPN Proxy ARP ND parameter. See 12.45 “To configure the global EVPN proxy ARP and node discovery on an NE” (p. 377) for more information.

7

Configure the parameters in the Duplicate Detect panel.

8

To configure a static proxy node discovery entry:

1. Click on the Static tab.
2. Click Create. The Static Proxy ND (Create) form opens.
3. Configure the IP Address, IEEE Address and ND Type parameters.
4. Save the changes and close the form.

9

Before a dynamic proxy node discovery entry can be configured, a MAC List must be configured on the NE; see 12.15 “To configure proxy ARP and proxy node discovery for an NE” (p. 351)

To configure a dynamic proxy node discovery entry:

1. Click on the Dynamic tab.
2. Click Create. The Dynamic Proxy ND (Create) form opens.
3. Configure the IP Address and MAC List parameters.
4. Save the changes and close the form.

10

Save the changes and close the forms.

END OF STEPS

77.48 To configure MVR for a VPLS site

77.48.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand the site on which you want to configure MVR and click Properties. The VPLS Site (Edit) form opens.

4

Click on the Multicast tab, then on the MVR tab.

5

Configure the required parameters.

The Administrative State parameter specifies whether a site is an MVR VPLS site.

After the multicast package policy is applied to the MVPLS, the policy is distributed as the routing policy to all MVR-capable MVPLS sites. If you apply another package policy to the site, the new policy is distributed to the site. The previously distributed policy remains on the site.

6

If you deselect the Use Component Package Policy parameter, you must specify a multicast package policy to associate with the MVR VPLS site. Perform one of the following.

a. Select a multicast package policy.

b. Manually enter a multicast package policy name as the Routing Policy Name parameter value.

7

View the VPLS SAPs that use the MVR VPLS site.

1. Click on the User MVR SAPs tab.
2. Click Search to list the VPLS SAPs.

8

Save the changes and close the forms.

END OF STEPS

77.49 To configure a GSMP group on a VPLS site

77.49.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand the site on which you want to configure a GSMP group and click Properties. The VPLS Site (Edit) form opens.

4

Click on the Multicast tab, then on the GSMP tab.

5

Click Create. The GSMP Group (Create) form opens.

6

Configure the required parameters.

7

Click on the GSMP Group Neighbor tab.

8

Click Create. The GSMP (Create) form opens.

9

Configure the required parameters.

The Priority Precedence parameter is configurable when the Priority Type parameter is set to Precedence.

The Priority Dscp parameter is configurable when the Priority Type parameter is set to Dscp.

10

Save the changes and close the forms.

END OF STEPS

77.50 To configure L2 management interfaces on a VPLS site

77.50.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Configure the filter criteria and click Search. A list of services appears.

3

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

4

On the service tree, expand the site on which you want to configure L2 management interfaces and click Properties. The VPLS Site (Edit) form opens.

5

Click on the L2 Management Interfaces tab.

6

Click Create. The VPLS L2 Management Interface, Service - Subscriber (Create) form opens.

7

Configure the required parameters.

Note: The NFM-P does not support the configuration of static ARP on a VPLS (MVPLS) L2 management interface. If required, this configuration must be done using CLI. Static ARP configuration must be removed from the interface using CLI before this interface can be removed using the NFM-P.

8

Click on the Addresses tab and click Create. The IP Address, Service - Subscriber (Create) Form opens.

9

Configure the required parameters.

10

Save the changes and close the forms.

END OF STEPS

77.51 To configure MLD snooping on a VPLS site

77.51.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand the site on which you want to configure MLD snooping and click Properties. The VPLS Site (Edit) form opens.

4

Click on the Multicast tab, then on the MLD Snooping tab.

5

Configure the required parameters.

6

Save the changes and close the forms.

END OF STEPS

77.52 To create a Virtual MEP on a VPLS site

77.52.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand the site on which you want to create a virtual MEP and click Properties. The VPLS Site (Edit) form opens.

4

Click on the OAM tab, then the ETH-CFM tab.

5

Configure the Tunnel Fault Notification parameter in the Facility MEPs panel.

6

Click Create in the Virtual MEP panel. The MEP (Create) form opens.

7

Select a MEG in the Maintenance Entity Group panel.

8

Configure the parameters in the MEP panel.

9

Configure the parameters in the CCM panel.

The CCM Padding Packet Size (Bytes) parameter cannot be configured when the CCM interval parameter is set to 10 ms or 100 ms.

10

Select a MEG sub-group in the MEG Sub-Grouping panel.

11

Configure the required Test Generation Options parameters.

Note: The Test Generation Options parameters are only displayed when you set the Direction parameter to Up.

12

Save the changes and close the forms.

Note: After the site is created and is operational, you can open the MEP (Edit) form and view an information field on the General tab that displays the number of Continuously Running Tests currently on the MEP.

END OF STEPS

77.53 To configure MVR for MLD on a VPLS site

77.53.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Configure the filter criteria and click Search. A list of services appears.

3

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

4

On the service tree, expand the site on which you want to configure MVR for MLD and click Properties. The VPLS Site (Edit) form opens.

5

Click on the Multicast tab.

6

Click on the MVR (MLD) tab.

7

Configure the required parameters.

The Administrative State parameter specifies whether the site is an MVR VPLS site.

The Routing Policy Name parameter is configurable when the Use Component Package Policy is disabled.

After a multicast package policy is applied to an MVPLS, the policy is distributed as the routing policy to all MVR-capable MVPLS sites. If you apply another package policy to the site, the new policy is distributed to the site and the previously distributed policy remains on the site.

8

If you deselect the Use Component Package Policy parameter, you must specify a multicast package policy to associate with the MVR VPLS site. Perform one of the following.

a. Select a multicast package policy.

b. Manually enter a multicast package policy name as the Routing Policy Name parameter value.

9

Click on the User MVR SAPs tab to view the VPLS SAPs that use the MVR VPLS site and click Search to list the VPLS SAPs.

10

Save the changes and close the forms.

END OF STEPS

77.54 To configure IGMP host tracking on a VPLS site

77.54.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand the site on which you want to configure IGMP host tracking and click Properties. The VPLS Site (Edit) form opens.

4

Click on the IGMP Host Tracking tab.

5

Configure the required parameters.

6

Save the changes and close the forms.

END OF STEPS

77.55 To configure WLAN GW L2 wholesale forwarding on a VPLS site

77.55.1 Purpose

Perform this procedure to enable L2 wholesale forwarding on a VPLS service that is bound to a WLAN GW as part of a L2 wholesale-retail configuration.

77.55.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand the site on which you want to configure a VPLS SAP template policy. Click Properties. The VPLS Site (Edit) form opens.

4

Click on the WLAN GW tab.

5

Select a SAP template policy (if required) and set the Administrative State parameter to Enabled.

6

Save the changes and close the forms.

END OF STEPS

77.56 To configure a non-system IP address VXLAN termination

77.56.1 Purpose

Use this procedure to configure a non-system IP address for VXLAN termination. The address terminating the VXLAN tunnels can be an IPv4 or IPv6 address, and the service where VXLAN is terminated can be:

- a VPLS service
- an R-VPLS service connected to a VPRN service

VXLAN is supported on 7450 ESS, 7750 SR, and 7950 XRS nodes in chassis mode D.

77.56.2 Steps

1

Create an FPE on the NE, with an SPD ID range configured and VXLAN termination enabled. See 12.41 “To create an FPE” (p. 374)

2

Create a VXLAN tunnel termination:

1. On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.
2. Click on the Globals tab, then the Service sub-tab, then the VXLAN sub-tab, then the Tunnel Termination sub-tab.
3. Enter the tunnel termination IP address. The address must be a loopback interface address and a non-system IP address.
4. In the FPE panel, click Select and choose the FPE ID created in the previous step.
5. Click Apply and close the form.

3

Create a VPLS Site. See 77.33 “To configure a VPLS site” (p. 2294).

In the VXLAN Tunnel End Point panel, click Select and choose the VXLAN tunnel termination created in the previous step.

4

Create a system interface with an IPv4 address at the NE routing instance. See 27.17 “To create an L3 network interface on a routing instance” (p. 856).

5

Configure the assisted replication IP address with the address configured in the previous step.

1. On the equipment tree, right-click on an NE and choose Properties. The Network Element (Edit) form opens.
2. Click on the Globals tab, then the Service sub-tab, then the General sub-tab.
3. Click Select and choose the interface created in the previous step, or enter the IP address of the interface.

6

Create a VXLAN identifier at the VPLS service:

1. Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.
2. Choose a VPLS service and click Properties. The VPLS Service (Edit) form opens.
3. Click on the BGP sub-tab, then the EVPN sub-tab.
4. Configure the parameters in the VXLAN panel.

   To configure the Assisted Replication type parameter as Replicator, step Step 5 must be completed.

END OF STEPS

77.57 To configure EVPN on a VPLS site

77.57.1 Purpose

Use this procedure to configure EVPN parameters on a VPLS site for EVPN -VXLAN or EVPN-MPLS. VXLAN is supported on 7450 ESS, 7750 SR, and 7950 XRS nodes in chassis mode D.

77.57.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose the required VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites and click on the site on which you want to configure EVPN.

4

Click on the BGP tab, and then on the EVPN sub-tab.

5

Configure BGP EVPN.

1. Click Create in the BGP EVPN panel. The BGP EVPN (Create) form opens.
2. Configure the parameters, as required.
3. Click Create in the VXLAN panel and configure the VXLAN parameters on the form that appears.

   If two EVPN VXLAN instances are created on the same VPLS, different BGP IDs should be assigned to each VXLAN.
4. Click Create in the MPLS panel and configure the MPLS parameters on the form that appears.

   To allow for both EVPN VXLAN and EVPN MPLS to be in an Admin Up state on the same VPLS, different BGP IDs should be assigned to VXLAN and MPLS.
5. Click Create in the Segment Routing V6 panel and configure the parameters on the form that appears.
6. Click OK and confirm to close the form.

6

Configure a network identifier for the VXLAN.

1. Click Create in the VXLAN panel. The VXLAN (Create) form opens.
2. Configure the network identifier.
3. Select a policy in the Network Ingress QoS Policy panel.
4. Select a queue group in the Forwarding Plane Queue Group panel.
5. Configure the Forwarding Plane Queue Group Instance ID parameter.
6. Configure the Assisted Replication Type parameter as needed. An assisted replication IP address must be previously configured in the NE properties.
7. Click OK and confirm to close the form.

7

Create one or more EVPN static MACs.

1. Click on the EVPN Static MAC tab, and click Create. The Conditional Static Mac (Create) form opens.
2. Configure a MAC address for the static MAC.
3. Select a SAP in the SAP panel.
4. Select a spoke SDP binding in the Spoke DSP Binding panel.
5. Click OK and confirm to close the form.

8

Save and close the form.

END OF STEPS

77.58 To configure segment routing v6 on a VPLS site

77.58.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose the required VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand the site on which you want to configure segment routing with IPv6 and click Properties. The VPLS Site (Edit) form opens.

4

Click on the Segment Routing V6 tab.

5

Create or select an entry and click Properties. The Segment Routing V6 (Create/Edit) form opens.

6

Configure the required parameters in the General tab.

7

Create or select an entry in the Locator panel and click Properties. The SRv6 Function (Create/Edit) form opens.

1. Associate a locator under Locator panel.
2. Configure the parameters under End Function panels.
3. Save your changes and close the form.

8

Save your changes and close the forms.

END OF STEPS

77.59 To configure PBB-EVPN on a VPLS site

77.59.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose the required VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites, click on the B-VPLS site on which you want to configure PBB-EVPN, and click Properties.

4

Click on the Backbone tab. Configure a source MAC address and enable the Use Ethernet Segment Backbone MAC parameter.

5

Click on the BGP tab, and then on the EVPN sub-tab.

6

Click the Create button in the BGP EVPN panel and configure the parameters on the form that appears.

7

Add one or more ISID route targets for the PBB-EVPN by performing the following.

1. Click on the ISIS Route Target sub-tab and click Create. The ISIS Route Target (Create) form opens.
2. Configure the required parameters.
3. Click OK to close the form.

8

Configure static MACs for the PBB-EVPN by performing the following.

1. Click on the Static MACs tab and click Create. The Conditional Static Mac form opens.
2. Configure the required parameters.
3. Save your changes and close the form.

9

Configure ISID policies for the PBB-EVPN by performing the following.

1. Click on the ISID Policy tab and click Create. The ISID Policy Range Entry form opens.
2. Configure the required parameters.
3. Save your changes and close the form.

10

Save your changes and close the forms.

END OF STEPS

77.60 To configure a black hole MAC address on a VPLS site

77.60.1 Purpose

Use this procedure to configure a conditional static black hole MAC address FDB entry on a VPLS service site to mitigate potential DOS, DDOS, and worm attacks and to quarantine hostile traffic. This feature is similar to a black hole static-route for VPRNs but is not associated with any particular SAP or SDP binding. If there is a hit on the black hole FDB entry, all frame packets are immediately discarded in the data path to a null route.

You can also use this procedure to configure a black hole MAC address for IP duplicate detection and anti-MAC address spoofing by enabling the VPLS services with a proxy ARP or proxy ND. The AS-MAC address provides a method to push traffic to a given IP address when a duplicate IP address is detected. However, the NFM-P drops the traffic addressed to the AS-MAC address.

The feature is supported on 7450 ESS, 7750 SR, and 7950 XRS devices.

77.60.2 Steps

Create a VPLS and enable BGP-EVPN

1

Create a VPLS for a supported device type if required; see 77.5 “To create a VPLS” (p. 2249) .

2

Create a VPLS site for the VPLS; see 77.33 “To configure a VPLS site” (p. 2294) .

3

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

4

Choose the required VPLS and click Properties. The VPLS Service (Edit) form opens.

5

On the VPLS Service tree, expand the Sites icon and click on the site on which you want to configure a black hole MAC address and click Properties. The VPLS Site form opens.

6

Click on the BGP tab, and then on the EVPN sub-tab.

7

Click the Create button in the BGP EVPN panel and configure the parameters on the form that appears.

Configure the static MAC address and black hole option

8

Click on the EVPN Static MAC sub-tab and click Create. The Conditional Static Mac form opens.

9

Configure a MAC address for the static MAC.

10

For Locale parameter, select the Blackhole option and click OK to close the form.

11

Save and close the form.

Enable a static black hole for a Proxy ARP or Proxy ND

12

Configure a proxy ARP (address Resolution Protocol) for a VPLS site; see 77.46 “To configure proxy ARP for a VPLS site” (p. 2306) .

13

Configure a proxy ND (node discovery) for a VPLS site; see 77.47 “To configure proxy node discovery for a VPLS site” (p. 2307) .

14

On the VPLS Service tree, expand the Sites icon and click on the site on which you want to configure a black hole MAC address and click Properties. The VPLS Site form opens.

15

Perform one of the following:

a. For a Proxy ARP, click on the Proxy ARP tab and configure the Anti-Spoofing MAC Address parameter and Static Black-Hole parameter on the Proxy ARP sub-tab.

b. For a Proxy ND, click on the Proxy ND tab and configure the Anti-Spoofing MAC Address parameter and Static Black-Hole parameter on the Proxy HD sub-tab.

16

Save and close the form.

END OF STEPS

77.61 To enable SPB on a control B-VPLS site

77.61.1 Purpose

Perform the following procedure to enable SPB on the B-VPLS and configure the B-site as a control B-VPLS.

Control and user B-VPLS SAPs and SDP bindings are fate-shared. You must configure these SAPs and SDP bindings to use the same links and resources. SAPs and spoke SDP bindings that do not use the same links and resources (non-fate-shared) can exist in the user B-VPLS configuration but do not carry traffic.

Consider the following when you enable SPB on a B-VPLS:

- B-VPLS mesh SDP bindings are not supported in control or user SPB B-VPLSs.
- STP can be configured but not enabled.
- two Dot1Q SAPs on the same physical port cannot exist in a user or control SPB B-VPLS.
- Two QinQ SAPs with same top bit on the same physical port cannot exist in a user or control SPB B-VPLS.
- Control or user SPB B-VPLS SAPs cannot exist on physical ports that are managed by MSTP.
- MVPLSs and SPB B-VPLSs cannot share the same spoke SDP tunnel.
- .0 and 0.* SAPs cannot exist on a user or control SPB B-VPLS.
- SPB B-VPLS services that support multiple I-VPLSs do not share forwarding IDs. A B-VPLS that has I-VPLS services must have a different forwarding ID.
- A control SPB B-VPLS can be associated with none or many user SPB B-VPLSs.
- A user SPB B-VPLS must be associated with a control SPB B-VPLS.
- MVPLS and SPB B-VPLS cannot share the same spoke SDP tunnel.
- SHG is not supported.
- G803.1 tunnels are not supported.
- G.8032 access is not supported.

Note: All of the B-sites in the VPLS must be configured as control B-VPLS sites.

77.61.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose the VPLS on which you want to enable SPB and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, right-click on the B-site and choose Properties. The VPLS Site (Edit) form opens.

4

Click on the Backbone tab, then on the SPB tab.

5

Set the SPB Mode parameter to Control B-VPLS.

6

Click Create in the SPB Instance for Control Service panel. The SPB (Create) form opens.

Note: The SPB instance configuration, except the ISIS instance and the Bridge Priority parameter on the Level 1 tab, must be identical on all the sites in a control B-VPLS.

7

Configure the required general SPB control instance parameters.

8

Configure required the SPB ISIS parameters in the ISIS panel.

The Overload Timeout (seconds) parameter is configurable only if the Overload parameter is set to Enabled.

The Overload On Boot Timeout (seconds) parameter is configurable only if the Overload On Boot parameter is set to Enabled.

9

Click on the Level 1 tab and configure the level 1 area parameters.

10

Create the IS-IS interface, or SPB link, of an access interface.

If you enabled the Automatic Enable Interface in Step 7 , all of the L2 access interfaces on the site and all of the L2 access interfaces that are subsequently created on the B-site are automatically enabled for SPB.

1. Click on the Access Interfaces tab.
2. Click Create. The Access Interface, ISIS Instance (Create) form opens.
3. Select an L2 access interface in the Interface panel.
4. Configure the required general parameters.
5. Click on the Behavior tab and configure the required parameters.
6. Click on the Level 1 tab and configure the required parameters.
7. Save your changes and close the form.

11

Configure SPB on the B-VPLS spoke SDP binding.

If you enabled the Automatic Enable Interface in Step 7 , all of the spoke SDP bindings on the site and all of the spoke SDP bindings that are subsequently created on the B-site are automatically enabled for SPB.

1. Click on the Spoke SDP Bindings tab.
2. Click Create. The Spoke SDP Binding Interface, ISIS Instance (Create) form opens.
3. Select a spoke SDP binding in the Circuit panel.
4. Configure the required general parameters.
5. Click on the Behavior tab and configure the required parameters.
6. Click on the Level 1 tab and configure the required parameters.
7. Save your changes and close the form.

12

To create one or more ECT-to-FID range mappings:

1. Click on the ECT Algorithm to FID Range Mappings tab.
2. Click Create. The ECT Algorithm to FID Range Mapping (Create) form opens.
3. Configure the required FID range parameters.
4. Save your changes and close the form.

   Note:

   The ECT-to FID range mapping parameter values must be identical on all the sites in the control SPB B-VPLS. In addition, each site must have the same number of ECT-to-FID range mapping objects.

13

Save your changes and close the forms.

END OF STEPS

77.62 To enable SPB on a user B-VPLS site

77.62.1 Purpose

Perform the following procedure to enable SPB on the B-VPLS and configure the B-site as a user B-VPLS. A control SPB B-VPLS service must already exist. See 77.61 “To enable SPB on a control B-VPLS site” (p. 2323) for more information about how to create a control SPB B-VPLS.

Control and user B-VPLS SAPs and SDP bindings are fate-shared. You must configure these SAPs and SDP bindings to use the same links and resources. SAPs and spoke SDP bindings that do not use the same links and resources (non-fate-shared) can exist in the user B-VPLS configuration but do not carry traffic.

Consider the following when you enable SPB on a B-VPLS:

- B-VPLS mesh SDP bindings are not supported in control or user SPB B-VPLSs.
- STP can be configured but not enabled.
- two Dot1Q SAPs on the same physical port cannot exist in a user or control SPB B-VPLS.
- Two QinQ SAPs with same top bit on the same physical port cannot exist in a user or control SPB B-VPLS.
- Control or user SPB B-VPLS SAPs cannot exist on physical ports that are managed by MSTP.
- MVPLSs and SPB B-VPLSs cannot share the same spoke SDP tunnel.
- .0 and 0.* SAPs cannot exist on a user or control SPB B-VPLS.
- SPB B-VPLS services that support multiple I-VPLSs do not share forwarding IDs. A B-VPLS that has I-VPLS services must have a different forwarding ID.
- A control SPB B-VPLS can be associated with none or many user SPB B-VPLSs.
- A user SPB B-VPLS must be associated with a control SPB B-VPLS.
- MVPLS and SPB B-VPLS cannot share the same spoke SDP tunnel.
- SHG is not supported.
- G803.1 tunnels are not supported.
- G.8032 access is not supported.

77.62.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select the VPLS on which you want to enable SPB and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, right-click on the B-site and choose Properties. The VPLS Site (Edit) form opens.

4

Click on the Backbone tab, then the SPB tab.

5

Set the SPB Mode parameter to User B-VPLS.

6

Select a user in the User Service panel to associate the user B-VPLS with a control B-VPLS.

7

Configure the Forwarding Identifier (FID) parameter.

Note: The Forwarding Identifier (FID) parameter must be the same for all the user B-VPLS sites within the SPB B-VPLS.

8

Save your changes and close the forms.

Note: You can perform an RCA audit on the SPB user B-VPLS service to ensure a correct configuration.

END OF STEPS

77.63 To view the last cleared BFD statistics and sessions on a VPLS site

77.63.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select a VPLS service and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, click on the site on which you want to view the last cleared BFD statistics and sessions.

4

Click on the Clear Status tab and view the five last cleared BFD statistics and the five last cleared BFD sessions.

5

Close the forms.

END OF STEPS

77.64 To enable the automatic selection of an RD on a VPLS site

77.64.1 Purpose

Since an RD must be unique on each PE in the network, you can allocate either a route distinguisher that you manually select or an NE-selected route distinguisher for each service. When you configure an auto-RD on a VPLS site, B-site, or I-site, a Type-1 RD is automatically allocated by the NE based on the community range that you configure.

77.64.2 Steps

1

Before you configure a site for auto-RD selection, you must:

1. Enable BGP on the routing instance of the NE. See 28.29 “To enable BGP on a routing instance” (p. 916) for more information.
2. Enable the automatic selection of an RD on the NE and specify the community range. See 12.11 “To enable the automatic selection of an RD on an NE” (p. 349) .

2

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

3

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

4

On the navigation tree, right-click on VPLS Service and choose Create VPLS Site, or right-click on a site and choose Properties. The VPLS Site (Create|Edit) form opens.

5

Click on the BGP tab, then on the General tab, and enable the Enable BGP parameter.

6

Configure the Auto Route Distinguisher parameter in the RD panel.

The Operational RD is displayed after you apply the changes to the site and to the service.

7

Save the changes and close the forms.

END OF STEPS

77.65 To create a static B-MAC on a B-VPLS site

77.65.1 Purpose

Perform the following procedure to create a static B-MAC to allow remote PBB Epipe VLL services to connect to an SPB network. You can create a static B-MAC on a B-L2 access interface or spoke SDP binding on a control or user B-VPLS site. See 77.61 “To enable SPB on a control B-VPLS site” (p. 2323) and 77.62 “To enable SPB on a user B-VPLS site” (p. 2326) for information about how to enable SPB on a control or user site.

77.65.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, click on the B-VPLS site. The Site (Edit) form opens.

4

Click on the Static MACs tab.

5

Click Create. The Conditional Static MAC (Create) form opens.

6

Configure the MAC Address parameter.

7

Perform one of the following:

a. Select a SAP.

b. Select a spoke SDP binding.

8

Save the changes and close the forms.

END OF STEPS

77.66 To create an ISID policy on a control or user B-VPLS site

77.66.1 Purpose

An ISID policy defines a group of actions for individual ISIDs or ISID ranges. You can define whether the default multicast tree is used and whether the advertisement of ISIDs in SPB is suppressed when I-VPLS or static ISIDs are used for unicast services. See 77.61 “To enable SPB on a control B-VPLS site” (p. 2323) and 77.62 “To enable SPB on a user B-VPLS site” (p. 2326) for information about how to enable SPB on a control or user site.

77.66.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, click on the B-VPLS site. The Site (Edit) form opens.

4

Click on the ISID Policy tab.

5

Click Create. The ISID Policy Range Entry (Create) form opens.

6

Configure the required parameters.

You cannot set the Use Default Multicast Tree and the Advertise Local parameters to False at the same time.

7

Save the changes and close the forms.

END OF STEPS

VPLS access interface management procedures

77.67 To create a VPLS or MVPLS L2 access interface

CAUTION

Service Disruption

The creation of a SAP that uses the same port and encapsulation values as an existing inactive MSAP fails under the following conditions:

- If you try to use the NFM-P to create a SAP, the configuration fails and the NFM-P displays an error message.
- If you use a CLI to create a SAP in a service other than the service that contains the MSAP, the configuration succeeds but the MSAP is inactive until the regular SAP is deleted. Although the NFM-P displays the SAP and MSAP, the MSAP remains inactive and consumes resources.
- If you use a CLI to create a SAP in the service that contains the MSAP, the SAP creation fails.

Nokia recommends that you delete an inactive MSAP from the NFM-P if you need to create a regular SAP on the same port using the same encapsulation values.

Note: If 7210 SAS-D, 7210 SAS-E, or 7210 SAS-K sites are connected in a ring network, you must configure an uplink SAP between each pair of sites.

77.67.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand the site to which you want to add the access interface.

For information on adding a GNE service interface to a VPLS service, see 77.34 “To configure a GNE site on a VPLS service” (p. 2295) .

4

Right-click on L2 Access Interfaces and choose Create VPLS L2 Access Interface. The VPLS L2 Access Interface (Create) form opens.

5

Configure the required parameters.

If you set the SAP Sub Type parameter to Regular, go to Step 10 .

If you set the SAP Sub Type parameter to Capture, the VPLS L2 Access Interface (Create) form refreshes to allow the configuration of the Capture SAP. To create a Capture SAP, see 74.26 “To configure a capture SAP” (p. 2049) .

6

Select an SHG for the interface in the Split Horizon Group panel.

Note: You must configure an SHG or residential SHG for a VPLS if you plan to create a spoke circuit from this VPLS site to a VLL or another VPLS.

7

Select an application profile for the L2 access interface.

8

To associate an AA transit prefix policy with the L2 access interface, select a transit prefix policy in the Transit Prefix Policy panel.

Note: To bind a transit policy to an access interface, a port must already exist on the interface.
You can bind a transit policy to only one access interface or spoke SDP binding per NE.
The transit policy and the application profile must belong to the same application assurance group or partition.

9

To associate a host lockout policy with the L2 access interface, select a host lockout policy in the Host Lockout panel.

10

Select an operational group for the L2 access interface to join as a member. To select an operational group for the L2 access interface to monitor, go to Step 11 .

11

Select an operational group for the L2 access interface to monitor.

12

Click on the Port tab and select a port for the L2 access interface.

Note: The form lists only ports in access or hybrid mode. To choose a port that is not listed, you must set the Mode parameter for the port to Access or Hybrid. After you do this, the port is listed when you click Search.
If you select an Ethernet Tunnel Endpoint, the Port form is refreshed and an Ethernet Tunnel tab is added.
If you are configuring a VLAN range SAP, you must choose a port with dot1q encapsulation type.

If you select the private port of an ISA tunnel, an L2TPV3 tab is added. On the L2TPV3 tab, select VPRN or Base Router in the Router ID parameter and enter the Tunnel Group name.

13

Configure the required parameters.

When the selected port uses dot1q encapsulation, you can enable the Auto-Assign ID parameter to have the Outer Encapsulation Value parameter automatically assigned. If you choose this, the system assigns the lowest unused encapsulation value.

You can set the Auto-Assign ID parameter to be the default parameter for dot1q encapsulation by enabling the Access Interface Encap Value (Dot1q only) parameter in the User Preferences form. Choose Application→ User Preferences from the main menu.

If the port you have chosen is an Ethernet Tunnel Endpoint, you will be able to set the Outer Encapsulation Value to 8191. This automatically enables the Ethernet Tunnel Endpoint Control SAP parameter.

SAP types X.0 and X.* as well as SAP types *.null and *.* can be configured on the same Q in Q port. You must enable the Enable Q in Q Untagged Sap parameter on the NE which allows the creation of the following default SAP types:

- The SAP type *.null functions as a default SAP for single-tagged frames on a Q in Q port. This SAP accepts single tags in the range 0 to 4095 as well as untagged traffic.
- The SAP type *.* functions as a default SAP for double-tagged frames on a Q in Q port. This SAP accepts untagged, single-tagged, and double-tagged frames with tags in the range 0 to 4095.

See 12.23 “To enable a Q in Q untagged SAP on an NE” (p. 360) for more information.

If you are configuring the port for an L2 Access Interface in a Control VPLS for an Ethernet ring, the Outer Encapsulation Value and Inner Encapsulation Value parameters for the port in each L2 Access Interface must have the same value as the R-APS Tag (Outer Encapsulation Value) and R-APS Tag (Inner Encapsulation Value) respectively, that you use for the particular path endpoint. This defines the interface as a Control SAP for the Ethernet ring. See 33.18 “To create an Ethernet G.8032 ring” (p. 1212) for additional information.

The Inner Encapsulation Value is configurable only when the port is an Ethernet or frame relay port with Q in Q encapsulation.

The Outer Encapsulation Value (VPI) and Inner Encapsulation Value (VCI) parameters are configurable only when the port is an ATM port.

14

If a VLAN Connection Profile policy was created and you want to use it for a VPLS service, configure the parameters in the VLAN Connection Profile panel on the Port tab. See Chapter 62, “VLAN Connection Profile policies” for details.

15

To configure VLAN ranges on a 7210 SAS:

1. Enable the VLAN Range SAP parameter.

You can configure the VLAN Range SAP parameter only when the SAP Type parameter is set to dot1q-range. See 77.33 “To configure a VPLS site” (p. 2294) .

2. Select a VLAN range.

   For more information about VLAN ranges for the 7210 SAS, including restrictions, see Chapter 63, “Connection profile policies” . See 63.4 “To configure a VLAN range for a 7210 SAS VPLS or VLL Epipe service” (p. 1825) for information about how to create a connection profile.

16

Configure the required parameters.

If the port you have chosen is an Ethernet port and uses ATM, dot1q or QinQ encapsulation, you can enable ingress VLAN translation.

17

Configure the Ethernet Tunnel Endpoint Control SAP parameter.

Enabling the Ethernet Tunnel Endpoint Control SAP parameter creates the control L2 Access Interface (also known as a Control SAP). It also automatically sets the value of the Outer Encapsulation Value parameter to 8191.

If you are currently creating a same-fate SAP or an L2 Access Interface for an Ethernet ring, the Ethernet Tunnel Endpoint Control SAP parameter must not be enabled.

18

If you are creating this L2 Access Interface for the Control VPLS of an Ethernet ring or for a data service using the ring, configure the ID parameter in the Ethernet Ring Element section to select the required Ethernet Ring Element. See 33.16 “To configure an Ethernet Ring Element” (p. 1208) for additional information.

19

If you are creating an VPLS and use dot1q or QinQ encapsulation, you can enable ingress VLAN translation. Configure the required parameters in the QinQ VLAN Translation panel.

20

Depending on the port that you have chosen, the Egress Multicast Group tab is configurable.

1. Click on the Egress Multicast Group tab.
2. Select an Egress Multicast Group.

   Only EMGs that have the same egress filter and encapsulation type as the interface are listed.

21

Configure the Enable Split Horizon parameter.

Note: If you are configuring the control SAP for a 7210 SAS-M (in Access Uplink mode) to be used as an interconnected NE in an Ethernet sub-ring, you must enable the Enable Split Horizon parameter.

22

For QTag Manipulation on the 7250 IXR, configure the parameters in the QTag Manipulation panel.

For the Ingress Action parameter, when you select the Push Outer or Replace Outer option, the Outer Tag parameter is available. You must configure the Outer Tag parameter.

If required, click Reset to restore the default values.

23

To assign ingress and egress ACL filters to the interface:

1. Click on the ACL tab.

   Note:

   When you assign ACL filters on a 7210 SAS, you must configure the system resource profile appropriately. See 6.5.13 “System resource profile” (p. 220) in 6.5 “7210 SAS” (p. 216) for more information.
2. Select the required ACL filter policies.

24

To assign an accounting policy to the interface:

1. Click on the Accounting tab.
2. Select an accounting policy.
3. Configure the required parameters.

   Collect Egress Queue Statistics parameter can be configured only during service creation.

25

To assign a virtual port to the interface:

1. Click on the Virtual Port Name tab.
2. Configure the required parameters.

26

To assign a time of day suite to the interface.

1. Click on the TOD Suite tab.
2. Select a Time Of Day Suite.

   Note:

You cannot assign a ToD suite to a L2 access interface if accounting statistics collection is enabled on the L2 access interface. You must first disable the Collect Accounting Statistics parameter in Step 24 .

SapEgrQosPlcyStats and SapIngQosPlcyStats statistics will only be collected if a Time Of Day Suite is applied on the SAP.

27

The ATM tab is configurable when the interface port is an ATM port. To specify OAM functionality and assign ingress and egress ATM policies to the interface:

1. Click on the ATM tab.
2. Configure the required parameters.
3. Select an ingress ATM policy in the Ingress ATM Policy panel.
4. Select an egress ATM policy in the Egress ATM Policy panel.

28

To configure policy overrides.

1. Click on the Override Policy Items tab.

   Note:

   The Override Policy Items tab contains a number of tabs. However, the tabs that are displayed depend on the port type that you have chosen for this interface.

   - If you configured a non-HSMDA port, the Access Ingress Queues, Access Egress Queues, Ingress Policer, and Egress Policer tabs are active.
   - If you configured an HSMDA port, the Access Ingress Queues, Access Egress HSMDA Queues, and Ingress Policer tabs are active.
2. Set the policy overrides, as described in 50.97 “To configure QoS policy overrides on an L2 or L3 access interface” (p. 1654) . To configure meter overrides on a 7210 SAS, see 50.98 “To configure QoS policy overrides on access ingress meters for the 7210 SAS” (p. 1657) . To configure queue overrides on a 7210 SAS, see 50.99 “To configure QoS policy overrides on access ingress queues for a 7210 SAS-X” (p. 1659) .

29

Save the changes and close the forms.

30

To configure LAG per-link hashing on the L2 access interface, perform 77.68 “To configure LAG per-link hashing on a VPLS L2 access interface” (p. 2339) .

31

To assign QoS policies or to enable a MAC override address to an L2 access interface, perform 77.69 “To assign QoS policies or to enable a MAC override address to a VPLS or MVPLS L2 access interface” (p. 2340) .

32

To configure scheduling on the L2 access interface, perform 77.71 “To configure scheduling on an L2 access interface” (p. 2345) .

33

To configure BPDU Termination, STP, and FIB parameters for the L2 access interface, perform 77.72 “To configure BPDU Termination, STP, and FIB parameters for the VPLS L2 access interface” (p. 2348) .

34

To assign a DoS protection policy or DDoS protection policy to the L2 access interface, perform 77.73 “To assign a DoS protection policy or DDoS protection policy to the VPLS L2 access interface” (p. 2350) .

35

To configure residential subscriber management on the L2 access interface, perform 77.74 “To configure residential subscriber management for the VPLS L2 access interface” (p. 2351) .

36

To configure an Ethernet tunnel on the L2 access interface, perform 77.75 “To configure an Ethernet tunnel on a VPLS L2 access interface” (p. 2352) .

37

To configure a redundant VLAN range on the L2 access interface, perform 77.76 “To configure a redundant VLAN range on a VPLS L2 access interface” (p. 2353) .

38

To configure IGMP snooping on the L2 access interface, perform 77.77 “To configure IGMP snooping for a VPLS L2 access interface” (p. 2354) .

39

To configure the ARP host for the L2 access interface, perform 77.78 “To configure the ARP host for the VPLS L2 access interface” (p. 2355) .

40

To configure DHCP on the L2 access interface, perform 77.79 “To configure DHCP for the VPLS L2 access interface” (p. 2356) .

41

To configure MVR for the L2 access interface, perform 77.80 “To configure MVR for a VPLS L2 access interface” (p. 2357) .

42

To configure anti-spoofing on the L2 access interface, perform 77.81 “To configure anti-spoofing filters for a VPLS L2 access interface” (p. 2358) .

43

To configure DHCPv6 snooping on the L2 access interface, perform 77.90 “To configure DHCPv6 snooping for a VPLS or MVPLS L2 access interface” (p. 2381) .

44

To associate a MEP to the L2 access interface, perform 77.82 “To create MIPs and MEPs on a VPLS L2 access interface” (p. 2360) .

45

To assign an ANCP policy to the L2 access interface, perform 77.83 “To assign an ANCP policy to a VPLS L2 access interface” (p. 2362) .

46

To configure PIM snooping on the L2 access interface, perform 77.42 “To configure PIM snooping on a VPLS site” (p. 2303) .

47

To configure MLD snooping on the L2 access interface, perform 77.85 “To configure MLD snooping for a VPLS L2 access interface” (p. 2364) .

48

To configure MVR (MLD) on the L2 access interface, perform 77.86 “To configure MVR (MLD) for a VPLS L2 access interface” (p. 2365) .

49

To configure custom object attributes for AA reporting on the L2 access interface, perform 77.23 “To configure custom object attributes for AA reporting” (p. 2282) .

END OF STEPS

77.68 To configure LAG per-link hashing on a VPLS L2 access interface

77.68.1 Purpose

You can configure weighted per-link hashing on a VPLS L2 access interface if the terminating port has LAG per-link hashing enabled. The interface must be a LAG member. This procedure applies to B-VPLS, I-VPLS and M-VPLS interfaces.

77.68.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Site→L2 Access Interfaces.

4

Right-click on the L2 access interface you want to modify and choose Properties. The VPLS L2 Access Interface (Edit) form opens.

5

Click on the LAG Per Link Hash tab.

6

Configure the Class and Weight parameters.

7

Save your changes and close the forms.

END OF STEPS

77.69 To assign QoS policies or to enable a MAC override address to a VPLS or MVPLS L2 access interface

77.69.1 Before you begin

The available panels and parameters vary depending on the NE, chassis type, and release.

77.69.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→site→L2 Access Interface.

4

Right-click on the L2 access interface and choose Properties. The VPLS L2 Access Interface (Edit) form opens.

5

Click on the QoS tab.

6

Configure the Ingress Match QinQ Dot1P parameter.

The Ingress Match QinQ Dot1P parameter is configurable only when the encapsulation type of the port is dot1q, BCP dot1q, or QinQ.

7

Select an ingress policy in the Ingress Policy panel.

Note: If you choose an access ingress policy which has a forwarding class mapped to an ingress queue group, you must ensure that port that you are configuring for the VPLS L2 access interface has the access ingress queue group with the same name created on it. See 16.24 “To configure Ethernet ports” (p. 599) for more information about how to configure Ethernet ports. See Chapter 49, “Policies overview” for more information about queue group template policies.

8

Select an ingress queue group template policy in the Forwarding Plane Redirect panel.

9

Configure the Instance ID parameter.

10

Configure the Egress Mark QinQ Top Bits Only parameter.

The Egress Mark QinQ Top Bits Only parameter is configurable only when the encapsulation type of the port is dot1q, BCP dot1q, or QinQ.

11

Configure the required parameters in the Aggregate Rate Limit panel.

12

Select an egress policy in the Egress Policy panel.

Note: If you choose an access egress policy which has a forwarding class mapped to an egress queue group, you must ensure that port that you are configuring for the VPLS L2 access interface has the access egress queue group with the same name created on it.

See 16.24 “To configure Ethernet ports” (p. 599) for more information about how to configure Ethernet ports. See Chapter 49, “Policies overview” for more information about queue group template policies.

13

Select an egress queue group template policy in the Port Redirect panel.

Note: Selecting an Egress Queue Group Template Policy permits the redirection of Ethernet traffic packets to a queue ID specified in the egress port queue group of the SAP. The following properties and restrictions apply:

- If an Egress Queue Group Template Policy is specified here, the policy must have port redirection enabled.
- You cannot use policy-based redirection with the queue group when the SAP has SAP-based redirection enabled.
- Port access egress redirection is only supported on Ethernet/LAG ports. It is not supported on SAPs bound on non-Ethernet, Eth-tunnel, or CCAG ports.
- Supported ports include access, hybrid, and HSMDA.
- Queue groups can be applied to SAPs that incorporate LAGs. The LAGs can include port members from just a single card or from multiple cards.
- If you edit a LAG incorporated by the SAP, you cannot remove the last LAG member if a queue group reference exists to the containing SAP.
- You cannot add a secondary LAG member that has a queue group mismatch with primary LAG member.

14

If you are configuring an L2 access interface for a 7705 SAR, or if the port you selected in 77.67 “To create a VPLS or MVPLS L2 access interface” (p. 2332) is not an HSMDA port, go to Step 6 of 77.71 “To configure scheduling on an L2 access interface” (p. 2345) .

15

Configure the Packet Byte Offset (bytes) parameter. Before you can configure the parameter, you must enable the associated Override check box.

16

Select a WRR policy in the Egress HSMDA Override panel.

17

Select an HSMDA egress secondary shaper policy in the Egress HSMDA Override panel.

18

In the Shaper Group panel, select a Shaper Group for the access ingress port or access egress port.

19

In the IXR Specific panel, select an Egress Remark policy, Egress VLAN QoS policy, and shared policer, and configure all other parameters, as required. See 50.82 “To configure a 7250 SROS Remarking policy” (p. 1634) and 50.54 “To configure a 7250 SROS VLAN QoS policy” (p. 1594).

20

To enable a destination MAC override address to the L2 access interface, select the Enable Mac Overwrite check box and enter a MAC address in the IEEE Address parameter.

21

Select an HS secondary shaper in the HS Overrides panel, if required.

22

Save the changes and close the forms.

END OF STEPS

77.70 To assign ingress and egress QoS policies to a VPLS L2 access interface on a 7210 SAS site

77.70.1 Before you begin

You can only assign policies and configure parameters for 7210 SAS NEs when the system resource profile is appropriately configured for the device. See 6.5.13 “System resource profile” (p. 220) in Chapter 6, “Device support” .

The available parameters and policies vary depending on the device type and chassis variant. The configurations that are supported on the site NE are shown on the form.

77.70.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the navigation tree, expand Sites→site→L2 Access Interfaces, right-click on the L2 access interface, and choose Properties. The VPLS L2 Access Interface (Edit) form opens.

If you are configuring an L2 Uplink SAP on a 7210 SAS-K site to preserve the dot1p values of ingress packets, expand to the Uplink SAP, open the properties form, and perform Step 4 and Step 10.

4

Click on the QoS tab and expand the 7210/7250 Specific panel.

5

Select a SAP Access Ingress policy in the Ingress Policy panel.

When you assign an ingress policy, the Color Mode parameter setting for the meters in the policy must coincide with the Enable DEI parameter setting on the physical port. When Enable DEI is selected, the Color Mode for meters must be set to Color Aware. When Enable DEI is not selected, the Color Mode for meters must be set to Color Blind. See 16.24 “To configure Ethernet ports” (p. 599) and 50.29 “To configure a 7210, 7250, and 1830 SAP Access Ingress policy” (p. 1544) .

To support H-metering, you must choose an ingress policy with all meter rate modes set to trTCM (RFC 4115).

For 7250 IXR sites, the selected SAP Access Ingress policy must contain an assigned 7250 Ingress CoS policy.

6

Select an egress policy in the Egress Policy panel.

See 50.32 “To configure a 7210 SAP access egress policy” (p. 1558)for more information about 7210 SAP access egress policies.

SAP-based remarking is defined in a 7210 SAP access egress policy. To enable SAP-based remarking on the 7210 SAS-X, you must enable the SAP QoS Marking parameter on the port; see 16.24 “To configure Ethernet ports” (p. 599).

7

To enable table-based color-aware ingress classification, select the Enable Table Classification parameter. See 50.23.2 “Table-based ingress classification on the 7210 SAS” (p. 1529).

8

Select an Egress Remarking policy in the Egress Remark Policy panel.

9

Configure the parameters in the Aggregate Rate Limit panel.

You can configure the Ingress Meter parameter only during SAP creation. The parameter must be set to true to support H-metering.

You can configure the Ingress Meter Rate (kbps) and Ingress Meter Burst parameters only after SAP creation.

You can configure the Egress Meter Rate and Egress Meter Burst parameters only when resources are allocated to the SAP Egress Aggregate Meter parameter in the system resource profile; see 12.50 “To configure the global system resource profile on a 7210 SAS or 7250 IXR” (p. 380). To allocate resources on the 7210 SAS-R, configure the Egress SAP Aggregate Meter

parameter in the system resource profile policy assigned to the device; see 12.51 “To configure a system resource profile policy for the 7210 SAS-R/T/Mxp, 7210 SAS-S/Sx, or 7210 SAS-S/Sx VC” (p. 382).

You must also enable port-based scheduling on 7210 SAS-Mxp and 7210 SAS-R NEs; see 12.53 “To configure port-based scheduling on the 7210 SAS” (p. 384).

The Enable Egress Meter Stats parameter is available when a value is configured for the Egress Meter Rate parameter.

10

For interfaces on 7210 SAS-K sites, configure the required parameters in the Egress Dot1p Remarking panel.

For access ports, configured parameters take effect only when the Remarking parameter is set to true in the 7210 SAP Access Egress policy assigned to the interface; see Step 6.

For L2 Uplink ports, configured parameters take effect only when the Remarking parameter is set to true in the 7210 and 1830 Network policy assigned to the port; see 16.45 “To assign QoS policies to a 7210 SAS Ethernet port” (p. 636).

11

Save the changes and close the forms.

END OF STEPS

77.71 To configure scheduling on an L2 access interface

77.71.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Configure the filter criteria and click Search. A list of services appears.

3

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

4

On the service tree, expand Sites→site→L2 Access Interfaces.

5

Right-click the L2 access interface and choose Properties. The VPLS L2 Access Interface (Edit) form opens.

6

Click on the Schedulers tab and configure the required parameters.

Note: The Schedulers tab is configurable only if a port is assigned to the interface.

7

To configure scheduling on a 7210 SAS site, enable and configure the required parameters in the Egress Aggregate Rate Limit panel and go to Step 30 .

8

To configure scheduling on a 7705 SAR site:

Note: For the 7705 SAR, scheduler behavior is determined by the scheduler mode, which is 4-Priority by default. You can only configure the Egress and Ingress Aggregate Rate Limit parameters when the Scheduler Mode parameter is set to 16-Priority. You can set the Scheduler Mode to 16-Priority only when the port is on an MDA that supports 16-Priority. See the 7705 SAR documentation for more information.

If you change the Scheduler Mode parameter from 16-Priority to 4-Priority, the NFM-P automatically restores the default settings for the Egress Aggregate Rate Limit and Ingress Aggregate Rate Limit panels when you Apply your changes.

1. In the Egress Scheduler panel, configure the Scheduler Mode parameter.
2. In the Ingress Scheduler panel, configure the Scheduler Mode parameter.
3. If you set the Scheduler Mode parameter to 16-Priority in the Egress Scheduler panel or Ingress Scheduler panel, configure the required parameters in the Egress Aggregate Rate Limit panel and Ingress Aggregate Rate Limit panel.
4. Go to Step 30 .

9

To apply an aggregation scheduler policy to the interface:

Note: You cannot specify an access scheduler policy if the port you selected 77.67 “To create a VPLS or MVPLS L2 access interface” (p. 2332) is an HSMDA port. Go to Step 30 .

1. Set the Aggregation parameter to On.
2. Select an aggregation scheduler in the Aggregation Scheduler panel.
3. Go to Step 30 .

10

To specify that an aggregation scheduler policy is not being applied to the interface, set the Aggregation parameter to Off.

Note: The Aggregation parameter is not configurable if the port you selected in 77.67 “To create a VPLS or MVPLS L2 access interface” (p. 2332) is an HSMDA port.

11

Select an ingress scheduler in the Ingress Scheduler panel to choose an ingress scheduler.

12

Configure the required parameters.

The Aggregate Rate Limit (kbps), Frame-Based Accounting, and Limit Unused Bandwidth parameters are configurable only when there is no scheduler specified in the Egress Scheduler panel.

The Frame-Based Accounting parameter is not configurable if the port you selected in 77.67 “To create a VPLS or MVPLS L2 access interface” (p. 2332) is an HSMDA port.

You cannot specify an egress scheduler when the Aggregate Rate Limit (kbps) parameter is set to a value greater than zero.

13

Select an ingress policer control policy in the Ingress Policer Control Policy panel.

14

Click Create in the Ingress Policer Control Override panel. The Ingress Policer Control Override (Create) form opens.

15

Configure the required parameters.

16

Click the Level Override Policy Items tab.

17

Select an item from the list and click Properties. The Ingress Policy Policer Level Override form opens.

18

Click the Override tab.

19

Configure the override for the Maximum Cumulative Buffer Space (bytes) parameter.

20

Close the forms.

21

If the port you selected in 77.67 “To create a VPLS or MVPLS L2 access interface” (p. 2332) is an HSMDA port, go to Step 30 .

22

Select an egress scheduler in the Egress Scheduler panel.

23

Select an egress policer control policy in the Egress Policer Control Policy panel.

24

Click Create in the Egress Policer Control Override panel. The Egress Policer Control Override (Create) form opens.

25

Configure the required parameters.

26

Click the Level Override Policy Items tab.

27

Select an item from the list and click Properties. The Egress Policy Policer Level Override form opens.

28

Click the Override tab.

29

Configure the override for the Maximum Cumulative Buffer Space (bytes) parameter.

30

Save the changes and close the forms.

END OF STEPS

77.72 To configure BPDU Termination, STP, and FIB parameters for the VPLS L2 access interface

77.72.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→site→L2 Access Interfaces.

4

Right-click the L2 access interface and choose Properties. The VPLS L2 Access Interface (Edit) form opens.

5

Click on the Forwarding Control tab. Depending on the device being configured, the BPDU Termination tab is displayed. Otherwise, go to Step 7 .

Note: For L2 access interfaces on the 7210 SAS-R, the BPDU Termination tab is displayed only when the Allow L2Pt Xstp BPDU parameter is enabled for the site. See 77.33 “To configure a VPLS site” (p. 2294) .

6

Configure the required parameters.

You can enable the L2 Protocol Termination parameter only when STP is disabled on the site. The Administrative State parameter for STP must be set to Down. See 77.35 “To configure MFIB, STP, FIB, and MAC learning protection for a VPLS site” (p. 2296) .

When the L2 Protocol Termination parameter is set to Enabled, a list of L2PT protocols is displayed. Select all that are required. You must select at least one protocol.

The Force L2PT on Managed L2 Access Interface parameter is only available for MVPLS L2 access interfaces. When the Force L2PT on Managed L2 Access Interface parameter is set to Enabled, a list of L2PT protocols is displayed. Select all that are required.

7

Click on the STP tab and configure the required parameters.

8

Click on the FIB tab and configure the required parameters.

The Restrict Protected Source Action parameter is configurable only when the Restrict Protected Source is set to true.

9

If you are creating an MVPLS to run MSTP:

1. Click on the MST Instances tab to edit a SAP MST instance.
2. Select an MST instance and click Properties. The L2 Access Interface MST Instance (Edit) form opens. Configure the required parameters.
3. Save the changes and close the form.

10

Save the changes and close the forms.

END OF STEPS

77.73 To assign a DoS protection policy or DDoS protection policy to the VPLS L2 access interface

77.73.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→site→L2 Access Interfaces.

4

Right-click the L2 access interface and choose Properties. The VPLS L2 Access Interface (Edit) form opens.

5

Click on the Security tab.

6

Select a DoS protection policy or DDos protection policy in the NE DoS Protection panel.

7

Configure the MAC Monitoring parameter.

8

Configure the Ethernet CFM Monitor Flags parameter.

9

Save the changes and close the forms.

END OF STEPS

77.74 To configure residential subscriber management for the VPLS L2 access interface

77.74.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→site→L2 Access Interfaces.

4

Right-click the L2 access interface and choose Properties. The VPLS L2 Access Interface (Edit) form opens.

5

Click on the Subscriber Management tab.

6

Enable the SHCV Enabled parameter to enable SHCV. Otherwise, go to Step 8 .

7

Configure the required parameters.

8

Click on the IGMP Host Tracking tab.

9

Select the import policy used to filter IGMP packets.

10

Configure the required parameters.

11

Click on the Profiles tab and configure the required parameters.

12

Select a default subscriber profile for the interface in the Default Subscriber Profile panel.

13

Select a default SLA profile for the SAP in the Default SLA Profile panel.

14

Select a subscriber identification policy for the SAP in the Subscriber Identification Policy panel.

15

Select a default application profile for the SAP in the Default Application Profile panel.

16

Select a non-subscriber subscriber profile for the SAP in the Non-Subscriber Traffic Subscriber Profile panel.

17

Select a non-subscriber traffic SLA profile for the SAP in the Non-Subscriber Traffic SLA Profile panel.

18

Select a non-subscriber traffic application profile for the SAP in the Non-Subscriber Traffic Application Profile panel.

19

Click on the Host Tracking Info tab to view a list of hosts that are being tracked on this L2 access interface.

20

Save the changes and close the forms.

END OF STEPS

77.75 To configure an Ethernet tunnel on a VPLS L2 access interface

77.75.1 Purpose

If you are creating a fate-sharing Ethernet Tunnel Endpoint SAP—or same-fate SAP—perform the following procedure to configure an Ethernet tunnel.

77.75.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→site→L2 Access Interfaces.

4

Right-click the L2 access interface and choose Properties. The VPLS L2 Access Interface (Edit) form opens.

5

Click on the Ethernet Tunnel tab and click Create. The Ethernet Tunnel (Create) form opens.

6

Configure the required parameters.

7

Save the changes and close the forms.

END OF STEPS

77.76 To configure a redundant VLAN range on a VPLS L2 access interface

77.76.1 Purpose

Configure a redundant VLAN range.

Note: If an MVPLS site has SAPs that manage traffic on the associated VPLS SAPs, you must define a redundant VLAN range during SAP creation. The redundant VLAN range defines the range of VC IDs for VPLS SAPs that the MVPLS manages.

77.76.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→site→L2 Access Interfaces.

4

Right-click the L2 access interface and choose Properties. The VPLS L2 Access Interface (Edit) form opens.

5

Click on the Redundancy tab and click Create. The RedundantVlanRange (Create) form opens.

6

Configure the required parameters.

7

Save the changes and close the forms.

END OF STEPS

77.77 To configure IGMP snooping for a VPLS L2 access interface

77.77.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→site→L2 Access Interfaces.

4

Right-click the L2 access interface and choose Properties. The VPLS L2 Access Interface (Edit) form opens.

5

Click on the IGMP Snooping tab.

6

Configure the required parameters.

The General Query Interval (seconds), Maximum Response Interval (seconds), Robust count, and IGMP Version parameters are configurable when the Send Queries parameter is enabled.

7

To configure a multicast CAC policy, select a policy in the Multicast CAC Policy panel.

8

Configure the required parameters.

9

Click on the Static Mcast Group tab to configure a static multicast group.

10

Click Create. The Access Interface Igmp Snooping Mcast Group Display (Create) form opens.

11

Configure the required parameters.

12

Close the form.

13

Save the changes and close the form.

14

To configure the LAG port down parameters:

1. Click on the LAG Port Down tab.
2. Click Create. The LAG Port Down (Create) form opens.
3. Configure the required parameters.
4. Click on the Levels tab and click Create. The Multicast CAC Level (Create) form opens.
5. Configure the required parameters.
6. Save the changes and close the form.

15

Save the changes and close the forms.

END OF STEPS

77.78 To configure the ARP host for the VPLS L2 access interface

77.78.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→site→L2 Access Interfaces.

4

Right-click the L2 access interface and choose Properties. The VPLS L2 Access Interface (Edit) form opens.

5

Click on the ARP Host Configuration tab.

6

Configure the required parameters.

7

Save the changes and close the forms.

END OF STEPS

77.79 To configure DHCP for the VPLS L2 access interface

77.79.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→site→L2 Access Interfaces.

4

Right-click on the L2 access interface and choose Properties. The VPLS L2 Access Interface (Edit) form opens.

5

Click on the DHCP tab.

6

Configure the required parameters.

When the Circuit ID or Remote ID parameter is set to HEX, you must configure the accompanying Circuit or Remote HEX String parameter.

When the Remote ID parameter is set to String, you must configure the accompanying Remote ID String parameter.

The Enable Lease Populate parameter is configurable when the Enable parameter is enabled.

Note: For access interfaces on 7210 SAS-E sites, you can only enable the Snooping parameter when the system resource profile for the 7210 SAS-E device is appropriately configured. See 12.50 “To configure the global system resource profile on a 7210 SAS or 7250 IXR” (p. 380) .

7

To configure the VPLS L2 access interface proxy server:

Note: You can configure a VPLS L2 access interface proxy server on a 7450 ESS or 7750 SR.

1. Click on the Server tab
2. Configure the required parameters.

   The Number of Days, Number of Hours, Number of Minutes, Number of Seconds, and Lease Time RADIUS Override parameters are configurable only when the Lease Time parameter is set to Specified Time Period.

8

Save the changes and close the forms.

END OF STEPS

77.80 To configure MVR for a VPLS L2 access interface

77.80.1 Purpose

Depending on the type of device that you are configuring, the MVR tab is configurable. Configure MVR for the SAP.

77.80.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→site→L2 Access Interfaces.

4

Right-click the L2 access interface and choose Properties. The VPLS L2 Access Interface (Edit) form opens.

5

Click on the MVR tab.

6

Select a source MVR VPLS in the Source MVR VPLS panel to associate an MVR VPLS with the SAP.

7

Select a proxy MVR SAP to which the multicast traffic is sent in the Proxy MVR SAP panel.

Note: If the SAP already has an MVR proxy SAP or is the MVR proxy SAP of another SAP, the SAP cannot be an MVR proxy SAP.

8

Save the changes and close the forms.

END OF STEPS

77.81 To configure anti-spoofing filters for a VPLS L2 access interface

77.81.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→site→L2 Access Interfaces.

4

Right-click the L2 access interface and choose Properties. The VPLS L2 Access Interface (Edit) form opens.

5

Click on the Anti-Spoofing tab.

6

Configure the required parameters.

The ARP Reply Agent parameter is configurable only when an IP address is specified for the static hosts on the SAP.

7

Click on the Static Hosts tab to configure a static subscriber host entry for each subscriber host that is not managed by DHCP.

8

Click Create. The Access Interface Anti-Spoofing Static Host Display (Create) form opens.

9

Configure the required parameters.

Note: You must specify at least one IP address or MAC address for each static host. The values that are specified for the Anti-Spoofing and ARP Reply Agent parameters determine the type of address entry that is required for the static host. For example, if you set the Anti-Spoofing parameter to Source Ip Addr, you must specify at least the IP address for the static host.

10

To configure residential subscriber management for the static host:

1. Select a subscriber profile for the static host in the Subscriber Profile panel.
2. Select a subscriber profile for the static host in the Subscriber Profile panel.
3. Select an SLA profile for the static host in the SLA Profile panel.
4. Select an application profile for the static host in the Application Profile panel.

11

Save the changes and close the forms.

END OF STEPS

77.82 To create MIPs and MEPs on a VPLS L2 access interface

77.82.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the navigation tree, expand the Sites icon and click the required site. The site's properties form is displayed.

4

Expand the required site's icon on the navigation tree to show the L2 Access Interfaces.

5

Right-click the required L2 access interface and choose Properties. The VPLS L2 Access Interface (Edit) form opens.

6

Click on the OAM tab, then on the Configuration sub-tab.

7

Configure the required Test Generation Options parameters.

Note: You can propagate test generation role settings to all MEPs on a SAP or service site by clicking Propagate to MEPs.

8

Click on the ETH-CFM sub-tab.

9

To create MIPS:

1. Click Create in the MIP Configurations panel. The MIP Configuration (Create) form opens.
2. Configure the parameters, then click OK. The MIP Configuration (Create) form closes.

   The Primary VLAN Enable, VLAN ID, and MAC Address parameters are configurable only when a port is assigned to the interface.

   Note: To enable Primary VLAN configuration for egress MIPs on supporting 7210 SAS-R NEs, the Bi Directional MIP Egress parameter in the system resource profile policy

assigned to the card must be set appropriately. See 12.51 “To configure a system resource profile policy for the 7210 SAS-R/T/Mxp, 7210 SAS-S/Sx, or 7210 SAS-S/Sx VC” (p. 382) .

Note: You cannot configure MIPs on an SPB-enabled SAP. See 77.2.6 “SPB in VPLS” (p. 2222) in “VPLS management overview” (p. 2210) for more information about SPB.

3. Repeat the previous two steps to create additional MIPs, as required.
4. Click Apply in the VPLS L2 Access Interface (Edit) form. The default MD objects are then automatically created on the service site.
5. Go to the service site's properties form and click the OAM tab and then on the ETH-CFM sub-tab.
6. Scroll down to the Default Domain panel and multi-select all required entries, then click Properties. The CFM Vlan Default Domain (Multiple Instances) form opens.
7. Configure the parameters for the selected entries and click OK. The CFM Vlan Default Domain (Multiple Instances) form closes.
8. Click Apply and then return to the VPLS L2 Access Interface (Edit) form.
9. Scroll down to the MIPs panel and click Resync MIPs. The default Up and Down MIPs that were automatically created by the NE are displayed in the list.

10

To enable a tunnel facility MEP on the L2 access interface, set the Tunnel Fault Notification parameter in the Facility MEPs panel to Accept.

Tunnel Fault Notification is only configurable on sites where the device has ports configured in access or hybrid mode with QinQ encapsulation.

11

If you are configuring a B-L2 Access Interface, go to Step 13 .

12

Configure the Enable Virtual MEP Filter parameter in the Virtual MEPs panel.

13

Configure the parameters in the Squelch Ingress Level panel.

14

Configure the parameters on the LMM Session Stats Collection panel as required.

15

To create a MEP:

1. Click Create in the MEPs panel. The MEP (Create) form opens.
2. Select a MEG in the MEP panel.
3. Configure the general parameters in the MEP panel.

For L2 access interfaces on 7210 SAS-R sites, you can create Up MEPs only when the system resource profile is set appropriately. See 12.50 “To configure the global system resource profile on a 7210 SAS or 7250 IXR” (p. 380) .

The Type and Interface Type parameters are automatically populated based on whether the MEP is created on a SAP, SDP binding, or Ethernet Tunnel Path Endpoint.

4. Configure the parameters in the CCM panel.

   The CCM Padding Packet Size (Bytes) parameter cannot be configured when the CCM interval parameter is set to 10 ms or 100 ms.

5. Select a MEG sub-group in the MEG Sub-Grouping panel.

6. Configure the required Test Generation Options parameters.

   The Test Generation Options parameters are only displayed when you set the Direction parameter to Up.

7. If the MD for the MEP has a Maintenance Domain Name Type of none and the associated MEG has a Maintenance Entity group Name Type of icc-based, then the Y.1731 Tests and AIS tabs are configurable. Click on the Y.1731 Tests tab and configure the required parameters.

   The Eth Test Pattern parameter is configurable when the Eth Test Enabled parameter is enabled.

8. Click on the AIS tab and configure the required parameters.

   The AIS Meg Level parameter is configurable when the AIS Enabled parameter is enabled.

9. Save the changes and close the form.

   Note: If you have configured a SAP, the SAP information is filled in when you configure the MEP.

   Once the site has been created and is operational, you can open the MEP (Edit) form and view an information field that displays the number of Continuously Running Tests currently on the MEP. This appears on the General tab of that form.

16

Save the changes and close the forms.

END OF STEPS

77.83 To assign an ANCP policy to a VPLS L2 access interface

77.83.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→site→L2 Access Interfaces.

4

Right-click the L2 access interface and choose Properties. The VPLS L2 Access Interface (Edit) form opens.

5

Click on the ANCP Static Map tab and click Create. The ANCP Static Map (Create) form opens.

6

Configure the ANCP String parameter.

7

Select an ANCP Policy.

8

Save the changes and close the form.The ANCP Static Map form closes.

9

Save the changes and close the forms.

END OF STEPS

77.84 To configure PIM snooping on a VPLS L2 access interface

77.84.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→L2 Access Interfaces.

4

Right-click the L2 access interface and choose Properties. The VPLS L2 Access Interface (Edit) form opens.

5

Click on the PIM Snooping tab and configure the Maximum Number of Groups parameter.

6

Save the changes and close the forms.

END OF STEPS

77.85 To configure MLD snooping for a VPLS L2 access interface

77.85.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→site→L2 Access Interfaces.

4

Right-click the L2 access interface and choose Properties. The VPLS L2 Access Interface (Edit) form opens.

5

Click on the MLD Snooping tab and configure the required parameters.

The General Query Interval (seconds), Maximum Response Interval (seconds), Robust count, and MLD version parameters are configurable when the Send Queries parameter is enabled.

6

To configure one or more static multicast groups:

1. Click on the Static Mcast Group tab.
2. Click Create. The Access Interface Mld Snooping Mcast Group Display (Create) form opens.
3. Configure the required parameters.
4. Save the changes and close the form.

7

Save the changes and close the forms.

END OF STEPS

77.86 To configure MVR (MLD) for a VPLS L2 access interface

77.86.1 Purpose

Depending on the type of device that you are configuring, the MVR (MLD) tab is configurable. Use the MVR (MLD) tab to use MLD snooping on the SAP. Configure MVR for the L2 access interface.

77.86.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→site→L2 Access Interfaces.

4

Right-click the L2 access interface and choose Properties. The VPLS L2 Access Interface (Edit) form opens.

5

Click on the MVR (MLD) tab.

6

Select an MVR VPLS with the SAP in the Source MVR VPLS panel.

7

Select a proxy MVR SAP to which the multicast traffic is sent in the Proxy MVR SAP panel.

If the SAP already has an MVR proxy SAP or is the MVR proxy SAP of another SAP, the SAP cannot be an MVR proxy SAP.

8

Save the changes and close the forms.

END OF STEPS

77.87 To create a VPLS or MVPLS B-L2 access interface

77.87.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Site→L2 Access Interfaces.

4

Right-click on L2 Access Interfaces and choose Create B-L2 Access Interface. The B-L2 Access Interface (Create) form opens.

5

Configure the required parameters.

6

Select a transit prefix policy for the interface in the Transit Prefix Policy panel.

7

Select an SHG for the interface in the Split Horizon Group panel.

Note: You must configure an SHG or residential SHG for a VPLS if you plan to create a spoke circuit from this VPLS site to a VLL or another VPLS.

8

Click on the Port tab.

9

Select a port for the B-L2 access interface.

Note: The form lists only ports in access or hybrid mode. To choose a port that is not listed, you must set the Mode parameter for the port to Access or Hybrid. After you do this, the port is listed when you click Search.

10

CAUTION

Service Disruption

The creation of a SAP that uses the same port and encapsulation values as an existing inactive MSAP fails under the following conditions:

- If you try to use the NFM-P to create a SAP, the configuration fails and the NFM-P displays an error message.
- If you use a CLI to create a SAP in a service other than the service that contains the MSAP, the configuration succeeds but the MSAP is inactive until the regular SAP is deleted. Although the NFM-P displays the SAP and MSAP, the MSAP remains inactive and consumes resources.
- If you use a CLI to create a SAP in the service that contains the MSAP, the SAP creation fails.

Nokia recommends that you delete an inactive MSAP from the NFM-P if you need to create a regular SAP on the same port using the same encapsulation values.

Configure the required parameters.

For a B-L2 access interface, only Null, dot1q, and QinQ encapsulation are supported.

When the selected port uses dot1q encapsulation, you can enable the Auto-Assign ID parameter to have the Outer Encapsulation Value parameter automatically assigned. If you choose this, the system assigns the lowest unused encapsulation value.

Note: You can set the Auto-Assign ID parameter to be the default parameter for dot1q encapsulation by enabling the Access Interface Encap Value (Dot1q only) parameter in the User Preferences form. Choose Application→ User Preferences from the main menu.

11

To configure the EMG:

1. Click on the Egress Multicast Group tab.
2. Select an EMG.

   Note:

   The Egress Multicast Group-L2 Interface form lists only EMGs that have the same egress filter and encapsulation type as the interface.

12

If the selected port uses FR encapsulation, configure Frame Relay for the interface:

1. Click on the Frame Relay tab.
2. Set the FRF-12 Mode parameter to Enabled.
3. Configure the required parameters.

13

To assign ingress and egress QoS policies to the interface:

1. Click on the QoS tab.

   Note:

   Items such as policies, schedulers, and filters can be applied later to multiple service components at once by selecting and right-clicking the components in the service navigation tree, choosing Properties, and configuring the parameters on the appropriate tab. This action opens a properties form in a new window for the component that was right-clicked. The navigation tree is not displayed in this new window.

2. Configure the Ingress Match QinQ Dot1P parameter.

   The Ingress Match QinQ Dot1P parameter is configurable only when the encapsulation type of the port is dot1q or QinQ.

3. Select an ingress in the Ingress Policy panel.

   If you select an access ingress policy that has a forwarding class mapped to an ingress queue group, the port that you choose for the VPLS L2 access interface must use the same access ingress queue group.

   See 16.24 “To configure Ethernet ports” (p. 599) for information about configuring Ethernet ports. See Chapter 49, “Policies overview” for information about queue group template policies.

4. Select an ingress queue group template policy in the Forwarding Plane Redirect panel.
5. Configure the Instance ID parameter in the Forwarding Plane Redirect panel.
6. Configure the Egress Mark QinQ Top Bits Only parameter.

   The Egress Mark QinQ Top Bits Only parameters are configurable only when the encapsulation type of the port is dot1q or QinQ.

7. Select an egress policy in the Egress Policy panel.

   Note:

   If you select an access egress policy that has a forwarding class mapped to an egress queue group, the port that you choose for the VPLS L2 access interface must use the same access egress queue group.

   See 16.24 “To configure Ethernet ports” (p. 599) for information about configuring Ethernet ports. See Chapter 49, “Policies overview” for information about queue group template policies.

8. If the port you selected in Step 9 is not an HSMDA port, go to Step 14 .
9. Configure the Packet Byte Offset (bytes) parameter. Before you can configure the parameter, you must enable the associated Override parameter.
10. Select a WRR policy in the Egress HSMDA Override panel.
11. Select an HSMDA egress secondary shaper policy in the Egress HSMDA Override panel.
12. Select an HS secondary shaper in the HS Overrides panel, if required.
13. Configure any required parameters.

14

To configure scheduling:

1. Click on the Schedulers tab.

   Note:

   The Schedulers tab is configurable only when a port is assigned to the interface.

2. To specify that an aggregation scheduler policy is not applied to the interface, set the Aggregation parameter to off and configure the required parameters.

   The Aggregation parameter is not configurable if the port you selected in Step 9 is an HSMDA port.

   The Aggregate Rate Limit (kbps), Frame-Based Accounting, and Limit Unused Bandwidth parameters are configurable only when there is no scheduler specified in the Egress Scheduler panel.

   The Frame-Based Accounting parameter is not configurable if the port you selected in Step 9 is an HSMDA port.

   You cannot specify an egress scheduler when the Aggregate Rate Limit (kbps) parameter is set to a value greater than zero.

3. Select and ingress and egress scheduler, and ingress and egress control policy, and an ingress and egress policer control policy.If the port you selected in Step 9 is an HSMDA port, go to Step 15 .

4. To specify that an access scheduler policy is applied to the interface, set the Aggregation parameter to on and configure the Frame-Based Accounting parameter.

   Note:

   You cannot specify an access scheduler policy if the port you selected in Step 9 is an HSMDA port. Go to Step 15 .

5. Select an aggregation scheduler in the Aggregation Scheduler panel.

15

To assign ingress and egress ACL filters to the interface:

Note: Only MAC filters are allowed for B-L2 Access Interfaces.

1. Click on the ACL tab.
2. Select an ingress filter in the Ingress Filter panel.
3. Select an egress filter in the Egress Filter panel.

16

To assign an accounting policy to the interface:

1. Click on the Accounting tab.
2. Configure the Collect Accounting Statistics and Ingress Counter Type parameters.
3. Select an accounting policy.

17

To configure BPDU Termination, STP, FIB, and MRP parameters for the interface:

1. Click on the Forwarding Control tab.
2. Configure the required parameters.

   When the L2 Protocol Termination parameter is set to Enabled, a list of L2PT protocols is displayed. Select all that are required.

   The Force L2PT on Managed L2 Access Interface parameter is only available for MVPLS B-L2 access interfaces. When the Force L2PT on Managed L2 Access Interface parameter is set to Enabled, a list of L2PT protocols is displayed. Select all that are required.
3. Click on the STP tab and configure the required parameters.
4. Click on the FIB tab and configure the required parameters.
5. If you are creating an MVPLS to run MSTP, the MST Instances tab is configurable. Click on the MST Instances tab to edit a SAP MST instance.
6. Select an MST instance and click Properties.
7. The B-L2 Access Interface MST Instance (Edit) form opens. Configure the required parameters.
8. Save the changes and close the form.
9. If you are configuring an MVPLS B-L2 access interface, go to Step 18 .
10. Click on the MRP tab and configure the required parameters.

    Note:

    You can view information regarding MMRP Entries by clicking on the MMRP tab.
11. Select an PBB MRP Policy.

18

To assign a DoS protection policy to the interface:

Note: A default DoS protection policy is automatically assigned to the interface.

1. Click on the Security tab.
2. Select an NE DoS protection policy.
3. Configure the MAC Monitoring parameter.

19

To assign test generation options to the interface:

1. Click on the OAM tab, then the Configuration tab.
2. Configure the required Test Generation Options parameters.

20

To configure a redundant VLAN range.:

Note: If an MVPLS site has SAPs that manage traffic on the associated VPLS SAPs, you must define a redundant VLAN range during SAP creation. The redundant VLAN range defines the range of VC IDs for VPLS SAPs that the MVPLS manages.

1. Click on the Redundancy tab.
2. Click Create. The RedundantVlanRange (Create) form opens.
3. Configure the required parameters.
4. Save the changes and close the form.

21

To configure anti-spoofing filters for the interface:

1. Click on the Anti-Spoofing tab.
2. Configure the MAC Pinning parameter.

22

To specify QoS policy overrides:

1. Click on the Override Policy Items tab.

   Note: The Override Policy Items tab contains a number of tabs. However, the tabs that are displayed depend on the port type that you have chosen for this interface.

   - If you configured a non-HSMDA port, then the Access Ingress Queues, Access Egress Queues, Ingress Policer, and Egress Policer tabs are active.
   - If you configured an HSMDA port, then the Access Ingress Queues, Access Egress HSMDA Queues and Ingress Policer tabs are active.
2. See 50.97 “To configure QoS policy overrides on an L2 or L3 access interface” (p. 1654) for information about setting policy overrides.

23

To associate a MEP with the B-L2 Access interface:

1. Click on the OAM tab, then on the ETH-CFM tab.
2. Perform Step 9 to Step 16 in 77.82 “To create MIPs and MEPs on a VPLS L2 access interface” (p. 2360) .

24

To assign an ANCP policy to the interface:

1. Click on the ANCP Static Map tab. The ANCP Static Map (Create) form opens.
2. Configure the ANCP String parameter.
3. Select an ANCP Policy.
4. Save the changes and close the form.

25

Save the changes and close the forms.

26

Close the Manage Services form.

END OF STEPS

77.88 To create a VPLS I-L2 access interface

77.88.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→site→L2 Access Interfaces.

4

Right-click on L2 Access Interfaces and choose Create I-L2 Access Interface. The I-L2 Access Interface (Create) form opens.

5

Configure the required parameters.

Tunnel Fault Notification is configurable on interfaces where the device has ports configured in access or hybrid mode with QinQ encapsulation.

If you are configuring a tunnel facility MEP, Tunnel Fault Notification must be set to Accept.

6

Select a transit prefix policy for the interface in the Transit Prefix Policy panel.

7

Select an SHG for the interface in the Split Horizon Group panel.

Note: You must configure an SHG or residential SHG for a VPLS if you plan to create a spoke circuit from this VPLS site to a VLL or another VPLS.

8

Click on the Port tab.

9

Select a port for the I-L2 access interface.

Note: The form lists only ports in access or hybrid mode. To choose a port that is not listed, you must set the Mode parameter for the port to Access or Hybrid. After you do this, the port is listed when you click Search.
If you select an Ethernet Tunnel Endpoint, the Port form is refreshed and an Ethernet Tunnel tab is added.

10

CAUTION

Service Disruption

The creation of a SAP that uses the same port and encapsulation values as an existing inactive MSAP fails under the following conditions:

- If you try to use the NFM-P to create a SAP, the configuration fails and the NFM-P displays an error message.
- If you use a CLI to create a SAP in a service other than the service that contains the MSAP, the configuration succeeds but the MSAP is inactive until the regular SAP is deleted. Although the NFM-P displays the SAP and MSAP, the MSAP remains inactive and consumes resources.
- If you use a CLI to create a SAP in the service that contains the MSAP, the SAP creation fails.

Nokia recommends that you delete an inactive MSAP from the NFM-P if you need to create a regular SAP on the same port using the same encapsulation values.

Configure the required parameters.

For an I-L2 access interface, only Null, dot1q, and QinQ encapsulations are supported. In the case of I-MPVLS L2-access interfaces, Null encapsulation is not supported. I-MPVLS L2-access interfaces with MSTP configured support QinQ. These ports must also be of Ethernet type PBB.

When the selected port uses dot1q encapsulation, you can enable the Auto-Assign ID parameter to have the Outer Encapsulation Value parameter automatically assigned. If you choose this, the system assigns the lowest unused encapsulation value.

Note: You can set the Auto-Assign ID parameter to be the default parameter for dot1q encapsulation by enabling the Access Interface Encap Value (Dot1q only) parameter in the User Preferences form. Choose Application→ User Preferences from the main menu.

The Inner Encapsulation Value is configurable only when the port is an Ethernet with QinQ encapsulation.

SAP types X.0 and X.* as well as SAP types *.null and *.* can be configured on the same Q in Q port. You must enable the Enable Q in Q Untagged Sap parameter on the NE which allows the creation of the following default SAP types:

- The SAP type *.null functions as a default SAP for single-tagged frames on a Q in Q port. This SAP accepts single tags in the range 0 to 4095 as well as untagged traffic.
- The SAP type *.* functions as a default SAP for double-tagged frames on a Q in Q port. This SAP accepts untagged, single-tagged, and double-tagged frames with tags in the range 0 to 4095.

See 12.23 “To enable a Q in Q untagged SAP on an NE” (p. 360) for more information.

If the port you have chosen is an Ethernet Tunnel Endpoint, you will be able to set the Outer Encapsulation Value to 8191. This automatically enables the Ethernet Tunnel Endpoint Control SAP parameter.

11

Configure the Ethernet Tunnel Endpoint Control SAP parameter.

Note: Enabling the Ethernet Tunnel Endpoint Control SAP parameter creates the control L2 Access Interface (also known as a Control SAP). It also automatically sets the value of the Outer Encapsulation Value parameter to 8191.
If you are currently creating a same-fate SAP, the Ethernet Tunnel Endpoint Control SAP parameter must not be enabled.

12

Depending on the port that you have chosen, the Egress Multicast Group tab is configurable. To configure the EMG:

1. Click on the Egress Multicast Group tab.
2. Select an EMG.

   Note:

   The Egress Multicast Group-L2 Interface form lists only EMGs that have the same egress filter and encapsulation type as the interface.

13

If the selected port uses FR encapsulation, configure Frame Relay for the interface:

1. Click on the Frame Relay tab.
2. Set the FRF-12 Mode parameter to Enabled.
3. Configure the required parameters.

14

To assign ingress and egress QoS policies to the interface:

1. Click on the QoS tab.

   Note:

   Items such as policies, schedulers, and filters can be applied later to multiple service components at once by selecting and right-clicking the components in the service navigation tree, choosing Properties, and configuring the parameters on the appropriate tab. This action opens a properties form in a new window for the component that was right-clicked. The navigation tree is not displayed in this new window.

2. Configure the Ingress Match QinQ Dot1P parameter.

   The Ingress Match QinQ Dot1P parameter is configurable only when the encapsulation type of the port is dot1q or QinQ.

3. Select an ingress Qos policy in the Ingress Policy panel.

   Note:

   If you select an access ingress policy which has a forwarding class mapped to an ingress queue group, you must ensure that port that you are configuring for the VPLS L2 access interface has the access ingress queue group with the same name created on it.

   See 16.24 “To configure Ethernet ports” (p. 599) in Chapter 16, “Port and channel object configuration” for more information about how to configure Ethernet ports. See Chapter 49, “Policies overview” for more information about queue group template policies.

4. Select an ingress queue group template policy in the Forwarding Plane Redirect panel to choose a policy.
5. Configure the Instance ID parameter.
6. Configure the Egress Mark QinQ Top Bits Only parameter.

   The Egress Mark QinQ Top Bits Only parameter is configurable only when the encapsulation type of the port is dot1q or QinQ.

7. Select an egress QoS policy in the Egress Policy panel.

   Note:

   If you select an access egress policy which has a forwarding class mapped to an egress queue group, you must ensure that port that you are configuring for the VPLS L2 access interface has the access egress queue group with the same name created on it.

   See 16.24 “To configure Ethernet ports” (p. 599) in Chapter 16, “Port and channel object configuration” for more information about how to configure Ethernet ports. See Chapter 49, “Policies overview” for more information about queue group template policies.

8. If the port you selected is not an HSMDA port then go to Step 15 .
9. Configure the Packet Byte Offset (bytes) parameter. Before you can configure the parameter, you must enable the associated Override parameter.
10. Select a WRR policy in the Egress HSMDA Override panel.
11. Select an HSMDA egress secondary shaper policy in the Egress HSMDA Override panel.
12. Select an HS secondary shaper in the HS Overrides panel, if required.

13. Configure the required parameters.

15

Click on the Schedulers tab to configure scheduling:

Note: The Schedulers tab is configurable only when a port is assigned to the interface.

16

Perform one of the following.

a. To specify that an aggregation scheduler policy is not applied to the interface.
   1. Set the Aggregation parameter to off.

      Note:

      The Aggregation parameter is not configurable if the port you selected is an HSMDA port.
   2. Configure the required parameters.

      Note:

      The Aggregate Rate Limit (kbps) and Frame-Based Accounting parameters are configurable only when there is no scheduler specified in the Egress Scheduler panel.

      The Frame-Based Accounting parameter is not configurable if the port you selected is an HSMDA port.

      You cannot specify an egress scheduler when the Aggregate Rate Limit (kbps) parameter is set to a value greater than zero.
   3. Select and ingress scheduler in the Ingress Scheduler panel.
   4. Select an ingress policer control policy in the Ingress Policer Control Policy panel.
   5. If the port you selected is an HSMDA port, go to Step 17 .
   6. Select an egress scheduler in the Egress Scheduler panel.
   7. Select a policer control policy in the Egress Policer Control Policy panel.
   8. Go to Step 17 .

b. To specify that an access scheduler policy is applied to the interface:

   Note: You cannot specify an access scheduler policy if the port you selected is an HSMDA port. Go to Step 17 .
   1. Set the Aggregation parameter to on.
   2. Select an aggregation scheduler in the Aggregation Scheduler panel.

17

To assign ingress and egress ACL filters to the interface:

1. Click on the ACL tab.
2. Select an ingress ACL filter in the Ingress Filter panel.
3. Select an egress ACL filter in the Egress Filter panel.

4. Select an IPv6 ingress ACL filter in the IPv6 Ingress Filter panel.
5. Select an IPv6 egress ACL filter in the IPv6 Egress Filter panel.

18

To assign an accounting policy to the interface:

1. Click on the Accounting tab.
2. Configure the Collect Accounting Statistics and Ingress Counter Type parameters.
3. Select an accounting policy.

19

To configure BPDU Termination, STP, and FIB parameters for the interface:

1. Click on the Forwarding Control tab. Depending on the device being configured, the BPDU Termination tab is displayed. Otherwise, go to 3 .
2. Configure the required parameters.

   When the L2 Protocol Termination parameter is set to Enabled, a list of L2PT protocols is displayed. Select all that are required.

   The Force L2PT on Managed L2 Access Interface parameter is only available for MVPLS I-L2 access interfaces. When the Force L2PT on Managed L2 Access Interface parameter is set to Enabled, a list of L2PT protocols is displayed. Select all that are required.
3. Click on the STP tab and configure the required parameters.
4. Click on the FIB tab and configure the required parameters.
5. If you are creating an MVPLS to run MSTP, Click on the MST Instances tab to edit a SAP MST instance. Otherwise, go to Step 20 .
6. Select an MST instance and click Properties.
7. The I-L2 Access Interface MST Instance (Edit) form opens. Configure the required parameters.
8. Save the changes and close the form.

20

To assign a DoS protection policy or DDoS protection policy to the interface:

Note: A default DoS protection policy is automatically assigned to the interface.

1. Click on the Security tab.
2. Select a DoS protection policy in the NE DoS Protection panel.
3. Configure the MAC Monitoring parameter.

21

To assign test generation options to the interface:

1. Click on the OAM tab, then the Configuration tab.

2. Configure the required Test Generation Options parameters.

22

To configure an Ethernet tunnel:

Note: You can only configure Ethernet tunnel SAP path parameters if you are creating a same-fate SAP.

1. Click on the Ethernet Tunnel tab.
2. If you are configuring a fate-sharing Ethernet Tunnel Endpoint SAP (also referred to as same-fate SAP) then go to 3 . Otherwise, go to Step 23 .
3. Click Create. The Ethernet Tunnel (Create) form opens.
4. Configure the required parameters.
5. Save the changes and close the form.

23

To configure a redundant VLAN range:

Note: If an MVPLS site has SAPs that manage traffic on the associated VPLS SAPs, you must define a redundant VLAN range during SAP creation. The redundant VLAN range defines the range of VC IDs for VPLS SAPs that the MVPLS manages.

1. Click on the Redundancy tab.
2. Click Create. The RedundantVlanRange (Create) form opens.
3. Configure the required parameters.
4. Save the changes and close the form.

24

To configure IGMP snooping for the interface:

1. Click on the IGMP Snooping tab.
2. Configure the required parameters.

   The General Query Interval (seconds), Maximum Response Interval (seconds), Robust count, and IGMP Version parameters are configurable when the Send Queries parameter is enabled.
3. Click on the Static Mcast Group tab to configure one or more static multicast groups. Otherwise, go to Step 26 .
4. Click Create. The Access Interface Igmp Snooping Mcast Group Display (Create) form opens.
5. Configure the required parameters.
6. Save the changes and close the form.

25

To configure MLD snooping for the interface:

1. Click on the MLD Snooping tab.
2. Configure the parameters in the General tab.
3. Click on the Static Mcast Group tab to configure one or more static multicast groups. Otherwise, go to Step 26 .
4. Click Create. The Access Interface Mld Snooping MCast Group Display (Create) form opens.
5. Configure the required parameters.
6. Save the changes and close the form.

26

To configure anti-spoofing filters for the interface:

1. Click on the Anti-Spoofing tab.
2. Configure the MAC Pinning parameter.

27

To specify QoS policy overrides:

1. Click on the Override Policy Items tab.

   Note: The Override Policy Items tab contains a number of tabs. However, the tabs that are displayed depend on the port type that you have chosen for this interface.
   - If you configured a non-HSMDA port, then the Access Ingress Queues, Access Egress Queues, Ingress Policer, and Egress Policer tabs are active.
   - If you configured an HSMDA port, then the Access Ingress Queues, Access Egress HSMDA Queues and Ingress Policer tabs are active.
2. See 50.97 “To configure QoS policy overrides on an L2 or L3 access interface” (p. 1654) for information about setting policy overrides.

28

To associate a MEP with the I-L2 Access interface:

1. Click on the OAM tab, then on the ETH-CFM tab.
2. Perform Step 9 to Step 16 in 77.82 “To create MIPs and MEPs on a VPLS L2 access interface” (p. 2360) .

29

To assign an ANCP policy to the interface:

1. Click on the ANCP Static Map tab.
2. Click Create. The ANCP Static Map (Create) form opens.

3. Configure the ANCP String parameter.
4. Select an ANCP Policy.
5. Save the changes and close the form.

30

Save the changes and close the forms.

END OF STEPS

77.89 To configure ETree on a VPLS L2 access interface

77.89.1 Purpose

Use this procedure to configure a SAP as an ETree leaf. If the interface is not configured as a leaf, it will configured as a root by default.

The following prerequisites apply:

- the ETree Enabled procedure must be configured in the VPLS site
- The encapsulation type of the terminating port must be Dot1Q or QinQ

77.89.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→site→L2 Access Interfaces.

4

Configure the parameters in the Etree panel.

The leaf tag cannot match the dot1q tag on the port. Null and the asterisk (*) are not supported as leaf tags.

5

Save the changes and close the forms.

END OF STEPS

77.90 To configure DHCPv6 snooping for a VPLS or MVPLS L2 access interface

77.90.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→site→L2 Access Interfaces.

4

Right-click the L2 access interface and choose Properties. The VPLS L2 Access Interface (Edit) form opens.

5

Click on the DHCPv6 tab.

6

Configure the required parameters.

7

Save the changes and close the forms.

END OF STEPS

VPLS SDP binding procedures

77.91 To create a VPLS or MVPLS mesh SDP binding

77.91.1 Prerequisites

The value of the Automatic Mesh SDP Binding Creation parameter determines the way that mesh SDP binding creation occurs in the VPLS.

Note: The maximum combined number of mesh and spoke SDP bindings that you can configure on a service site depends on the NE type and release on which the site is configured. A deployment error occurs when you attempt to create an SDP binding if this limit is reached on the NE.

The maximum number of VPLS sites that can be automatically connected using mesh SDP bindings is 100. You can perform automatic creation of a full mesh in a VPLS in one or more passes, as required.

Nokia recommends that you perform automatic mesh SDP binding creation on only 50 sites at one time. Performing automatic mesh SDP binding creation on 100 sites at one time may result in a substantial delay in building the network.

77.91.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→site→Mesh SDP Bindings.

4

Right-click on Mesh SDP Bindings and choose Create Mesh SDP Binding. The Mesh SDP Binding (Create) form opens.

5

If automatic mesh SDP binding creation is enabled on the VPLS, a dialog box appears. The message in the dialog box discourages manual mesh SDP binding creation when automatic mesh SDP binding creation is specified for a VPLS. Perform one of the following.

a. Choose not to override automatic SDP binding creation. Nokia recommends this action.

   1. Click No.
   2. Click cancel to close the VPLS management form with no action.

b. Choose to override automatic SDP binding creation. Nokia does not recommend this action.
   1. Click Yes. The Mesh SDP Binding (Create) form opens.
   2. Consult an Nokia technical representative before proceeding.

6

Specify a destination NE for the mesh SDP binding:

a. If the destination NE is a managed NE, select an NE from a list of managed NEs.

b. If the destination NE is an unmanaged NE, specify the system ID for the Tunnel Termination Site parameter.

7

Configure the required general parameters.

The range of the Ingress Label parameter depends on the parameter value set for the Static Label Range on the MPLS instance. See 31.6 “To configure an MPLS instance” (p. 1116) .

8

To specify a transport tunnel for the mesh SDP binding:

a. Let the NFM-P configure the transport tunnel automatically.
   1. Enable the Auto-Select Transport Tunnel parameter.
   2. Configure either the Profile Name or the Tunnel Auto-Selection Transport Preference parameter.

b. Configure the transport tunnel manually by selecting a service tunnel for the mesh SDP binding in the Tunnel panel.

9

Configure the required general parameters.

10

Configure the parameters in the Hash Label panel, if required.

11

Configure the Force VLAN VC Forwarding parameter in the VLAN panel.

The Force VLAN VC Forwarding parameter does not appear if you are creating a Mesh SDP binding for a B-site.

You cannot enable the Force VLAN VC Forwarding parameter if you enable the Force Q-in-Q VC Forwarding parameter in Step 12 .

12

Configure the Force Q-in-Q VC Forwarding parameter in the Q in Q panel.

The Force Q-in-Q VC Forwarding parameter does not appear if you are creating a Mesh SDP binding for a B-site.

You cannot enable the Force Q-in-Q VC Forwarding parameter if you enable the Force VLAN VC Forwarding parameter in Step 11 .

You cannot enable the Force Q-in-Q VC Forwarding parameter if the Enable IP Interface Binding parameter is enabled on the VPLS site in 77.33 “To configure a VPLS site” (p. 2294) .

13

Click on the States tab to specify whether the mesh SDP binding is in service and configure the Administrative State parameter.

14

To specify a transport tunnel for the Return SDP binding:

Note: You can create a return tunnel only between sites that are in the same service. If the sites are not in the same service, the Return tab does not appear.

a. Let the NFM-P configure the transport tunnel automatically.
   1. Click on the Return tab.
   2. Enable the Auto Select Return Transport Tunnel parameter.
   3. Configure either the Profile Name or the Return Tunnel Auto-Selection Transport Preference parameter.

b. Configure the transport tunnel manually.
   1. Click on the Return tab.
   2. Select a return tunnel in the Return Tunnel panel.

15

If you are configuring a 7705 SAR, go to Step 17 .

16

To configure QoS:

1. Click on the QoS tab.
2. Select a network policy in the Forwarding Plane Redirect panel.
3. Select an ingress queue group template policy in the Forwarding Plane Redirect panel.
4. Configure the Instance ID parameter in the Forwarding Plane Redirect panel.
5. Select a network policy in the Port Redirect panel.
6. Select an egress queue group template policy in the Port Redirect panel.
7. Configure the Instance ID parameter in the Port Redirect panel.

17

Click on the Pseudowire OAM tab and configure the Control Word parameter.

18

To assign ingress and egress ACL filters to the mesh SDP binding:

1. Click on the ACL tab.
2. Select an ingress filter in the Ingress Filter panel.
3. Select an egress filter in the Egress Filter panel.
4. Select an IPv6 ingress ACL filter in the IPv6 Ingress Filter panel.
5. Select an IPv6 egress ACL filter in the IPv6 Egress Filter panel.

19

To configure anti-spoofing for the mesh SDP binding:

1. Click on the Anti-Spoofing tab.
2. Configure the MAC Pinning parameter.

20

To assign an accounting policy to the mesh SDP binding:

1. Click on the Accounting tab.
2. Configure the Collect Accounting Statistics parameter.
3. Select an accounting policy.

21

Save the changes and close the forms.

22

To assign a DoS protection policy to the mesh SDP binding, perform 77.94 “To assign a DoS protection policy to a VPLS SDP binding” (p. 2393) .

23

To add or delete MFIB allowed daughter cards or configure MRP on the mesh SDP binding, perform 77.105 “To configure learning protection parameters on a VPLS SDP binding” (p. 2403) .

24

To configure DHCP on the mesh SDP binding, perform 77.95 “To configure DHCP for the VPLS SDP binding” (p. 2394) .

25

To configure IGMP snooping on the mesh SDP binding, perform 77.96 “To configure IGMP snooping for the VPLS SDP binding” (p. 2395) .

26

To configure DHCPv6 snooping on the mesh SDP binding, perform 77.108 “To configure DHCPv6 snooping for the VPLS or MVPLS SDP binding” (p. 2407) .

27

To associate a MEP to the mesh SDP binding, perform 77.98 “To create a MIP on a VPLS SDP binding” (p. 2396) .

28

To configure MLD snooping on the mesh SDP binding, perform 77.100 “To configure MLD Snooping for the VPLS SDP binding” (p. 2399) .

END OF STEPS

77.92 To create a VPLS or MVPLS spoke SDP binding

Note: The maximum combined number of mesh and spoke SDP bindings that you can configure on a service site depends on the NE type and release on which the site is configured. A deployment error occurs when you attempt to create an SDP binding if this limit is reached on the NE.

You cannot create a spoke SDP binding on an MVPLS site that runs MSTP. Likewise, you cannot enable MSTP for a site that has a spoke SDP binding, or on a SAP with a non-zero encapsulation value.

For services employing BGP AD and BGP VPLS, you should create SDP bindings manually at non-BGP AD or BGP VPLS enabled sites, or to other BGP AD or BGP VPLS sites where auto-created pseudowires are not expected to be created.

77.92.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

If you are creating a redundant spoke SDP binding under an endpoint, go to Step 4 . Otherwise go to Step 6 .

Note: Redundant spoke SDP bindings under an endpoint are only valid for VPLS regular sites and B-Sites. They do not apply to I-Sites.

4

On the service tree, expand Sites→site→Spoke SDP Bindings.

5

Right-click on Spoke SDP Bindings below the endpoint and choose Create Spoke SDP Bindings. The Spoke SDP Binding (Create) form opens. Go to Step 8 .

6

On the service tree, expand the site on which you want to create a VPLS spoke SDP binding.

7

Right-click on Spoke SDP Bindings and choose Create Spoke SDP Bindings. The Spoke SDP Binding (Create) form opens.

8

Specify a destination NE for the spoke SDP binding:

a. If the destination NE is a managed NE, select an NE from a list of managed NEs.

b. If the destination NE is an unmanaged NE, specify the system ID for the Tunnel Termination Site parameter.

9

Configure the required parameters.

The Block on Mesh SDP Failure parameter does not appear if you are creating a Spoke SDP binding for a B-site or an I-site.

The range of the Ingress Label parameter depends on the parameter value set for the Static Label Range on the MPLS instance. See 31.6 “To configure an MPLS instance” (p. 1116) .

10

Perform one of the following to specify a transport tunnel for the spoke SDP binding.

a. Let the NFM-P configure the transport tunnel automatically.

1. Enable the Auto-Select Transport Tunnel parameter.
2. Configure either the Profile Name or the Tunnel Auto-Selection Transport Preference parameter.

Note: If you are creating a Spoke SDP binding for a B-site, the Tunnel Auto-Selection Preference must be either MPLS:LDP or MPLS:RSVP. For I-sites, you can use MPLS:LDP, MPLS:RSVP, GRE, or Any.

b. Configure the transport tunnel manually by selecting a tunnel in the Tunnel panel.

c. Configure an MPLS-TP transport tunnel manually by selecting a tunnel in the Tunnel panel. See 33.9 “To create an IP/MPLS service tunnel” (p. 1190) for more information about how to create an MPLS-TP service tunnel.

11

If you are creating the spoke SDP binding for a B-Site or an I-Site, go to Step 19 .

12

If you are creating the spoke SDP binding under an endpoint, go to Step 14 .

13

Select an endpoint in the Redundancy panel.

14

Configure the required general parameters.

15

Configure the parameters in the Hash Label panel, if required.

The Enable Hash Label parameter is not configurable if you selected an MPLS-TP tunnel in Step 10 .

16

Configure the Force VLAN VC Forwarding parameter in the VLAN panel.

The Force VLAN VC Forwarding parameter does not appear if you are creating a Spoke SDP binding for a B-Site or an I-Site.

You cannot enable the Force VLAN VC Forwarding parameter if you enable the Force Q-in-Q VC Forwarding parameter in Step 17 .

17

Configure the Force Q-in-Q VC Forwarding parameter in the Q in Q panel.

The Force Q-in-Q VC Forwarding parameter does not appear if you are creating a Spoke SDP binding for a B-site or an I-Site.

You cannot enable the Force Q-in-Q VC Forwarding parameter if you enable the Force VLAN VC Forwarding parameter in Step 16 .

You cannot enable the Force Q-in-Q VC Forwarding parameter if the Enable IP Interface Binding parameter is enabled on the VPLS site in 77.33 “To configure a VPLS site” (p. 2294) .

18

Configure the Enable PW Status Signaling parameter in the Pseudowire Signaling panel.

The Enable PW Status Signaling parameter is not configurable if you selected an MPLS-TP tunnel in Step 10 .

19

Select an SHG for the spoke SDP binding in the Split Horizon Group panel.

Note: You must configure an SHG or residential SHG on a spoke SDP binding for an HVPLS that includes another VPLS or a VLL service.

20

Select an application profile for the spoke SDP binding.

Only local profiles on the NE can be selected.

21

Select a transit prefix policy to associate with the spoke SDP binding in the Transit Prefix Policy panel.

Note: You can bind a transit policy to only one access interface or spoke SDP binding per NE.
The transit policy and the application profile must belong to the same application assurance group or partition.

22

Select an operational group for the spoke SDP Binding to join as a member.

23

Select an operational group for the spoke SDP Binding to monitor.

24

Perform one of the following to specify a transport tunnel for the Return SDP binding.

Note: You can create a return tunnel only between sites that are in the same service. If the sites are not in the same service, the Return tab does not appear.
If you are creating a Return SDP binding for a B-site, the Return Tunnel Auto-Selection Preference must be either MPLS:LDP or MPLS:RSVP. For I-sites, you can use MPLS:LDP, MPLS:RSVP, GRE, or Any.

a. Let the NFM-P configure the transport tunnel automatically.
   1. Click on the Return tab.
   2. Enable the Auto Select Return Transport Tunnel parameter.
   3. Configure either the Profile Name or the Return Tunnel Auto-Selection Transport Preference parameter.

b. Configure the transport tunnel manually.
   1. Click on the Return tab.
   2. Select a return tunnel in the Return Tunnel panel.

25

To configure QoS:

1. Click on the QoS tab.
2. Select a network policy in the Forwarding Plane Redirect panel.
3. Select an ingress queue group template policy in the Forwarding Plane Redirect panel.

4. Configure the Instance ID parameter in the Forwarding Plane Redirect panel.
5. Select a network policy in the Port Redirect panel.
6. Select an egress queue group template policy in the Port Redirect panel.
7. Configure the Instance ID parameter in the Port Redirect panel.

26

Click on the States tab to specify whether the spoke SDP binding is in or out of service and configure the Administrative State parameter.

27

Click on the Pseudowire OAM tab and configure the Control Word parameter.

Note: If you are creating a spoke SDP binding using an MPLS-TP service tunnel for pseudowire static configuration, you must set the Control Word parameter to Preferred.

28

If you are configuring a 7210 SAS-M, 7210 SAS-Mxp, 7210 SAS-R, 7210 SAS-S, 7210 SAS-Sx, 7210 SAS-T, or 7210 SAS-X, go to Step 31 .

29

To assign ingress and egress ACL filters to the spoke SDP binding:

1. Click on the ACL tab.
2. Select an ingress filter in the Ingress Filter panel.
3. Select an egress filter in the Egress Filter panel to choose an ingress ACL filter.
4. Select an IPv6 ingress filter in the IPv6 Ingress Filter panel.
5. Select an IPv6 egress filter in the IPv6 Egress Filter panel.

30

If you are configuring a 7705 SAR, go to Step 32 .

31

To assign an accounting policy to the interface:

1. Click on the Accounting tab.
2. Select an accounting policy.
3. Configure the required parameters.

32

To configure anti-spoofing for the spoke SDP binding.

1. Click on the Anti-Spoofing tab.

2. Configure the MAC Pinning parameter.

33

If you are configuring a 7210 SAS-M, 7210 SAS-R, 7210 SAS-S, 7210 SAS-Sx, 7210 SAS-T, or 7210 SAS-X, go to Step 34 .

34

Save the changes and close the forms.

35

To assign a DoS protection policy to the spoke SDP binding, perform 77.94 “To assign a DoS protection policy to a VPLS SDP binding” (p. 2393) .

36

To configure MFIB, STP, FIB, MRP, and MAC learning parameters on the spoke SDP binding, perform 77.105 “To configure learning protection parameters on a VPLS SDP binding” (p. 2403) .

37

To configure DHCP on the spoke SDP binding, perform 77.95 “To configure DHCP for the VPLS SDP binding” (p. 2394) .

38

To configure IGMP snooping on the spoke SDP binding, perform 77.96 “To configure IGMP snooping for the VPLS SDP binding” (p. 2395) .

39

To configure DHCPv6 snooping on the spoke SDP binding, perform 77.108 “To configure DHCPv6 snooping for the VPLS or MVPLS SDP binding” (p. 2407) .

40

To associate a MEP to the spoke SDP binding, perform 77.98 “To create a MIP on a VPLS SDP binding” (p. 2396) .

41

To configure MLD snooping on the spoke SDP binding, perform 77.100 “To configure MLD Snooping for the VPLS SDP binding” (p. 2399) .

42

To configure PIM snooping for the spoke SDP binding, perform 77.104 “To configure PIM snooping for a VPLS spoke SDP binding” (p. 2403) .

43

To configure custom object attributes for AA reporting, perform 77.106 “To configure custom object attributes for AA reporting for a spoke SDP binding” (p. 2405) .

END OF STEPS

77.93 To configure an MPLS-TP static pseudowire on a VPLS spoke SDP binding

77.93.1 Purpose

Create an MPLS-TP static pseudowire on the spoke SDP binding. An MPLS-TP service tunnel must be used in the SDP binding, and the Control Word parameter for pseudowire OAM must be set to Preferred. See 77.92 “To create a VPLS or MVPLS spoke SDP binding” (p. 2386) .

77.93.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→site→Spoke SDP Bindings.

4

Click on the SDP binding on which you want to configure the MPLS-TP static pseudowire. The Spoke SDP Binding (Edit) form opens.

5

Click on the Control Channel tab and configure the required parameters.

6

Click on the Static PW tab and click Create. The PW Path ID (Create) form opens.

7

Configure the Path AGI parameter.

8

Configure the parameters in the Source Attachment Individual Identifier panel.

9

Configure the parameters in the Target Attachment Individual Identifier panel.

10

Save the changes and close the forms.

END OF STEPS

77.94 To assign a DoS protection policy to a VPLS SDP binding

Note: A default DoS protection policy is automatically assigned.

77.94.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→site→Mesh|Spoke SDP Bindings.

4

Right-click on the SDP binding you want to configure and choose Properties. The [Mesh|Spoke] SDP Binding (Edit) form opens.

5

Click on the Security tab.

6

Select and NE DoS protection policy.

7

Configure the MAC Monitoring parameter.

8

Configure the Ethernet CFM Monitor Flags parameter.

9

Save the changes and close the forms.

END OF STEPS

77.95 To configure DHCP for the VPLS SDP binding

77.95.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→site→Mesh|Spoke SDP Bindings.

4

Right-click on the mesh or spoke SDP binding you need to configure and choose Properties. The [Mesh|Spoke] SDP Binding (Edit) form opens.

5

Click on the DHCP tab.

Note: The DHCP tab does not appear if you are configuring a mesh or spoke SDP binding for a B-site.

6

Configure the required parameters.

7

Save the changes and close the forms.

END OF STEPS

77.96 To configure IGMP snooping for the VPLS SDP binding

77.96.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Configure the filter criteria and click Search. A list of services appears.

3

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

4

On the service tree, expand Sites→site→Mesh|Spoke SDP Bindings.

5

Right-click on the mesh or spoke SDP binding you need to configure and choose Properties. The [Mesh|Spoke] SDP Binding (Edit) form opens.

6

Click on the IGMP Snooping tab.

7

Configure the required parameters.

The General Query Interval (seconds), Maximum Response Interval (seconds), Robust count, and IGMP Version parameters are configurable when the Send Queries parameter is enabled.

8

To configure a multicast CAC policy, select a policy in the Multicast CAC Policy panel.

9

Configure the required parameters.

10

Click on the Static Mcast Group tab to configure a static multicast group.

11

Click Create. The Access Interface Igmp Snooping Mcast Group Display (Create) form opens.

12

Configure the required parameters.

13

Save the changes and close the forms.

END OF STEPS

77.97 To configure ETree on a VPLS SDP binding

77.97.1 Purpose

Use this procedure to configure a spoke SDP as an ETree leaf. If the interface is not configured as a leaf, it will configured as a root by default.

The VC Type parameter must be set to VLAN.

77.97.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→site→Spoke SDP Bindings.

4

Configure the parameters in the Etree panel.

5

Save the changes and close the forms.

END OF STEPS

77.98 To create a MIP on a VPLS SDP binding

77.98.1 Purpose

This procedure is applicable to both VPLS spoke and mesh SDP bindings. You can also create an SDP binding MIP from the service topology view.

Note: You cannot configure MIPs on SPB-enabled SDP bindings. See 77.2.6 “SPB in VPLS” (p. 2222) in “VPLS management overview” (p. 2210) for more information about SPB.

77.98.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

Click on the OAM tab, then the Tests sub-tab, then the CFM Global MEG sub-tab.

4

Select a Global MEG or refer to 91.15 “To configure an Ethernet CFM MD policy and subordinate objects” (p. 3109) to create one.

Note: A Global MEG suitable for MIP creation on an SDP binding has a couple of specific requirements. When creating a Global MEG in 91.15 “To configure an Ethernet CFM MD policy and subordinate objects” (p. 3109) , on the General tab you must set the Initial MHF-Creation parameter to default. On the Service you create there, the MIP(s) Creation on SDP Bindings parameter in the Auto-Creation of MIP(s) panel must also be enabled.

5

On the service tree, expand Sites→site→Mesh|Spoke SDP Bindings.

6

Right-click on the mesh or spoke SDP binding you need to configure and choose Properties. The [Mesh|Spoke] SDP Binding (Edit) form opens.

7

Click on the OAM tab, then the ETH-CFM sub-tab.

8

To configure a MIP, enable the MIP parameter and configure the MIP MAC Address parameter in the MIP Configuration panel.

Note: If the MIP is later disabled and subsequently re-enabled, the MIP MAC Address will return to a default value on the NE.

9

To view MIPs on the SDP binding, click Resync MIPs and then Search in the MIPs panel.

10

Save the changes and close the forms.

END OF STEPS

77.99 To create a MEP on a VPLS SDP binding

77.99.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→site→Mesh|Spoke SDP Bindings.

4

Right-click on the mesh or spoke SDP binding you need to configure and choose Properties. The [Mesh|Spoke] SDP Binding (Edit) form opens.

5

Click on the OAM tab, then the ETH-CFM tab.

6

Configure the Enable Virtual MEP Filter parameter in the Virtual MEPs panel.

7

Configure the parameters in the Squelch Ingress Level panel.

Levels must be assigned contiguously from Level 0. If you select a level greater than 0, then all levels lower than the one you chose will automatically be selected.

The Squelch Ingress Levels configured for all the mesh or spoke bindings on a site can be compared in one view when you click on the Mesh SDP Bindings or Spoke SDP Bindings item below a site on the navigation tree. Use the scroll bar to locate the Squelch Ingress Level columns.

8

Configure the parameters on the LMM Session Stats Collection panel as required.

9

To create a MEP:

1. Click Create in the MEPs panel. The MEP (Create) form opens.
2. Select a MEG in the MEP panel.
3. Configure the general parameters in the MEP panel.

   For L2 access interfaces on 7210 SAS-R sites, you can create Up MEPs only when the system resource profile is set appropriately. See 12.50 “To configure the global system resource profile on a 7210 SAS or 7250 IXR” (p. 380) .

   The Type and Interface Type parameters are automatically populated based on whether the MEP is created on a SAP, SDP binding, or Ethernet Tunnel Path Endpoint.
4. Configure the parameters in the CCM panel.

   The CCM Padding Packet Size (Bytes) parameter cannot be configured when the CCM interval parameter is set to 10 ms or 100 ms.
5. Select a MEG sub-group in the MEG Sub-Grouping panel.
6. If the MD for the MEP has a Maintenance Domain Name Type of none and the associated MEG has a Maintenance Entity group Name Type of icc-based, then the Y.1731 Tests and AIS tabs are configurable. Click on the Y.1731 Tests tab and configure the required parameters.

   The Eth Test Pattern parameter is configurable when the Eth Test Enabled parameter is enabled.
7. Click on the AIS tab and configure the required parameters.

   The AIS Meg Level parameter is configurable when the AIS Enabled parameter is enabled.

10

To add a MIP to the SDP binding, perform 77.98 “To create a MIP on a VPLS SDP binding” (p. 2396) .

11

Save the changes and close the forms.

END OF STEPS

77.100 To configure MLD Snooping for the VPLS SDP binding

77.100.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→site→Mesh|Spoke SDP Bindings.

4

Right-click on the SDP binding you want to configure and choose Properties. The [Mesh|Spoke] SDP Binding (Edit) form opens.

5

Click on the MLD Snooping tab.

Note: The MLD Snooping tab does not appear if you are creating a Mesh SDP binding for a B-site or I-site.

6

Configure the required parameters.

The General Query Interval (seconds), Maximum Response Interval (seconds), Robust count, and MLD version parameters are configurable when the Send Queries parameter is enabled.

7

To configure one or more static multicast groups:

1. Click on the Static Mcast Group tab.
2. Click Create. The Circuit Mld Snooping Mcast Group Display (Create) form opens.
3. Configure the required parameters.

8

Save the changes and close the forms.

END OF STEPS

77.101 To configure BFD on a VPLS SDP binding

77.101.1 Purpose

BFD is used over the VCCV control channel for PW fault detection. BFD carried over a PW associated channel enables the monitoring of the PW between the terminating PEs, regardless of whether the service spans multiple hops. This allows faults that are local to individual PWs to be detected.

77.101.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select a VPLS service and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→Spoke SDP Bindings or Mesh SDP Bindings and click on the SDP binding on which you want to configure BFD.

4

Click on the BFD tab and configure BFD on the spoke SDP binding:

1. On the General tab, enable the Enable BFD parameter.
2. Choose a BFD template. To create a BFD template, see 28.25 “To configure a BFD template policy” (p. 911) .

   Note:

   You must assign a BFD template to the SDP binding if you enable BFD.
3. In the Failure Action dropdown, select the action to be performed on BFD failure.
4. Configure the Up-Timer parameter.

   Note:

   The Up-Timer parameter is applicable only when the value of Failure Action is set to down.

5

Save and close the forms.

END OF STEPS

77.102 To clear BFD sessions and statistics on a VPLS SDP binding

77.102.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select a VPLS service and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→Spoke SDP Bindings and click on the spoke SDP binding on which you want to view the BFD session information.

4

Clear BFD sessions or statistics on the spoke SDP binding:

1. Click on the BFD tab, then on the BFD Session tab.
2. Click Clear All to clear all BFD sessions.
3. Click Clear All Statistics to clear all BFD statistics.

5

Close the forms.

END OF STEPS

77.103 To view the BFD session status on a VPLS SDP binding

77.103.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select a VPLS service and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→Spoke SDP Bindings and click on the spoke SDP binding on which you want to configure BFD.

4

Click on the BFD tab and view the status of the BFD session on the spoke SDP binding:

1. Click on the BFD Session tab.
2. Choose a BFD session and click Properties. The BFD Session (View) form opens.

5

Close the forms.

END OF STEPS

77.104 To configure PIM snooping for a VPLS spoke SDP binding

77.104.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→Spoke SDP Bindings and click on the spoke SDP binding on which you want to configure PIM snooping.

4

Click on the PIM Snooping tab.

5

Configure the Max Number of Groups parameter.

6

Save the changes and close the forms.

END OF STEPS

77.105 To configure learning protection parameters on a VPLS SDP binding

77.105.1 Purpose

This procedure applies to MFIB, STP, FIB, MRP, and MAC learning protection parameters on a VPLS SDP binding.

Note: The single-slot models of the 7450 ESS and 7750 SR support the addition or deletion of MFIB allowed daughter cards.

The MFIB Allowed Daughter Card tab does not appear if you are creating a Mesh SDP binding for a B-site.

77.105.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→site→Mesh|Spoke SDP Bindings.

4

Right-click on the mesh or spoke SDP binding you need to configure and choose Properties. The [Mesh|Spoke] SDP Binding (Edit) form opens.

5

Click on the Forwarding Control tab.

6

Perform the following if you are configuring a spoke SDP binding. Otherwise, go to Step 7 .

1. Depending on the device being configured, the BPDU Termination tab is displayed.

   Note:

   For spoke SDPs on the 7210 SAS-R, the BPDU Termination tab is displayed only when the Allow L2Pt Xstp BPDU parameter is enabled for the site. See 77.33 “To configure a VPLS site” (p. 2294) .
2. Configure the required parameters.

   You can enable the L2 Protocol Termination parameter only when STP is disabled for the site. The Administrative State parameter for STP must be set to Down; see 77.35 “To configure MFIB, STP, FIB, and MAC learning protection for a VPLS site” (p. 2296) .

   When the L2 Protocol Termination parameter is set to Enabled, a list of L2PT protocols is displayed. Select all that are required. You must select at least one protocol.
3. Click on the STP tab and configure the required parameters.
4. Click on the FIB tab and configure the required parameters.

   The Maximum Entries parameter does not appear if you are creating a Spoke SDP binding for a B-site.

   The Restrict Protected Source Action parameter is configurable when the Restrict Protected Source parameter is set to true.

7

If you are configuring a mesh SDP binding, click on the FIB tab and configure the parameters. Otherwise, go to Step 8 .

8

Click on the MFIB Allowed Daughter Card tab and click Create. The SDP Binding MFIB Allowed Daughter Card (Create) form opens.

9

Select a daughter card, save the changes and close the form.

10

Click on the MRP tab if you are configuring a mesh or spoke SDP binding for a B-site and configure the parameters. Otherwise, go to Step 12 .

Note: The MRP tab does not appear if you are creating an SDP binding for an I-site.

11

Select an PBB MRP Policy.

12

Save the changes and close the forms.

END OF STEPS

77.106 To configure custom object attributes for AA reporting for a spoke SDP binding

77.106.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→Spoke SDP Bindings and click on the spoke SDP binding on which you want to configure custom object attributes for AA reporting.

4

On the General tab, choose an Application Profile for the applicable Group and Partition.

5

Click on the Application Assurance tab, then the NSP Analytics Parameters sub-tab.

6

Click on the Reporting tab and click Create. The AA Reporting (Create) form opens.

7

Configure the required parameters.

8

Save the changes and close the forms.

END OF STEPS

77.107 To force a switchover to a redundant spoke SDP binding

77.107.1 Prerequisites

This procedure can only be performed on a VPLS that has been configured with endpoints that are associated redundant spoke SDP bindings.

77.107.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu.

2

Choose the required VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand the site on which you want to perform the switchover.

4

Right-click on the redundant spoke SDP binding under an endpoint for the site for which you want to perform the switchover and choose Force Switchover.

5

You can clear the switchover at a later time by performing Step 1 to Step 4 again and selecting the Clear Forced Switchover.

Note: You must clear a manually forced switchover by using the Clear Forced Switchover button when the active spoke SDP binding is restored. The NFM-P cannot automatically switch to another active spoke SDP binding if this is not done.

6

Close the forms.

END OF STEPS

77.108 To configure DHCPv6 snooping for the VPLS or MVPLS SDP binding

77.108.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites→site→Mesh|Spoke SDP Bindings.

4

Right-click on the mesh or spoke SDP binding you need to configure and choose Properties. The [Mesh|Spoke] SDP Binding (Edit) form opens.

5

Click on the DHCPv6 tab.

6

Configure the required parameters.

7

Save the changes and close the forms.

END OF STEPS

BGP AD and BGP VPLS procedures

77.109 To configure the VPLS for BGP auto-discovery

77.109.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPLS and click Properties. The VPLS Service (Edit) form opens.

3

Click on the BGP AD tab.

4

Set the BGP AD Administrative Status parameter to Up. The BGP AD Service Identification group appears.

5

Configure the VPLS ID parameter. This parameter must be a unique network-wide ID.

6

Save the changes and close the forms.

END OF STEPS

77.110 To configure a site for BGP AD or BGP VPLS

77.110.1 Purpose

This procedure provides the steps required to enable BGP Auto Discovery or configure BGP VPLS on a VPLS site.

- BGP AD enables a VPLS PE router to discover other PE routers that are part of the same VPLS domain. T-LDP based label signaling is used for the pseudowire.
- BGP VPLS provides the mechanism for service member auto-discovery based on Route Target. MP-BGP based label signaling is used for the pseudowire.

The following considerations apply:

- BGP AD and BGP VPLS implementations only apply to regular VPLS sites and B-Sites, but not to I-Sites. For BGP VPLS, the B-Site cannot be used as a backbone for an I-Site or Epipe.

- For 7210 SAS NEs that support BGP AD, only VPLS service sites are supported (not MVPLS or B-sites).
- Up to two BGP instances can be created per VPLS site.

77.110.2 Steps

1

Prior to configuring a site for BGP AD or BGP VPLS, you must complete the following actions:

a. Create a routing policy statement to define the required community members. See 54.5 “To configure a routing policy statement” (p. 1745) . This defines the VSI Import/Export Routing Targets.

b. Enable BGP on the routing instance of each NE in the VPLS or BGP VPLS. See 28.29 “To enable BGP on a routing instance” (p. 916) for more information.

c. Configure global-level BGP on each NE in the VPLS or BGP VPLS. See 28.31 “To configure global-level BGP” (p. 918) for more information.

The following items are required for BGP AD implementation:

- You must enable the L2 VPN parameter in the Family panel on one or more of the following:
  - the VPN tab of the BGP site form
  - the VPN tab of the BGP Peer Group form, which contains the peers that are involved in the BGP multi-homing
  - the VPN tab of the BGP peer form, which participates in BGP signaling
- Create a peer group under BGP. This peer group is used to collectively define the peers involved in the VPLS.
- Create the required peers under the peer group. These peers are the NEs involved in the VPLS.

d. Create a PW template policy. See Chapter 83, “Service PW template policies” for information about PW template policies.

e. Distribute the PW template policy to each NE that is or will be a component of the VPLS or BGP VPLS.

f. Ensure that the BGP AD Administrative Status parameter is set to Up and that the VPLS ID parameter is configured.

2

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

3

Choose the required VPLS and click Properties. The VPLS Service (Edit) form opens.

4

On the service tree, expand Sites and click on the site on which you want to configure BGP AD or BGP VPLS.

5

Click on the BGP tab.

6

Enable the Enable BGP parameter. The BGP panel is displayed.

7

Click Create. The BGP Configuration form opens.

8

Configure the Route Distinguisher parameter.

9

Click on the VSI Import Policies tab.

10

Select up to five import policies. Alternatively, you can enter the policy names manually.

11

Perform one of the following:

a. Enter the Import Route Target name manually in the provided field. The format be “target:x:y”.

b. Select an import route target. The community members you defined when creating a routing policy in Step 1 can be selected.

12

Click on the VSI Export Policies tab and select up to five export policies. Alternatively, you can enter the policy names manually.

13

Perform one of the following:

a. Enter the Export Route Target name manually in the provided field. The format must be “target:x:y”.

b. Select an export route target. The community members you defined when creating a routing policy in Step 1 can be selected.

14

Click on the PW Template Binding tab and perform one of the following:

a. Select an existing PW Template Binding.

b. Add a new PW Template Binding. Go to Step 15 .

15

Create one or more PW Template Bindings:

1. Click Create. The PW Template Binding (Create) form opens.
2. Enter a Split Horizon Group name.
3. Select the PW Template you created in Step 1 .
4. Select an operational group.
5. Click on the BFD tab and configure the required BFD parameters.
6. Click on the PW Templates Binding Route Target tab and click Create. The PW Template Binding Route Target (Create) form opens.

   Note:

   This Import Route Target is used by the NE to decide which PW Template to use to create SDP bindings. If a far-end neighbor has a matching export target (that is, to the PW Template Import Target being defined here), then this PW Template is selected by the NE to create the pseudowire that is used to link both sites of the VPLS. If nothing is entered, and multiple PW Templates are defined, the first one found by the NE is used (most likely the one with the lowest PW Template Policy ID).

   Enter the required Import Route Target in the field and click OK. The PW Template Binding Route Target (Create) form closes and the entered Import Route Target is displayed in the table on the PW Template Binding Route Target tab.
7. Click OK to accept the selection. The PW Template Binding (Create) form closes and the new PW Template Binding is displayed in the table on the PW Template Binding tab.
8. Select the required entry or entries from the list.

16

Save the changes and close the form.

17

If you are configuring a BGP VPLS, go to Step 18 . Otherwise go to Step 21 .

18

Enable the Enable BGP VPLS parameter.

19

Configure the required BGP parameters.

20

Select an operational group for the BGP site to monitor.

21

To configure BGP AD, enable the Enable BGP AD parameter and configure the required BGP AD parameters.

Note: The Global Service VPLS ID is set to the value defined at the service level.
If VPLS ID is defined at the service level, then the NFM-P ensures that each site has the same VPLS ID. If a site has a different VPLS ID, an alarm is raised and the ID mismatch is indicated in the Status panel of the VPLS site properties form.
The same VPLS ID value is propagated to each site in a VPLS. If you change the VPLS ID of a site without using the NFM-P, the NFM-P displays a warning form.

22

Save and close the forms.

END OF STEPS

77.111 To configure a site for BGP VPLS Multi-homing

77.111.1 Purpose

This procedure provides the steps required to configure a site for BGP VPLS Multi-homing. BGP VPLS Multi-homing provides redundancy support through the configuration of a number of multi-homed sites, rather than through the use of MC-LAG or MC-Ring as access mechanisms. Dual-homing between a CE device and a pair of VPLS PE devices (potentially in different autonomous systems) is an example of such a configuration.

Note: VPLS sites, I-sites, and B-Sites can be configured for BGP VPLS Multi-homing. However, the B-Sites cannot be used as a backbone for an Epipe.

MVPLS services cannot be configured for this application.

An RD or RT configured under the BGP of a VPLS site cannot be removed as long as there is a multi-homing site ID configured whose administration state is up.

You can see a list of all current BGP VPLS Multi-homing sites in a multi-homing VPLS service by viewing the BGP Multi-homing Sites tab on the service configuration form.

77.111.2 Steps

1

Prior to configuring a site for BGP VPLS Multi-homing, you must complete the following actions:

a. Create a routing policy statement to define the required community members. See 54.5 “To configure a routing policy statement” (p. 1745) for more information. This defines the VSI Import/Export Routing Targets.

b. Enable BGP on the routing instance of each NE in the VPLS or BGP VPLS. See 28.29 “To enable BGP on a routing instance” (p. 916) for more information.

c. Configure global-level BGP on each NE in the VPLS or BGP VPLS. See 28.31 “To configure global-level BGP” (p. 918) for more information.

   The following items are required:

   - Enable the L2 VPN parameter on one or more of the following:
     - the VPN tab of the BGP site form
     - the VPN tab of the BGP Peer Group form, which contains the peers that are involved in the BGP multi-homing
     - the VPN tab of the BGP peer form, which participates in BGP signaling
   - Create a peer group under BGP. This peer group is used to collectively define the peers involved in the VPLS.
   - Create the required peers under the peer group. These peers are the NEs involved in the VPLS.**Note:** For optimal processing while a BGP multi-homing site is activated or de-activated, or the system is rebooted, you should also:
   - Enable the L2 VPN parameter in the Rapid Update Address Family panel on the BGP site VPN tab.
   - Enable the Enable Rapid Withdrawal parameter on the BGP site Behavior tab.

d. Create a PW template. See Chapter 83, “Service PW template policies” for information about PW templates.

e. Distribute the PW Template to each NE that is or will be a component of the VPLS or BGP VPLS.

f. Create SDPs for the BGP VPLS Multi-homing site(s), if manually-provisioned service tunnels are required. See 33.9 “To create an IP/MPLS service tunnel” (p. 1190)

2

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

3

Choose the required VPLS or HVPLS and click Properties. The VPLS Service (Edit) form opens.

4

On the service tree, expand Sites and click on the site on which you want to configure BGP VPLS multi-homing.

5

Click on the BGP tab.

6

Enable the Enable BGP parameter.

7

Configure the Route Distinguisher parameter.

8

Click Configuration to configure the Route Targets and the PW Templates. The BGP Configuration form opens.

9

Select up to five import policies. Alternatively, you can enter the policy names manually.

10

Perform one of the following:

a. Enter the Import Route Target name manually. The format must be “target:x:y”.

b. Select an import route target. The community members you defined when creating a routing policy in Step 1 can be selected.

11

Click on the VSI Export Policies tab and select up to five export policies. Alternatively, you can enter the policy names manually.

12

Perform one of the following:

a. Enter the Export Route Target name manually. The format must be “target:x:y”.

b. Select an export route target. The community members you defined when creating a routing policy in Step 1 can be selected.

13

Click on the PW Template Binding tab and perform one of the following:

a. Select an existing PW Template Binding.

b. Create a new PW Template Binding.

1. Click Create. The PW Template Binding (Create) form opens.
2. Enter a Split Horizon Group name.
3. Select the PW Template you created in Step 1 .
4. Click on the PW Templates Binding Route Target tab and click Create. The PW Template Binding Route Target (Create) form is displayed.

   This Import Route Target is used by the NE to decide which PW Template to use to create SDP bindings. If a far-end neighbor has a matching export target (that is, to the PW Template Import Target being defined here), then this PW Template is selected by the NE to create the pseudowire that is used to link both sites of the VPLS. If nothing is entered, and multiple PW Templates are defined, the first one found by the NE is used (most likely the one with the lowest PW Template Policy ID).

Enter the required Import Route Target in the field and click OK. The PW Template Binding Route Target (Create) form closes and the entered Import Route Target is displayed in the table on the PW Template Binding Route Target tab.

5. Click OK to accept the selection.
6. Select the required entry or entries from the list.

14

Save the changes and close the form.

15

Click on the Multi-homing tab and click Create. The BGP Multi-homing Site (Create) form opens.

16

Configure the required parameters in the Service Panel.

You cannot turn up a BGP multi-homing site without specifying a Multi-homing ID. In addition, the Multi-homing ID of the site can only be removed at a later time when the site is shutdown.

17

Select a SAP, Spoke SDP, Split Horizon Group, or Mesh SDP Binding, based on the option you selected for the Enable Multi-homing to parameter.

You cannot turn up a BGP multi-homing site without specifying a SAP. The SAP configured under this site can be part of an endpoint, but the only other object allowed in the endpoint is an ICB spoke-SDP. In addition, an assigned SAP can only be removed at a later time when the BGP multi-homing site is shutdown.

18

Configure the required parameters in the Timer panel.

If you enable either the Use Node Level Boot Timer and/or Use Node Level Site Activation Timer parameters, then the associated Boot Timer (seconds) and/or Activation Timer (seconds) parameters are not configurable. These parameter values are inherited from the network element configuration.

The Boot Timer (seconds) and Activation Timer (seconds) parameters can be configured for an NE on the BGP Multi-homing sub-tab under the Redundancy tab in the Network Element (Edit) form. See 12.5 “To modify NE properties” (p. 343) for more information about how to change device properties.

If you enable the Use Node Level Site-Down Minimum Timer parameter, the Site-Down Minimum Timer (seconds) parameter and Site-Down Minimum Timer Remaining (seconds) parameters are ignored and the values configured on the NE are used.

19

Select a Monitored Group Name.

20

Save the changes and close the form.

21

Check the following indicators:

- Operational State: indicates the operational status of the multi-homing site.
- Designated Forwarder: indicates whether this site has been declared as designated forwarder, depending on the result of the BGP election.

22

Save the changes and close the forms.

END OF STEPS

77.112 To re-evaluate the PW Templates associated with a BGP AD or BGP VPLS

77.112.1 Purpose

Use this procedure to re-evaluate changes made to the Route Targets associated with the PW Template bindings of an existing site with BGP configuration. This procedure can only be performed on an existing VPLS that has been configured with BGP AD or BGP VPLS. The procedure allows you to make configuration changes and propagate them to the service without having to shutdown and then turn up a site.

77.112.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu.

2

Choose the required VPLS and click Properties. The VPLS Service (Edit) form opens.

3

On the service tree, expand Sites and click on the site for which you want to re-evaluate the PW templates.

4

Click on the BGP tab.

5

Click Configuration to open the BGP Configuration form.

6

Make any required changes to the Route Targets or PW Template bindings. See 77.110 “To configure a site for BGP AD or BGP VPLS” (p. 2408) or 77.111 “To configure a site for BGP VPLS Multi-homing” (p. 2412) as required, for detailed instructions on configuring these items.

7

Click on the PW Template Binding tab and click Apply to apply your changes.

8

Perform one of the following:

a. If you need to update the PW Templates under other sites for this service, repeat Step 4 to Step 7 as required, then go to Step 11 .

b. If you do not need to update the PW Templates under other sites for this service go to Step 9 .

9

Click on the Re-evaluate PW Template button to run an evaluation of the PW Template bindings. A pop-up window appears indicating if the re-evaluation was successful. If it was not, the reason for the failure is displayed.

If you make any subsequent modifications, you can re-evaluate the template again.

10

Save the changes and close the forms.

11

Return to the VPLS Service (Edit) form.

12

Click Re-evaluate PW Template. The Add form opens to allow you to select one of the PW Templates you modified.

13

Select the required PW template.

14

Click OK to run an evaluation of the selected PW Template. A pop-up window appears indicating if the re-evaluation was successful. If it was not, the reason for the failure is displayed.

15

Repeat Step 12 to Step 14 for any other sites that you want to re-evaluate a PW Template for.

16

Close the forms.

END OF STEPS

77.113 To assign tunnel administrative groups to a BGP or BGP AD VPLS

77.113.1 Purpose

Perform this procedure to assign tunnel administrative groups to a BGP or BGP AD VPLS. The tunnel administrative groups are applicable only when the VPLS is configured as a PBB tunnel. The VPLS must be configured to include B-sites and Multi-Segment Tunnel Selection must be enabled in the system preferences. See Chapter 88, “Tunnel administrative groups” for more information about tunnel administrative groups.

77.113.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu.

2

Select the required BGP or BGP AD VPLS and click Properties. The VPLS Service (Edit) form opens.

3

Click on the Tunnel Admin Groups tab.

4

Select the tunnel administrative groups in the Unassigned list that you want to assign to the tunnel and click the right arrow to move them into the Assigned list.

5

Close the forms.

END OF STEPS

78 IES management

IES management

78.1 Overview

78.1.1 General information

An IES is a routed connectivity service in which the customer traffic passes through an L3 IP router interface to the Internet.

IES allows customer-facing IP interfaces in the same routing instance to be used for service network core-routing connectivity. IES requires that the IP addressing scheme that is used by the customer be unique among other provider addressing schemes and potentially the entire Internet.

Packets that arrive at the edge device are associated with an IES based on the access interface on which they arrive. An access interface is uniquely identified using:

- port
- service ID
- IP address

78.1.2 IES configuration overview

The NFM-P supports end-to-end IES configuration using tabbed configuration forms with an embedded navigation tree.

The NFM-P supports the configuration in IES of an L3 aggregation mechanism called routed CO. Routed CO uses DHCP relay to manage dynamic subscriber hosts; the network resources for static subscriber hosts are explicitly provisioned. Routed CO supports all residential subscriber management functions of the NFM-P. See Chapter 74, “Residential subscriber management” for more information about residential subscriber management and routed CO.

Routed CO uses a subscriber interface that defines up to 256 subnets. A subscriber interface has child objects called group interfaces. A group interface supports the configuration of multiple SAPs as child objects. A SAP in a group interface supports all residential subscriber management functions. A group interface does not allow the specification of IP subnets or addresses, but inherits the addressing scheme of the parent subscriber interface. The NFM-P service topology map displays IES subscriber interfaces, group interfaces, and the associated SAPs.

You can configure NAT for dynamic subscriber hosts in a routed CO deployment. NAT implementation in an IES requires a NAT configuration on the NE base routing instance and a NAT policy that is associated with a subscriber profile. See Chapter 27, “NE routing and forwarding” for information about configuring and deploying NAT on a base routing instance. See Chapter 66, “NAT policies” for information about configuring a NAT policy. See Chapter 74, “Residential subscriber management” for information about associating a NAT policy with a subscriber profile.

When you use the NFM-P to create or discover a service, the NFM-P assigns a default Service Tier value to the service. The Service Tier parameter value is relevant only in the context of composite

service topology views. See Chapter 85, “Composite service management” for more information about the hierarchical organization of composite services.

Common to all device services, such as IES, are policies that are assigned to the service. Policies are defined at a global level and can then be applied to components of the service, such as interfaces or circuits, when the service is configured or modified. The following policies are common to all device services:

- QoS policies define ingress classification, policing, shaping, and marking on the ingress side of the interface. QoS policies are configured using the SAP Access Ingress Policy form, the SAP Access Egress Policy form, and the ATM QoS Policy form.
- Policer control policies to control access ingress policers and access egress policers under a common hierarchy. Policer control policies are configured using the Policer Control Policy Manager.
- Scheduling policies define hierarchical rate limiting and scheduling to govern the scheduling of queues. Scheduler policies are configured using the Scheduler Policy form.
- Port scheduler policies define hierarchical bandwidth allocation and scheduling at the egress port level. Port scheduler policies are configured using the Port Scheduler Policy form.
- Filter policies control network traffic into or out of an interface or circuit based on DHCP, IP, or MAC matching criteria. Filter policies are configured using the ACL IP Filter form, the ACL MAC Filter form, and the DHCP Filter form.
- Accounting policies measure the traffic on a service to ensure proper billing and enforcement of SLAs. Accounting policies are configured using the Accounting Policy form.
- ANCP policies provide status and control information based on port-up and port-down messages and current line rate changes between the edge device and the access NE. ANCP policies are configured using the Manage Subscriber Policies form.
- Routing policies control the size and content of the routing tables, the routes that are advertised, and the best route to take to reach a destination. Routing policies are configured using the Routing Policy Manager.
- Time of day suites specify time and day restriction policies that are assigned to QoS policies and schedulers, ACL filters, and aggregation schedulers. Time of day suites and time range policies are configured using the Time of Day Suite form and Time Range form, respectively.

See Chapter 49, “Policies overview” for more information about policies.

Although IES is part of the routing domain, the usable IP address space may be limited. IES allows a portion of the service provider address space to be reserved for service IP provisioning and to be administered by a separate, but subordinate, address authority.

Multiple IESs can be created to separate customer-owned IP interfaces. More than one IES can be created for one customer. More than one IP interface can be created in one IES. All IP interfaces created in an IES belong to the same customer.

The IES IP interfaces are restricted to the routing protocols that can be defined on the interface based on the fact that the customer has a different routing domain for this service. The IP interfaces support the following routing protocols:

- RIP
- OSPF

- BGP
- IS-IS
- PIM
- IGMP

Customer routes can be advertised to the network core using static routes, RIP, or BGP. BGP and static routes are the most commonly used routing methods.

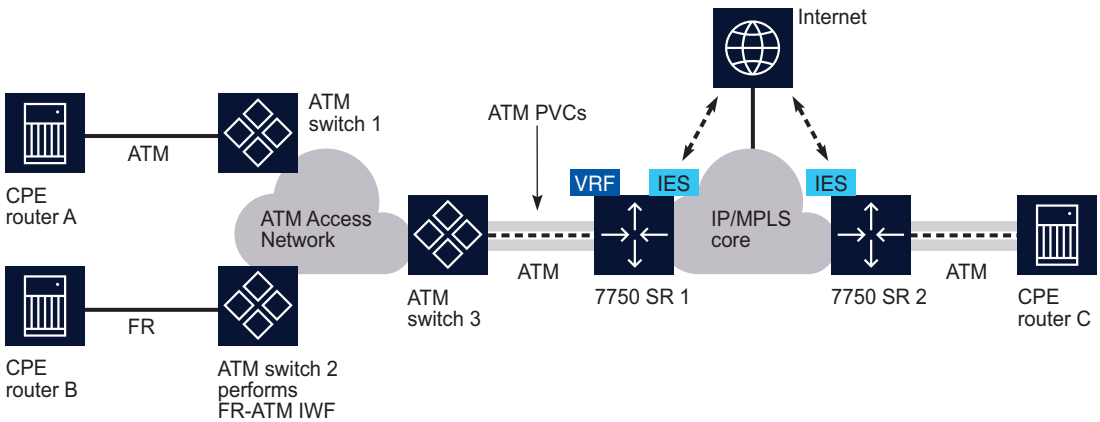
An IES can be connected to a VLL service or to a VPLS by an internal cross-connect through a CCAG adapter. This configuration eliminates the need for the physical port, cable, and other MDA-specific components and results in a less costly and more reliable interconnection. See Chapter 85, "Composite service management" for information about joining services to form composite services.

78.1.3 ATM SAP terminations for IES

CE routers that have access to an ATM network can connect with an IES service using ATM SAP terminations on a 7750 SR. The interconnection between ATM point-to-point and L3 services uses RFC 2684-encapsulated IPv4 traffic over an ATM PVC that terminates on a specially configured SAP. All RFC 2684-encapsulated traffic can be routed over ATM networks, frame relay, and directly through ATM connections.

The figure below shows how CPE router A in an existing ATM network can access L3 IP services, such as an IES, using a statically configured ATM PVC on a 7750 SR (SR #1). CPE router B is connected to a frame relay, which connects to ATM switch 2 through IWF (service interworking). The RFC 2684-encapsulated traffic moves from both CPE routers through the ATM access network to a SAP configured on a 7750 SR #1 to serve a specific IES. At the same time, SDPs on the router are configured to a service to forward traffic over the IP/MPLS core. Destination CPE router C can receive RFC 2684-encapsulated traffic over an IP network over an ATM switch connected directly using 7750 SR #2.

Figure 78-1 ATM SAP network connection to an IES

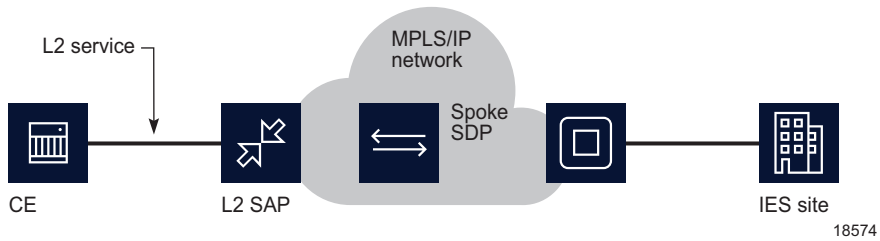


The two connection methods used between an ATM network and the IES router: LLC/SNAP encapsulation and VC multiplexing.

A VLL Epipe service can terminate directly on an IES service using an SDP spoke on the 7750 SR, 7450 ESS, or 7950 XRS. Traffic that terminates on an IES service is identified by the interface ID of the SDP on the L2 access router and the VC ID label in the service packet. All routing protocols supported by IES are also supported for spoke SDP termination.

The figure below shows a spoke SDP terminating directly on an IES. The spoke SDP could be tied to VLL Epipe or VPLS. No configuration is required for the CE-to-PE connection on the SAP.

Figure 78-2 SDP spoke termination on an L2 service



78.1.4 Routed CO dual homing using SRRP

Subscriber Router Redundancy Protocol (SRRP) allows two separate connections to an access NE such as DSLAM to operate in an active/standby configuration similar to the way in which VRRP interfaces operate. SRRP is a collection of functions and messaging protocols that allows a system to create a set of redundant gateway IP addresses that are shared by a local and remote NE.

Each SRRP instance is created within the context of a subscriber group IP interface and is identified by a unique SRRP instance ID, which must be unique within the NE. This SRRP instance controls the redundant routing for all subscriber subnets configured or associated with the group interface. One SRRP instance is supported for each group interface and the SRRP ID must be the same as the SRRP instance ID on the group IP interface on the redundant NE.

A subscriber subnet redundant gateway IP host address is assigned at the subscriber IP interface level and is used for each SRRP instance associated with the subscriber subnet. The redundant IP host address must be configured for a subscriber subnet before it can be associated with an SRRP instance.

When SRRP is active on a group interface, the SRRP instance advertises to a remote NE using in-band messaging on the group-interface SAPs and out-of-band messaging on the group-interface redundant interface. If the remote NE uses the same SRRP instance ID, one NE enters a master state, while the other NE enters a backup state. Since the NEs share a common SRRP gateway MAC address (used for the SRRP gateway IP address and for proxy ARP functions), either NE can act as the default gateway for the attached subscriber hosts. This functionality helps to preserve subscriber QoS enforcement. The master state allows routing to and from the subscriber hosts associated with the group IP interface. The backup state stops ingress forwarding for packets

destined to the SRRP gateway MAC and causes all packets destined to subscriber hosts on the group IP interface to be forwarded to a redundant IP interface associated with the group IP interface.

Normally, when anti-spoofing is enabled on a group-interface SAP, the SAP drops SRRP packets because they do not contain a subscriber MAC or IP address. However, you can use a configuration option to enable anti-spoofing for subscriber hosts on a group-interface SAP that participates in SRRP advertisements.

The underlying mechanism that controls state transitions is based on a dynamic priority level that an SRRP instance maintains. The SRRP instance with the highest priority level assumes the master operating state. An SRRP instance with a higher current priority level always preempts an SRRP instance with a lower priority level. If the priority levels are equal, the SRRP instance with the lowest source SRRP host IP address assumes the master state. The local SRRP instance priority may also be controlled by associating the instance with an existing VRRP policy.

To prevent a flood of AccessInterfaceDown alarms that an SRRP fault or link failure may generate for LAG-based MSAPs, the NFM-P performs alarm suppression. See Chapter 74, “Residential subscriber management” for more information.

The redundant IP interface is a special interface that connects two systems with one or more common SRRP instances. The interface is configured with a /31 address and a spoke SDP binding, creating an Ethernet pseudowire shortcut between the redundant NEs. When the SRRP instance is in backup state, the group interface associated with this instance is not allowed to forward or route traffic downstream towards the subscriber. As a result of this, the packets are shunted across the redundant interface so that the active group interface does the forwarding or routing.

If the redundant IP interface goes down, the system allows the group IP interfaces associated with the down interface to forward locally downstream, when they are in the backup SRRP state. While forwarding downstream in the backup state, the system uses the MAC address associated with the group IP interface, not the SRRP redundant gateway MAC address.

SRRP is supported on the 7450 ESS in mixed mode and 7750 SR.

78.1.5 DoS protection

To protect an IES from a high incoming packet rate that characterizes a DoS attack, you can use the NFM-P to create DoS protection policies for the IES L3 access interfaces. A DoS protection policy limits the number of control-plane packets that an interface receives each second, and optionally logs a violation notification if a policy limit is exceeded. You can use the NE System Security form to view the violations for a specific NE.

You can configure a DoS protection policy to control the following on an IES L3 access interface:

- the control-plane packet arrival rate per subscriber host on the interface
- the overall control-plane packet arrival rate for the interface
- whether an NE sends a notification trap if a policy limit is exceeded

Each IES L3 access interface on an NE that supports DoS protection is automatically assigned a default DoS protection policy. This default policy limits only the overall packet arrival rate for the interface, and cannot be deleted or modified. See the procedure to configure an NE DoS protection policy in the *NSP System Administrator Guide* for information about creating a DoS protection policy.

78.1.6 DDoS protection

To protect an IES from a high incoming packet rate that characterizes a DDoS attack, you can use the NFM-P to configure TMS interfaces to route malicious traffic through the ISA-TMS MDA where the malicious traffic is cleaned before being released to the network.

The TMS interface on an IES consists of one IES and two VPRNs as follows:

- The management VPRN communicates with the TMS server to determine whether incoming packets are malicious. Configuration of this VPRN is optional.
- The Off-Ramp VPRN receives the malicious traffic and routes it through the ISA-TMS MDA where the traffic is scrubbed. Configuration of this VPRN is mandatory.
- The On-Ramp IES returns the cleaned traffic to the network. Configuration of this IES is mandatory.

See 78.25 “To add a TMS interface to an IES” (p. 2467) for information about creating a TMS interface on an IES.

You can configure a DDoS protection policy on an IES group interface SAP or L3 access interface. See the procedure to configure an NE DDoS protection policy in the *NSP System Administrator Guide* for information about configuring a DDoS protection policy.

78.1.7 Local DHCP servers

A local DHCP server can be associated with a network interface or L3 access interface on an IES. See 74.2 “Residential subscriber components” (p. 1992) .

78.1.8 Local user database

A local user database can be associated with a local DHCP server and PPPoE configurations on group interfaces. See 74.2 “Residential subscriber components” (p. 1992) .

78.1.9 PPPoE protocol on IES

An IES can be configured to support PPPoE. PPPoE is used in subscriber networks to encapsulate PPP frames inside Ethernet frames. PPPoE combines the point-to-point protocol used by DSL sessions with Ethernet framing to support multiple subscribers in a LAN. Using the group interface configuration form, you can assign a PPPoE policy and a local user database to authenticate PPPoE subscribers.

78.1.10 L2TP configuration for IES

An IES group interface can be configured to terminate LNS PPP sessions. L2TP is a session-layer protocol that extends the PPP model by allowing L2 and PPP endpoints to reside on different devices that are interconnected by a PSN. L2TP extends the PPP sessions between the CPE and PPP/L2TP termination points on the L2TP network server (LNS), via an intermediate L2TP access concentrator (LAC). The LAC is the initiator of session-generated L2TP tunnels; the LNS is the server that waits for new tunnels. Manually configured and initiated L2TP tunnels can be initiated or stopped from either the LNS or LAC.

After a tunnel is established, the network traffic between the peers is bidirectional. If a tunnel carrying a session fails, another tunnel from the same tunnel group re-establishes the session. Within each L2TP tunnel, one or more L2TP sessions can exist. Each L2TP session transports PPP packets.

At least one ISA-LNS group must be configured for the LNS NE.

On an LNS NE, L2TP destinations configured for L2TP tunnel profiles can include the following:

- loopback L3 access interfaces for a VPRN or IES service
- loopback interfaces configured for a base routing instance

See Chapter 13, “Logical group object configuration” for more information about ISA-LNS groups. See 13.12 “To configure an ISA-LNS group” (p. 426) for information about creating and configuring an ISA-LNS group. See Chapter 28, “Routing protocol configuration” for more information about L2TP. See 78.19 “To configure a group interface on an IES” (p. 2449) for information about configuring an IES group interface to terminate LNS PPP sessions.

78.1.11 PIM on IES group interfaces

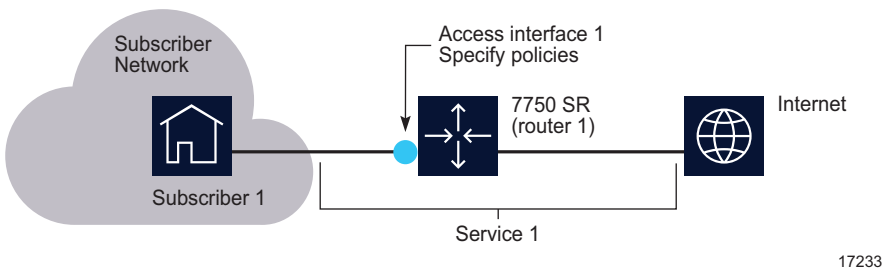
You can configure Protocol-Independent Multicast (PIM) functionality on an IES group interface. PIM on a subscriber group interface allows SAP-level replication over ESM group interfaces by establishing PIM adjacency to a downstream L3 router. On each group interface, a single Ethernet SAP is configured (LAG or physical port). Multiple default hosts can be configured, and a static host is configured for connectivity to a downstream L3 aggregation device. When PIM is enabled on the static host interface, a SAP configured under the group interface is added to the OIF list for SAP-level replication towards a downstream L3 router.

To configure PIM on an IES group interface, see 78.24 “To configure a PIM interface on an IES group interface” (p. 2466) .

78.2 IES configuration

78.2.1 Sample IES configuration

Figure 78-3 Sample IES configuration



78.2.2 Sample configuration steps

The following high-level tasks are necessary to configure this sample IES.

1

Configure policies as required, for example, QoS access ingress and egress interface, Scheduler, ACL IP, Accounting, and ANCP.

2

Create and configure Subscriber 1.

3

Create and configure Service 1.

78.2.3 Workflow to configure an IES

The following workflow lists the high-level steps required to create an IES. As a prerequisite for creating a IES, this workflow assumes the following:

- a group or customer with the required user access privileges has been configured.
- the IP or IP/MPLS core network exists.
- any required service tunnels are created including the static or dynamic LSP required to create the service tunnel; see 33.9 “To create an IP/MPLS service tunnel” (p. 1190) .
- the access ports for the service are created; see Chapter 16, “Port and channel object configuration” for more information.
- any required pre-defined routing, QoS, scheduling, filter, accounting, and time of day suite policies are created; see Chapter 49, “Policies overview” for more information. You do not have to create pre-defined policies if policies are created on a per-service basis.
- any required MP-BGP for PE-to-PE routing is configured; see Chapter 28, “Routing protocol configuration” for more information about protocol configuration.

78.2.4 Stages

1

Create the IES. See 78.3 “To create an IES” (p. 2430) .

1. Choose a customer to associate with the IES.
2. Define the general properties for the IES.
3. Turn up the IES service.

2

As required, configure AA reporting. See 78.4 “To configure an IES for AA reporting” (p. 2430) .

3

As required, create an IES site or GNE IES site. See 78.5 “To configure an IES site” (p. 2431) and 78.6 “To configure a GNE site on an IES service” (p. 2432) .

4

As required, perform one or more of the following on an IES site.

a. Apply routing protocols, such as OSPF, RIP, or IS-IS, to an IES site, if required. See 78.7 “To apply OSPF, RIP, or IS-IS to an IES site” (p. 2433) .

b. Add an IGMP interface to an IES. See 78.8 “To add an IGMP interface to an IES” (p. 2433) .

c. Add a PIM interface to an IES. See 78.9 “To add a PIM interface to an IES” (p. 2435) .

d. Create an L2 SDP spoke termination on an IES service. See 78.10 “To create an L2 SDP spoke termination on an IES service” (p. 2437) .

e. Add a subscriber interface to an IES. See 78.16 “To configure a subscriber interface on an IES” (p. 2444) .

f. Add an AA interface to an IES. See 78.17 “To add an AA interface to an IES or a VPRN site” (p. 2447) .

g. Add an AARP interface to an IES. See 78.18 “To add an AARP interface to an IES or a VPRN site” (p. 2448) .

h. Add a group interface to an IES. See 78.19 “To configure a group interface on an IES” (p. 2449) .

i. Configure WLAN GW for an IES group interface. See 78.23 “To configure a WLAN GW on an IES group interface” (p. 2462) .

j. Add a TMS interface to the IES. See 78.25 “To add a TMS interface to an IES” (p. 2467) .

k. Implement dual homing using SRR. See 78.26 “To implement dual homing using SRRP” (p. 2469) .

l. Create and enable a video interface for the IES site, if required. See 35.3 “To add a video interface to an IES or VPRN site” (p. 1275) .

5

As required, create an L3 access interface on an IES site. See 78.28 “To configure an L3 access interface on an IES site” (p. 2472) .

6

As required, perform one or more of the following on an IES L3 access interface.

a. Configure custom object attributes for AA reporting. See 78.4 “To configure an IES for AA reporting” (p. 2430) .

b. Bind the L3 access interface to a VPLS site. See 78.30 “To bind an IES L3 access interface to a VPLS site or VPLS I-site” (p. 2475) .

c. Apply OSPF, RIP, or IS-IS to an IES L3 interface. See 78.31 “To apply OSPF, RIP, or IS-IS to an IES L3 interface” (p. 2476) .

d. Assign ingress and egress QoS policies. See 78.32 “To assign ingress and egress QoS policies to an IES L3 access interface” (p. 2477) or 78.33 “To assign ingress and egress QoS policies to an IES L3 access interface on a 7210 SAS site” (p. 2479).

e. Configure scheduling. See 78.34 “To configure scheduling on an IES L3 access interface” (p. 2481) .

f. Assign ingress and egress ACL filters. See 78.35 “To assign ingress and egress ACL filters to an IES L3 access interface” (p. 2483) .

g. Assign a virtual port to an IES L3 access interface. See 78.36 “To assign a virtual port to an IES L3 access interface” (p. 2484).

h. Associate a local DHCPv4 or DCHPv6 server. See 78.37 “To associate a local DHCPv4 or DHCPv6 server to an IES L3 access interface” (p. 2484) .

i. Assign an accounting policy. See 78.38 “To assign an accounting policy to an IES L3 access interface” (p. 2485) .

j. Assign an ANCP policy. See 78.41 “To assign an ANCP policy to an IES L3 access interface” (p. 2488) .

k. Assign a time of day suite. See 78.43 “To assign a time of day suite to an IES L3 access interface” (p. 2490) .

l. Configure residential subscriber management. See 78.44 “To configure residential subscriber management for an IES L3 access interface” (p. 2490) .

m. Assign a DoS protection policy or DDoS protection policy. See 78.45 “To assign a DoS protection policy or DDoS protection policy to an IES L3 access interface” (p. 2491) .

n. Assign an IP address. See 78.46 “To assign an IP address to an IES L3 access interface” (p. 2492) .

o. Configure BFD. See 78.47 “To configure BFD for an IES L3 access interface” (p. 2493) .

p. Configure ICMPv4. See 78.48 “To configure ICMPv4 for an IES L3 access interface” (p. 2494) .

q. Configure ICMPv6. See 78.49 “To configure ICMPv6 on an IES L3 access interface” (p. 2495) .

r. Assign an ICMP Ping template. See 78.50 “To assign an ICMP ping template to an IES L3 access interface” (p. 2495).

s. Configure ARP. See 78.51 “To configure ARP for an IES L3 access interface” (p. 2497) .

t. Configure neighbor discovery. See 78.52 “To configure neighbor discovery on an IES L3 access interface” (p. 2497) .

u. Configure DHCPv4. See 78.53 “To configure DHCPv4 for an IES L3 access interface” (p. 2498) .

v. Create a VRRP instance. See 78.54 “To create a VRRP instance on an IES L3 access interface for a virtual router” (p. 2500) .

w. Configure anti-spoofing filters. See 78.55 “To configure anti-spoofing filters for an IES L3 access interface” (p. 2501) .

x. Configure router advertisement. See 78.56 “To configure router advertisement on an IES L3 access interface” (p. 2502) .

y. Specify queue overrides. See 78.57 “To specify QoS policy overrides on an IES L3 access interface” (p. 2503) .

z. Configure DHCPv6. See 78.58 “To configure DHCPv6 on an IES L3 access interface” (p. 2504) .

aa. Configure an MLD interface on the L3 access interface. See 28.124 “To configure an MLD interface on an IES L3 access interface” (p. 1037) .

7

As required, view IES information.

a. View the IES service operational status. See 78.61 “To view the service operational status” (p. 2506) .

b. View the service topology map associated with an IES. See 78.62 “To view the service topology” (p. 2507) .

8

As required, modify an IES.

a. Using the Manage Services form. See 78.63 “To modify an IES” (p. 2508) .

b. Using the topology view. See 78.64 “To modify an IES using the topology view” (p. 2509) .

9

As required, delete an IES. See 78.65 “To delete an IES” (p. 2511) .

IES management procedures

78.3 To create an IES

78.3.1 Steps

1

Choose Create→Service→IES from the NFM-P main menu. The IES Service (Create) form opens.

2

Select a customer to associate with the IES.

3

Configure the required general parameters.

The Service ID and SVC Mgr Service ID parameters are configurable when the Auto-Assign ID parameter is disabled.

4

Save the changes and close the forms.

END OF STEPS

78.4 To configure an IES for AA reporting

78.4.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES in the list and click Properties. The IES Service (Edit) form opens.

3

Click on the Application Assurance tab, then on the NSP Analytics Parameters tab.

4

Configure the required parameters.

5

To configure one or more custom DCP groups, see the custom DCP group configuration procedure in Chapter 87, “Application assurance” .

6

To specify one or more application or application groups for IP detail reporting:

1. Click on the IP Detail Application or IP Detail Application Group tab, as required. The IP Detail Application or IP Detail Application Group (Create) form opens.
2. Select an application or application group from the Select Application or Select Application Group form.
3. Save the changes and close the forms.

7

Save the changes and close the forms.

Note: You can specify up to 10 applications and up to 10 application groups.

END OF STEPS

78.5 To configure an IES site

78.5.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES and click Properties. The IES Service (Edit) form opens.

3

On the service tree, right-click on the Site icon and choose Create IES Site and select a site, or expand the Site icon and choose Properties. The IES Site (Create|Edit) form opens.

4

Configure the general site parameters.

Tunnel Fault Notification is configurable on sites where the device has ports configured in access or hybrid mode with QinQ encapsulation.

If you are configuring a tunnel facility MEP, Tunnel Fault Notification must be set to Accept in order to receive the fault notification from the tunnel facility MEP.

5

Save the changes and close the forms.

END OF STEPS

78.6 To configure a GNE site on an IES service

78.6.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES service and click Properties. The IES Service (Edit) form opens.

3

On the service tree, choose a site by right-clicking on IES Service and choosing Create GNE Site. The GNE Site (Create) form opens.

4

Configure the general site parameters.

5

Click Apply.

6

To configure an interface for the GNE site:

1. Click on the GNE Service Interfaces tab and click Create. The GNE Service Interface (Create) form opens.
2. Configure the required parameters.
3. Click on the Ports tab and select a generic NE interface.
4. Configure the required parameters.
5. Save the changes and close the form.

7

Save the changes and close the forms.

You can use the topology maps to view the service. See Chapter 4, “Topology map management” for more information about service topology maps.

END OF STEPS

78.7 To apply OSPF, RIP, or IS-IS to an IES site

Note: OSPF, RIP, or IS-IS must be enabled at the routing instance level before you can apply OSPF, RIP, or IS-IS to an IES.

78.7.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES in the list and click Properties. The IES Site (Edit) form opens.

3

On the service tree, expand the Sites icon and click on a site. The IES Site (Edit) form opens.

4

Click on the Routing tab, then the Protocols tab.

5

Click Add. The Create Interface form opens.

6

Specify the interface type by configuring the What type of interface would you like to create? parameter.

7

Click OK. The Interface (Create) form opens for the selected protocol. See “Routing protocol configuration workflow and procedures” (p. 909) for information about configuring specific routing protocols.

END OF STEPS

78.8 To add an IGMP interface to an IES

Note: IGMP must be enabled on the NE routing instance before you can create an IGMP interface.

78.8.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand the Sites icon and click on a site. The IES Site (Edit) form opens.

4

Click on the Multicast tab, then the Interfaces tab.

5

Click Add. The Create Interface form opens.

6

Set the What type of interface would you like to create? parameter to IGMP.

7

Click OK. The IGMP Interface (Create) form opens.

8

Select an interface and configure the parameters.

9

Click on the Behavior tab and configure the parameters.

10

To add a multicast CAC policy:

1. Click on the Multicast CAC tab.
2. Select a multicast CAC policy in the Multicast CAC Policy panel.
3. Configure the required parameters.
4. Click on the Levels tab and click Create. The Multicast CAC Level, IGMP Interface (Create) form opens.
5. Configure the parameters and close the form.
6. Click on the LAG Port Down tab and click Create. The LAG Port Down, IGMP Interface (Create) form opens.
7. Configure the parameters and close the form.

11

To configure SSM translation:

1. Click on the SSM Translation tab and click Create. The SSM Translation, IGMP Interface (Create) form opens.

2. Configure the required parameters and close the form.

12

To add a static multicast group or source:

1. Click on the Static Group/Source tab and click Create. The StaticGrpSrc, Interface ID - 6, Routing Instance (Create) form opens.
2. Configure the required parameters, save the changes and close the form.

13

Save the changes and close the form.

14

On the multicast tab, click on the IGMP Group Interfaces tab to identify an IGMP group interface for the IES service.

1. Click Create. The IGMP Group Interface - Routing Instance (Create) form opens.
2. Configure the required parameters.
3. Select an IGMP group interface in the IGMP Group Interface panel and configure the parameters.
4. Click on the Behavior tab. select an import policy and configure the required parameters.
5. Click on the Multicast CAC tab to add a multicast CAC policy.
6. Select a multicast CAC policy in the Multicast CAC Policy panel and configure the required parameters.
7. Close the form.

15

Close the forms.

END OF STEPS

78.9 To add a PIM interface to an IES

Note: Before you can add a PIM interface to an IES, PIM must be applied to All or IES during the PIM configuration at the routing instance level. See 28.98 “To configure PIM on a routing instance” (p. 998) for more information.

78.9.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand the Sites icon and click on a site. The IES Site (Edit) form opens.

4

Click on the Multicast tab.

5

Click Add. The Create Interface form opens.

6

Set the What type of interface would you like to create? parameter to PIM.

7

Click OK. The PIM Interface (Create) form opens.

8

Select an interface and configure the required parameters.

9

Click on the Behavior tab and configure the required parameters.

The Sticky DR Priority parameter is configurable when the Sticky DR parameter is enabled.

10

To add a multicast CAC policy:

1. Click on the Multicast CAC tab.
2. Select a multicast CAC policy in the Multicast CAC Policy panel.
3. Configure the required parameters.
4. Click on the Levels tab and click Create. The Multicast CAC Level, IGMP Interface (Create) form opens.
5. Configure the parameters and close the form.
6. Click on the LAG Port Down tab and click Create. The LAG Port Down, IGMP Interface (Create) form opens.
7. Configure the parameters and close the form.

11

Click on the IPv6 Specifics tab and configure the IPv6 Administrative State parameter.

12

Close the forms.

END OF STEPS

78.10 To create an L2 SDP spoke termination on an IES service

78.10.1 Purpose

Ensure that a service and site are created in the IES. To terminate an L2 service on an IES SDP spoke, you must identify the VC and an interface that belong to the VC. The interface must not have an associated port.

78.10.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand Sites→site, right-click on Spoke Sdp Bindings and choose Create Spoke SDP Binding. The Spoke SDP Binding (Create) form opens.

4

Select a source interface for the spoke SDP binding in the Source Interface panel.

5

Specify a destination NE for the spoke SDP binding:

a. If the destination NE is a managed NE, select an NE in the Tunnel Termination Site panel.

b. If the destination NE is an unmanaged NE, specify the system ID for the Tunnel Termination Site parameter.

6

Configure the required general parameters.

These parameters appear only when a source interface is assigned to the spoke SDP binding.

The range of the Ingress Label parameter depends on the parameter value set for the Static Label Range on the MPLS instance. See 31.6 “To configure an MPLS instance” (p. 1116) .

7

Configure the parameters in the Hash Label panel.

The Enable Hash Label and Enable Signal Capability parameters can only be configured for spoke-SDP bindings that are access interface terminated.

8

Perform one of the following to specify a transport tunnel for the spoke SDP binding.

a. Let the NFM-P configure the transport tunnel automatically by enabling the Auto-Select Transport Tunnel parameter and configuring the Tunnel Auto-Selection Transport Preference parameter.

b. Configure the transport tunnel manually by selecting a tunnel in the Tunnel panel.

c. Configure an MPLS-TP transport tunnel manually by selecting a tunnel in the tunnel panel. See 33.9 “To create an IP/MPLS service tunnel” (p. 1190) for more information about how to create an MPLS-TP service tunnel.

9

To specify an application profile for the spoke SDP binding, by selecting an application profile string.

Note: The Application Profile String: - Spoke SDP Binding - IES service form displays only local profiles on the NE.

10

Choose one of the following AA transit policy types, if required.

Note: You can only associate one AA transit policy type with a service object.
To bind a transit policy to an L3 access interface, a port must already exist on the interface.
You can bind a transit policy to only one L3 access interface or spoke SDP binding per NE.
The transit policy and the application profile must belong to the same application assurance group or partition.

a. Associate an AA transit IP policy with the service object by selecting a transit IP policy in the Transit IP Policy panel.

b. Associate an AA transit prefix policy with the service object by selecting a transit prefix policy in the Transit Prefix Policy panel.

11

To associate an AA redundant protocol with the service object, select an AA redundant protocol in the AA Redundant Protocol panel.

12

Configure the AARP Service Reference Type parameter.

13

To configure custom object attributes for AA reporting:

1. Click on the NSP Analytics Parameters tab, then the Reporting tab.
2. Click Create. The AA Reporting (Create) form opens.
3. Configure the required parameters.
4. Save the changes and close the form.
5. Click on the General tab.

14

To configure QoS:

1. Click on the QoS tab.
2. Select a network policy and an ingress queue group template policy in the Forwarding Plane Redirect panel.
3. Configure the Instance ID parameter in the Forwarding Plane Redirect panel.
4. Select a network policy and egress queue group template policy to assign to the Spoke SDP Binding in the Port Redirect panel.
5. Configure the Instance ID parameter in the Port Redirect panel.

15

Click on the States tab and configure the Administrative State parameter.

16

To assign ingress and egress ACL filters to the spoke SDP binding:

1. Click on the ACL tab.
2. Select an ingress ACL filter in the Ingress Filter panel.
3. Select an egress ACL filter in the Egress Filter panel.

17

To assign an accounting policy to the spoke SDP binding:

1. Click on the Accounting tab.
2. Configure the Collect Accounting Statistics parameter.
3. Select an accounting policy.

18

Note: A default DoS protection policy is automatically assigned to the SAP.

To assign a DoS protection policy or DDoS protection policy to the SAP:

1. Click on the Security tab.
2. Select a DoS protection policy in the NE DoS Protection panel.
3. Select an NE DDoS protection policy.
4. Configure the required parameters.

19

To associate a MEP with an SDP binding:

1. Click on the OAM tab, then the ETH-CFM tab.
2. Click Create in the MEPs panel. The MEP (Create) form opens.
3. Select a maintenance entity group.
4. Configure the required parameters.

   The CCM Padding Packet Size (Bytes) parameter cannot be configured when the CCM interval parameter is set to 10 ms or 100 ms.
5. If the MD for the MEP has a Name Type of none and the associated MEG has a Name Format of icc-based, the Y.1731 Tests and AIS tabs are configurable. Click on the Y.1731 Tests tab. Otherwise, go to Step 20 .
6. Configure the required parameters.

   The Eth Test Pattern parameter is configurable when the Eth Test Enabled parameter is enabled.
7. Click on the AIS tab and configure the required parameters.

20

Save the changes and close the forms.

END OF STEPS

78.11 To configure an MPLS-TP static pseudowire on an IES spoke SDP binding

78.11.1 Purpose

An MPLS-TP service tunnel must be used in the SDP binding, and the Control Word parameter for pseudowire OAM must be set to Preferred. See 78.10 “To create an L2 SDP spoke termination on an IES service” (p. 2437) .

78.11.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select an IES and click Properties. The IES Service (Edit) form opens.

3

Click on the Control Channel tab.

4

Configure the required parameters.

5

Configure the static PW:

1. Click on the Static PW tab.
2. Click Create. The PW Path ID (Create) form opens.
3. Configure the Path AGI parameter.
4. Configure the parameters in the Source Attachment Individual Identifier panel.
5. Configure the parameters in the Target Attachment Individual Identifier panel.
6. Click OK. The PW Path ID (Create) form closes.

6

Save the changes and close the forms.

END OF STEPS

78.12 To configure BFD on an IES spoke SDP binding

78.12.1 Purpose

BFD is used over the VCCV control channel for PW fault detection. BFD carried over a PW associated channel enables the monitoring of the PW between the terminating PEs, regardless of whether the service spans multiple hops. This allows faults that are local to individual PWs to be detected.

78.12.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select an IES and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand Sites→Spoke SDP Bindings and click on the spoke SDP binding on which you want to configure BFD.

4

Click on the BFD tab and configure BFD on the spoke SDP binding:

1. On the General tab, enable the Enable BFD parameter.
2. Choose a BFD template. To create a BFD template, see 28.25 “To configure a BFD template policy” (p. 911) .

   You must assign a BFD template to the spoke SDP binding if you enable BFD.
3. In the Failure Action dropdown, select the action to be performed on BFD failure.
4. Configure the Up-Timer parameter.

   Note:

   The Up-Timer parameter is applicable only when the value of Failure Action is set to down.

5

Save and close the forms.

END OF STEPS

78.13 To clear BFD sessions and statistics on an IES SDP binding

78.13.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select an IES and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand Sites→Spoke SDP Bindings and click on the spoke SDP binding on which you want to view the BFD session information.

4

Clear BFD sessions or statistics on the spoke SDP binding:

1. Click on the BFD tab, then on the BFD Session tab.
2. Click Clear All to clear all BFD sessions.
3. Click Clear All Statistics to clear all BFD statistics.

5

Close the forms.

END OF STEPS

78.14 To view the BFD session status on an IES SDP binding

78.14.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select an IES and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand Sites→Spoke SDP Bindings and click on the spoke SDP binding on which you want to configure BFD.

4

Click on the BFD tab and view the status of the BFD session on the spoke SDP binding:

1. Click on the BFD Session tab.
2. Choose a BFD session and click Properties. The BFD Session (View) form opens.

5

Close the forms.

END OF STEPS

78.15 To view the last cleared BFD statistics and sessions on an IES site

78.15.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Select an IES and click Properties. The IES Service (Edit) form opens.

3

On the service tree, click on the site on which you want to view the last cleared BFD statistics and sessions.

4

Click on the Clear Status tab and view the five last cleared BFD statistics and the five last cleared BFD sessions.

5

Close the forms.

END OF STEPS

78.16 To configure a subscriber interface on an IES

78.16.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand Sites→Subscriber Interfaces, right-click on the Subscriber Interfaces object and choose Create IES Subscriber Interface or right-click on a subscriber interface and choose Properties. The IES Subscriber Interface (Create|Edit) form opens

4

Configure the required general parameters.

The Export Host Routes parameter is only available on retail subscriber interfaces when the Allow Unmatched Subnets parameter is enabled, or when the Interface Class parameter is set to Unnumbered.

The Tunnel Fault Notification parameter is configurable on interfaces where the device has ports configured in access or hybrid mode with QinQ encapsulation.

If you are configuring a tunnel facility MEP, Tunnel Fault Notification must be set to Accept, in order to receive the fault notification from the tunnel facility MEP.

Note: The Name value for a subscriber interface must be unique in the NE.
You must configure the Default Primary DNS Server Address parameter before you can configure the Default Secondary DNS Server Address parameter.
The WAN Mode parameter is configurable only on subscriber interface creation. The parameter is read-only on existing interfaces. The WAN Mode parameter is validated on retail/wholesale subscriber interfaces, in which case the parameter value should be equal across interfaces.

5

Select a forwarding service in the Forwarding Service panel.

6

Select a forwarding subscriber interface in the Forwarding Subscriber Interface panel.

7

In the WLAN GW panel, set the Redundancy/Pool Manager parameter to Enabled if you need to configure WLAN GW redundancy or an IPv6 pool manager. The WLAN GW Redundancy and WLAN GW IPv6 Pool Manager tabs appear.

8

Click on the WLAN GW Redundancy tab to configure WLAN GW redundancy.

9

Click on the WLAN GW IPv6 Pool Manager tab to configure DHCPv6 functionality for the subscriber interface.

In order to support WLAN GW IPv6 address pools, the subscriber interface must have the IPv6 and WLAN Redundancy/Pool Manager parameters enabled on the General configuration tab, and must be configured with a soft GRE group interface.

1. Select a WLAN GW group.
2. Configure the required parameters.

   The DHCPv6 Lease Query parameter must be enabled before the DHCPv6 Lease Query Max Retry parameter can be configured.

   The SLAAC and IA-NA Administrative State parameters must be set to Out Of Service before their related parameters can be configured.

10

To configure IPv6 forwarding on the subscriber interface:

1. Configure the IPv6 Allowed parameter.
2. Configure the required IPv6 parameters.

   You must remove the check mark from the Default check box to access the Default Primary IPv6 DNS Server Address and Default Secondary IPv6 DNS Server Address parameters.
3. Click on the IPv6 Subscriber Prefixes tab.
4. Choose a subscriber prefix and click Properties, or click Create to create a new subscriber prefix. The Subscriber Prefix (Create|Edit) form opens.
5. Configure the required parameters.

11

To configure the interface class parameters:

1. Configure the Class parameter in the Interface Class panel.
2. If you selected a value of Unnumbered for the Class parameter, configure the Unnumbered Type parameter.
3. Configure the Interface Name parameter or the IP Address parameter.

12

Configure the DHCP server synchronization parameters in the DHCP Server Synchronization panel.

13

To create one or more IP addresses for the subscriber interface that are inherited by the SAPs in the group interfaces that are child objects of the subscriber interface:

1. Click on the Addresses tab.
2. Click Create. The IP Address (Create) form opens.
3. Configure the required parameters.
4. Save the changes and close the form.

14

Click on the DHCP tab and configure the required parameters.

15

If the subscriber interface is part of a wholesale/retail configuration, click on the IPoE Linking tab and configure the required parameters.

The IPoE Linking tab is only configurable if a forwarding service is specified for the subscriber interface (see Step 5).

16

Click on the Server tab and configure the required parameters.

The Number of Days, Number of Hours, Number of Minutes, Number of Seconds, and Lease Time Override parameters are configurable only when the Lease Time parameter is set to Specified Time Period.

17

Click on the Client Applications tab and configure the Client Applications parameter. You can enable either or both of the PPPoE or DHCP choices.

18

Click on the PPPoE tab and configure the required parameters.

19

Save the changes and close the forms.

END OF STEPS

78.17 To add an AA interface to an IES or a VPRN site

78.17.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose the required IES or VPRN service and click Properties. The IES or VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites→Sites or Sites→Routing Instance, right-click on an AA Interface and choose Create IES or VPRN AA Interface. The IES/VPRN AA Interface (Create) form opens

4

Configure the required parameters on the General tab.

5

Click on the Port tab and click Select to choose a terminating port.

6

Save the changes. The IES/VPRN AA Interface (Create) form refreshes with addition tabs.

7

As required, click on the QoS tab to select an ingress policy or egress policy for the AA interface.

8

As required, click on the ACL tab to select an ingress filter for the AA interface.

9

Click on the Addresses tab and click Create. The IP Address, Service forms opens.

10

Configure the required parameters.

11

Save the changes and close the forms.

END OF STEPS

78.18 To add an AARP interface to an IES or a VPRN site

78.18.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose the required IES or VPRN service and click Properties. The IES or VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites→Sites or Sites→Routing Instance, right-click on an AARP Interface and choose Create AARP Interface. The AARP Interface (Create) form opens.

4

Configure the required parameters.

5

Save the changes and close the forms.

END OF STEPS

78.19 To configure a group interface on an IES

78.19.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Configure the filter criteria. A list of services appears at the bottom of the Manage Services form.

3

Choose an IES and click Properties. The IES Service (Edit) form opens.

4

On the service navigation tree, expand Sites→site→Subscriber Interfaces, right-click on a subscriber interface and choose Create IES Group Interface, or expand the subscriber interface, right-click on a group interface and choose Properties. The IES Group Interface (Create|Edit) form opens.

5

Configure the required parameters.

The LNS parameter defines the type of group interface. This parameter is set at creation time and cannot be modified. Regular group interfaces cannot configure LNS attributes, and an LNS group interface does not allow PPPoE configuration or SAPs.

The Unicast RPF configuration is intended to enhance security for a MAC-only anti-spoofing configuration on the WLAN GW for soft GRE group interfaces; see 78.23 “To configure a WLAN GW on an IES group interface” (p. 2462) .

6

To configure cflowd sampling:

1. Click Create in the Cflowd Sampling panel. The Cflowd Sampling (Create) form opens.
2. Configure the required parameters and click Apply. The Cflowd sampling object appears in the Cflowd Sampling panel.
3. To associate a service template with the Cflowd sampling object, select the newly created Cflowd sampling object and click Properties. The Cflowd Sampling (Edit) form opens.
4. Click on the Template tab and select an associated template.
5. Save your changes.

7

Select a redundant interface.

8

Select a Diameter Application Policy.

9

Select a diameter authentication policy.

10

Configure the required parameters in the IPv4/IPv6 panel. To configure IPv6:

1. Enable the IPv6 Allowed parameter and configure the required parameters.
2. Click on the IPv6 Advertisement tab and configure the required parameters.

   If the No Default Router check box is enabled, the Router Lifetime parameter is not configurable.
3. Configure the parameters in the Prefix Options panel.

   If the either of the Infinite check boxes is enabled, the associated parameter is set to its maximum value.
4. Configure the parameters in the DNS Options panel.

   If the Infinite check box is enabled, the RDNSS Lifetime parameter is set to -1.

11

To configure IPv6 router solicitation on the group interface:

1. Ensure the IPv6 Allowed parameter is enabled on the General tab.
2. Click on the IPv6 Router Solicit tab.
3. Configure the Administrative State parameter.
4. Select a local user database.
5. Configure the parameters in the Minimum Authentication Time panel.
6. Configure the parameters in the Inactivity Timer panel.

   If you enable the Infinite check box, the Inactivity Timer parameters are disabled.

12

To configure DHCPv6 on the group interface:

1. Ensure the IPv6 Allowed parameter is enabled on the General tab.
2. Click on the DHCPv6 tab and configure the parameters.

   The Interface ID String parameter is configurable only if the Interface ID Option parameter is set to String.

   If the PD Managed Route parameter is enabled, the PD Managed Route Next Hop parameter is configurable.
3. Select a local user database.
4. Select a python policy.

5. Select a DHCPv6 filter.
6. Click on the Proxy Server tab and configure the parameters.

   The ID Type and Value parameters are configurable only if the Server ID Type parameter is set to Enterprise.
7. Click on the Relay tab and configure the parameters.
8. Configure the Server 1 through Server 8 parameters.
9. Select the interface name for each DHCPv6 server in the Zone Index panel.

   If you have entered a Unicast address, then the Interface Name parameter is not required.

13

To configure IPv6 router solicitation on the group interface:

1. Ensure the IPv6 Allowed parameter is enabled on the General tab.
2. Click on the IPv6 Router Solicit tab and configure the Administrative State parameter.
3. Select a local user database.
4. Select a python policy.
5. Configure the parameters in the Minimum Authentication Time panel.
6. Configure the parameters in the Inactivity Timer panel.

14

To configure WPP on the group interface:

1. Ensure the Enable WPP parameter is enabled on the General tab.
2. Click on the WPP tab.
3. Configure the Administrative State parameter.
4. Select a WPP site in the WPP Site panel.
5. Configure the Portal Name parameter.
6. Select an Initial Subscriber Profile.
7. Select an Initial SLA Profile.
8. Select an Initial Application Profile.
9. Configure the Restore Default Profile On Disconnection parameter.
10. Select a Local User DB.
11. Configure the Enable Triggered Hosts parameter.
12. Disable the Default check box and configure the Lease Time (Days, Hours, Minutes, and Seconds) parameters, if required.

15

To configure anti-spoofing:

1. Click on the Anti-Spoofing tab.

2. Configure the ARP Populate parameter.

16

To configure subscriber management:

1. Click on the Subscriber Management tab.
2. Configure the required parameters.

17

To configure ICMP for the group interface:

1. Click on the ICMP tab.
2. Configure the required parameters.

   The parameters on the SHCV panel are configurable when the SHCV Enabled parameter is configured.
3. On the Subscriber Host Connectivity Verification panel, select an IPv4/IPv6 policy, IPv4 policy, and IPv6 policy, as required.

18

To configure ARP for the group interface:

1. Click on the ARP tab.
2. Configure the Timeout (seconds) parameter.
3. Click on the Proxy ARP tab.
4. Configure the required parameters.

19

To configure DHCPv4 relay for the group interface:

1. Click on the DHCP tab.
2. Configure the required general parameters.

   When the Relay Unicast Message parameter is set to Renew or Release Update Source IP, the GI address parameter can be configured as any local configured address in the same routing instance as the GI address for the DHCP relayed messages. If the Relay Unicast Message parameter is set to None, the GI address is restricted to the IP address configured on the subscriber interface.
3. Select a subscriber authentication policy in the Subscriber Authentication panel.
4. Select a local user database in the Local User Database panel.
5. Select a filter policy in the DHCP Filter panel.
6. Click on the Server tab and configure the required parameters.

The Number of Days, Number of Hours, Number of Minutes, Number of Seconds, and Lease Time Override parameters are configurable only when the Lease Time parameter is set to Specified Time Period.

7. Click on the Client Applications tab and configure the Client Applications parameter.

20

To configure IPoE sessions for the group interface:

1. Click on the IPoE Session tab.
2. Configure the required parameters.

   The Stateless Redundancy parameter is configurable only on a regular (not soft GRE) group interface.

   Certain conditions and restrictions apply to an IPoE session on a soft GRE group interface:
   - RADIUS Session Timeout is set to Backwards Compatible by default
   - The IPoE session policy is set to a default policy (with SAP MAC address as key); cannot be changed
   - SAP Session Limit is set to 131071; cannot be changed
   - Administrative Sate is set to Enabled; cannot be changed.
3. Select an IPoE session policy.
4. Select a local user database.

21

To configure neighbor discovery on the group interface:

Neighbor discovery is configurable when the IPv6 Allowed parameter is enabled on the group interface.

1. Click on the Neighbor Discovery tab.
2. Configure the Maximum Number of Neighbors Learned and Duplicate Address Detection parameters.

22

To configure PPP for the group interface:

1. Click on the PPP tab.
2. Configure the Description and Administrative State parameters in the PPPoE panel.
3. Select a PPPoE policy in the PPPoE panel.
4. Select a PPPoE Local User DB in the PPPoE panel.
5. Select a python policy in the PPPoE panel.
6. Configure the required parameters in the PPPoE panel.
7. Configure the Description and Administrative State parameters in the PPP panel.
8. Select a PPP policy in the PPP panel.
9. Select a PPP Local User DB in the PPP panel.

10. Configure the Session Limit parameter in the PPP panel.

23

To configure IPoE linkage for the group interface:

1. Click on the IPoE Linkage tab.
2. Configure the required parameters.

24

To configure the ARP host for the group interface:

1. Click on the ARP Host Configuration tab.
2. Configure the required parameters.

25

To configure local address assignment for the group interface:

1. Click on the Local Address Assignment tab.
2. Configure the required parameters.
3. In the IPv4 Options panel, configure the PPP-v4 parameter and select a local DHCP server.
4. In the IPv6 Options panel, configure the IPoE SLAAC, IPoE WAN, and PPP SLAAC parameters and select a local DHCPv6 server.

26

To configure GTP for the group interface:

1. Ensure the Specific Type parameter is set to GTP on the General tab.
2. Click on the GTP tab.
3. Configure the Administrative State parameter.
4. Select a forward path extension.

27

To configure BRG for the group interface:

1. Click on the BRG Configuration tab.
2. Configure the Administrative State parameter.
3. Select a default BRG profile.
4. Enable the Authenticate BRG Only parameter, if only authenticated BRGs are permitted on the group interface.

28

After you create an LNS group interface, you must configure the L2TP tunnel group profile or tunnel profile to terminate sessions for the LNS group interface that you just created; see 28.89 “To configure L2TP on a routing instance” (p. 989) . You can also configure the termination of sessions on a group interface using a RADIUS server.

To configure LNS for the group interface:

1. Ensure that the LNS parameter is enabled on the General tab.
2. Click on the LNS tab.
3. Configure the Description parameter.
4. Select a subscriber profile in the Default Subscriber Profile panel.
5. Select an SLA profile in the Default SLA Profile panel.
6. Select a subscriber identification policy in the Subscriber Identification Policy panel.
7. Select an application profile in the Default Application Profile panel.
8. Configure the Default Subscriber Identification String parameter.

29

To configure SRRP for the group interface:

1. Click on the SRRP tab.
2. Configure the parameters in the Routing panel.
3. Click Create in the SRRP Instance panel. The SRRP Instance (Create) form opens.
4. Configure the required parameters in the SRRP Instance Information panel.
5. Select an operational group in the Operational Group panel.
6. Configure the Priority Step parameter.
7. Click on the Behavior tab.
8. Configure the required general parameters.
9. Select the SAP you need to use for the in-band messaging between the sites in the Message Path panel.
10. Select a policy pointer in the Policy Pointer 1 and Policy Pointer 2 panels.
11. Save the changes and close the form.

30

Save the changes and close the forms.

END OF STEPS

78.20 To create a bonding group interface on an IES

78.20.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES and click Properties. The IES (Edit) form opens.

3

On the service navigation tree, expand Sites→Routing Instance→Subscriber Interfaces, right-click on a subscriber interface and choose Create IES Group Interface. The IES Group Interface (Create) form opens.

4

Configure the Name and Description parameters.

5

Select a redundant interface.

6

Select a diameter application policy.

7

Select a diameter authentication policy.

8

To configure bonding for the group interface:

1. Click on the Bonding tab.
2. On the General tab, configure the required parameters.
3. Select an FPE with subscriber management extensions enabled.
4. Click on the Connections tab.
5. Click Create. The Bonding Connection Object (Create) form opens.
6. Configure the required parameters, setting the Connection ID parameter to 1.
7. Save you changes and close the form.
8. Create a second bonding connection object, setting the Connection ID parameter to 2.

9

On the IES Group Interface, General tab set the Specific Type parameter to Bonding.

10

Save your changes and close the forms.

END OF STEPS

78.21 To configure a SAP on an IES group interface

78.21.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES and click Properties. The IES Service (Edit) form opens.

3

On the service navigation tree, expand Sites→site→Subscriber Interfaces→*subscriber_interface*, right-click on a group interface and choose Properties. The IES Group Interface (Edit) form opens.

4

Click on the Service Access Points tab.

5

Click Create. The IES Service Access Point (Create) form opens.

6

Configure the required general parameters.

7

Select a host lockout policy in the Host Lockout panel.

8

Configure a port:

1. Click on the Port tab.
2. Select a port for the L3 access interface from the Select Terminating Port form.

   The form lists only ports in access or hybrid mode. To choose a port that is not listed, you must set the Mode parameter for the port to Access or Hybrid. After you do this, the port is listed when you click Search.
3. Configure the required parameters.

   The Auto-Assign ID parameter is configurable if the port uses dot1q encapsulation. When

the parameter is enabled, the NFM-P automatically configures the Outer Encapsulation Value parameter using the lowest unassigned value.

You can set the Auto-Assign ID parameter to be the default parameter for dot1q encapsulation by enabling the Access Interface Encap Value (Dot1q only) parameter on the User Preferences form. Choose Application→ User Preferences from the main menu.

The Inner Encapsulation Value is configurable only when the port is an Ethernet or frame relay port with QinQ encapsulation.

The Outer Encapsulation Value (VPI) and Inner Encapsulation Value (VCI) parameters are configurable only for ATM ports.

9

Items such as policies, schedulers, and filters can be applied later to multiple service components at once. Choose and right-click the components in the service navigation tree, choose Properties, and configure the parameters on the appropriate tab.

To assign ingress and egress QoS policies to the SAP:

1. Click on the QoS tab.
2. Configure the required parameters.

   The Ingress Match QinQ Dot1P and Egress Mark QinQ Top Bits Only parameters are configurable only when the encapsulation type of the port is BCP dot1q, dot1q, or QinQ.
3. Select a policy in the Ingress Policy and Egress policy panels.

   If you select an ingress or egress policy which has a forwarding class mapped to an ingress or egress queue group, you must ensure that the port you selected in Step 8 has the access ingress or egress queue group with the same name created on it.

   See 16.24 “To configure Ethernet ports” (p. 599) for more information about how to configure Ethernet ports. See Chapter 49, “Policies overview” for more information about queue group template policies.
4. Select an HS secondary shaper in the HS Overrides panel, if required.

10

To specify that an aggregation scheduler policy is not applied to the interface:

1. Set the Aggregation parameter to Off.

   The Aggregation parameter is not configurable if the port you selected in Step 8 is an HSMDA port.
2. Configure the required parameters.

   The Aggregate Rate Limit (kbps), Frame-Based Accounting, and Limit Unused Bandwidth parameters are configurable only when there is no scheduler specified in the Egress Scheduler panel.

   The Frame-Based Accounting parameter is not configurable if the port you selected is an HSMDA port.

   You cannot specify an egress scheduler when the Aggregate Rate Limit (kbps) parameter is set to a value greater than zero.

3. Select an ingress scheduler in the Ingress Scheduler panel.
4. Select an ingress policer control policy in the Ingress Policer Control Policy panel.
5. If the port you selected in Step 8 is an HSMDA port, save the changes and close the forms.
6. Select an egress scheduler in the Egress Scheduler panel.
7. Select an egress policer control policy in the Egress Policer Control Policy panel.

11

To specify that an aggregation scheduler policy is applied to the interface:

1. Set the Aggregation parameter to On.

   You cannot specify an access scheduler policy if the port you selected in Step 8 is an HSMDA port.
2. Select an aggregation scheduler in the Aggregation Scheduler panel.

12

To assign ingress and egress ACL filters to the SAP:

1. Click on the ACL tab.
2. Select an ingress ACL filter in the Ingress Filter panel.
3. Select an egress ACL filter in the Egress Filter panel.

13

To assign an accounting policy to the SAP:

1. Click on the Accounting tab.
2. Configure the Collect Accounting Statistics parameter.
3. Select an accounting policy.

14

To assign a virtual port to the SAP:

1. Click on the Virtual Port Name tab.
2. Configure the required parameters.

15

To configure anti-spoofing for the SAP, click on the Anti-Spoofing tab. Configure the Anti-Spoofing parameter and static hosts, as described in 74.24 “To create a static host for residential subscriber management on a SAP” (p. 2045) .

16

Note: A default DoS protection policy is automatically assigned to the SAP.

To assign a DoS protection policy or DDoS protection policy to the SAP:

1. Click on the Security tab.
2. Select a DoS protection policy in the NE DoS Protection panel.
3. Select an NE DDoS protection policy.
4. Configure the required parameters.

17

To define the levels of the ETH-CFM PDUs that are discarded on ingress into the SAP or to configure LMM or ETH-LMM frame loss measurement statistics collection:

1. Click on the OAM tab, then on the ETH-CFM tab.
2. Configure the Tunnel Fault Notification parameter.
3. In the MEPs panel, click Create. The MEP (Create) form opens.
4. Configure the required parameters.
5. Save the changes and close the form.
6. Configure the parameters in the Squelch Ingress Level panel.

   Levels must be assigned contiguously from Level 0. If you select a level greater than 0, then all levels lower than the one you chose will automatically be selected.
7. Configure the required parameters in the LMM Session Stats Collection panel.

18

To configure residential subscriber management on the SAP:

1. Click on the Subscriber Management tab, then on the IGMP Host Tracking tab.
2. Select the import policy used to filter IGMP packets.
3. Configure the required parameters.
4. You can click on the Host Tracking Info tab to view a list of hosts that are being tracked on this service access point.
5. Click on the Profiles tab.
6. Configure the required general parameters.
7. Select a default subscriber profile, subscriber authentication policy, and default application profile in the Policies panel.
8. Configure the Profiled Traffic Only parameter in the Single Subscriber Configuration panel.
9. Select a non-subscriber subscriber profile for the SAP in the Non-Subscriber Traffic Subscriber Profile panel.
10. Select a non-subscriber traffic SLA profile for the SAP in the Non-Subscriber Traffic SLA Profile panel.

11. Select a non-subscriber traffic application profile for the SAP in the Non-Subscriber Traffic Application Profile panel.
12. To view active hosts for the subscriber instance, click on the Subscriber Hosts tab.

19

To configure a default host in cases where the associated DHCP filter policy is configured with the Bypass Host Creation action:

1. Click on the Default Hosts tab.
2. Depending on the required addressing format, click on either the IPv4 or IPv6 tab.
3. Click Create. The (IPv4|IPv6) Default Host (Create) form opens.
4. In the Default Host Configuration panel, Select an (IPv4|IPv6) address to associate with the subscriber interface SAP.

   The address must be one of the addresses on the subscriber interface that the SAP belongs to, and not another default host.
5. Configure the Next Hop (IPv4|IPv6) Address parameter.

   The next hop address can be duplicated on the same SAP, but not on another SAP default host on the same routing instance.
6. Save your changes and close the form.

   Default host configuration settings cannot be changed once the default host is created.

20

To assign an ANCP policy to the SAP:

1. Click on the ANCP Static Map tab.
2. Click Create. The ANCP Static Map (Create) form opens.
3. Configure the ANCP String parameter.
4. Select an ANCP policy in the ANCP Policy panel.
5. Save the changes and close the forms.

21

To configure ATM on the SAP:

1. Click on the ATM tab.
2. Configure the required parameters.
3. Select an ingress ATM policy in the Ingress ATM Policy panel.
4. Select an egress ATM policy in the Egress ATM Policy panel.

22

Save the changes and close the forms.

END OF STEPS

78.22 To configure LAG per-link hashing on an IES group interface SAP

78.22.1 Purpose

You can configure weighted per-link hashing on a SAP on an IES group interface if the terminating port has LAG per-link hashing enabled. The interface must be a LAG member.

78.22.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES and click Properties. The IES (Edit) form opens.

3

On the service tree, expand Site→Subscriber Interfaces→*Interface*→*Group Interface*→*SAP*.

4

Right-click on the SAP you want to modify and choose Properties. The IES Service Access Point (Edit) form opens.

5

Click on the LAG Per Link Hash tab.

6

Configure the Class and Weight parameters.

7

Save your changes and close the forms.

END OF STEPS

78.23 To configure a WLAN GW on an IES group interface

78.23.1 Purpose

Before you can configure a WLAN GW for an IES group interface, you must configure an IES group interface with the Specific Type parameter set to Soft GRE. See 78.19 “To configure a group interface on an IES” (p. 2449) .

78.23.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES and click Properties. The IES (Edit) form opens.

3

On the service tree, expand Sites→*routing_instance*→Subscriber Interfaces→*subscriber_interface*.

4

Right-click on a soft GRE group interface. The IES Group Interface (Edit) form opens.

5

Click on the WLAN GW tab.

6

Configure the required parameters.

7

Select a WLAN GW group.

8

Select a tunnel router instance.

9

Select a default retail IES.

10

Configure egress QoS.

1. In the Egress QoS panel, configure the required parameters.

   Do not configure the Aggregate Rate Limit parameter with a positive value if you specify a scheduler policy in 3 .
2. Select a QoS policy.
3. Select a Scheduler Policy.

11

If the WLAN GW is part of the home LAN extension configuration, configure the Maximum Number of Bridged Domains parameter on the LAN Extension panel.

This parameter can only be configured when the administrative state of the WLAN GW is Out of Service.

12

Select an authentication policy.

13

Configure an authentication hold time.

1. Enable the check box in the Authentication Hold Time panel.
2. Specify an authentication hold time in the Hours, Minutes, and Seconds fields.

14

Click on the SAP Parameters tab to configure SAP parameters.

1. Configure the required parameters.

   If the Default ID Type parameter is set to Use String, configure the Default ID String parameter.

   If the WLAN GW is supporting managed routes, set the Anti-Spoofing parameter to Next Hop IP and MAC Address. To enhance security for MAC-only anti-spoofing, configure unicast RPF on the group interface; see 78.19 “To configure a group interface on an IES” (p. 2449) .
2. Select a subscriber profile.
3. Select an SLA profile.
4. Select an application profile.
5. Select a subscriber identification policy.

15

Click on the Gateway Addresses tab to configure gateway addresses for the WLAN GW.

1. Click Create or choose a gateway address entry and click Properties. The Gateway Address (Create|Edit) form opens.
2. Type a gateway IP address in the field and click OK.

   You can configure up to 10 gateway addresses (six IPv6 and four IPv4).

   One IPv6 address can be configured with the XConnect option.

16

Click on the VLAN Tag Ranges tab to configure VLAN tag ranges.

1. Click Create or choose a VLAN tag range entry and click Properties. The VLAN Tag Range (Create|Edit) form opens.
2. Configure the required parameters.
3. Select a retail service.
4. Select a NAT policy.
5. Select an HTTP redirect policy.
6. Select an authentication policy.
7. Select a RADIUS proxy cache server.
8. If the VLAN tag range is part of an L2 wholesale-retail configuration, select a VPLS site in the L2 Retail panel, and configure the Administrative State and Description parameters as required.
9. Click on the DHCP tab and configure DHCP parameters, as required.
10. Click on the Distributed Subscriber Management tab to configure distributed subscriber management.
11. Configure the required parameters.
12. Select an accounting policy.
13. Select an ingress policer policy.
14. Select an egress policer policy.
15. Select an IP filter policy.
16. Select an application profile string, if required.
17. Click on the SLAAC tab to configure lifetimes for SLAAC-configured IPv6 hosts.

    The Administrative State parameter must be Up to configure parameters on the SLAAC tab.
18. Disable the Default check box and configure the lifetime parameters (in hours, minutes, and seconds) for any of the following categories:
    - Preferred Lifetime (Initial State)
    - Preferred Lifetime (Active State)
    - Valid Lifetime (Initial State)
    - Valid Lifetime (Active State)
19. Click on the DHCP6 tab to configure lifetimes for DHCPv6-configured IPv6 hosts.

    The Administrative State parameter must be Up to configure parameters on the DHCP6 tab.
20. Disable the Default check box and configure the lifetime parameters (in hours, minutes, and seconds) for any of the following categories:
    - Preferred Lifetime (Initial State)
    - Preferred Lifetime (Active State)
    - Valid Lifetime (Initial State)
    - Valid Lifetime (Active State)

21. If the VLAN tag range is part of a home LAN extension configuration, click on the Cross Connect tab.

    Configure the required parameters and select an ISA RADIUS policy.

    You must enable Authentication on DHCP on the VLAN Tag Range - General tab in order to enable the Cross Connect configuration.
22. If the VLAN tag range is part of a home LAN extension configuration, click on the Home LAN Extension tab.

    Configure the required parameters.

    You must enable Authentication on DHCP on the VLAN Tag Range - General tab, and enable the Administrative State of the BRG on the VLAN Tag Range - BRG Configuration tab in order to enable the home LAN extension configuration.
23. Save your changes and close the form.

17

Click on the L2 AP tab to configure an L2 access point.

1. Click Create or select an existing L2 AP entry and click Properties. The WLAN GW L2 Access Point (Create|Edit) form opens.
2. Select a port.
3. Configure the required parameters.

18

Save your changes and close the forms.

END OF STEPS

78.24 To configure a PIM interface on an IES group interface

78.24.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES and click Properties. The IES (Edit) form opens.

3

On the service tree, expand Sites→*routing_instance*→Subscriber Interfaces→*subscriber_interface*.

4

Right-click on a group interface. The IES Group Interface (Edit) form opens.

5

Click on the PIM Interfaces tab.

6

Click on the Add button. The PIM Interface (Create) form opens.

7

Configure the required parameters.

8

Click on the Behavior tab.

1. Configure the required parameters.
2. To change the IPv4 or IPv6 administrative state for the PIM interface, click on the IPv4 and IPv6 tabs and configure the Administrative State parameter, as required.

9

Click on the Multicast CAC tab to configure multicast CAC on the PIM interface.

1. Select a multicast CAC policy.
2. Configure the Unconstrained Bandwidth and Mandatory Bandwidth parameters.
3. Click on the Levels tab.
4. Click Create. The PIM Interface Multicast CAC level form opens.
5. Configure the Level ID and Bandwidth parameters.
6. Save your changes and close the form.
7. Click on the LAG Port Down tab.
8. Click Create. The PIM Interface Multicast CAC LAG Port Down form opens.
9. Configure the Number of Ports Down and Level parameters.

10

Save your changes and close the forms.

END OF STEPS

78.25 To add a TMS interface to an IES

78.25.1 Purpose

The 7750 SR-7 and 7750 SR-12 devices support the configuration of a TMS interface in an IES.

The following conditions must be met before you can configure a TMS interface.

- You must have one IES configured.The TMS interface is configured on this on-ramp IES.

- You must have one VPRN configured for the off-ramp VPRN.
- Optionally, you can have one VPRN configured for the management VPRN.
- Each service must be associated within the same site on the same NE.
- An XP-IOM-3 is required.
- The ISA-TMS daughter card must be installed.

78.25.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES and click Properties. The IES Service Subscriber (Edit) form opens.

3

On the service navigation tree, expand Sites→site, right-click on TMS Interfaces and choose Create TMS Interface. The TMS Interface (Create) form opens.

4

Configure the required parameters.

The Name value for a TMS interface must be unique in the context of the IES Site. That is, there cannot be another L3 access interface, subscriber interface, group interface or TMS interface with the same name on the same IES site.

5

To assign an off-ramp VPRN to the TMS interface, select a VPRN in the Off-Ramp VPRN panel.

6

Set the off-ramp ingress routing context. Configure the Routing Instance parameter.

7

To assign a management VPRN to the TMS interface, select a VPRN in the Management VPRN panel.

8

To associate an ISA-TMS daughter card with the TMS interface, select an ISA-TMS in the TMS Info panel.

Note: An ISA-TMS card can only be assigned to one TMS interface.

9

Configure the ISA-TMS Authentication parameter.

10

To assign an IP address to the TMS interface:

1. Click on the Addresses tab.
2. Click Create. The IP Address (Create) form opens.
3. Configure the required parameters.
4. Save the changes and close the form.

11

Save the changes and close the forms.

END OF STEPS

78.26 To implement dual homing using SRRP

78.26.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES service and click Properties. The IES Service (Edit) form opens.

3

Create the redundant interface used for SRRP out-of-band messaging between the two NEs:

Note: The two sites that participate in the dual homing configuration do not have to be part of the same service.
Ensure that the pair of sites each contains a properly configured subscriber interface and SAPs underneath the group interface that are participating in the redundant configuration.

Ensure that all subscriber interface IP addresses have a gateway address configured on them.

1. On the service navigation tree, click on the site to which you need to add the redundant pair; expand the entries for that site.
2. Right-click on Redundant Interfaces for one site of the redundant pair, and choose Create Redundant Interface. The Redundant Interface (Create) form opens.
3. Configure the required parameters.
4. Click on the Addresses tab.
5. Click Create. The IP Address (Create) form opens.

6. To specify IP addresses for the redundant interface on the current and remote sites, configure the required parameters.

   The remote IP address must be on the same subnet as the redundant interface IP address of the current site. For example, if the IP address of the current site is 7.7.7.7, with a prefix length of 24, then the redundant interface IP address of the remote site must be 7.7.7.d, where d is a value from 0 to 255, excluding 7.

7. Save the changes and close the forms.

4

Create an SDP spoke binding between the current and remote sites. The Source Interface is the Redundant Interface you created in Step 3 and the Tunnel Termination Site is the remote site. The Return Tunnel must come from the remote site.

5

Assign the Redundant Interface to the Group Interface for the current site.

1. On the service navigation tree under the Subscriber Interface, right-click on the Group Interface and choose Properties. The IES Group Interface (Edit) form opens.
2. Select a redundant interface you created in Step 3 in the Redundant Interface panel.
3. Save the changes and close the form.

6

Create an SRRP Instance for the current site.

1. On the service navigation tree under Group Interfaces, right-click on the SRRP Instances item for the current site, and choose Create SRRP Instance. The SRRP Instance (Create) form opens.
2. Configure the required parameters.

   The SRRP ID value must be the same for the current and remote sites.

3. Click on the Behavior tab and configure the general parameters.
4. Select the SAP you need to use for the in-band messaging between the sites in the Port field.
5. Configure the Policy Pointers for the SRRP Instance.
6. Save the changes and close the form.

7

Click Turn Up to activate the SRRP instance.

8

Repeat Step 3 to Step 7 for the remote site.

Note: When you repeat Step 3 to Step 7 for the remote site, that site becomes the current site and the previously configured site is the remote site.

After the two sites have been properly set up, you can examine the SRRP peer associations at any time by right-clicking an SRRP Instance in the service navigation tree. This opens the SRRP Instance - Edit form, which contains a read-only field called SRRP Peer. The Site ID, Service ID, and Operational State of the associated peer appear in this field.
You can also examine the state of an SRRP Instance by checking the Operational Flags field. The flags indicate specific problems that might occur with the SRRP Instance, as follows:

- Duplicate Subscriber IF Address: one of the local subscriber IP addresses is the same as a subscriber IP address on the remote node.
- Redundant Interface Mismatch: the local SRRP instance and remote SRRP instance have mismatched redundant interfaces.
- SAP Mismatch: the local SRRP instance is backing a different set of SAPs than the peer.
- Subnet Mismatch: one of the subnets that SRRP is backing up does not have a match with the peer.
- Dual Master: both SRRP instances are master at the same time.
- SAP Tag Mismatch: the local SRRP instance is backing a set of SAPs with different remote and local tags.
- SRRP ID Mismatch: the peer has a different SRRP instance ID backing the same subnet.

9

Save the changes and close the forms.

END OF STEPS

78.27 To configure IGMP host tracking on an IES site

78.27.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES service and click Properties. The IES Service (Edit) form opens.

3

Expand the Sites icon in the service navigation tree, right-click on a Site icon and choose Properties. The IES Site (Edit) form opens.

4

Click on the Multicast tab, then on the IGMP Host Tracking tab.

5

Configure the required parameters.

6

Save the changes and close the forms.

END OF STEPS

78.28 To configure an L3 access interface on an IES site

78.28.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES and click Properties. The IES Service (Edit) form opens.

3

On the service navigation tree, expand Sites→site, right-click on L3 Access Interfaces and choose Create IES L3 Access Interface, or expand L3 Access Interfaces, right-click on an access interface and choose Properties. The IES L3 Access Interface (Create|Edit) form opens.

4

Configure the required parameters.

The Unnumbered Type parameter is configurable when the Class parameter is set to Unnumbered.

The Unnumbered IP Address parameter is configurable when the Unnumbered Type parameter is set to IP Address.

The Unnumbered Interface Name parameter is configurable when the Unnumbered Type parameter is set to Name.

For a 7705 SAR, if a port or LAG is associated with the L3 access interface, the loopback parameter cannot be enabled. If the loopback is enabled, a port or LAG cannot be associated with the L3 access interface.

The Admin Link Local Address parameters are only configurable when the IPv6 Allowed parameter is enabled.

The Enable Ingress FlowSpec IPv4 and Enable Ingress FlowSpec IPv6 parameters appear only when a port is configured on the interface.

The Tunnel Fault Notification parameter is configurable on interfaces where the device has

ports configured in access or hybrid mode with QinQ encapsulation.

If you are configuring a tunnel facility MEP, Tunnel Fault Notification must be set to Accept, in order to receive the fault notification from the tunnel facility MEP.

5

Configure the Configured IP MTU (Octets) parameter in the Frame Size Constraints panel.

6

Configure the parameters in the Unicast RPF panel.

The URPF Check State IPv6 and URPF Check Mode IPv6 parameters are only configurable when the IPv6 Allowed parameter is enabled.

7

To associate a host lockout policy with the L3 access interface, select a policy in the Host Lockout panel.

8

Configure the PTP HW Assist parameter in the PTP HW panel.

You can only enable the PTP HW Assist parameter after the port is associated to the interface, and an IP address is configured on the interface.

9

To configure cflowd sampling:

1. Click Create in the Cflowd Sampling panel. The Cflowd Sampling (Create) form opens.
2. Configure the required parameters and click Apply. The Cflowd sampling object appears in the Cflowd Sampling panel.
3. Save your changes.

10

Select an operational group in the Operational Group panel.

11

Associate a port with the L3 access interface:

1. Click on the Port tab.

   If the Loopback Enabled parameter in Step 4 is enabled, you cannot associate a port with the L3 access interface.
2. Select a port in the Terminating Port panel.

   Only ports in access or hybrid mode, or PW ports are listed. To choose a port that is not listed, you must set the Mode parameter for the port to Access or Hybrid. The port is listed when you click Search.

The form only lists PW ports that are bound to a service tunnel. See 33.9 “To create an IP/MPLS service tunnel” (p. 1190) for information about creating a service tunnel with a PW port binding.

You can select a bundle in the Terminating Port panel.

3. Configure the required parameters.

   The Auto-Assign ID parameter is configurable if the port uses dot1q encapsulation. When the parameter is enabled, the NFM-P automatically configures the Outer Encapsulation Value parameter using the lowest unassigned value.

   You can set the Auto-Assign ID parameter to be the default parameter for dot1q encapsulation by enabling the Access Interface Encap Value (Dot1q only) parameter on the User Preferences form. Choose Application→ User Preferences from the main menu.

   The Inner Encapsulation Value is configurable only when the port is an Ethernet or frame relay port with QinQ encapsulation.

   The Outer Encapsulation Value (VPI) and Inner Encapsulation Value (VCI) parameters are configurable only for ATM ports.

4. Configure the required parameters in the Properties panel.
5. Select an NE DoS protection policy in the Security panel and configure the required parameters.

12

Save the changes and close the forms.

END OF STEPS

78.29 To configure LAG per-link hashing on an IES L3 access interface

78.29.1 Purpose

You can configure weighted per-link hashing on an IES L3 access interface if the terminating port has LAG per-link hashing enabled. The interface must be a LAG member.

78.29.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES and click Properties. The IES (Edit) form opens.

3

On the service tree, expand Site→L3 Access Interfaces, right-click on the L3 access interface you want to modify and choose Properties. The IES L3 Access Interface (Edit) form opens.

4

Click on the LAG Per Link Hash tab.

5

Configure the Class and Weight parameters.

6

Save your changes and close the forms.

END OF STEPS

78.30 To bind an IES L3 access interface to a VPLS site or VPLS I-site

78.30.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand Site→L3 Access Interfaces, right-click on the L3 access interface you want to modify and choose Properties. The IES L3 Access Interface (Edit) form opens.

4

Click on the Routed VPLS tab.

Note: You can create and manage a routed VPLS connector from the navigation tree on the Composite Service (Edit) form.

5

Enter a VPLS site name or select a VPLS site.

The site that you select must be enabled for RVPLS; see 77.33 “To configure a VPLS site” (p. 2294).

The operational state of the IP interface binding will not be turned up until the Enable IP Interface Binding parameter is set to true.

6

Expand the Ingress or Egress panels as needed.

7

To configure the filter policies:

1. Select an IPv4 filter in the IPv4 Filter panel.
2. Select an IPv6 filter in the IPv6 Filter panel.

8

To enable table-based color-aware ingress classification, select the Enable Table Classification For VPLS parameter, then select a 7210/7250 DSCP classification policy as the Routed Override QoS policy. See 50.23.2 “Table-based ingress classification on the 7210 SAS” (p. 1529).

9

Select an egress QoS policy in the Egress - QoS Policy panel.

10

Save your changes and close the forms.

END OF STEPS

78.31 To apply OSPF, RIP, or IS-IS to an IES L3 interface

Note: OSPF, RIP, or IS-IS must be enabled at the routing instance level before you can apply OSPF, RIP, or IS-IS to an L3 interface.

78.31.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES and click Properties. The IES Service (Edit) form opens.

3

Click on the Interfaces tab, then on the L3 Access Interfaces tab.

4

Choose an L3 interface in the list and click Properties. The L3 Access Interface (Edit) form opens.

5

Click on the Protocols tab and click Create. The Create Interface form opens.

6

Specify the interface type by configuring the What type of interface would you like to create? parameter.

7

Click OK. The Interface (Create) form opens. See “Routing protocol configuration workflow and procedures” (p. 909) for information about configuring specific routing protocols.

END OF STEPS

78.32 To assign ingress and egress QoS policies to an IES L3 access interface

78.32.1 Before you begin

The available panels and parameters vary depending on the NE, chassis type, and release.

78.32.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand Site→L3 Access Interfaces, right-click on the L3 access interface you want to modify and choose Properties. The IES L3 Access Interface (Edit) form opens.

4

Click on the QoS tab and configure the Ingress Match QinQ Dot1P parameter.

The QoS tab is configurable only if a port is assigned to the interface.

The Ingress Match QinQ Dot1P parameter is configurable only when the encapsulation type of the port is BCP dot1q, dot1q, or QinQ.

5

Select an ingress QoS policy in the Ingress Policy panel.

Note: If you select an ingress policy which has a forwarding class mapped to an ingress queue group, you must ensure that the port you selected in 78.28 “To configure an L3 access interface on an IES site” (p. 2472) has the access ingress queue group with the same name created on it.

See 16.24 “To configure Ethernet ports” (p. 599) for more information about how to configure Ethernet ports. See Chapter 49, “Policies overview” for more information about queue group template policies.

6

Select an ingress queue group template policy in the Forwarding Plane Redirect panel.

7

Configure the Instance ID and the Egress Mark QinQ Top Bits Only parameters.

The Egress Mark QinQ Top Bits Only parameter is configurable only when the encapsulation type of the port is BCP dot1q, dot1q, or QinQ.

8

Configure the required parameters in the Aggregate Rate Limit panel.

9

Select a redirect list policy in the Ingress SAP Queue Group Redirect List panel.

See 50.76 “To configure a queue group redirect list policy” (p. 1624) for more information about how to configure a redirect list policy.

10

Select an egress policy in the Egress Policy panel.

Note: If you select an egress policy which has a forwarding class mapped to an egress queue group, you must ensure that the port you selected in 78.28 “To configure an L3 access interface on an IES site” (p. 2472) has the access egress queue group with the same name created on it.
See 16.24 “To configure Ethernet ports” (p. 599) for more information about how to configure Ethernet ports. See Chapter 49, “Policies overview” for more information about queue group template policies.
Queue Group Template policies are not applicable to L3 interfaces associated with HSMDA ports.

11

Select an Egress Queue Group Template Policy in the Port Redirect panel.

Note: Selecting an Egress Queue Group Template Policy here permits the redirection of Ethernet traffic packets to a queue ID specified in the egress port queue group of the SAP. The following properties and restrictions apply:

- If an Egress Queue Group Template Policy is specified here, the policy must have port redirection enabled.
- You cannot use policy-based redirection with the queue group when the SAP has SAP-based redirection enabled.

- Port access egress redirection is only supported on Ethernet/LAG ports. It is not supported on SAPs bound on non-Ethernet, Eth-tunnel, or CCAG ports.
- Supported ports include access, hybrid, and HSMDA.
- Queue groups can be applied to SAPs that incorporate LAGs. The LAGs can include port members from just a single card or from multiple cards.
- If you edit a LAG incorporated by the SAP, you cannot remove the last LAG member if a queue group reference exists to the containing SAP.
- You cannot add a secondary LAG member that has a queue group mismatch with primary LAG member.

12

Select a redirect list policy in the Egress SAP Queue Group Redirect List panel.

See 50.76 “To configure a queue group redirect list policy” (p. 1624) for more information about how to configure a redirect list policy.

13

In the Shaper Group panel, select a Shaper Group for the access ingress port or access egress port.

14

In the IXR Specific panel, select an Egress Remark policy, Egress VLAN QoS policy, and shared policer, and configure all other parameters, as required. See 50.82 “To configure a 7250 SROS Remarking policy” (p. 1634) and 50.54 “To configure a 7250 SROS VLAN QoS policy” (p. 1594).

15

Select an HS secondary shaper in the HS Overrides panel, if required.

16

Save the changes and close the forms.

END OF STEPS

78.33 To assign ingress and egress QoS policies to an IES L3 access interface on a 7210 SAS site

Note: The available parameters and policies vary depending on the device type and chassis variant. The configurations that are supported on the site NE are shown on the form.

78.33.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand Site→L3 Access Interfaces, right-click on the L3 access interface you want to modify and choose Properties. The IES L3 Access Interface (Edit) form opens.

4

Click on the QoS tab and expand the 7210/7250 Specific panel.

5

Select a SAP Access Ingress policy in the Ingress Policy panel.

When you assign an ingress policy, the Color Mode parameter setting for the meters in the policy must coincide with the Enable DEI parameter setting on the physical port. When Enable DEI is selected, the Color Mode for meters must be set to Color Aware. When Enable DEI is not selected, the Color Mode for meters must be set to Color Blind. See 16.24 “To configure Ethernet ports” (p. 599) and 50.29 “To configure a 7210, 7250, and 1830 SAP Access Ingress policy” (p. 1544) .

To support H-metering, you must choose an ingress policy with all meter rate modes set to trTCM (RFC 4115).

For 7250 IXR sites, the selected SAP Access Ingress policy must contain an assigned 7250 Ingress CoS policy.

6

Select an Egress policy.

7

To enable table-based color-aware ingress classification, select the Enable Table Classification parameter. See 50.23.2 “Table-based ingress classification on the 7210 SAS” (p. 1529).

8

Select an Egress Remarking policy in the Egress Remark Policy panel.

9

Configure the required parameters in the Aggregate Rate Limit panel.

You can configure the Ingress Meter parameter only during SAP creation. The parameter must be set to true to support H-metering.

You can configure the Ingress Meter Rate (kbps) and Ingress Meter Burst parameters only after SAP creation

You can configure the Egress Meter Rate and Egress Meter Burst parameters only when resources are allocated to the SAP Egress Aggregate Meter parameter in the system resource profile; see 12.50 “To configure the global system resource profile on a 7210 SAS or 7250 IXR” (p. 380). To allocate resources on the 7210 SAS-R, configure the Egress SAP Aggregate Meter parameter in the system resource profile policy assigned to the device; see 12.51 “To configure a system resource profile policy for the 7210 SAS-R/T/Mxp, 7210 SAS-S/Sx, or 7210 SAS-S/Sx VC” (p. 382).

You must also enable port-based scheduling on 7210 SAS-Mxp and 7210 SAS-R NEs; see 12.53 “To configure port-based scheduling on the 7210 SAS” (p. 384).

The Enable Egress Meter Stats parameter is available when a value is configured for the Egress Meter Rate parameter.

10

Save the changes and close the forms.

END OF STEPS

78.34 To configure scheduling on an IES L3 access interface

78.34.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES service and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand Site→L3 Access Interfaces, right-click on the L3 access interface you want to modify and choose Properties. The IES L3 Access Interface (Edit) form opens.

4

Click on the Schedulers tab and configure the required parameters.

Note: The Schedulers tab is configurable only if a port is assigned to the SAP in 78.28 “To configure an L3 access interface on an IES site” (p. 2472) .

5

To configure scheduling on a 7210 SAS site, enable and configure the required parameters in the Egress Aggregate Rate Limit panel and go to Step 9 .

6

To configure scheduling on a 7705 SAR site:

Note: For the 7705 SAR, scheduler behavior is determined by the scheduler mode, which is 4-Priority by default. You can only configure the Egress and Ingress Aggregate Rate Limit parameters when the Scheduler Mode parameter is set to 16-Priority. You can set the Scheduler Mode to 16-Priority only when the port is on an MDA that supports 16-Priority. See the 7705 SAR documentation for more information.

If you change the Scheduler Mode parameter from 16-Priority to 4-Priority, the NFM-P automatically restores the default settings for the Egress Aggregate Rate Limit and Ingress Aggregate Rate Limit panels when you click Apply or OK.

1. In the Egress Scheduler panel, configure the Scheduler Mode parameter.
2. In the Ingress Scheduler panel, configure the Scheduler Mode parameter.
3. If you set the Scheduler Mode parameter to 16-Priority in the Egress Scheduler panel or Ingress Scheduler panel, configure the parameters in the Egress Aggregate Rate Limit panel and Ingress Aggregate Rate Limit panel.

7

To specify that an aggregation scheduler policy is not applied to the interface:

1. Set the Aggregation parameter to Off.

   The Aggregation parameter is not configurable if the port you selected in 78.28 “To configure an L3 access interface on an IES site” (p. 2472) is an HSMDA port.
2. Configure the required parameters.

   The Aggregate Rate Limit (kbps), Frame-Based Accounting, and Limit Unused Bandwidth parameters are configurable only when there is no scheduler specified in the Egress Scheduler panel.

   The Frame-Based Accounting parameter is not configurable if the port you selected in 78.28 “To configure an L3 access interface on an IES site” (p. 2472) is an HSMDA port.

   You cannot specify an egress scheduler when the Aggregate Rate Limit (kbps) parameter is set to a value greater than zero.
3. Select an ingress scheduler in the Ingress Scheduler panel.
4. Select an ingress policer control policy in the Ingress Policer Control Policy panel.
5. If the port you selected in 78.28 “To configure an L3 access interface on an IES site” (p. 2472) is an HSMDA port, go to Step 8 .
6. Select an egress scheduler in the Egress Scheduler panel.
7. Select an egress policer control policy in the Egress Policer Control Policy panel.
8. Go to Step 9 .

8

Note: You cannot specify an access scheduler policy if the port you selected in 78.28 “To configure an L3 access interface on an IES site” (p. 2472) is an HSMDA port. Go to Step 9 .

To specify that an aggregation scheduler policy is applied to the interface:

1. Set the Aggregation parameter to On.
2. Select an aggregation scheduler in the Aggregation Scheduler panel.

9

Save the changes and close the forms.

END OF STEPS

78.35 To assign ingress and egress ACL filters to an IES L3 access interface

78.35.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand Site→L3 Access Interfaces, right-click on the L3 access interface you want to modify and choose Properties. The IES L3 Access Interface (Edit) form opens.

4

Click on the ACL tab.

Note: When you configure ACL filters on a 7210 SAS NE, you must configure the system resource profile appropriately. See 6.5.13 “System resource profile” (p. 220) in 6.5 “7210 SAS” (p. 216) for more information.

5

Select the required ACL filter policies.

Note: Select the Ingress IP Filter Pair option to configure IP and IPv6 filters simultaneously to filter IP and IPv6 traffic respectively. Once the filters are paired, they can

not be used separately or paired with another filter. This option is supported only for IES services on 7250 IXR NE, 22.2 R1 or later.

6

Save the changes and close the forms.

END OF STEPS

78.36 To assign a virtual port to an IES L3 access interface

78.36.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES service and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand Site→L3 Access Interfaces, right-click on the L3 access interface you want to modify and choose Properties. The IES L3 Access Interface (Edit) form opens.

4

Click on the Virtual Port Name tab.

5

Configure the required parameters.

6

Save the changes and close the forms.

END OF STEPS

78.37 To associate a local DHCPv4 or DHCPv6 server to an IES L3 access interface

78.37.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES service and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand Site→L3 Access Interfaces, right-click on the L3 access interface you want to modify and choose Properties. The IES L3 Access Interface (Edit) form opens.

4

Click on the Local DHCP tab:

a. For local DHCPv4 servers, select a local DHCP server in the Local DHCP Server panel.

Note: You cannot associate a local DHCPv4 server to the L3 group Interface if the Administrative State parameter in the Local Proxy Service panel is up.

b. For local DHCPv6 servers, select a local DHCPv6 server in the Local DHCPv6 Server panel.

Note: To associate local DHCPv6 servers the IPv6 Allowed parameter must be enabled on the General tab.

5

Save the changes and close the forms.

END OF STEPS

78.38 To assign an accounting policy to an IES L3 access interface

78.38.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES service and click Properties. The IES Service (Edit) form opens.

3

Expand the Sites icon in the service navigation tree.

4

On the service tree, expand Site→L3 Access Interfaces, right-click on the L3 access interface you want to modify and choose Properties. The IES L3 Access Interface (Edit) form opens.

5

Click on the Accounting tab.

6

Select an accounting policy.

7

Configure the required parameters.

The Collect Egress Queue Statistics parameter can be configured only during IES L3 access interface creation. See 78.28 “To configure an L3 access interface on an IES site” (p. 2472).

8

Save the changes and close the forms.

END OF STEPS

78.39 To assign an accounting template policy to an IES interface

78.39.1 Purpose

This procedure applies to IES L3 access interfaces, tunnel interfaces, or subscriber group interfaces.

For information about creating an accounting template policy, see 54.12 “To configure an accounting template policy” (p. 1757).

78.39.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES service and click Properties. The IES Service (Edit) form opens.

3

Expand the Sites icon in the service navigation tree.

4

Expand the Routing Instance icon in the service navigation tree on which you need to configure the accounting template policy.

5

Right-click on the L3 access interface, tunnel interface, or subscriber group interface you need to configure and choose Properties.

6

Click on the Policies tab.

7

Select an accounting template policy in the Accounting Template panel.

8

Save and close the form.

END OF STEPS

78.40 To configure application assurance on an L3 access interface

78.40.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES service and click Properties. The IES Service (Edit) form opens.

3

Expand Sites→Routing Instance in the service navigation tree and right-click on the L3 access interface and choose Properties. The IES L3 Access Interface (Edit) form opens.

4

Click on the Application Assurance tab.

5

To bind an application profile to the IES L3 access interface, select an application profile string.

Note: Only local profiles that already exist on the NE can be selected.

6

To choose one of the following AA transit policy types:

Note: You can only associate one AA transit policy type with a service object.
To bind a transit policy to an L3 access interface, a port must already exist on the interface.
You can bind a transit policy to only one L3 access interface or spoke SDP binding per NE.
The transit policy and the application profile must belong to the same application assurance group or partition.

a. Select an AA transit IP policy in the Transit IP Policy panel.

b. Select an AA transit prefix policy in the Transit Prefix Policy panel.

7

To associate an AA redundant protocol with the service object, select an AA redundant protocol in the AA Redundant Protocol panel.

8

Save your changes and close the forms.

END OF STEPS

78.41 To assign an ANCP policy to an IES L3 access interface

78.41.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES service and click Properties. The IES Service (Edit) form opens.

3

Expand the Sites icon in the service navigation tree.

4

On the service tree, expand Site→L3 Access Interfaces, right-click on the L3 access interface you want to modify and choose Properties. The IES L3 Access Interface (Edit) form opens.

5

Click on the ANCP Static Map tab.

6

Click Create. The ANCP Static Map (Create) form opens.

7

Configure the ANCP String parameter.

8

Select an ANCP policy in the ANCP Policy panel.

9

Save the changes and close the forms.

End of steps

78.42 To associate a security zone policy with an IES L3 access interface on a 7705 SAR

78.42.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES service and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand Site→L3 Access Interfaces, right-click on the L3 access interface you want to modify and choose Properties. The IES L3 Access Interface (Edit) form opens.

4

Click on the Zone tab.

5

Select a security zone policy.

You can create a security zone policy by clicking Create.

You can associate a security zone policy with an IES service that is configured with a tunnel port as a SAP.

6

Configure the ByPass Zone Config parameter.

7

Save the changes and close the forms.

End of steps

78.43 To assign a time of day suite to an IES L3 access interface

78.43.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES service and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand Site→L3 Access Interfaces, right-click on the L3 access interface you want to modify and choose Properties. The IES L3 Access Interface (Edit) form opens.

4

Click on the TOD Suite tab.

5

Select a time of day suite.

Note: SapEgrQosPlcyStats and SapIngQosPlcyStats statistics are collected only if a Time Of Day Suite is applied on the SAP.

6

Save the changes and close the forms.

END OF STEPS

78.44 To configure residential subscriber management for an IES L3 access interface

78.44.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES service and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand Site→L3 Access Interfaces, right-click on the L3 access interface you want to modify and choose Properties. The IES L3 Access Interface (Edit) form opens.

4

Click on the Subscriber Management tab.

5

Enable the SHCV Enabled parameter.

6

Configure the required parameters on the Subscriber Host Connectivity Verification panel.

7

Select an SHCV IPv4 policy.

8

Save the changes and close the forms.

END OF STEPS

78.45 To assign a DoS protection policy or DDoS protection policy to an IES L3 access interface

Note: A default DoS protection policy is automatically assigned to the interface.
See the procedure to configure an NE DoS protection policy in the *NSP System Administrator Guide* for more information about configuring and applying NE DoS protection policies.

78.45.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a IES service and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand Site→L3 Access Interfaces, right-click on the L3 access interface you want to modify and choose Properties. The IES L3 Access Interface (Edit) form opens.

4

Click on the Security tab.

Note: If you are assigning a DoS protection policy for 7210 SAS-R6 or 7210 SAS-R12 nodes, click on the Port tab.

5

Select a DoS protection policy in the NE DoS Protection panel.

6

Select an NE DDoS protection policy.

7

Save the changes and close the forms.

END OF STEPS

78.46 To assign an IP address to an IES L3 access interface

78.46.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES service and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand Site→L3 Access Interfaces, right-click on the L3 access interface you want to modify and choose Properties. The IES L3 Access Interface (Edit) form opens.

4

Click on the Addresses tab.

5

Click Create. The IP Address (Create) form opens.

6

Configure the required parameters.

The Broadcast Address Format parameter only appears if the IP Address parameter is set to an IPv4 address.

The parameters in the IPv6 panel only appear if the IP Address parameter is set to an IPv6 address.

7

Select a Track SRRP Instance, if required.

8

Save the changes and close the forms.

END OF STEPS

78.47 To configure BFD for an IES L3 access interface

78.47.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES service and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand Site→L3 Access Interfaces, right-click on the L3 access interface you want to modify and choose Properties. The IES L3 Access Interface (Edit) form opens.

4

Click on the BFD tab.

5

In the IPv4 BFD Configuration panel, set the Admin Status parameter to Up and configure the required parameters.

6

In the IPv6 BFD Configuration panel, set the Admin Status parameter to Up and configure the required parameters.

7

To view local and remote session peers that are managed by the NFM-P, click on the BFD Session tab. A list of BFD current sessions on a router interface or an L3 interface appears.

8

Click on a session. The properties form for the session opens. View the following:

- BFD status
- protocol used

- local address
- remote address
- operational status and statistics

9

Save the changes and close the forms.

END OF STEPS

78.48 To configure ICMPv4 for an IES L3 access interface

78.48.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Configure the filter criteria. A list of services appears.

3

Choose an IES service and click Properties. The IES Service (Edit) form opens.

4

On the service tree, expand Site→L3 Access Interfaces, right-click on the L3 access interface you want to modify and choose Properties. The IES L3 Access Interface (Edit) form opens.

5

Click on the ICMP tab and configure the required parameters.

6

Configure the required parameters in the Redirects panel.

7

Configure the required parameters in the Unreachables panel.

8

Configure the required parameters in the TTL Expired panel.

9

Save the changes and close the forms.

END OF STEPS

78.49 To configure ICMPv6 on an IES L3 access interface

78.49.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a IES service and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand Site→L3 Access Interfaces, right-click on the L3 access interface you want to modify and choose Properties. The IES L3 Access Interface (Edit) form opens.

4

Ensure that the IPv6 Allowed parameter is enabled.

5

Click on the ICMPv6 tab.

6

Configure the required parameters.

7

Save the changes and close the forms.

END OF STEPS

78.50 To assign an ICMP ping template to an IES L3 access interface

78.50.1 Before you begin

ICMP ping templates are used to populate values for ICMP ping tests when the tests are used on L3 interfaces to control the operational state. ICMP ping templates are supported for IPv4 only. See 90.51 “To configure an ICMP Ping template” (p. 3079) for information about configuring ICMP ping templates.

Note: Nokia recommends that you assign an NE DoS protection policy, configured with a protocol of ICMP-Ping-Check, to the affected interfaces; see 78.45 “To assign a DoS protection policy or DDoS protection policy to an IES L3 access interface” (p. 2491).

78.50.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES service and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand Site→L3 Access Interfaces, right-click on the L3 access interface you need to modify, and choose Properties. The IES L3 Access Interface (Edit) form opens.

4

Click on the ICMP Ping Template tab.

5

Click Create, or choose the template in the list and click Properties. The Virtual Interface ICMP Template Config form opens.

6

Click Select to choose a template pointer for the template. The Select Template Pointer form opens.

7

Choose an ICMP Ping template from the list and click OK to close the Select Template Pointer form.

8

On the Virtual Interface ICMP Template Config form, configure the Admin State and Destination Address parameters for the ICMP Ping test.

9

Save the changes and close the forms.

END OF STEPS

78.51 To configure ARP for an IES L3 access interface

78.51.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES service and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand Site→L3 Access Interfaces, right-click on the L3 access interface you want to modify and choose Properties. The IES L3 Access Interface (Edit) form opens.

4

Click on the ARP tab and configure the required parameters.

5

To configure static ARP:

1. Click Create. The Static ARP (Create) form opens.
2. Configure the required parameters.
3. Save the changes and close the form.

6

Click on the Proxy ARP tab and configure the required parameters.

7

Save the changes and close the forms.

END OF STEPS

78.52 To configure neighbor discovery on an IES L3 access interface

78.52.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES service and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand Site→L3 Access Interfaces, right-click on the L3 access interface you want to modify and choose Properties. The IES L3 Access Interface (Edit) form opens.

4

Set the IPv6 Allowed parameter to enabled.

5

Click on the Neighbor Discovery tab and click Create. The Neighbor Discovery (Create) form opens.

6

Configure the required parameters.

7

Save the changes and close the form.

8

Click on the Proxy ND tab and configure the required parameters.

Note: Do not leave an empty policy parameter between two configured policy parameters. For example, do not configure the Policy 1 and Policy 3 parameters and leave the Policy 2 parameter unconfigured, or the NFM-P reorders the policies and moves the policy specified for the Policy 3 parameter to the Policy 2 parameter.

9

Click on the Secure ND tab and configure the required parameters.

10

Save the changes and close the forms.

END OF STEPS

78.53 To configure DHCPv4 for an IES L3 access interface

78.53.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a IES service and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand Site→L3 Access Interfaces, right-click on the L3 access interface you want to modify and choose Properties. The IES L3 Access Interface (Edit) form opens.

4

Click on the DHCP tab and configure the required parameters.

The Lease Populate parameter is configurable when the Enable parameter is enabled.

5

Select a subscriber authentication policy in the Subscriber Authentication Policy panel.

6

Configure the required parameters in the Option 82 panel.

The Remote ID String parameter is configurable when the Remote ID is set to Remote ID String.

When the Relay Unicast Message parameter is set to Renew or Release Update Source IP, the GI address parameter can be configured as any local configured address in the same routing instance as the GI address for the DHCP relayed messages. If the Relay Unicast Message parameter is set to None, the GI address is restricted to the IP address configured on the subscriber interface.

7

Configure the parameters in the Vendor Specific Option panel.

8

Configure the parameters in the GI-Address panel.

9

Select a Python policy, if required.

10

Click on the Server tab and configure the required parameters in the DHCP Servers and Local Proxy Server panels.

The Number of Days, Number of Hours, Number of Minutes, Number of Seconds, and Lease Time Override parameters are configurable only when the Lease Time parameter is set to Specified Time Period.

11

Depending on the type and release of device that you are configuring, the Subscriber Authentication Policy panel is present. Select a Subscriber Authentication policy.

12

Save the changes and close the forms.

END OF STEPS

78.54 To create a VRRP instance on an IES L3 access interface for a virtual router

78.54.1 Prerequisites

You must know the VRID for an existing virtual router and ensure that the interface is a member of the same subnet as the virtual router.

See Chapter 37, “VRRP” for configuration information about VRRP instances.

The following configurations are required for the operation of the IPv6 VRRP instance:

- You can only create an IPv6 VRRP Instance if you enable the IPv6 Allowed parameter on the General tab of the IES L3 Access Interface (Edit) form.
- The Link Local Address on the parent interface must be set to preferred or to disable DAD, depending on your node release, and configured as one of the backup addresses (or same subnet) for the IPv6 VRRP instance. The Admin Link Local Address related parameters on the General tab of the IES L3 Access Interface (Edit) form must be set accordingly.
- The IPv6 address on the parent interface must be set to preferred or disable DAD to be used as a backup address (on same subnet) for the IPv6 VRRP instance. The IPv6 parameters in Step 6 of 78.46 “To assign an IP address to an IES L3 access interface” (p. 2492) must be set accordingly.
- The Send Advertisement and Use Virtual MAC Address parameters must be enabled in Step 6 of 78.56 “To configure router advertisement on an IES L3 access interface” (p. 2502) for the router advertisement on the parent interface.

78.54.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES service and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand Site→L3 Access Interfaces, right-click on the L3 access interface you want to modify and choose Properties. The IES L3 Access Interface (Edit) form opens.

4

Click on the VRRP tab.

5

Click Create. The VRRP Instance (Create) form opens.

6

Configure the Virtual Router ID parameter.

7

Perform Step 3 to Step 15 of 37.4 “To create and configure a VRRP instance” (p. 1283) .

You can use the VR Instances tab to create, modify, and view VR instances.

8

Save the changes and close the forms.

END OF STEPS

78.55 To configure anti-spoofing filters for an IES L3 access interface

78.55.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES service and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand Site→L3 Access Interfaces, right-click on the L3 access interface you want to modify and choose Properties. The IES L3 Access Interface (Edit) form opens.

4

Click on the Anti-Spoofing tab and configure the required parameters.

5

Configure the required general parameters.

The ARP Populate parameter is configurable when all of the IP addresses of the defined static hosts on the interface are in one of the subnets configured for the interface.

6

To configure static subscriber host entries, if subscriber entries are not available through DHCP lease management:

1. Click on the Static Hosts tab.

2. Click Create. The Access Interface Anti-Spoofing Static Host Display (Create) form opens.
3. Configure the required parameters.

   Specify at least one IP address or MAC address for each static host. The values specified for the Anti-Spoofing and ARP Populate parameters determine the type of address entry that is required for the static host. For example, when you set the Anti-Spoofing parameter to Source Ip Addr, you must specify at least the IP address for the static host.

   You can configure a static host on a SAP only when no static ARP entries exist on the IP interface.

   When the ARP Populate parameter is enabled, the IP address of the new static host must be in one of the subnets that is configured for the interface in Procedure 78.46 “To assign an IP address to an IES L3 access interface” (p. 2492) .

7

Save the changes and close the forms.

END OF STEPS

78.56 To configure router advertisement on an IES L3 access interface

78.56.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES service and click Properties. The IES Service (Edit) form opens.

3

On the service tree, expand Site→L3 Access Interfaces, right-click on the L3 access interface you want to modify and choose Properties. The IES L3 Access Interface (Edit) form opens.

4

Click on the Advertisement tab.

5

Click Create to add a router advertisement entry. The Router Advertisement (Create) form opens.

6

Configure the required parameters.

If you are configuring the L3 interface for an IPv6 VRRP instance, then the Send Advertisement and Use Virtual MAC Address parameters must both be enabled.

7

Click on the Prefix tab.

8

Click Create. The Router Advertisement Prefix (Create) form opens.

9

Configure the required parameters.

10

Save the changes and close the forms.

END OF STEPS

78.57 To specify QoS policy overrides on an IES L3 access interface

78.57.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES service and click Properties. The IES Service (Edit) form opens.

3

Expand the Site icon in the service navigation tree on which you need to configure the L3 access interface, right-click on the L3 Access Interface icon and choose Properties. The IES L3 Access Interface (Edit) form opens.

4

Click on the Override Policy Items tab.

Note: The Override Policy Items tab contains a number of tabs. However, the tabs that are displayed depend on the port type that you have chosen for this interface.

- If you configured a non-HSMDA port, the Access Ingress Queues, Access Egress Queues, Ingress Policer, and Egress Policer tabs are active.
- If you configured an HSMDA port, the Access Ingress Queues, Access Egress HSMDA Queues, and Ingress Policer tabs are active.

Configure the policy overrides, as described in 50.97 “To configure QoS policy overrides on an L2 or L3 access interface” (p. 1654) .

To configure meter overrides on a 7210 SAS, see 50.98 “To configure QoS policy overrides on access ingress meters for the 7210 SAS” (p. 1657) . To configure queue overrides on a 7210 SAS, see 50.99 “To configure QoS policy overrides on access ingress queues for a 7210 SAS-X” (p. 1659) .

5

Save the changes and close the forms.

END OF STEPS

78.58 To configure DHCPv6 on an IES L3 access interface

78.58.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES service and click Properties. The IES Service (Edit) form opens.

3

Expand the Site icon in the service navigation tree on which you need to configure the L3 access interface, right-click on the L3 Access Interface icon and choose Properties. The IES L3 Access Interface (Edit) form opens.

4

Ensure that the IPv6 Allowed parameter is enabled.

5

Click on the DHCPv6 tab and configure the required parameters on the DHCPv6 Relay — General tab.

6

Select a python policy, if required.

7

Select a local user database, if required.

8

Click on the Server tab.

9

Configure the Server 1 through Server 8 parameters.

10

Configure the interface name for each DHCPv6 server that you configured in Step 9 by selecting the an interface in the Zone Index panel.

11

Click on the DHCPv6-Prefix tab.

12

Click Create. The DhcpRelayV6PrefixDelegation (Create) form opens.

13

Configure the required parameters.

14

Save the changes and close the forms.

END OF STEPS

78.59 To associate a Multi-Chassis shunting profile to an IES L3 access interface

78.59.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES service and click Properties. The IES Service (Edit) form opens.

3

Expand the Site icon in the service navigation tree on which you need to configure the L3 access interface, right-click on the L3 Access Interface icon and choose Properties. The IES L3 Access Interface (Edit) form opens.

4

Select a profile in the Multi-Chassis Shunting Profile panel; see 27.31 “To configure a Multi-Chassis shunting profile on a base routing instance or VPRN routing instance” (p. 876) .

Note: Only the shunting profile created on a base routing instance can be selected.

5

Save the changes and close the forms.

END OF STEPS

78.60 To start or stop the ignore SAP port state tool on an IES interface

78.60.1 Purpose

Use the ignore SAP port state tool to bypass the checking of the physical port operational state if it is down during operational checks on the NE. The tool is available for 7x50 NEs on L3 and subscriber interfaces of IES and VPRN services. The interface can be IPV4/IPV6 or dual stack. An SAP must be attached.

If this procedure is performed when the IP interface is operationally up the command will be accepted but will enter a pending state. It will not become active unless the port state becomes non-operational.

78.60.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a service and click Properties. The IES Service (Edit) form opens.

3

Perform one of the following:

a. On the service navigation tree, expand Site→L3 Access Interfaces and right-click on an L3 access interface.

b. On the service navigation tree, expand Site→Subscriber Interfaces→Group Interface and right-click on a group interface.

4

Choose Start Ignore SAP Port State or Stop Ignore SAP Port State.

END OF STEPS

78.61 To view the service operational status

78.61.1 Purpose

The Aggregated Operational State and State Cause indicators on the General tab of the service management form display information about service faults.

78.61.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a service and click Properties. The IES Service (Edit) form opens.

3

View the Aggregated Service Site Operational State and State Cause indicators. When the Aggregated Operational State is Down or Partially Down, a check mark beside the appropriate State Cause indicator identifies the type of associated service fault.

4

Click on the appropriate tab to view or edit an object that is identified as faulty by a State Cause indicator.

5

Click on the Faults tab to view the alarms for the object. The Object Alarms tab is displayed.

6

Click on the Aggregated Alarms tab to view the aggregated alarms for the object. The Aggregated Alarms tab is displayed.

7

Close the forms.

END OF STEPS

78.62 To view the service topology

78.62.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES and click Topology View. A Topology View dialog box appears.

3

Click Yes to proceed. The Service Topology - map opens.

See Chapter 4, “Topology map management” for more information about service topology views.

END OF STEPS

78.63 To modify an IES

CAUTION

Service Disruption

Modifying parameters can be service-affecting.

78.63.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES and click Properties. The IES Service (Edit) form opens.

The following tabs list the service elements that can be individually or collectively selected and configured:

- General tab — displays general customer and service information
- Sites tab — lists the sites that are included in the service
- Interfaces tab — lists the interfaces, such as L3 access, that are included in the service, and allows the creation and configuration of subscriber, group, and redundant interfaces
- SDP Bindings tab — displays the spoke SDP bindings that are associated with the service
- Addresses tab — lists the IP addresses that are associated with the service

  You cannot remove an IP address from an interface when the IP address of a static host is defined in the subnet of the interface IP address and the ARP Populate parameter is enabled on the Anti-Spoofing tab.
- Faults tab — displays the faults associated with the service

3

Modify the parameters for the service, as required.

4

Save the changes and close the forms.

END OF STEPS

78.64 To modify an IES using the topology view

78.64.1 Purpose

The topology view for a service provides a graphical representation of the various components and their interconnections. You can also use this view to add, modify, or just navigate to service components. This provides an alternative approach to performing these functions from the navigation tree view.

Working from the topology view can expedite the creation of the components, since many of the fields you would ordinarily have to set in the configuration forms will be automatically populated using this approach. The configuration forms can also be accessed directly at any time from this view by right-clicking a component. This allows quick access to conduct more detailed component configuration.

78.64.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose an IES and click on Topology View. The Service Topology map opens.

The remainder of this procedure contains two sub-procedures describing the components that can be created and modified from the topology view. These include:

- Creating a new site. Go to Step 3 .
- Creating spoke SDP bindings. Go to Step 8 .

Adding a new site

3

Right-click on any blank space in the service topology map. A contextual menu is displayed. Choose the Create IES Site option.

The Select Network Elements form appears.

4

Select one or more sites to add to the service and click OK. The IES Site (Create) form for the new site is displayed. If you selected more than one site, the IES Site (Multiple Instances) (Create) form for the new sites is displayed.

5

Click OK. The IES Site (Create) (or IES Site (Multiple Instances) (Create)) form closes and the new site (or sites) is displayed on the map.

6

If you need to perform detailed configuration of site properties for the new site, right-click the site icon and choose Properties. The Site (Edit) form opens. See 78.5 “To configure an IES site” (p. 2431) for detailed site configuration information.

7

Go to Step 8 if you need to create spoke SDP bindings or go to Step 15 to finish.

Creating spoke SDP bindings

8

Select the sites you need to connect in the service topology map and right-click on any one of them. A contextual menu is displayed.

Note: When you create a spoke binding between two sites, the order in which you select them is important. The first site you select will become the source site and the second site will become the destination site. Therefore, it is not recommended that you do a marquee-select in the topology view, since you will not be sure of this hierarchy. Instead, select the sites individually, and hold down the Shift or Ctrl key after your first selection.

9

Select Connect and choose the Create Spoke SDP Binding option.

The Spoke SDP Binding (Create) form is displayed.

Note: For this function, it is assumed that you clicked on the source site first and then held down the Shift or Ctrl key while right-clicking on the destination site to display the contextual menu.

10

Enable the Auto-Select Transport Tunnel parameter.

11

You can manually configure other parameters here if required, or click OK. One of the following will result:

- If an available transport tunnel exists between the two sites, then the Spoke SDP Binding (Create) form closes and the new binding between the two sites is displayed in the topology view. See 78.10 “To create an L2 SDP spoke termination on an IES service” (p. 2437) for more detailed information on creating and configuring spoke SDP bindings, if required.
- If an available transport tunnel does not exist between the two sites, then an error message is displayed to that affect. See Chapter 33, “Service tunnels” for information on how to create the required tunnel. Once the tunnel is created, you can repeat this sub-procedure.

12

Assuming that the spoke SDP binding was successfully created in Step 11 , select the same two sites again in the topology view, although this time do so in the opposite order that you originally selected them. This will allow you to create a spoke binding for the return tunnel.

13

Right-click on the second site you selected and choose the Create Spoke SDP Binding ... option. The Spoke SDP Binding (Create) form is displayed.

14

You can manually configure other parameters here if required, or click OK. One of the following will result:

- If an available transport tunnel exists between the two sites, then the Spoke SDP Binding (Create) form closes and the new return binding between the two sites is displayed in the topology view.
- If an available transport tunnel does not exist between the two sites, then an error message is displayed to that affect. See Chapter 33, “Service tunnels” for information on how to create the required tunnel. Once the tunnel is created, you can repeat this sub-procedure.

15

Close the Service Topology forms.

END OF STEPS

78.65 To delete an IES

CAUTION

Service Disruption

Deleting a service may result in a service disruption for customers. Consider the implication of deleting the service before proceeding.

78.65.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a service or a range of services from the list.

3

Click Delete. A warning form appears. This form is dynamic based on the priority of the service. Perform one of the following:

a. For services with a low priority, go to Step 4 .

b. For services with a medium priority, configure the “Enter the highest priority of the service being deleted” text field by typing: Medium. Go to Step 4 .

c. For services with a high priority, configure the “Enter the highest priority of the service being deleted” text field by typing: High. Go to Step 4 .

4

For all services regardless of how their priority is configured, acknowledge the check box that prompts you confirm that you understand the implications of deleting the service.

Note: If you select multiple services with different priorities, you must enter the highest priority level of selected services before you can delete the services.

5

Click Yes to confirm the action. The service is deleted and removed from the list.

6

Close the forms.

END OF STEPS

79 VPRN service management

VPRN service management

79.1 Overview

79.1.1 General information

The NFM-P supports the creation of VPRN services using the 7450 ESS in mixed mode, the 7750 SR, the 7705 SAR, and the 7950 XRS as a PE and provider core (P) router. VPRNs, also called IP VPNs or BGP/MPLS VPNs, are defined in RFC 2547bis. This standard describes a method of forwarding data and distributing routing information across an IP/MPLS service provider core network.

The NFM-P does not support the configuration of CE routers or devices.

The NFM-P supports end-to-end VPRN configuration using tabbed configuration forms with an embedded navigation tree.

The NFM-P supports the configuration in a VPRN of an L3 aggregation mechanism called routed CO. Routed CO uses DHCP relay to manage dynamic subscriber hosts; the network resources for static subscriber hosts are explicitly provisioned. Routed CO supports all residential subscriber management functions of the NFM-P. See Chapter 74, “Residential subscriber management” for more information about residential subscriber management and routed CO.

Routed CO uses a subscriber interface that defines up to 256 subnets. A subscriber interface has child objects called group interfaces. A group interface supports the configuration of multiple SAPs as child objects. A SAP in a group interface supports all residential subscriber management functions. A group interface does not allow the specification of IP subnets or addresses, but inherits the addressing scheme of the parent subscriber interface. The NFM-P service topology map displays VPRN subscriber interfaces, group interfaces, and the associated SAPs.

You can configure NAT for dynamic subscriber hosts in a routed CO deployment. NAT implementation in a VPRN service requires a NAT configuration on the VPRN routing instance and a NAT policy that is associated with a subscriber profile. See Chapter 30, “NAT” for information about configuring and deploying NAT, and about configuring a NAT policy. See 64.4 “To configure a subscriber profile” (p. 1840) for information about associating a NAT policy with a subscriber profile. See 30.9 “To configure NAT on a routing instance” (p. 1086) for information about how to configure NAT on a VPRN site.

A VPRN routed CO allows a service provider to resell wholesale carrier services while providing direct DSLAM connectivity. You can create a VPRN service for the retailer and also define subscriber access and configuration information for the retailer network. See 79.37 “To configure a group interface on a VPRN” (p. 2586) for more information on how to define a wholesale and retail VPRN configuration.

The General tab of the NFM-P service management form displays useful information about the operational state of the service and its sites through the Aggregated Operational State and State Cause indicators.

When you use the NFM-P to create or discover a service, the NFM-P assigns a default Service Tier value to the service. The Service Tier parameter value is relevant only in the context of composite service topology views. See Chapter 85, “Composite service management” for more information about the hierarchical organization of composite services.

Route advertisement

VPRN services use BGP to exchange the VPRN routes among the PE routers that participate in the VPRN. This is done in a way that ensures that routes from different VPRNs remain distinct and separate, even if two VPRNs have an overlapping address space. PE routers distribute routes to CE routers in the VPRN. Since the CE routers do not peer with each other, there is no overlay visible to the routing algorithm of the VPRN. The PE routers use BGP, RIP, OSPFv2, or OSPFv3 as the IGP to distribute internal routes to the CE routers.

Each route in a VPRN service is assigned an MPLS label. When BGP distributes a VPRN route, it also distributes an MPLS label for that route. Before a customer data packet travels across the backbone network, it is encapsulated with the MPLS label that corresponds, in the customer VPRN, to the route that best matches the destination address of the packet.

The MPLS packet is further encapsulated with either another MPLS label or with an IP or GRE tunnel header, so that it gets tunneled across the backbone to the proper PE router. Each route exchanged by the MP-BGP protocol includes an RD that identifies the VPRN association. Thus the backbone core routers do not need to know the VPRN routes.

In addition to exchanging routes using BGP, other types of routes can be leaked from the GRT to a VPRN instance so that they can be used for traffic forwarding or to redistribute those routes to other routers within the routing instance using either BGP or the VPRN IGP instance. Leaking of routes is administered using routing policies. A set of leak export routing policies is added to the NE routing interface. These policies determine the pool of GRT routes that can be imported by a VPRN instance. In the VPRN routing instance, the set of import policies determines which GRT routes from the pool will be added to the route table of the VPRN.

The following types of routes can be leaked from the GRT to a VPRN:

- Direct or local routes
- Static routes
- OSPF routes
- IS-IS routes
- RIP routes

79.1.2 VPRN routing instances

VPRN routing instances are a representation of the objects assigned to a VPRN service such as the assigned interfaces, protocols, confederations, and spoke SDP bindings managed by the NFM-P. The supported objects are displayed in the service navigation tree as child objects to the VPRN routing instance.

You do not create VPRN routing instances; they are created automatically by the NFM-P when you create a VPRN service. You cannot view VPRN routing instances in the navigation tree routing view. You can view them using the Manage→Service→Services main menu, selecting a pre-

configured VPRN service, then choose Properties. The VPRN routing instances are displayed under the Site icon in the service navigation tree.

79.1.3 VPRN service policies

Common to all device services, such as VPRN, are policies that are assigned to the service. Policies are defined at a global level and can then be applied to components of the service, such as interfaces or circuits, when the service is configured or modified. The following policies are common to all device services:

- QoS policies define ingress classification, policing, shaping, and marking on the ingress side of the interface. QoS policies are configured using the SAP Access Ingress Policy form, the SAP Access Egress Policy form, and the ATM QoS Policy form.
- Policer control policies to control access ingress policers and access egress policers under a common hierarchy. Policer control policies are configured using the Policer Control Policy Manager.
- Scheduling policies define hierarchical rate limiting and scheduling to govern the scheduling of queues. Scheduler policies are configured using the Scheduler Policy and HSMDA Scheduler Policy forms.
- Port scheduler policies define hierarchical bandwidth allocation and scheduling at the egress port level. Port scheduler policies are configured using the Port Scheduler Policy form.
- Filter policies control network traffic into or out of an interface or circuit based on DHCP, IP, or MAC matching criteria. Filter policies are configured using the ACL IP Filter form, the ACL MAC Filter form, and the DHCP Filter form.
- Accounting policies measure the traffic on a service to ensure proper billing and enforcement of SLAs. Accounting policies are configured using the Accounting Policy form.
- ANCP policies provide status and control information based on port-up and port-down messages and current line rate changes between the edge device and the access node. ANCP policies are configured using the Manage Subscriber Policies form.
- Routing policies control the size and content of the routing tables, the routes that are advertised, and the best route to take to reach a destination. Routing policies are configured using the Routing Policy Manager.

See Chapter 49, “Policies overview” for more information about policies.

79.1.4 VPRN service validation

The NFM-P provides OAM tools for service validation and for troubleshooting service and network transport issues. You can run an OAM Validation test suite for the service by clicking Validate, or by clicking More Actions and choosing Validate. Alternatively, you can also perform a One Time Validation. If a check mark appears beside the OAM Validation Failed state cause indicator, the test has failed. The Tested Entity Result tab on the Tests tab displays detailed information about the OAM test result. See Chapter 90, “OAM diagnostic tests” for general information about alarm

management using OAM tools. See Chapter 89, “Service Test Manager” for more information about how to configure OAM validation test suites.

The Aggregated Operational State indicator has four possible values: Up, Down, Partially Down, and Unknown. The value is derived from the operational states of the sites that are part of the service, as follows:

- Up—all sites are operationally up
- Partially Down—at least one site is operationally down
- Down—all sites are operationally down
- Unknown—the service has no provisioned sites

When the Aggregated Service Site Operational State is Partially Down or Down, a check mark appears beside the appropriate State Cause indicator to identify the type of fault to the NFM-P operator. You can view alarms on the Faults page.

When the Aggregated Operational State is Partially Down or Down, a check mark appears beside the appropriate State Cause indicator to identify the type of fault to the NFM-P operator.

79.1.5 VPRN service routers

A VPRN service consists of CE routers or devices connected to PE routers. PE routers connected to P routers transport data across the IP/MPLS provider core network in service tunnels.

Packets that arrive at an edge 7450 ESS, 7705 SAR, 7750 SR, or 7950 XRS are associated with a VPRN service based on the access interface on which they arrive. An access interface is uniquely identified by the following parameters.

- physical Ethernet port or POS port and channel
- encapsulation type
- encapsulation identifier (if required)

The following table describes the general functions performed by PE, P, and CE routers in a VPRN. See Figure 79-4, “Sample VPRN Configuration” (p. 2525) in this chapter for a sample VPRN. See the appropriate hardware services guide for more detailed information about VPRN functionality on the supported managed devices.

Table 79-1 VPRN router functionality

Router type	Functionality
PE	• Are directly connected to PE, CE, and P routers • Learn VPRN routes from CE devices using e-BGP, RIP, OSPFv2 or OSPFv3, or static routes • Maintain a separate routing table, called a VRF, for each service • Exchange multicast VPRN route information with PE routers in other autonomous systems using MP-BGP • Distribute MPLS inner labels using MP-BGP. Before data traverses the IP/MPLS backbone, it is encapsulated with the MPLS label that corresponds, within the VPRN, to the route that best matches the packet's destination address. • Distribute MPLS outer labels using RSVP-TE or LDP. Before the MPLS packet traverses the IP/MPLS backbone, it is further encapsulated with either another MPLS label or with a GRE or MPLS LSP service tunnel header, so that it is tunneled across the backbone to the appropriate PE router. • Use RDs to identify the VPRN associations • Use RTs to determine when a received route is destined for a VPRN • Terminate RFC 2684-encapsulated IPv4 traffic from ATM access network on SAPs
P	• Are directly connected to PE and P routers • Act as transit LSRs • Maintain routes to PE routers and are unaware of specific VPRN routing information
CE	• Are directly connected to PE routers • Provide customer access to the VPRN

79.1.6 Inter-AS connections

You can connect VPRN service sites (or VRFs) on multiple ASs using EBGP. ASs set up mutual connections by exchanging routing information, such as routes and labels. Labeled VPN-IPv4 routes are distributed within an AS on a PE router using IGBP and between ASs using EGBP on an ASBR. The ASBR redistributes VPN-IPv4 routes to an ASBR in another AS, which in turn distributes the routes to PE routers in its own AS or to an ASBR.

When a VPRN inter-AS connection is between two service providers, the ASs must be on private peering points. For an LSP to operate between ASBRs on the AS borders, EBGP peering must be set up between the ASBRs and MPLS label exchange must be supported. Furthermore, an LSP must run from a packet's ingress PE router to its egress PE router.

You can enable inter-AS connections from the BGP settings in 79.22 "To configure ISIS, L2TP, MLD, OSPFv2, OSPFv3, PIM, RIP, or WPP on a VPRN routing instance" (p. 2555) .

79.1.7 MP-BGP Multicast IPv4

The MP-BGP multicast extension allows for a network topology that supports both multicast and unicast routing. Routes from the unicast routing table can be imported into the multicast routing table, and routes from the multicast routing table can be imported into the unicast routing table. An ASBR can be configured to advertise VPRN routes to peers in other ASs, redistributing unicast routes learned by BGP into MP-BGP routes, and MP-BGP routes into unicast routes. This configuration enables the support of the two sets of routing information.

The MP-BGP multicast extension specifies that BGP can exchange routing information for the

multicast IPv4 address family within and between BGP ASs. All configurations entered in a multicast IPv4 address family for a BGP instance affect multicast services and are applied to the multicast routing table. See Chapter 28, “Routing protocol configuration” for more information about the configuration of BGP and the MP-BGP multicast extension.

79.1.8 IPv6 support

To configure IPv6 in a VPRN, you must first enable VPN IPv6 for BGP on the base routing instance of each device that acts as a site in the VPRN.

A customer can use an SNMP utility to manage the IPv6 objects in a VPRN service. SNMP mediation of VPRN objects requires the configuration of a community string on each site in the VPRN, regardless of the IP or SNMP version. SNMPv3 mediation of VPRN IPv6 objects, however, requires the additional configuration of an SNMP context for the VPRN using a CLI. See Chapter 9, “Device discovery” for information about configuring an SNMPv3 context for a VPRN.

79.1.9 PIM for VPRN

The PIM protocol can be applied to a VPRN service to create a private multicast distribution network. PIM uses an MDT group address to identify multicast traffic for the VPRN instance to prevent flooding of multicast packets to PE devices in the VPRN. VRFs with the same MDT address are members of that group and receive multicast traffic from each other. The MDT address cannot be in the SSM range.

By default, the PIM protocol only uses the information in the unicast routing table to determine the RPF interface. PIM can be configured to use the separate multicast and unicast routing tables built by MP-BGP to perform RPF lookups for multicast-capable sources to build and maintain distribution trees for multicast traffic forwarding. See Chapter 28, “Routing protocol configuration” for more information about configuring PIM to use multicast or unicast routing tables in RPF lookups.

Data-MDT

A data-MDT is a tunnel for high-bandwidth source traffic through the P-network to interested PE routers. Data-MDTs do not broadcast customer multicast traffic to all PE routers in a multicast domain.

Note: Data-MDTs are only supported for VPRN services.

Multicast data transmission from a CE router is typically delivered to all CE routers in the same multicast group. Some CE routers do not require the delivery of a specific multicast stream because there no downstream receivers for the multicast group. You can prune a PE router from the MDT if the router does not deliver multicast traffic to the attached CE routers. This task is beneficial for high-traffic multicast applications.

A data-MDT allows you to configure a traffic threshold in Kb/s. The NFM-P signals the data-MDTs when the bandwidth for the SSM group exceeds the configured threshold. The PE router sends an MDT join TLV, at 60 s intervals, over the default MDT to all PE routers. The routers respond with the following actions:

- PE routers that require the SSM group specified in the MDT join TLV; join the data-MDT used by the PE router to transmit the SSM group

- PE routers that do not require the SSM group specified in the MDT join TLV; do not join the data-MDT, pruning the PEs from the MDT

The transmitting PE router switches the multicast stream to the data-MDT after allowing the PE routers to join the data MDT. You can configure the data-MDT delay interval using the NFM-P.

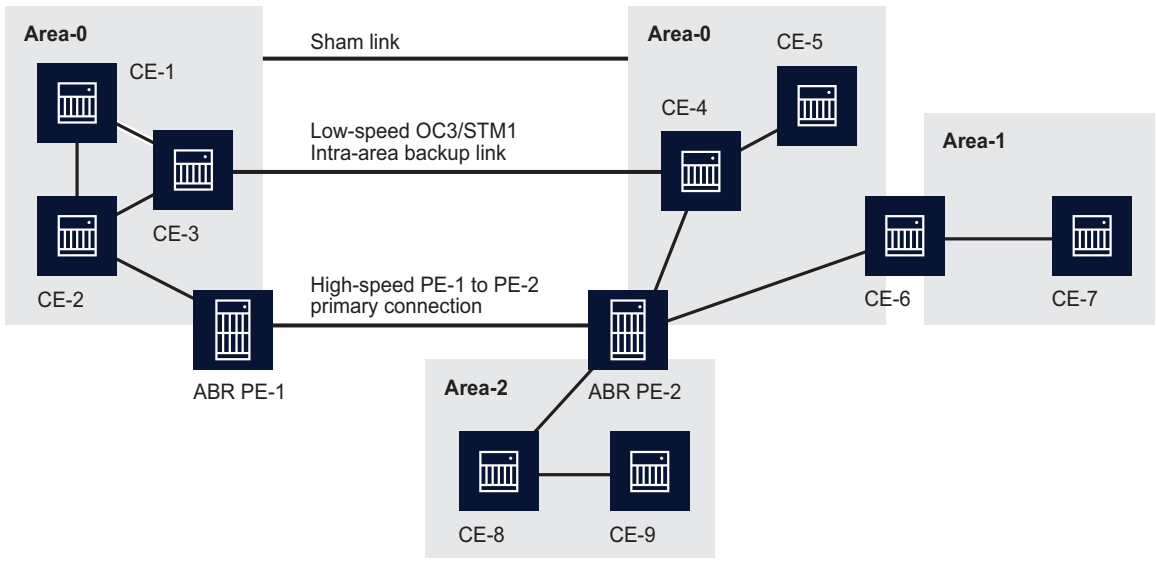
The PE router stops sending the MDT join TLV when the transmission bandwidth no longer exceeds the configured threshold. The PE routers using the data-MDT leave the group and transmission resumes over the default MDT.

79.1.10 OSPF sham link support

You can use the OSPF protocol to connect CE routers to PE routers over an MPLS VPN backbone. This can be useful for customers who subscribe to a VPN service and need to use OSPF as their intra-site routing protocol to exchange routing information between their sites. However, there is a potential configuration issue associated with this approach.

OSPF PE-CE connections assume that the only path between two client sites is across the MPLS VPN backbone. OSPF treats a link through a Layer 3 VPN as an inter-area link. However, other paths between VPN sites may also exist. For example, in the following figure, the link between CE-3 and CE-4 (two CE routers in the same OSPF area) might be a low-speed OC3/STM1 intra-area backup link. OSPF preferentially utilizes intra-area links over inter-area links, and since it establishes an intra-area route connection between CE-3 and CE-4, the potentially high-speed PE-1 to PE-2 primary connection is not utilized.

Figure 79-1 Sham link configuration example



OSPF sham links can be created to resolve this problem. By creating and configuring a sham link as an intra-area link between PE-1 and PE-2, a normal OSPF adjacency is formed, and the link-state database is exchanged across the MPLS VPN. As a result, the desired intra-area connectivity

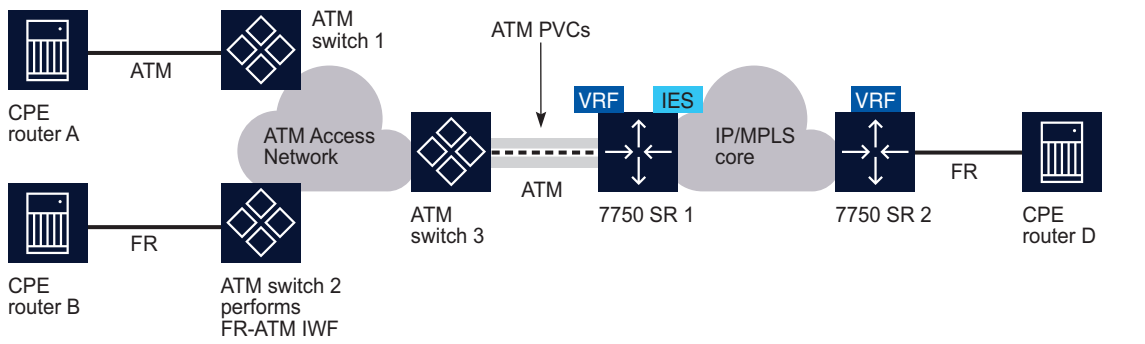
is created between PE-1 and PE-2. In addition, the cost of the CE-3/CE-4 and PE-1/PE-2 links can be managed by the use of a numerical metric. You could then configure the service so that the CE-3/CE-4 link becomes a standby link only in event that the VPN fails.

79.1.11 ATM SAP terminations for VPRN

CE routers that have access to an ATM network can connect with a VPRN using ATM SAP terminations on a 7750 SR. The interconnection between ATM point-to-point and L3 services uses RFC 2684-encapsulated IPv4 traffic over an ATM PVC that terminates on a specially configured SAP. All RFC 2684- encapsulated traffic can be routed over ATM networks, frame relay, or directly through ATM connections.

The following figure shows how CPE Router A in an ATM network can access L3 IP services, such as a VPRN, using a statically configured ATM PVC on a 7750 SR (SR#1). A SAP is configured on SR #1 to serve a specific VPRN as identified by the VRF. Destination CPE router D can receive RFC 2684-encapsulated traffic over an IP network through a frame relay over 7750 SR 2.

Figure 79-2 ATM SAP network connection to a VPRN



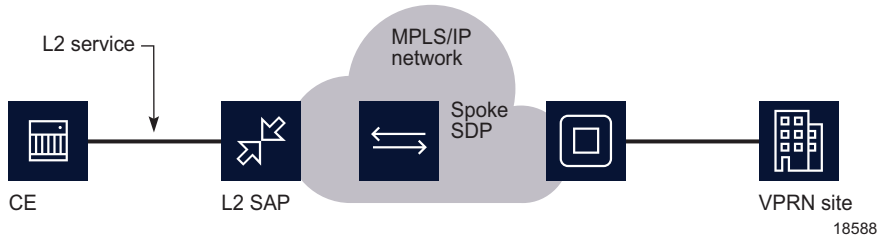
The two connection methods used between ATM and VPRN, which appear in NFM-P as AAL5 Encapsulation parameters. LLC/SNAP encapsulation and VC-multiplexing.

79.1.12 Epipe SDP spoke termination on VPRN services

A VLL Epipe service can terminate directly on a VPRN service using an SDP spoke on the 7750 SR, 7450 ESS, or 7950 XRS. Traffic that terminates on a VPRN service is identified by the interface ID of the SDP on the L2 access router and the VC ID label in the service packet. All routing protocols supported by VPRN are also supported for spoke SDP termination.

The following figure shows a spoke SDP terminating directly on a VPRN. The spoke SDP could be tied to an Epipe or VPLS. No configuration is required for the CE-to-PE connection on the SAP.

Figure 79-3 SDP spoke termination on an L2 service



79.1.13 Routed CO dual homing using SRRP

Subscriber Router Redundancy Protocol (SRRP) allows two separate connections to an access NE such as DSLAM to operate in an active/standby configuration similar to the way in which VRRP interfaces operate. SRRP is a collection of functions and messaging protocols that allows a system to create a set of redundant gateway IP addresses that are shared by a local and remote NE.

Each SRRP instance is created within the context of a subscriber group IP interface and is identified by a unique SRRP instance ID, which must be unique within the NE. This SRRP instance controls the redundant routing for all subscriber subnets configured or associated with the group interface. One SRRP instance is supported for each group interface and the SRRP ID must be the same as the SRRP instance ID on the group IP interface on the redundant NE.

A subscriber subnet redundant gateway IP host address is assigned at the subscriber IP interface level and is used for each SRRP instance associated with the subscriber subnet. The redundant IP host address must be configured for a subscriber subnet before it can be associated with an SRRP instance.

When SRRP is active on a group interface, the SRRP instance advertises to a remote NE using in-band messaging on the group-interface SAPs and out-of-band messaging on the group-interface redundant interface. If the remote NE uses the same SRRP instance ID, one NE enters a master state, while the other NE enters a backup state. Since the NEs share a common SRRP gateway MAC address (used for the SRRP gateway IP address and for proxy ARP functions), either NE can act as the default gateway for the attached subscriber hosts. This functionality helps to preserve subscriber QoS enforcement. The master state allows routing to and from the subscriber hosts associated with the group IP interface. The backup state stops ingress forwarding for packets destined to the SRRP gateway MAC and causes all packets destined to subscriber hosts on the group IP interface to be forwarded to a redundant IP interface associated with the group IP interface.

Normally, when anti-spoofing is enabled on a group-interface SAP, the SAP drops SRRP packets because they do not contain a subscriber MAC or IP address. However, you can use a configuration option to enable anti-spoofing for subscriber hosts on a group-interface SAP that participates in SRRP advertisements.

The underlying mechanism that controls state transitions is based on a dynamic priority level that an SRRP instance maintains. The SRRP instance with the highest priority level assumes the master operating state. An SRRP instance with a higher current priority level always preempts an SRRP instance with a lower priority level. If the priority levels are equal, the SRRP instance with the

lowest source SRRP host IP address assumes the master state. The local SRRP instance priority may also be controlled by associating the instance with an existing VRRP policy.

To prevent a flood of AccessInterfaceDown alarms that an SRRP fault or link failure may generate for LAG-based MSAPs, the NFM-P performs alarm suppression. See Chapter 74, “Residential subscriber management” for more information.

The redundant IP interface is a special interface that connects two systems with one or more common SRRP instances. The interface is configured with a /31 address and a spoke SDP binding, creating an Ethernet pseudowire shortcut between the redundant NEs. When the SRRP instance is in backup state, the group interface associated with this instance is not allowed to forward or route traffic downstream towards the subscriber. As a result of this, the packets are shunted across the redundant interface so that the active group interface does the forwarding or routing.

If the redundant IP interface goes down, the system allows the group IP interfaces associated with the down interface to forward locally downstream, when they are in the backup SRRP state. While forwarding downstream in the backup state, the system uses the MAC address associated with the group IP interface, not the SRRP redundant gateway MAC address.

SRRP is supported on the 7450 ESS in mixed mode and 7750 SR.

79.1.14 DoS protection

To protect a VPRN from a high incoming packet rate that characterizes a DoS attack, you can use the NFM-P to create DoS protection policies for the VPRN L3 access interfaces. A DoS protection policy limits the number of control-plane packets that an interface receives each second, and optionally logs a violation notification if a policy limit is exceeded. You can use the NE System Security form to view the violations for a specific NE.

You can configure a DoS protection policy to control the following on a VPRN L3 access interface:

- the control-plane packet arrival rate per subscriber host on the interface
- the overall control-plane packet arrival rate for the interface
- whether an NE sends a notification trap if a policy limit is exceeded

Each VPRN L3 access interface on an NE that supports DoS protection is automatically assigned a default DoS protection policy. This default policy limits only the overall packet arrival rate for the interface, and cannot be deleted or modified. See the procedure to configure an NE DoS protection policy in the *NSP System Administrator Guide* for information about creating a DoS protection policy.

79.1.15 DDoS protection

To protect a VPRN from a high incoming packet rate that characterizes a DDoS attack, you can use the NFM-P to configure TMS interfaces to route malicious traffic through the ISA-TMS MDA where the malicious traffic is cleaned before being released to the network.

The TMS interface on a VPRN consists of three VPRNs as follows:

- The management VPRN communicates with the TMS server to determine whether incoming packets are malicious. Configuration of this VPRN is optional.
- The Off-Ramp VPRN receives the malicious traffic and routes it through the ISA-TMS MDA where the traffic is scrubbed. Configuration of this VPRN is optional.

- The On-Ramp VPRN returns the cleaned traffic to the network. Configuration of this VPRN is mandatory.

See 79.49 “To add a TMS interface to a VPRN” (p. 2614) for information about creating a TMS interface.

You can configure a DDoS protection policy on a VPRN group interface SAP, network interface, or L3 access interface. See the procedure to configure an NE DDoS protection policy in the *NSP System Administrator Guide* for more information.

79.1.16 Local DHCP servers

A local DHCP server can be associated with an L3 access interface on a VPRN service. See 74.2 “Residential subscriber components” (p. 1992) .

79.1.17 Local user database

A local user database can be associated with a local DHCP server and PPPoE configurations on group interfaces. See 74.2 “Residential subscriber components” (p. 1992) .

79.1.18 PPPoE protocol on VPRN services

A VPRN service can be configured to run PPPoE protocol. PPPoE is used in subscriber networks to encapsulate PPP frames inside Ethernet frames. PPPoE combines the point-to-point protocol used with DSL sessions with the Ethernet protocol used to support multiple subscribers in a local area network. From the group interface configuration form you can assign a PPPoE policy and a local user database to authenticate PPPoE subscribers.

PPPoE termination in a business VPRN environment is also supported. This ability targets applications such as PPPoE VPRN with IP overlap, where there are two participants in the service:

- The “Wholesale VPRN”, which is a VPRN that provides access to the SAP.
- The “Retail VPRN”, which is a business VPRN that routes the packets belonging to the PPPoE sessions terminating in it. The Retail VPRNs may have overlapping IP addresses.

In this configuration, the PPPoE subscriber host terminates in a Retail VPRN and provides a routed path to the customer site. The VPRN service-id that carries it is determined by the service configuration, specifically:

- If a local user database is used, the Retail Service ID property that you specify in the PPPoE host configuration provides a reference to the VPRN service-id that should be used.
- If RADIUS is used for authentication, the retailer service-id is provided by an Nokia VSA.
- If MSAP is used, the SAP is created in the wholesale VPRN using the information from RADIUS.

The PPPoE session is negotiated with the parameters defined by the Wholesale VPRN interface. Since the IP address space of the subscriber management host may overlap between VPRN services, the node anti-spoofs the packets at access ingress with the session-id.

79.1.19 L2TP on VPRN services

The NFM-P supports the configuration of L2TP on a 7750 SR or 7950 XRS, and on the 7450 ESS in mixed mode. L2TP is a session-layer protocol that extends the PPP model by allowing L2 and

PPP endpoints to reside on different devices that are interconnected by a PSN. L2TP extends the PPP sessions between the CPE and PPP/L2TP termination points on the L2TP network server (LNS), via an intermediate L2TP access concentrator (LAC). The LAC is the initiator of session-generated L2TP tunnels; the LNS is the server that waits for new tunnels. Manually configured and initiated L2TP tunnels can be initiated or stopped from either the LNS or LAC.

At least one ISA-LNS group must be configured for the LNS NE.

On an LNS NE, L2TP destinations configured for L2TP tunnel profiles can include the following:

- loopback L3 access interfaces for a VPRN or IES service
- loopback interfaces configured for a base routing instance

See Chapter 13, “Logical group object configuration” for more information about ISA-LNS groups. See 13.12 “To configure an ISA-LNS group” (p. 426) for information about how to create and configure an ISA-LNS group. See Chapter 28, “Routing protocol configuration” for more information about L2TP.

See 79.22 “To configure ISIS, L2TP, MLD, OSPFv2, OSPFv3, PIM, RIP, or WPP on a VPRN routing instance” (p. 2555) for information about enabling L2TP on a VPRN router instance site. See 79.37 “To configure a group interface on a VPRN” (p. 2586) for information about configuring a VPRN group interface to terminate LNS PPP sessions.

79.1.20 IPsec

You can configure a VPRN with a tunnel interface for secure and encrypted tunneling between sites. An IPsec VPRN allows you to share secure and encrypted VPN traffic among multiple sites.

IPsec VPRN services include:

- NAT traversal
- DES, 3DES, AES-128, AES-192 and AES-256 encryption methods
- HMAC-MD5 and HMAC-SHA1 authentication and hashing methods
- Diffie-Hellman key generation algorithms
- Pre-shared keys and IKE shared secret with PFS key management authentication methods

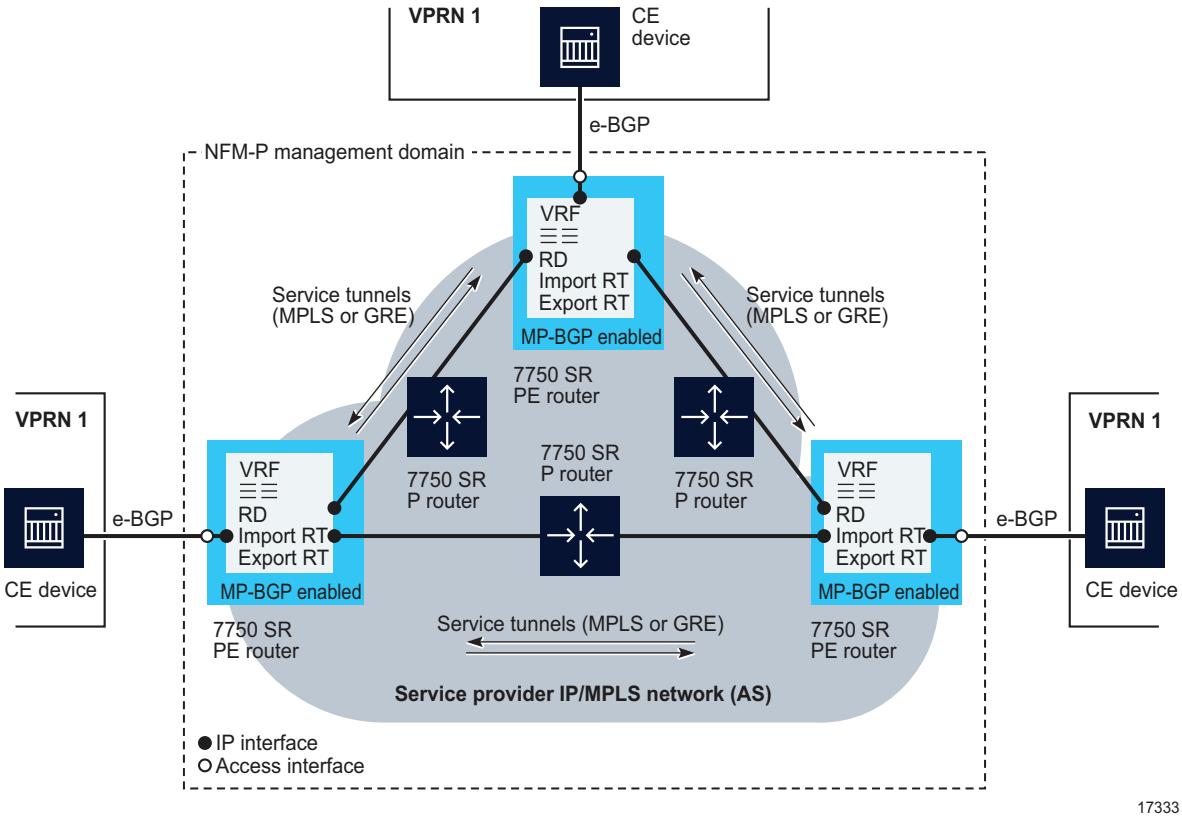
See Chapter 34, “IPsec” for more information about IPsec configuration.

79.2 Sample VPRN service configuration

79.2.1 Sample VPRN service

The following figure shows a sample VPRN service configuration.

Figure 79-4 Sample VPRN Configuration



79.2.2 Configuration steps

Assuming the core IP/MPLS or GRE network is already configured, the following high-level tasks are required to configure the sample VPRN service.

1

Configure policies as required, for example, access ingress and egress, Routing, Scheduler, ACL IP, Accounting, and ANCP.

2

Configure ports as access ports for use in the service.

3

Configure service tunnels as required.

4

Configure MP-BGP for PE-to-PE routing.

5

Create and configure customers.

6

Create and configure VPRN 1.

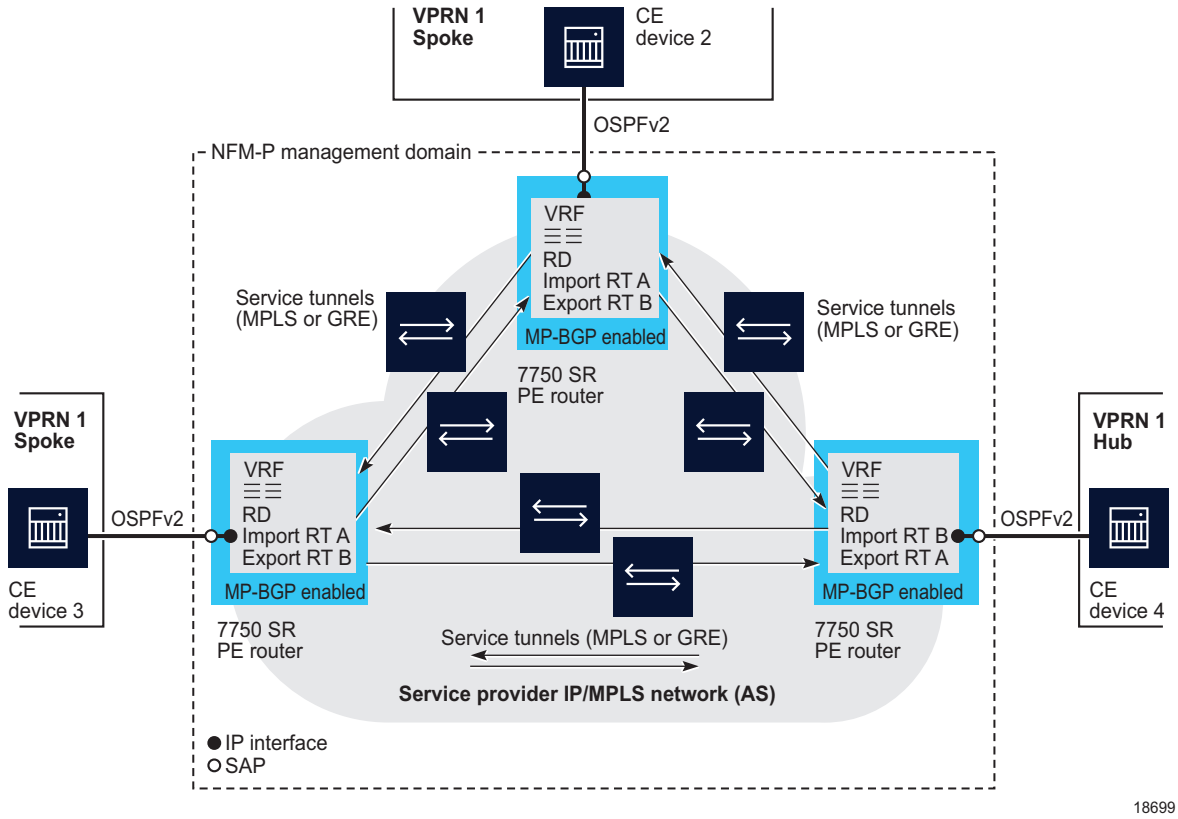
79.3 Sample hub-and-spoke VPRN configuration

79.3.1 Sample hub-and-spoke VPRN

In a hub-and-spoke VPRN, the majority of the traffic is exchanged between the hub (for example, headquarters) and spoke sites (for example, branches). Traffic between spoke sites passes through the hub site. Spoke sites advertise their routes to the hub site, which in turn advertises these routes to the other spoke sites.

The following figure shows a sample hub-and-spoke VPRN service configuration. Your configuration will vary depending on your network requirements.

Figure 79-5 Sample hub-and-spoke VPRN Configuration



79.3.2 Configuration steps

Assuming the core IP/MPLS or GRE network is already configured, the following table high-level tasks are required to configure this sample hub-and-spoke VPRN service.

1

Configure policies as required, for example, access ingress and egress, Routing, Scheduler, ACL IP, Accounting, ANCP, and DoS protection.

2

Configure ports as access ports for use in the service.

3

Configure service tunnels as required.

4

Configure MP-BGP for PE-to-PE routing.

5

Create and configure customers.

6

Create and configure VPRN 1.

VPRN service management procedures

79.4 Workflow to create a VPRN service

79.4.1 Overview

The following workflow lists the high-level steps required to create a VPRN service. As a prerequisite for creating a VPRN service, this workflow assumes the following:

- a group or customer with the required user access privileges has been configured.
- the IP or IP/MPLS core network exists.
- any required service tunnels are created including the static, dynamic or SR-TE LSP required to create the service tunnel; see 33.9 “To create an IP/MPLS service tunnel” (p. 1190) .
- the access ports for the service are created; see Chapter 16, “Port and channel object configuration” .
- any required pre-defined routing, QoS, scheduling, filter, accounting, and time of day suite policies are created; see Chapter 49, “Policies overview” . You do not have to create pre-defined policies if policies are created on a per-service basis.
- any required MP-BGP for PE-to-PE routing is configured; see Chapter 28, “Routing protocol configuration” for more information about protocol configuration.

79.4.2 Stages

1

Create a VPRN service; see 79.5 “To create a VPRN service” (p. 2534) .

2

Create a VPRN site; see 79.11 “To configure a VPRN site” (p. 2545) .

3

Configure the VPRN site TCP/IP assignments, IP addressing, and timing protocols as required.

a. Configure NAT on a VPRN site; see 30.9 “To configure NAT on a routing instance” (p. 1086) .

b. Configure DNS for a VPRN site; see 79.12 “To configure DNS for a VPRN site” (p. 2546) .

c. Configure QoS for self-generated traffic on a VPRN site; see 79.13 “To configure QoS for self-generated traffic on a VPRN site” (p. 2546) .

d. Configure NTP on a VPRN site; see 79.14 “To configure NTP on a VPRN site” (p. 2547) .

e. Configure PTP on a VPRN site; see 79.15 “To configure PTP on a VPRN site” (p. 2548) .

f. Configure an SNMP community for mediating the IPv6 objects on a VPRN site; see 79.17 “To configure an SNMP community on a VPRN site” (p. 2551) .

g. Configure IGMP host tracking on a VPRN sit; see 79.18 “To configure IGMP host tracking on a VPRN site” (p. 2552) .

h. Configure an override source IP address on a VPRN site; see 79.19 “To configure an override source IP address on a VPRN site” (p. 2553) .

4

Enable one or more routing protocols on a VPRN site as required.

a. Enable routing protocols on a VPRN site; see 79.21 “To enable routing protocols on a VPRN site” (p. 2554) .

b. Configure ISIS, L2TP, MLD, OSPFv2, OSPFv3, PIM, RIP, or WPP on a VPRN routing instance; see 79.22 “To configure ISIS, L2TP, MLD, OSPFv2, OSPFv3, PIM, RIP, or WPP on a VPRN routing instance” (p. 2555) .

c. Configure BGP on a VPRN routing instance; see 79.23 “To configure BGP on a VPRN routing instance” (p. 2557) .

d. Configure IGMP on a VPRN routing instance; see 79.24 “To configure IGMP on a VPRN routing instance” (p. 2560) .

5

Configure or add the following objects or instances on a VPRN site or service.

a. Routing instance; see 79.26 “To configure a routing instance on a VPRN site” (p. 2564) .

b. VRF instance; see 79.27 “To configure a VRF instance on a VPRN site” (p. 2567) .

c. MVPN VRF instance; see 79.28 “To configure an MVPN VRF instance on a VPRN site” (p. 2570) .

d. BGP confederation; see 79.29 “To configure a BGP confederation on a VPRN site” (p. 2574) .

e. GSMP group; see 79.30 “To configure a GSMP group on a VPRN site” (p. 2575) .

f. GNE site; see 79.31 “To configure a GNE site and GNE service interface on a VPRN service” (p. 2576) .

6

Configure the following server types for a VPRN site or service as required.

a. Local DHCPv4 server; see 79.33 “To configure a local DHCPv4 server on a VPRN site” (p. 2579) .

b. Local DHCPv6 server; see 79.34 “To configure a local DHCPv6 server on a VPRN site” (p. 2581) .

c. RADIUS server; see 27.8 “To configure a RADIUS server on a routing instance” (p. 846) .

d. RADIUS proxy server; see 27.9 “To configure a RADIUS proxy server on a routing instance” (p. 847) .

7

Create or add the following interfaces to a VPRN site as required.

a. AA interfaces; see 78.17 “To add an AA interface to an IES or a VPRN site” (p. 2447) .

b. AARP interfaces; see 78.18 “To add an AARP interface to an IES or a VPRN site” (p. 2448) .

c. GNE service interfaces; see 79.31 “To configure a GNE site and GNE service interface on a VPRN service” (p. 2576) .

d. Group interfaces; see 79.37 “To configure a group interface on a VPRN” (p. 2586) .

   In addition, perform the following as required on VPRN group interfaces:

   - Configure a SAP on a VPRN group interface; see 79.39 “To configure a SAP on a VPRN group interface” (p. 2594) .
   - Configure LAG per-link hashing on a VPRN group interface SAP; see 79.40 “To configure LAG per-link hashing on a VPRN group interface SAP” (p. 2599) .
   - Configure a WLAN GW for a VPRN group interface; see 79.66 “To configure a WLAN GW for a VPRN group interface” (p. 2631) .

e. IGMP interfaces; see 79.41 “To add an IGMP interface to a VPRN” (p. 2600) .

f. IGMP Group interfaces; see 79.42 “To add an IGMP group interface to a VPRN” (p. 2601) .

g. IP mirror interfaces; see 79.43 “To add an IP mirror interface to a VPRN” (p. 2602) .

h. ISIS interfaces; see 28.60 “To configure IS-IS on a routing instance” (p. 953) .

i. L3 access interfaces; see 79.83 “To configure an L3 access interface on a VPRN site” (p. 2656) . See the workflow in 79.82 “Workflow to configure VPRN L3 access interfaces” (p. 2653) for detailed instructions/tasks that apply to VPRN L3 access interfaces.

j. MLD interfaces; see 28.123 “To configure an MLD interface on a base routing instance or VPRN routing instance” (p. 1035) .

k. Network interfaces; see 79.44 “To configure a network interface on a VPRN site” (p. 2603) .

l. PIM interfaces; see 79.45 “To add a PIM interface to a VPRN” (p. 2606) .

m. Redundant interfaces; see 79.46 “To implement dual homing using SRRP” (p. 2607) .

n. Subscriber interfaces; see 79.47 “To configure a subscriber interface on a VPRN” (p. 2610) .

   In addition, perform the following as required on VPRN subscriber interfaces:

   - Force a WLAN GW switchover to standby management on a VPRN subscriber interface; see 79.48 “To force a WLAN GW switchover to standby management on a VPRN subscriber interface” (p. 2613) .

o. TMS interfaces; see 79.49 “To add a TMS interface to a VPRN” (p. 2614) .

p. Tunnel interfaces; see 34.20 “To configure a tunnel interface on an IES or VPRN” (p. 1249) .

q. Video interfaces; see 35.3 “To add a video interface to an IES or VPRN site” (p. 1275) .

8

Create and assign policies to VPRN sites as required:

a. Configure VRF import and export policies on a VPRN site; see 79.50 “To configure VRF import and export policies on a VPRN site” (p. 2615) .

b. Configure a range policy to reserve route targets and route distinguishers on a VPRN site; see 79.51 “To configure a policy to reserve an RT and RD range for VPRN services” (p. 2616) .

c. Automatically assign RT policies and RD configuration to VPRN sites; see 79.52 “To automatically assign RT policies and RD configuration to VPRN sites” (p. 2617) .

d. Configure a network ingress filter policy on a VPRN site; see 79.53 “To configure a network ingress filter policy on a VPRN site” (p. 2618) .

e. Configure ingress QoS control on a VPRN site; see 79.54 “To configure ingress QoS policies on a VPRN site” (p. 2619) .

9

If GRT route leaking is required, configure the following:

a. Configure routing policies as required; see 54.5 “To configure a routing policy statement” (p. 1745).

b. Configure leak export policies on the NE routing instance; see 27.2 “To configure a routing instance or a VRF instance” (p. 826).

c. Configure leak import policies on the VPRN routing instance; see 79.26 “To configure a routing instance on a VPRN site” (p. 2564).

10

Configure the VPRN service connections/routes/targets/links/tunnels between devices as required.

a. Bind a VPRN site to service tunnels; see 79.56 “To bind a VPRN site to service tunnels” (p. 2620) .

b. Configure static routes on a VPRN site; see 79.57 “To configure static routes on a VPRN site” (p. 2621) .

c. Configure route aggregates on a VPRN site; see 79.58 “To configure route aggregates on a VPRN site” (p. 2622) .

d. Enable a tunnel facility MEP on the VPRN site; see 79.59 “To enable a tunnel facility MEP on the VPRN site” (p. 2623) .

e. Enable the automatic selection of an RD on a VPRN site; see 79.60 “To enable the automatic selection of a route distinguisher on a VPRN site” (p. 2624) .

f. Add a Global Route Table to a VPRN site; see 79.61 “To add a Global Route Table to a VPRN site” (p. 2625) .

g. Create an intra-area OSPF sham link between two VPRN sites; see 79.62 “To create an OSPF sham link between two VPRN sites” (p. 2626) .

h. Reserve route targets for specific VPRN services; see 79.63 “To reserve route targets for specific VPRN services” (p. 2628) .

i. Create a VXLAN tunnel termination; see 79.64 “To configure a VXLAN termination on a VPRN” (p. 2629).

11

Configure WLAN Gateway functionality on a VPRN site as required.

a. Configure WLAN GW functionality on a VPRN site; see 79.65 “To configure WLAN GW functionality on a VPRN site” (p. 2630) .

b. Configure a WLAN GW for a VPRN group interface; see 79.66 “To configure a WLAN GW for a VPRN group interface” (p. 2631) .

c. Resync WLAN GW tunnels on a VPRN site; see 79.67 “To resync WLAN GW tunnels on a VPRN site” (p. 2635) .

12

Configure or add Spoke SDP Binding to a VPRN site as required.

a. Create a VPRN spoke SDP binding; see 79.68 “To configure a VPRN spoke SDP binding” (p. 2635) .

b. Create an L2 SDP spoke termination on a VPRN service; see 79.69 “To create an L2 SDP spoke termination on a VPRN service” (p. 2638) .

c. Configure an MPLS-TP static pseudowire on a VPRN spoke SDP binding; see 79.70 “To configure an MPLS-TP static pseudowire on a VPRN spoke SDP binding” (p. 2641) .

d. Configure BFD on a VPRN spoke SDP binding; see 79.71 “To configure BFD on a VPRN spoke SDP binding” (p. 2642) .

e. Clear BFD sessions and statistics on a VPRN spoke SDP binding; see 79.72 “To clear BFD sessions and statistics on a VPRN spoke SDP binding” (p. 2643) .

f. View the BFD session status on a VPRN SDP spoke binding; see 79.73 “To view the BFD session status on a VPRN SDP spoke binding” (p. 2644) .

13

Perform service assurance/OAM related task as required on VPRN services or sites:

a. Run an OAM validation test for a VPRN; see 79.74 “To run an OAM validation test for a VPRN service” (p. 2644) .

b. Configure OAM components on a VPRN site; see 79.75 “To configure OAM components on a VPRN site” (p. 2646) .

c. Create a TWAMP Light reflector on a VPRN site; see 79.76 “To create a TWAMP Light reflector on a VPRN site” (p. 2647) .

d. Assign an ICMP Ping template. See 79.105 “To assign an ICMP ping template to a VPRN L3 access interface” (p. 2679).

14

View VPRN service information assigned to a VPRN site; as required:

a. MVPN extranet objects; see 27.28 “To list MVPN Extranet objects for a NE” (p. 873) .

b. Last cleared BFD statistics and sessions; see 79.77 “To view the last cleared BFD statistics and sessions on a VPRN site” (p. 2648) .

c. VPRN services that use an auto-assigned RT and RD or reservation table; see 79.78 “To view VPRN services that use an auto-assigned RT and RD or reservation table” (p. 2649) .

d. DHCPv6 prefixes that the server has given out; see 79.79 “To view DHCPv6 leases” (p. 2649) .

e. Lease not owner and pool unknown log events for local DHCPv6 servers; see 79.80 “To view DHCPv6 log events” (p. 2651) .

f. Service topology map associated with a VPRN service; see 79.81 “To view the service topology map associated with a VPRN service” (p. 2652) .

g. VPRN service operational status; see 79.6 “To view the VPRN service operational status” (p. 2535) .

15

As required, modify the VPRN service:

a. Using the Show Info form. See 79.8 “To view VPRN service contents” (p. 2537) .

b. Using the Manage Services form; see 79.7 “To modify a VPRN service” (p. 2536) .

c. Using the topology view; see 79.9 “To modify a VPRN service using the topology view” (p. 2538) .

16

As required, delete the VPRN service; see 79.10 “To delete a VPRN service” (p. 2544) .

79.5 To create a VPRN service

79.5.1 Steps

1

Choose Create→Service→VPRN from the NFM-P main menu. The VPRN Services (Create) form opens.

2

Select a customer in the Customer panel to associate with the VPRN.

3

Configure the general VPRN service parameters.

The SVC Mgr Service ID parameter is configurable when the Auto-Assign ID parameter is disabled.

4

Save and close the forms.

END OF STEPS

79.6 To view the VPRN service operational status

79.6.1 Purpose

The Aggregated Operational State and State Cause indicators on the General tab of the service management form display information about service faults.

79.6.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a service and click Properties. The VPRN Service (Edit) form opens.

3

View the Aggregated Operational State and State Cause indicators. When the Aggregated Operational State is Down or Partially Down, a check mark beside the appropriate State Cause indicator identifies the type of associated service fault.

4

Click on the appropriate tab to view or edit an object that is identified as faulty by a State Cause indicator.

5

Click on the Faults tab to view the alarms for the object. The Object Alarms tab is displayed.

6

Click on the Aggregated Alarms tab to view the aggregated alarms for the object. The Aggregated Alarms tab is displayed.

7

Close the forms.

END OF STEPS

79.7 To modify a VPRN service

CAUTION

Service Disruption

Modifying parameters can be service-affecting.

The behavior of the VPRN service may become unpredictable if modifications to the configuration affect the IPsec portion of the service configuration. For example, if a VPRN service is configured with IPsec tunnels, IPsec SAPS, and policies are deleted, the service is not deleted from the NFM-P and the service will be in an inconsistent state. The IPSEC portion of the VPRN configuration must be deleted using CLI scripts or the CLI before the VPRN service can be deleted from the NFM-P.

79.7.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

The following tabs list the service elements that can be individually or collectively selected and configured:

- Tests tab — allows the creation and execution of service-specific diagnostic tests
- Sites tab — lists the sites that are included in the service
- L3 Access Interfaces tab — lists the L3 access interfaces that are included in the service
- Spoke SDP Bindings tab — displays the spoke SDP bindings that are associated with the service
- Addresses tab — lists the IP addresses that are associated with the service

  Note:

  You cannot remove an IP address from an interface when the IP address of a static host is defined in the subnet of the interface IP address and the ARP Populate parameter is enabled on the Anti-Spoofing tab.
- Faults tab — displays the faults associated with the service

3

Modify the parameters for the service, as required.

To configure items in the tabs that contain lists of service elements, select the items and click Properties.

4

Save the changes and close the forms.

END OF STEPS

79.8 To view VPRN service contents

79.8.1 Purpose

Use this procedure to view various contents of a VPRN service and any modifications you make to it before deploying the changes.

Note: The procedure also provides information on the following policy types associated with the service:

- QoS SAP ingress and QoS SAP egress polices
- ACL IP/IPv6 filters and ACL MAC filter policies
- VRF Import and Export policies

Two information views are available. The Committed info view displays the current contents of a service, and the Committed menu item is always enabled. The Modified info view allows you to review any changes you make to a service before committing them. Modified, created, and deleted attributes and objects are displayed.

79.8.2 Steps

1

Choose Manage Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Click Search and select the service that you want to view or modify.

3

On the service navigation tree, expand the Sites icon and click on the required routing instance. The site properties form is displayed.

4

Perform one of the following:

a. To view the currently committed service contents, go to Step 5 .

b. To view modified service contents before committing any changes, go to Step 6 .

5

Click on the Show Info and choose the Committed menu item. A Committed Values form is displayed and shows various policy attributes that have been previously configured and saved

in the local policy. The information displayed in the form is similar to the information retrieved in CLI by running the “config>service>*Service Type#* info” command, where *Service Type#* is the type of service (followed by its Service ID, for example: vprn77) that you want to query.

6

Modify any service parameters or objects, as required. Otherwise go to Step 9 .

7

Click on the Show Info and choose the Modified menu item. A Modified Values form is displayed. The table lists modified, created, and deleted actions, as well as specific attributes and objects, along with their old value, new value, and tab location. The Attribute Title corresponds to the attribute or object name acted upon by your current modifications. For created objects, the values of mandatory attributes are shown in comma-separated format.

8

Select an item in the Modified Values form and then click Show on Form. The service form tab containing the changed item is displayed and the modified attribute is highlighted in blue.

9

Save your changes if required, and close the form.

END OF STEPS

79.9 To modify a VPRN service using the topology view

79.9.1 Purpose

The topology view for a service provides a graphical representation of the various components and their interconnections. You can also use this view to add, modify, or just navigate to service components. This provides an alternative approach to performing these functions from the navigation tree view.

Working from the topology view can expedite the creation of the components, since many of the fields you would ordinarily have to set in the configuration forms will be automatically populated using this approach. The configuration forms can also be accessed directly at any time from this view by right-clicking a component. This allows quick access to conduct more detailed component configuration.

79.9.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Configure the filter criteria. A list of services appears.

3

Choose a VPRN service and click Topology View. The Service Topology map opens.

The remainder of this procedure contains a number of sub-procedures describing the various components that can be viewed, created, or modified from the topology view. These include:

- Creating a new site. Go to Step 4 .
- Creating site components. Go to Step 9 .
- Creating spoke SDP bindings. Go to Step 36 .
- Viewing the route target topology. Go to Step 44 .

Adding a new site

4

Right-click on any blank space in the service topology map. A contextual menu is displayed. Choose the Create VPRN Site option.

The Select Network Elements form opens.

5

Select one or more sites to add to the service and click OK. The VPRN Site (Create) form for the new site is displayed. If you selected more than one site, the VPRN Site (Multiple Instances) (Create) form for the new sites is displayed.

6

Click on OK. The VPRN Site (Create) (or VPRN Site (Multiple Instances) (Create)) form closes and the new site (or sites) is displayed on the map.

7

If you need to perform detailed configuration of site properties for the new site, right-click the site icon and select Properties. The VPRN Site (Edit) form opens. See 79.5 “To create a VPRN service” (p. 2534) for detailed site configuration information.

8

Return to Step 3 for a list of other functions you can perform from the topology view or go to Step 46 to finish.

Creating site components

9

Right-click on any site icon in the service topology map. A contextual menu is displayed. You can choose to create one of the following:

- VPRN L3 Access Interface. Go to Step 10 .
- Tunnel Interface. Go to Step 15 .

- VPRN Subscriber Interface. Go to Step 20 .
- Redundant Interface. Go to Step 24 .
- IP Mirror Interface. Go to Step 28 .
- Video Interface. Go to Step 32 .

10

If you choose to create a VPRN L3 Access Interface, then the VPRN L3 Access Interface (Create) form is displayed.

11

Configure the Name parameter on the General tab.

12

Click on the Port tab and assign a port to the interface.

See 79.83 “To configure an L3 access interface on a VPRN site” (p. 2656) for detailed information on further configuring the interface, if required.

13

Click OK. The VPRN L3 Access Interface (Create) form closes and the new L3 access interface is displayed in the topology view.

14

Go to Step 35 .

15

If you choose to create a tunnel interface, then the Tunnel Interface (Create) form is displayed.

16

Configure the Name parameter on the General tab.

17

Click on the Port tab and assign a port to the interface.

See 34.20 “To configure a tunnel interface on an IES or VPRN” (p. 1249) in Chapter 34, “IPsec” for detailed information on further configuring the interface, if required.

18

Click OK. The Tunnel Interface (Create) form closes and the new tunnel interface is displayed in the topology view.

19

Go to Step 35 .

20

If you choose to create a VPRN Subscriber Interface, then the VPRN Subscriber Interface (Create) form is displayed.

21

Configure the Name parameter for the interface.

See 79.47 “To configure a subscriber interface on a VPRN” (p. 2610) for detailed information on further configuring the interface, if required.

22

Click OK. The VPRN Subscriber Interface (Create) form closes and the new subscriber interface is displayed in the topology view.

23

Go to Step 35 .

24

If you choose to create a Redundant Interface, then the Redundant Interface (Create) form is displayed.

25

Configure the Name parameter for the interface.

See 79.46 “To implement dual homing using SRRP” (p. 2607) for detailed information on further configuring the interface, if required.

26

Click OK. The Redundant Interface (Create) form closes and the new redundant interface is displayed in the topology view.

27

Go to Step 35 .

28

If you choose to create an IP Mirror Interface, then the IP Mirror Interface (Create) form is displayed.

29

Configure the Name parameter for the interface.

See 79.43 “To add an IP mirror interface to a VPRN” (p. 2602) for detailed information on further configuring the interface, if required.

30

Click OK. The IP Mirror Interface (Create) form closes.

31

Go to Step 35 .

32

If you choose to create a Video Interface, then the Video Interface (Create) form is displayed.

33

Configure the Name parameter for the interface.

See 35.3 “To add a video interface to an IES or VPRN site” (p. 1275) in Chapter 35, “ISA-Video” for detailed information on further configuring the interface, if required.

34

Click OK. The Video Interface (Create) form closes and the new video interface is displayed in the topology view.

35

Return to Step 3 for a list of other functions you can perform from the topology view or go to Step 46 to finish.

Creating spoke SDP bindings

36

Select the sites you need to connect in the service topology map and right-click on any one of them. A contextual menu is displayed.

Note: When you create a spoke binding between two sites, the order in which you select them is important. The first site you select will become the source site and the second site will become the destination site. Therefore, it is not recommended that you do a marquee-select in the topology view, since you will not be sure of this hierarchy. Instead, select the sites individually, and hold down the Shift or Ctrl key after your first selection.

37

Select Connect and choose the Create Spoke SDP Binding option.

The Spoke SDP Binding (Create) form is displayed.

Note: For this function, it is assumed that you clicked on the source site first and then held down the Shift or Ctrl key while right-clicking on the destination site to display the contextual menu.

38

Enable the Auto-Select Transport Tunnel parameter.

39

You can manually configure other parameters here if required, or click OK. One of the following will result:

- If an available transport tunnel exists between the two sites, then the Spoke SDP Binding (Create) form closes and the new binding between the two sites is displayed in the topology view. See 79.68 “To configure a VPRN spoke SDP binding” (p. 2635) for more detailed information on creating and configuring spoke SDP bindings, if required.
- If an available transport tunnel does not exist between the two sites, then an error message is displayed to that affect. See Chapter 33, “Service tunnels” for information about how to create the required tunnel. After the tunnel is created, you can repeat this sub-procedure.

40

Assuming that the spoke SDP binding was successfully created in Step 39 , select the same two sites again in the topology view, although this time do so in the opposite order that you originally selected them. This allows you to create a spoke binding for the return tunnel.

41

Right-click on the second site you selected and choose the Create Spoke SDP Binding ... option. The Spoke SDP Binding (Create) form is displayed.

42

You can manually configure other parameters here if required, or click OK. One of the following will result:

- If an available transport tunnel exists between the two sites, then the Spoke SDP Binding (Create) form closes and the new return binding between the two sites is displayed in the topology view.
- If an available transport tunnel does not exist between the two sites, then an error message is displayed to that affect. See Chapter 33, “Service tunnels” for information about how to create the required tunnel. After the tunnel is created, you can repeat this sub-procedure.

43

Return to Step 3 for a list of other functions you can perform from the topology view or go to Step 46 to finish.

Viewing the route target topology

44

Right-click on any blank space in the service topology map. A contextual menu is displayed. Choose the Highlight Route Target Topology option.

This option essentially draws dotted lines to represent the route target topology between NEs. For example, for two NEs A and B, if the import and export route targets match, then two dotted lines will be drawn on the map. One will represent the route target going from A to B, and the other from B to A.

45

Return to Step 3 for a list of other functions you can perform from the topology view or go to Step 46 to finish.

46

Close the Service Topology form.

47

Close the Manage Services form.

END OF STEPS

79.10 To delete a VPRN service

CAUTION

Service disruption

Deleting a service may result in a service disruption for customers.

Consider the implication of deleting the service before proceeding.

79.10.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

As required, configure the filter criteria to locate the service or range of services to be deleted. A list of services appears.

3

Choose a service or a range of services from the list.

Note: You cannot delete a VPRN service when IPsec security policies, interfaces, or tunnels are configured. See the appropriate node documentation for more information about modifying or deleting IPsec configurations.
For example, if a VPRN service is configured with IPsec tunnels, IPsec SAPS, and policies is deleted, the service is not deleted from the NFM-P and the service will be in an inconsistent state. The IPSEC portion of the VPRN configuration must be deleted using the CLI scripts or through the CLI before the VPRN service can be deleted from the NFM-P.
The L3 interface properties for the IPSEC SAP cannot be configured using the NFM-P.

4

Click Delete. A warning form opens. This form is dynamic based on the priority of the service. Perform one of the following:

a. For services with a low priority, go to Step 5 .

b. For services with a medium priority, configure the “Enter the highest priority of the service being deleted” text field by typing: Medium. Go to Step 5 .

c. For services with a high priority, configure the “Enter the highest priority of the service being deleted” text field by typing: High. Go to Step 5 .

5

For all services regardless of how their priority is configured, acknowledge the check box that prompts you confirm that you understand the implications of deleting the service.

Note: If you select multiple services with different priorities, you must enter the highest priority level of selected services before you can delete the services.

6

Click Yes to confirm the action. The service is deleted and removed from the list.

7

Close the forms.

END OF STEPS

79.11 To configure a VPRN site

79.11.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, right-click on the Sites icon and choose Create VPRN Site, or expand the Sites icon, right-click on a routing instance and choose Properties. The VPRN Site (Create|Edit) form opens.

4

Configure the general site parameters.

5

Save and close the forms.

END OF STEPS

79.12 To configure DNS for a VPRN site

79.12.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites icon, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Enable the Enable DNS parameter.

5

Click on the DNS tab and configure the required parameters.

6

Save the changes and close the forms.

END OF STEPS

79.13 To configure QoS for self-generated traffic on a VPRN site

79.13.1 Before you begin

NEs produce SGT for various applications, for example Telnet, SNMP, SSH. For each application, you can configure the DSCP or dot1p value for the traffic generated by that application. You can also map DSCP values to forwarding classes.

79.13.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites icon, right-click on a routing instance, and choose Properties. The VPRN Site (Edit) form opens.

4

Click on the Self Generated Traffic tab and perform the following as required:

a. Configure DSCP values for the required SGT applications.
   1. Click on the DSCP Marking tab and select an application in the list, then click Properties. The Application DSCP Marking form opens.
   2. Configure the DSCP parameter.
   3. Save your changes and close the form.

b. Map DSCP names to forwarding classes.
   1. Click on the DSCP Mapping tab and select a DSCP name in the list, then click Properties. The Application DCSP Mapping form opens.
   2. Configure the Forwarding Class parameter.
   3. Save your changes and close the form.

c. Configure dot1p values for the required SGT applications.
   1. Click on the Dot1p Marking tab and select an application in the list, then click Properties. The Application Dot1p Marking form opens.
   2. Configure the Dot1p parameter.
   3. Save your changes and close the form.

5

Save your changes and close the forms.

END OF STEPS

79.14 To configure NTP on a VPRN site

Note: NTP must be enabled on the base router before it can be configured on a VPRN site. See 15.34 “To configure NTP on supported devices” (p. 490) for information about configuring NTP on the 7705 SAR and 7750 SR.

79.14.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites icon, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Set the NTP State parameter to Enabled.

5

Click on the NTP tab and configure the required parameters.

6

To create an authentication key:

1. Click on the Authentication tab.
2. Click Create. The Network Time Protocol Authentication (New Instance) form opens.
3. Configure the required parameters.
4. Save the changes and close the form.

7

To configure an NTP broadcast source:

1. Click on the Broadcast tab.
2. Click Create. The NTP Broadcast (New Instance) form opens.
3. Select a source interface (NTP Broadcast).
4. Configure the required parameters.
5. Save the changes and close the form.

8

Save the changes and close the forms.

END OF STEPS

79.15 To configure PTP on a VPRN site

Note: PTP must be enabled on the base router before it can be configured on a VPRN site. See 15.21 “To configure the IEEE 1588 PTP clock on a 7210 SAS, 7250 IXR, 7450 ESS, or 7750 SR” (p. 478) for information about configuring PTP on the 7705 SAR and 7750 SR.

79.15.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Set the PTP State parameter to Enabled.

5

Click on the PTP tab and configure the required general parameters.

6

To create PTP peers:

1. Click on the Peers tab.
2. Click Create. The IEEE 1588 PTP Peer (Create) form opens.
3. Configure the required parameters.
4. Save the changes and close the form.

7

Save the changes and close the forms.

END OF STEPS

79.16 To configure GTP on a VPRN site

Note: GTP must be enabled on the base router before it can be configured on a VPRN site; 27.14 “To configure GTP on a routing instance” (p. 853).

79.16.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Set the Enable GTP Uplink parameter to Enabled.

5

Click on the GTP tab to configure S11 and uplink interfaces.

6

Click on the On the S11 tab to configure S11 interfaces and peer profile mappings:

1. On the Interfaces tab, click Create. The S11 Interface (Create) form opens.
2. Select an interface and an APN policy.
3. Save the changes and close the form.
4. Click on the Peer Profile Mapping tab and click Create. The S11 Peer Profile Mapping (Create) form opens.
5. Configure the Address Prefix and Prefix Length parameters.
6. Select a Peer Profile.
7. Save the changes and close the form.

7

Click on the On the Uplink tab to configure an uplink interface and peer profile mappings:

1. On the General tab, configure the APN Network Identifier and PDN Type parameters.
2. Click on the Peer Profile Mapping tab and click Create. The Uplink Peer Profile Mapping (Create) form opens.
3. Configure the Address Prefix and Prefix Length parameters.
4. Select a Peer Profile.
5. Save the changes and close the form.

8

Save the changes and close the forms.

END OF STEPS

79.17 To configure an SNMP community on a VPRN site

79.17.1 Purpose

If the VPRN site is to support IPv6 addressing (for router advertisement or neighbor discovery) or VRRP objects, perform the following procedure to configure an SNMP community for mediating the IPv6 objects. You can configure multiple read-only and read-write SNMP communities on a VPRN site for virtual CPE management.

When the NFM-P uses SNMPv2 for device mediation, you must configure one and only one SNMP community string for the VPRN site. Otherwise, there is no mediation of the VPRN IPv6 objects on the site, and the NFM-P raises an alarm. The alarm is cleared and mediation resumes after the configuration is modified so that exactly one SNMP community string is associated with the VPRN site. The SNMP community must be set before an ISIS site can be added to the VPRN.

You can associate a list of IP addresses with an SNMP community. Only addresses that appear on the list have permission to use the associated SNMP community. Creating and configuring the list is performed using CLI; see the appropriate node documentation for more information about using SNMP community configuration commands.

79.17.2 Source access lists

You can use SNMP source access lists configured on the NE when configuring an SNMP community on a VPRN service. You can add SNMP source access lists to a VPRN site SNMP community string. Source access control lists cannot be configured through SNMP. They need to be configured on the NE using the CLI. You cannot modify or delete SNMP source access lists in the NFM-P.

79.17.3 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites icon, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Configure the SNMP community:

1. Click on the SNMP Community tab.
2. Click Create. The SNMP Community (Create) form opens.
3. Configure the SNMP Community String parameter.

4. Configure the Read Only parameter to specify whether the community string of the VPRN is read-only or read-write for virtual CPE management.

   Note:

   You must also enable the Allow SNMP Access parameter on the VPRN routing instance. See Step 7 of 79.26 “To configure a routing instance on a VPRN site” (p. 2564) .

5. Select an SNMP source access list configured on the NE, if required.
6. Save your changes and close the form.

5

Save and close the forms.

END OF STEPS

79.18 To configure IGMP host tracking on a VPRN site

79.18.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites icon, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Click on the Multicast tab, then on the IGMP Host Tracking tab.

5

Configure the required parameters.

6

To clear host tracking info or host tracking statistics, click Clear.

7

Save the changes and close the forms.

END OF STEPS

79.19 To configure an override source IP address on a VPRN site

79.19.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites icon, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Click on the Source Addresses tab and click Create. The Source Address (Create) form opens.

5

Configure the Source IP Application parameter.

6

Set the Source Address Termination parameter to IP Address.

7

Configure the Source IP Address parameter. Enter a valid IP address that the VPRN virtual routing instance will identify.

Note: An IPv6 address option for the Source IP Address parameter is available when the IPv6 Allowed parameter is set during network interface creation.
You must select an IPv6 Source IP Address before you can select IPv6 Source IP Applications.

8

Save the changes and close the forms.

END OF STEPS

79.20 To configure unequal ECMP on a VPRN site

79.20.1 Purpose

Perform this procedure to apply a weighted ECMP distribution of flows for EVPN-IFL and EVPN-IFF routes.

79.20.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Click on the Segment Routing V6 tab, then on the BGP-EVPN tab.

5

Create or select an entry and click Properties. The SRv6 BGP EVPN (Create/Edit) form opens.

6

Configure the parameters in the EVPN Link Bandwidth panel, as required.

7

Save the changes and close the forms.

END OF STEPS

79.21 To enable routing protocols on a VPRN site

79.21.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Click on the Routing tab, then the Protocols tab.

5

Enable the required protocol parameters.

When you choose a protocol, the site and the protocols that are enabled on the site appear in the list panel.

Note: If both the OSPFv2 Enabled parameter and the OSPFv3 Enabled parameter are disabled, navigate to the Components view of the VPRN, right-click on Protocols, then select Create OSPF Site. The OSPF Site (Create) form opens. In the OSPF Instance panel, configure the Version parameter.

6

To configure multicast for the site, click on the Multicast tab and enable the required protocol parameters.

When you choose a protocol, the site and the protocols that are enabled on the site appear in the list panel.

7

Save and close the forms.

END OF STEPS

79.22 To configure ISIS, L2TP, MLD, OSPFv2, OSPFv3, PIM, RIP, or WPP on a VPRN routing instance

Note: To configure BGP on a VPRN routing instance, see 79.23 “To configure BGP on a VPRN routing instance” (p. 2557) .

To configure IGMP on a VPRN routing instance, see 79.24 “To configure IGMP on a VPRN routing instance” (p. 2560).

To configure MSDP on a VPRN routing instance, see 79.25 “To configure MSDP on a VPRN routing instance” (p. 2562).

79.22.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose the VPRN service on which you want to configure the protocols and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites→Routing Instance→Routing Instance→Routing Instance→Protocols.

4

Right-click on the Protocols icon and choose:

a. Create ISIS Site to configure ISIS on the VPRN routing instance, and see 28.60 “To configure IS-IS on a routing instance” (p. 953) .

b. Create L2TP Site to configure L2TP on the VPRN routing instance, and see 28.89 “To configure L2TP on a routing instance” (p. 989) .

c. Create OSPF Site to configure OSPFv2 on the VPRN routing instance, and configure the parameters as described in 28.72 “To configure OSPF on a default routing instance or a VRF routing instance” (p. 969) .

d. Create OSPF Site to configure OSPFv3 on the VPRN routing instance, and configure the parameters as described in 28.72 “To configure OSPF on a default routing instance or a VRF routing instance” (p. 969) .

e. Create RIP Site to configure RIP on the VPRN routing instance, and see 28.45 “To configure global-level RIP or RIPng” (p. 937) .

f. Create WPP Site to configure WPP on the VPRN routing instance, and see 28.134 “To create a web portal routing instance” (p. 1051) .

g. Create PIM Site to configure PIM on the VPRN routing instance, and see 28.99 “To create a PIM site on a VPRN routing instance” (p. 1003) .

h. Create MLD Site to configure MLD on the VPRN routing instance, and see 28.121 “To enable MLD on a base routing instance” (p. 1034) .

Note: You must ensure that the VPRN routing instance has an associated L3 access interface, and that the IPv6 Allowed parameter on the interface is enabled. You must add an IPv6 address to the L3 access interface. See 79.83 “To configure an L3 access interface on a VPRN site” (p. 2656) and 79.102 “To assign an IP address to a VPRN L3 access interface” (p. 2677) .

5

Save the changes and close the forms.

END OF STEPS

79.23 To configure BGP on a VPRN routing instance

79.23.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites→Routing Instance, right-click on the site on which you need to configure BGP and choose Properties. The VPRN Site (Edit) form opens.

4

Click on the Routing tab.

5

Enable the BGP Enabled parameter on the Protocols tab. A list of BGP routing instances appears.

6

Select a routing instance and click Properties. The BGP Site, routing instance (Create) form opens.

7

Configure the required parameters.

8

To assign a TCP key chain, select a TCP key chain in the KeyChain panel.

Note: You can assign a TCP key chain to a BGP site, group, or peer on a 7450 ESS in mixed mode, 7705 SAR, 7750 SR, or a 7950 XRS.

9

Configure the parameters in the Graceful Restart panel.

The graceful restart parameters are configurable when you enable the Graceful Restart parameter.

10

Configure the parameters in the MED panel.

These parameters are used to find a way to leave the AS when there are multiple methods of leaving the AS.

11

Configure the parameters in the MultiPath panel.

Set the Multi Path parameter to 1 to disable. When set from 2 to 16, multipath is enabled and BGP load shares traffic across the number of links specified. If the equal cost routes available are greater than the configured value, then routes with the lowest next hop IP address are chosen.

12

Configure the EIBGP Load Balance parameter in the EIBGP LoadBalance panel.

13

Configure the Backup Path parameter in the Backup Path panel.

14

Configure the parameters in the Best Path Selection panel.

When you set the MED Compare parameter to off, the Strict parameter is set to true and is not configurable. When you set the MED Compare parameter to on, the Strict parameter is set to false and is not configurable.

15

Click on the Behavior tab and configure the required parameters.

16

Configure the parameters in the Hold Time panel.

17

Configure the Fault Tolerance parameter in the Error Handling panel. The Fault Tolerance parameter allows BGP routers to be more tolerant of some Update message errors, use less disruptive error recovery mechanisms, and provide better operational and diagnostics information.

18

Configure the parameters in the Damp Peer Oscillations panel.

19

Click on the AS Properties tab and configure the Disable 4Byte ASN parameter.

20

Configure the parameters in the Local AS panel.

The No Prepend Global AS is configurable only if you set the Local AS parameter to a value other than 0.

The Local AS parameters are used to configure a virtual AS. A virtual AS is used when a router (RTA) is moved from one AS (AS1) to another AS (AS2). However, the customer router (CR1) is configured to belong to the AS1. To avoid reconfiguring CR1 to belong to AS2, CR1 can continue to belong to AS1, but RTA has its local AS value set to AS1. RTA can advertise AS1 for routes advertised to CR1.

21

Configure the parameters in the Remove Private AS panel.

22

Click on the VPN tab and configure the required parameters.

Note: The Apply Import Route Policies and Apply Export Route Policies parameters specify whether to apply the existing import and export route policies configured on the Import Policies and Export Policies tabs.

23

To add a group:

1. Click on the Groups tab.
2. Click Create. The Peer Group (Create) form opens.
3. Perform Step 3 to Step 23 of 28.32 “To configure peer-group-level BGP” (p. 922) .

24

To add a peer:

1. Click on the Peers tab.
2. Click Create. The Peer (Create) form opens.
3. Perform Step 3 to Step 19 of 28.33 “To configure peer-level BGP” (p. 927) .

25

Click on the Next-Hop Resolution tab and configure the Policy parameter.

Configure the parameters in the Use Leaked Routes panel.

26

Click on the Import Policies tab and configure the required parameters.

Configure the import route policies to determine which routes are accepted from peers. These policies should match the policies you configure using the Routing Policy Manager, as described in Chapter 27, “NE routing and forwarding” . The router does not validate to ensure that the policies match.

27

Click on the Export Policies tab and configure the required parameters.

Configure the export route policies to determine which routes are advertised to peers. These policies should match the policies you configure using the Routing Policy Manager, as described in Chapter 27, “NE routing and forwarding” . The router does not validate to ensure that the policies match.

28

Click on the RIB Management tab to assign leak import and export policies:

1. On the IPv4 Leak Import Policies, IPv6 Leak Import Policies, Label IPv4 Leak Import Policies, and Label IPv6 Leak Import Policies tabs, assign up to 15 leak import policies to the BGP site as required.
2. Click on the IPv4 Leak Export Policies tab and assign up to 15 leak export policies to the BGP site.
3. Click on the Route Table Import tab and configure the required parameters.

29

To configure interface instance, perform the following steps:

1. Click on the Dynamic Peer Interfaces tab.
2. Create or select an entry and click Properties. The Dynamic Peer Interface (Create/Edit) form opens.
3. Configure the required parameters in General tab.
4. Click on the AS Allowed Ranges tab and configure the Minimum and Maximum values.

   Note:

   Upto 32 AS Allowed Range can be configured.
5. Save the changes and close the form.

30

Click on the Authentication tab and configure the required parameters.

31

Save the changes and close the forms.

END OF STEPS

79.24 To configure IGMP on a VPRN routing instance

Note: PIM-SSM for IPv6 is not supported in VPRN services.

79.24.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites→Routing Instance→Routing Instance→Routing Instance→Protocols, right-click on Protocols and choose Create IGMP Site. The IGMP Site (Edit) form opens.

4

Configure the required general parameters.

5

To configure SSM:

1. Click on the SSM Translation tab.
2. Click Create to create a new entry. The SSM Translation (Create) form opens.
3. Configure the required parameters.
4. Save the changes and close the form.

6

To add an interface:

1. Click on the Interfaces tab.
2. Click Create. The IGMP Interface (Create) form open.
3. Select an interface and configure the required parameters.
4. Save the changes and close the form.

7

To identify an IGMP group interface for a VPRN service:

1. Click on the Group Interfaces tab
2. Click Create. The IGMP Group Interface (Create) form opens.
3. Configure the required parameters.
4. Select an IGMP group interface in the IGMP Group Interface panel and configure the required parameters.

5. To configure behavior, click on the Behavior tab, select an import policy and configure the required parameters.
6. To configure multicast CAC, click on the Multicast CAC tab, select a multicast CAC policy and configure the required parameters.
7. Save the changes and close the form.

8

Save the changes and close the forms.

END OF STEPS

79.25 To configure MSDP on a VPRN routing instance

79.25.1 MSDP on VPRN Service object

You can configure MSDP on the VPRN Service object. The configuration forms are identical to those used to configure MSDP on the routing instance, and the behavior of the VPRN MSPD is the same as that of the base router MDSP.

Note: You can enable and configure MSDP without PIM. However, you need to configure PIM before MSDP can be operationally up. At a minimum, you need to configure the PIM Candidate BootStrap Router and Candidate Rendezvous Point (C-RP) on a pair of NEs. The MSDP peer is the C-RP Address parameter. See 28.99 “To create a PIM site on a VPRN routing instance” (p. 1003) for details.

79.25.2 Before you begin

Before you configure MSDP on a VPRN routing instance, you need to enable MSDP:

1. On the service navigation tree, expand VPRN Site→Routing Instance→Routing Instance *name*, right-click on Routing Instance *name* and choose Properties. The VPRN Site (Edit) form opens.
2. Click on the Multicast tab, and select the MSDP Enabled parameter.
3. Save your changes and close the form.

79.25.3 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand VPRN Site→Routing Instance - NE System ID→Routing Instance→Routing Instance *VPRNinstance*→Protocols, right-click on Protocols and choose Create MSDP Site. The MSDP Site (Create) form opens.

4

Configure the required parameters in the General panel.

5

Configure the parameters in the Receive Message Rate Parameters panel.

6

Configure the State parameter.

7

Configure an MSDP peer group.

1. Click on the Group tab and then click Create. The MSDP Peer Group (Create) form opens.
2. Configure the required parameters on the General tab.
3. Click on the Import Policies and configure the import route policies to determine which routes are accepted from peers.

   The policies need to match the policies that you set when configuring the Routing Policy Manager. The router performs no validation to ensure that the policies match.
4. Click on the Export Policies tab and configure the export route policies to determine which routes are advertised to peers.

   The policies need to match the policies that you set when configuring the Routing Policy Manager. The router performs no validation to ensure that the policies match.
5. Save the changes and close the form.

You can also configure an MSDP peer group separately, after you completed the configuration of the MSDP site. On the service navigation tree, expand VPRN Site→Routing Instance - NE System ID→Routing Instance→Routing Instance *VPRNinstance*→Protocols→MSDP, right-click on MSDP and choose Create MSDP Peer Group. The MSDP Peer Group (Create) form opens.

8

Configure an MSDP peer.

1. Click on the Peer tab and then click Create. The MSDP Peer (Create) form opens.
2. Configure the required parameters on the General tab.
3. Click on the Import Policies and configure the import route policies to determine which routes are accepted from peers.

   The policies need to match the policies that you set when configuring the Routing Policy Manager. The router performs no validation to ensure that the policies match.

4. Click on the Export Policies tab and configure the export route policies to determine which routes are advertised to peers.

   The policies need to match the policies that you set when configuring the Routing Policy Manager. The router performs no validation to ensure that the policies match.
5. Click on the Authentication tab and configure the required parameters.
6. Save the changes and close the form.

You can also configure an MSDP peer separately, after you completed the configuration of the MSDP site. On the service navigation tree, expand VPRN Site→Routing Instance - NE System ID→Routing Instance→Routing Instance *VPRNinstance*→Protocols→MSDP, right-click on MSDP and choose Create MSDP Peer. The MSDP Peer (Create) form opens.

9

Click on the Source tab to create an MSDP multicast source.

1. Click Create. The MSDP Source (Create) form opens.
2. Configure the required parameters.
3. Save the changes and close the form.

10

Click on the following tabs to review MSDP Site information, as required:

- Data Source Active
- Data Source Active Rejected
- Statistics
- Faults

11

Save the changes and close the form.

END OF STEPS

79.26 To configure a routing instance on a VPRN site

Note: The tabs and parameters that are configurable vary depending on the NE.

79.26.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites icon, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Click on the Routing tab.

5

Configure the required parameters.

You cannot configure the Carrier Carrier VPN parameter on a VPRN site if interfaces are configured on the site.

When you set the Route Distinguisher Type parameter to Type 0, the following configurable parameters appear:

- Type 0 Administrative Value
- Type 0 Assigned Value

You can click on Suggest Value to let the NFM-P assign these values. Choose Generate Unique RD from the drop-down menu.

The Type 0 Administrative Value parameter is the Autonomous System (AS) number of the PE node. For the Type 0 Assigned Value parameter, the NFM-P assigns the next unused number within the valid range. When all of the numbers within the valid range have been used once, the system starts at the beginning of the range and assigns the next available number.

When you set the Route Distinguisher Type parameter to Type 1, the following configurable parameters appear:

- Type 1 IP Address
- Type 1 Assigned Value

When you set the Route Distinguisher Type parameter to Type 2, the following configurable parameters appear:

- Type 2 Administrative Value
- Type 2 Assigned Value

If you enabled the Enable RT/RD Auto Assignment parameter when you created the VPRN service, the NFM-P automatically configures the Route Distinguisher parameter with the values in the VPRN RT/RD Auto Assignment policy. See 79.51 “To configure a policy to reserve an RT and RD range for VPRN services” (p. 2616) for information about how to create a VPRN RT/RD Auto Assignment range policy.

6

To configure importing of leaked GRT routes, add routing policies in the GRT Import Policies sub-tab.

7

To specify whether SNMP requests are allowed using the VPRN interface, configure the Allow SNMP Access parameter.

8

Configure the parameters in the GRT panel.

9

Configure the Enforce Maximum Number Of Routes parameter in the Maximum Number Of Routes panel.

Note: When you select the Enforce Maximum Number Of Routes parameter, the following parameters are configurable:

- Maximum Number Of Routes
- Log Only
- Threshold (%)

10

Configure the Enforce Maximum Number Of IPv6 Routes parameter in the Maximum Number Of IPv6 Routes panel.

Note: When you select the Enforce Maximum Number Of IPv6 Routes parameter, the following parameters are configurable:

- Maximum Number Of IPv6 Routes
- Log Only
- Threshold (%)

11

Configure the Enable Backup BGP-VPN Routes parameter in the Backup BGP-VPN Routes panel.

12

Configure the parameters in the D-Path panel.

13

Configure the Single SFM Overload Admin State parameter in the Single SFM Overload panel.

The Hold-Off Time (seconds) parameter is configurable when the Single SFM Overload Admin State parameter is set to Up.

14

Configure the parameters in the Static Route Hold-Down Time panel.

The Initial Hold-Down Time, Hold-Down Time Multiplier, and Maximum Hold-Down Time parameters are configurable when you enable the Enable Hold-Down Time parameter.

15

Configure the IPv4 Max Size and IPv6 Max Size parameters in the Embedded Flowspec panel, as required.

16

Configure the Enforce Maximum Number Of Multicast Routes parameter in the Maximum Number Of Multicast Routes panel.

Note: When you enable the Enforce Maximum Number Of Multicast Routes parameter, the following configurable parameters appear:

- Maximum Number Of Multicast Routes
- Log Only
- Threshold (%)

17

To configure ingress multicast forwarding:

1. Click on the Mcast Path Mgmt tab.
2. Select an ingress info policy.

   Note:

   The Mcast Path Mgmt Channels tab displays data on the operational channels after actual traffic from a specific multicast source for a specific multicast group passes through the virtual router. You must click Search to refresh the data. See Chapter 49, “Policies overview” for a listing of the displayed operational channel parameters.

18

Save and close the forms.

END OF STEPS

79.27 To configure a VRF instance on a VPRN site

79.27.1 Purpose

Route targets are used to identify the VRFs of a VPRN. A PE router that is not a route reflector or an AS border router installs a VPRN route only when its import target matches the target of the route.

A fully-meshed VPRN requires one target for all participating VRFs. A hub-and-spoke VPRN requires VRF import and export targets. The export target of the hub VRF must be the same as the import target of the spoke VRFs. The import target of the hub VRF must be the same as the export target of the spoke VRF. VPRN VRF targets must not overlap.

79.27.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites icon, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Click on the VRF Target tab and configure the VRF Target Type parameter.

Set the VRF Target Type parameter to Define Default if you need to specify a default VRF target for the site. Otherwise, go to Step 6 .

5

To specify a two-byte AS number for the default target, set the Target Format parameter to AS and configure the required parameters.

a. You can click Suggest Value to let the NFM-P assign these values. Choose Generate Unique VRF Target from the drop-down menu.

   The Target AS Value parameter is the Autonomous System number of the PE NE. For the Target Extended Community Value parameter, the NFM-P assigns the next unused number within the valid range. When all of the numbers within the valid range have been used once, the system starts at the beginning of the range and assigns the next available number.

b. To specify an IP Address for the default target, set the Target Format parameter to IP Address and configure the required parameters.

c. To specify a four-byte AS number for the default target, set the Target Format parameter to AS-4Byte Address and configure the required parameters.

   You can click Suggest Value to let the NFM-P assign these values. Choose Generate Unique VRF Target from the drop-down menu.

   The Target AS Value (4Byte) is the Autonomous System number of the PE NE. For the Target Community Value parameter, the NFM-P assigns the next unused number within the valid range. When all of the numbers within the valid range have been used once, the system starts at the beginning of the range and assigns the next available number.

6

Set the VRF Target Type parameter to Define Import and Export if you need to specify import and export VRF targets for the service site.

7

To specify no VRF import target format for the site, set the Import Target Format parameter to None and go to Step 10 . Otherwise, go to Step 8 .

8

To specify a two-byte import target format for the site, set the Import Target Format parameter to AS and configure the required parameters. Otherwise, go to Step 9 .

You can click on the Suggest Value button to let the NFM-P assign these values. Choose Generate Unique VRF Target from the drop-down menu.

The Import Target AS Value parameter is the two-byte Autonomous System number of the PE node. For the Import Target Extended Community Value, the NFM-P assigns the next unused number within the valid range. When all of the numbers within the valid range have been used once, the system starts at the beginning of the range and assigns the next available number.

9

To specify an IP Address as the import target, set the Import Target Format parameter to IP Address and configure the required parameters. Otherwise, go to Step 11 .

10

To specify a four-byte AS number for the import target format, set the Import Target Format parameter to AS-4Byte Address and configure the required parameters.

You can click on the Suggest Value button to let the NFM-P assign these values. Choose Generate Unique VRF Target from the drop-down menu.

The Import Target AS Value (4Byte) is the four-byte Autonomous System number of the PE node. For the Import Target Community Value parameter, the NFM-P assigns the next unused number within the valid range. When all of the numbers within the valid range have been used once, the system starts at the beginning of the range and assigns the next available number.

11

To specify no VRF export target format for the site, set the Export Target Format parameter to None and go to Step 15 . Otherwise, go to Step 12 .

12

To specify a two-byte export target format for the site, set the Export Target Format parameter to AS and configure the required parameters. Otherwise, go to Step 13 .

You can click on the Suggest Value button to let the NFM-P assign these values. Choose Generate Unique VRF Target from the drop-down menu.

The Export Target AS Value parameter is the two-byte Autonomous System number of the PE node. For the Export Target Extended Community Value, the NFM-P assigns the next unused number within the valid range. When all of the numbers within the valid range have been used once, the system starts at the beginning of the range and assigns the next available number.

13

To specify an IP Address as the export target, set the Export Target Format parameter to IP Address and configure the required parameters. Otherwise, go to Step 14 .

14

To specify a four-byte AS number for the export target format, set the Export Target Format parameter to AS-4Byte Address and configure the required parameters.

You can click on the Suggest Value button to let the NFM-P assign these values. Choose Generate Unique VRF Target from the drop-down menu.

The Export Target AS Value (4Byte) is the four-byte Autonomous System number of the PE node. For the Import Target Community Value parameter, the NFM-P assigns the next unused number within the valid range. When all of the numbers within the valid range have been used once, the system starts at the beginning of the range and assigns the next available number.

15

Save and close the forms.

END OF STEPS

79.28 To configure an MVPN VRF instance on a VPRN site

79.28.1 Before you begin

For 7750 SR, 7450 ESS, and 7950 XRS NEs starting in Release 16.0 R1, PIM must be enabled before MVPN can be configured; see 79.21 “To enable routing protocols on a VPRN site” (p. 2554). If PIM is disabled, MVPN configuration is removed.

79.28.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites icon, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

If the site you are configuring is a 7210 SAS-R, you must configure the device properties. See 12.55 “To configure 7210 SAS-R device properties for MVPN” (p. 386).

4

Click on the Multicast tab, the MVPN tab, then the Routing tab.

5

Configure the MVPN VRF Target Type parameter:

Note: Route targets are used to identify the VRFs of a VPRN. A PE router that is not a route reflector or an AS border router installs a VPRN route only when its import target matches the target of the route.
A fully-meshed VPRN requires one target for all participating VRFs. A hub-and-spoke VPRN requires VRF import and export targets. The export target of the hub VRF must be the same as the import target of the spoke VRFs. The import target of the hub VRF must be the same as the export target of the spoke VRF. VPRN VRF targets must not overlap.

a. If you do not need to specify a VRF target for the site, set the MVPN VRF Target Type parameter to None. Go to Step 9 .

b. If you need to specify a default VRF target for the site, set the MVPN VRF Target Type. Go to Step 6 .

c. If you need to specify import and export VRF targets for the service site, set the MVPN VRF Target Type parameter to Define Import and Export. Go to Step 7 .

6

Configure the Target Format parameter by performing one of the following steps:

a. To specify a two-byte AS number for the default target:
   1. Configure the required parameters.
      - Target AS Value
      - Target Extended Community Value

      The Target AS Value is the Autonomous System number of the PE node. For the Target Extended Community Value, the NFM-P assigns the next unused number within the valid range. When all of the numbers within the valid range have been used once, the system starts at the beginning of the range and assigns the next available number.
   2. Go to Step 11 .

b. To specify an IP Address for the default target:
   1. Configure the required parameters.
      - Target IP Address
      - Target Community Value
   2. Go to Step 11 .

c. To specify a four-byte AS number for the default target:
   1. Configure the required parameters.
      - Target AS Value (4Byte)
      - Target Community Value

      The Target AS Value (4Byte) is the Autonomous System number of the PE node. For the Target Community Value, the NFM-P assigns the next unused number within the valid range. When all of the numbers within the valid range have been used once, the system starts at the beginning of the range and assigns the next available number.
   2. Go to Step 11 .

7

Configure the Import Target Format parameter by performing one of the following steps:

a. Choose None to specify no VRF import target format for the site, then go to Step 8 .

b. Choose AS as the two-byte import target format for the site.

1. Configure the required parameters.
   - Import Target AS Value
   - Import Target Extended Community Value

   The Import Target AS Value is the two-byte Autonomous System number of the PE node. For the Import Target Extended Community Value, the NFM-P assigns the next unused number within the valid range. When all of the numbers within the valid range have been used once, the system starts at the beginning of the range and assigns the next available number.
2. Go to Step 8 .

c. Choose IP Address as the import target format for the site.

1. Configure the required parameters.
   - Import Target IP Address
   - Import Target Community Value
2. Go to Step 8 .

d. Choose AS-4Byte as the four-byte import target format for the site.

1. Configure the required parameters.
   - Import Target AS Value (4Byte)
   - Import Target Community Value

   The Import Target AS Value (4Byte) is the four-byte Autonomous System number of the PE node. For the Import Target Community Value, the NFM-P assigns the next unused number within the valid range. When all of the numbers within the valid range have been used once, the system starts at the beginning of the range and assigns the next available number.
2. Go to Step 8 .

8

Configure the Export Target Format parameter by performing one of the following steps:

a. Choose None to specify no VRF export target format for the site, then go to Step 9 .

b. Choose AS as the two-byte export target format for the site.

1. Configure the required parameters.
   - Export Target AS Value
   - Export Target Extended Community Value

   The Export Target AS Value parameter is the two-byte Autonomous System number of the PE node. For the Export Target Extended Community Value, the NFM-P assigns the next unused number within the valid range. When all of the numbers within the valid range have been used once, the system starts at the beginning of the range and assigns the next available number.

2. Go to Step 9 .

c. Choose IP Address as the export target format for the site.

1. Configure the required parameters.
   - Export Target IP Address
   - Export Target Community Value
2. Go to Step 9 .

d. Choose AS-4Byte as the four-byte export target format for the site.

1. Configure the required parameters.
   - Export Target AS Value (4Byte)
   - Export Target Community Value

   The Export Target AS Value (4Byte) parameter is the four-byte Autonomous System number of the PE node. For the Export Target Community Value, the NFM-P assigns the next unused number within the valid range. When all of the numbers within the valid range have been used once, the system starts at the beginning of the range and assigns the next available number.
2. Go to Step 9 .

9

To configure import policies:

1. Click on the Import Policies tab and set the Import Unicast parameter to False.
2. Select the required unicast import policies 1 through 15. You can use the Select button to choose a single policy, or click on the Create Expression button to use a logical expression, as described in 28.36 “To create a BGP policy expression” (p. 931).

10

To configure export policies:

1. Click on the Export Policies tab and set the Export Unicast parameter to False.
2. Select the required unicast export policies 1 through 15. You can use the Select button to choose a single policy, or click on the Create Expression button to use a logical expression, as described in 28.36 “To create a BGP policy expression” (p. 931).

11

Save and close the forms.

END OF STEPS

79.29 To configure a BGP confederation on a VPRN site

79.29.1 Purpose

A BGP confederation allows for the full distribution of external routing information within an AS.

You can configure BGP confederations only when:

- no VRF import or export policies are configured on the VPRN site
- no VRF target is configured on the VPRN site
- no VPRN GRT lookup or export policies are configured on the VPRN site

You cannot configure VRF import or export policies, VRF target, or GRT lookup or export policies when a BGP confederation is configured.

79.29.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites icon, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Click on the Routing tab, then on the General tab.

5

Configure the Confederation Autonomous System parameter. When you set the Confederation Autonomous System to a value other than 0, the BGP Confederations tab appears.

6

To configure one or more BGP confederations members:

1. Click on the BGP Confederations tab and click Create. The Confederation (Create) form opens.
2. Click on the Members tab and click Create. The Confederation Member (Create) form opens.
3. Configure the Member AS parameter.
4. Save the changes and close the forms.

7

Save the changes and close the forms.

END OF STEPS

79.30 To configure a GSMP group on a VPRN site

79.30.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites icon, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Click on the Multicast tab, then on the GSMP tab.

5

Click Create. The GSMP Group (Create) form opens.

6

Configure the required parameters.

7

To configure ANCP, configure the parameters in the ANCP panel.

8

To configure one or more GSMP group neighbours:

1. Click on the GSMP Group Neighbor tab and click Create. The GSMP (Create) form opens.
2. Configure the required parameters.

   The Priority Dscp parameter is configurable when you set the Priority Type to Dscp.

   The Priority Precedence parameter is configurable when you set the Priority Type to Precedence.
3. Save the changes and close the form.

9

Save the changes and close the forms.

END OF STEPS

79.31 To configure a GNE site and GNE service interface on a VPRN service

79.31.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, right-click on VPRN Service and choose Create GNE Site.

4

Select a site.

5

Configure the required parameters.

6

Click Apply.

7

To configure an interface for the GNE site:

1. Click on the GNE Service Interfaces tab and click Create. The GNE Service Interface (Create) form opens.
2. Configure the required parameters.
3. Click on the Ports tab and select a Generic NE Interface.
4. Configure the required parameters.
5. Save the changes and close the form.

8

Save the changes and close the forms.

END OF STEPS

79.32 To configure a RADIUS proxy server on a VPRN site

79.32.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites icon, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Click on the RADIUS/DHCP/Diameter tab, then on the RADIUS tab.

5

On the RADIUS Proxy Servers tab, click Create or select a RADIUS proxy server and click Properties. The RADIUS Proxy Server (Create|Edit).

6

Configure the parameters as required.

7

Select a Python Policy, if required.

If you intend to configure a WLAN GW group with a distributed Python policy in Step 8, the Python policy you select in this step must be the same Python policy that is distributed to the WLAN GW group.

8

Click Select in the WLAN GW panel to assign a ISA-WLAN GW Group, if required.

9

Configure default RADIUS policies:

Perform the following steps:

1. Select a RADIUS authentication policy.
2. Select a RADIUS accounting policy.

   Note:

   If you configure a ISA-WLAN GW group in Step 8, the default RADIUS policies must be a ISA RADIUS policy.

10

Click on the Caching tab and configure the parameters as required.

11

Click on the Interfaces tab and click Create or select an existing network Interface and click Properties. The RADIUS Proxy Interface form opens.

Perform the following steps:

1. Click Select and choose an interface from the Select Interface form.
2. Select an interface and click OK. The RADIUS Proxy Server (Create|Edit) form reappears.

12

Click on the Attribute Matching/Users tab to configure RADIUS attribute matching type and matching entries for RADIUS policies.

Perform the following steps:

1. On the Type tab, configure the Type and Vendor ID parameters.
2. Click on the Entry tab.
3. Click Create to create a new RADIUS attribute matching entry, or select an existing entry in the list and click Properties. The Attribute Matching Entry form appears.
4. Configure the Entry ID, Prefix Match String, and Suffix Match String parameters as required.
5. Select a RADIUS authentication policy and a RADIUS accounting policy.
6. Save your changes and close the form.

13

Save the changes and close the forms.

END OF STEPS

79.33 To configure a local DHCPv4 server on a VPRN site

79.33.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites icon, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Click on the RADIUS/DHCP/Diameter tab, then on the Local DHCP Servers tab.

5

On the DHCPv4 tab, click Create or select a server and click Properties. The Local DHCP Server, Site (Create|Edit).

6

Configure the required general parameters.

7

Configure the required parameters in the Client Pool panel.

8

Select a local user database in the Local User Database panel.

9

To configure DHCP failover support:

1. Click on the Failover tab.
2. Configure the Administrative State parameter.
3. Configure the parameters in the Client Lead Time panel.
4. Configure the parameters in the Startup Wait Time panel.
5. Configure the parameters in the Partner Down Delay panel.
6. To configure a failover DHCP server peer, click on the Peer tab.
7. Click Create. The Failover Peer, Site (Create) form opens.
8. Select a failover MC peer site.

9. Configure the Sync Tag parameter. The Sync Tag setting must be the same on both failover servers.
10. To configure node redundancy for the failover peer, click Node Redundancy. The Manage Node Redundancy form opens, pre-configured for MC peer groups.
11. Select an MC peer group, or click Create to configure a new MC peer group. See 40.4 “To configure an MC peer group” (p. 1330) . The Node Redundancy button allows you to access the MC sync group configuration within the MC peer group in order to add failover peer sync tags.
12. Save the changes and close the forms.

10

To create a pool of one or more subnets on the local DHCP server:

1. Click on the IP Address Pools tab and click Create. The IP Address Pool form opens.
2. Configure the required general parameters.
3. Configure the parameters in the Minimum Lease Time panel.
4. Configure the parameters in the Maximum Lease Time panel.
5. Configure the parameters in the Offer Time panel.
6. Configure the parameters in the Pool Notifications (Minimum Free) panel.
7. Save the changes and close the form.

11

To add a subnet to the IP address pool:

1. Click on the Subnets tab click Create. The Subnet, Site (Create) form opens.
2. Configure the required general parameters.
3. Configure the required parameters in the Pool Notifications (Minimum Free) panel.
4. Click on the Address Ranges tab and click Create. The Subnet Address Range form opens.
5. Click Create. The Subnet Address Range, Site (Create) form opens.
6. Configure the parameters.

   You must exclude static IP addresses from the subnet address range because static IP addresses are dedicated.
7. Save the changes and close the form.
8. Click on the Options tab and click Create. The Subnet Option, Site (Create) form opens.
9. Configure the Option parameter and configure the required parameters.

   The Number parameter is configurable when the Option parameter is set to Custom Option.

   The Value parameter is configurable when the Type parameter is set to ASCII String or Hex String.

   The IP Address 1, IP Address 2, IP Address 3, and IP Address 4 parameters are configurable when the Type parameter is set to IP Address.
10. Save the changes and close the forms.

12

To configure IP address pool options, click on the Options tab and perform the following:

1. Click Create. The IP Address Pool Option, Site (Create) form opens
2. Configure the Option parameter and configure the required parameters.

   The Number parameter is configurable when the Option parameter is set to Custom Option.

   The Value parameter is configurable when the Type parameter is set to ASCII String or Hex String.

   The IP Address 1, IP Address 2, IP Address 3, and IP Address 4 parameters are configurable when the Type parameter is set to IP Address.
3. Save the changes and close the IP Address Pool Option and IP Address Pool forms.

13

To add a sticky lease to an IP address pool, perform the following:

1. Click on an IP address pool entry and click Create Sticky Lease. The Sticky Lease Action (Create) form opens.
2. Configure the required parameters.

   The Host Name parameter value must be unique. The MAC Address can be duplicated across multiple sticky lease objects, provided that each has a different corresponding Circuit ID value. Similarly, the Circuit ID value can be duplicated across multiple sticky lease objects, provided that each has a different corresponding MAC Address.

14

Save the changes and close the forms.

END OF STEPS

79.34 To configure a local DHCPv6 server on a VPRN site

Note: The tabs and parameters that are configurable vary depending on the NE.

79.34.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites icon, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Click on the RADIUS/DHCP/Diameter tab, then on the Local DHCP Servers tab.

5

On the DHCPv6 tab, click Create or select a server and click Properties. The Local DHCPv6 Server, Site (Create|Edit).

6

Configure the required general parameters.

7

Configure the required parameters in the Client Pool panel.

8

Configure the required parameters in the Lease Hold Time panel.

9

Configure the required parameters in the DHCP Unique Identifier (DUID) panel.

10

To configure DHCPv6 failover support:

1. Click on the Failover tab.
2. Configure the Administrative State parameter.
3. Configure the parameters in the Client Lead Time panel.
4. Configure the parameters in the Startup Wait Time panel.
5. Configure the parameters in the Partner Down Delay panel.
6. To configure a failover DHCPv6 server peer, click on the Peer tab.
7. Click Create. The Failover Peer, Site (Create) form opens.
8. Select a failover MC peer site.
9. Configure the Sync Tag parameter. The Sync Tag setting must be the same on both failover servers.
10. To configure node redundancy for the failover peer, click Node Redundancy. The Manage Node Redundancy form opens, pre-configured for MC peer groups.
11. Select an MC peer group, or click Create to configure a new MC peer group. See 40.4 “To configure an MC peer group” (p. 1330) . The Node Redundancy button allows you to access the MC sync group configuration within the MC peer group in order to add failover peer sync tags.

12. Save the changes and close the forms.

11

To configure an IPv6 address pool:

1. Click on the IPv6 Address Pools tab click Create. The IPv6 Address Pool, Site (Create) form opens.
2. Configure the required general parameters.

12

To configure IPv6 address pool failover:

1. Click on the Failover tab, then the General tab.
2. Configure the Administrative State parameter.
3. Configure the parameters in the Client Lead Time panel.
4. Configure the parameters in the Startup Wait Time panel.
5. Configure the parameters in the Partner Down Delay panel.

13

To configure IPv6 address pool failover peer:

1. To configure a failover peer, click on the Peer tab.
2. Click Create. The Failover Peer, Site (Create) form opens.
3. Select a failover MC peer site.
4. Configure the Sync Tag parameter. The Sync Tag setting must be the same on both failover servers.
5. To configure node redundancy for the failover peer, click Node Redundancy. The Manage Node Redundancy form opens, pre-configured for MC peer groups.
6. Select an MC peer group, or click Create to configure a new MC peer group. See 40.4 “To configure an MC peer group” (p. 1330) . The Node Redundancy button allows you to access the MC sync group configuration within the MC peer group in order to add failover peer sync tags.
7. Save the changes and close the form.

14

To add prefixes to the IP address pool:

1. Click on the Prefixes tab.
2. Click Create. The Prefix, Site (Create) form opens.
3. Configure the required general parameters.
4. Configure the parameters in the Preferred Life Time panel.
5. Configure the parameters in the Valid Life Time panel.

6. Configure the parameters in the Renew Timer panel.
7. Configure the parameters in the Rebind Timer panel.
8. Click on the Options tab.
9. Click Create. The Prefix Option, Site (Create) form opens.
10. Configure the Option parameter and configure the required parameters.

    The Number parameter is configurable when the Option parameter is set to Custom Option.

    The Value parameter is configurable when the Type parameter is set to ASCII String, Hex String, or Domain.

    The IP Address 1, IP Address 2, IP Address 3, and IP Address 4 parameters are configurable when the Type parameter is set to IP Address.
11. Save your changes and close the form.
12. Click on the Minimum Free Thresholds tab.
13. Click Create or select an existing minimum free threshold entry and click Properties. The Prefix Minimum Free Threshold (Create|Edit) form opens.
14. Configure the required parameters:

    The Minimum Threshold and Minimum Number parameters are mutually exclusive. They cannot both be configured at the same time.
15. Save your changes and close the forms.

15

To configure IPv6 address pool options:

1. Click on the Options tab.
2. Click Create. The IP Address Pool Option, Site (Create) form opens.
3. Configure the Option parameter and configure the required parameters.

    The Number parameter is configurable when the Option parameter is set to Custom Option.

    The Value parameter is configurable when the Type parameter is set to ASCII String, Hex String, or Domain.

    The IP Address 1, IP Address 2, IP Address 3, and IP Address 4 parameters are configurable when the Type parameter is set to IP Address.
4. Save the changes and close the form.

16

To configure IPv6 address pool minimum free thresholds:

1. Click on the Minimum Free Thresholds tab.
2. Click Create or select an existing minimum free threshold entry and click Properties. The Address Pool Minimum Free Threshold (Create|Edit) form opens.
3. Configure the required parameters.
4. Save your changes and close the form.

17

Save the changes and close the forms.

END OF STEPS

79.35 To clear DHCP leases from a VPRN site local DHCP server

79.35.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites icon, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

Click on the RADIUS/DHCP/Diameter tab, then on the Local DHCP Servers tab.

5

On the DHCPv4 tab, select a server and click Properties. The Local DHCP Server, Site (Edit) form opens.

6

Click on the Leases tab.

7

Click on the Regular tab to clear DHCP leases, and then do the following:

1. Select the DHCP lease you want to clear and click Clear DHCP Lease.
2. If you want to clear all of the leases on the local DHCPv4 server, click Clear All DHCP Leases.

8

Click on the Sticky tab to clear sticky leases, and then do the following:

1. Select the sticky lease you want to clear and click Clear Sticky Lease.
2. If you want to clear all sticky leases with a specific host name prefix, click Clear Sticky Lease With Host Name Prefix.

3. Specify a host name prefix and click Ok.

9

Confirm the deletion(s) and close the forms.

END OF STEPS

79.36 To configure TCP MSS adjustment on a VPRN site

Note: Perform this procedure to specify an ISA-BB group and a maximum segment size on a VPRN site that is to be part of a TCP MSS adjustment configuration. For more information, see 27.1.15 “TCP MSS adjustment for PPPoE sessions” (p. 822) and 27.1.16 “Workflow to configure TCP MSS adjustment” (p. 823).

79.36.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand the Sites icon, right-click on a routing instance and choose Properties. The VPRN Site (Edit) form opens.

4

On the General tab, select an ISA-BB group and configure the TCP Maximum Segment Size parameter.

5

Save your changes and close the forms.

END OF STEPS

79.37 To configure a group interface on a VPRN

79.37.1 Prerequisites

The 7450 ESS in mixed mode, 7750 SR supports the configuration of a group interface in a VPRN.

79.37.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites→Routing Instance→Subscriber Interfaces, right-click on a subscriber interface and choose Create VPRN Group Interface, or expand the subscriber interface, right-click on a group interface and choose Properties. The VPRN Group Interface (Create|Edit) form opens.

4

Configure the required general parameters.

The LNS parameter defines the type of group interface (regular or LNS). This parameter is set at creation time and cannot be modified. Regular group interfaces cannot configure LNS attributes and an LNS group interface does not allow PPPoE configuration or SAPs.

The Unicast RPF configuration is intended to enhance security for a MAC-only anti-spoofing configuration on the WLAN GW for soft GRE group interfaces; see 79.66 “To configure a WLAN GW for a VPRN group interface” (p. 2631) .

5

To configure cflowd sampling:

1. Click Create in the Cflowd Sampling panel. The Cflowd Sampling (Create) form opens.
2. Configure the required parameters and click Apply. The Cflowd sampling object appears in the Cflowd Sampling panel.
3. Save your changes.

6

Select a redundant interface.

7

Select a diameter application policy.

8

Select a diameter authentication policy.

9

Configure the required parameters in the IPv4/IPv6 panel. To configure IPv6:

1. Enable the IPv6 Allowed parameter and configure the required parameters.
2. Click on the IPv6 Advertisement tab and configure the required parameters.

   If the No Default Router check box is enabled, the Router Lifetime parameter is not configurable.
3. Configure the parameters in the Prefix Options panel.

   If the either of the Infinite check boxes is enabled, the associated parameter is set to its maximum value.
4. Configure the parameters in the DNS Options panel.

   If the Infinite check box is enabled, the RDNSS Lifetime parameter is set to -1.

10

To configure IPv6 router solicitation on the group interface:

1. Ensure the IPv6 Allowed parameter is enabled on the General tab.
2. Click on the IPv6 Router Solicit tab.
3. Configure the Administrative State parameter.
4. Select a local user database.
5. Configure the parameters in the Minimum Authentication Time panel.
6. Configure the parameters in the Inactivity Timer panel.

   If you enable the Infinite check box, the Inactivity Timer parameters are disabled.

11

To configure DHCPv6 on the group interface:

1. Ensure the IPv6 Allowed parameter is enabled on the General tab.
2. Click on the DHCPv6 tab and configure the required parameters.

   The Interface ID String parameter is configurable only if the Interface ID Option parameter is set to String.

   If the PD Managed Route parameter is enabled, the PD Managed Route Next Hop parameter is configurable.
3. Select a local user database.
4. Select a python policy.
5. Select a DHCPv6 filter.
6. Click on the Proxy Server tab and configure the required parameters.

   The ID Type and Value parameters are configurable only if the Server ID Type parameter is set to Enterprise.
7. Click on the Relay tab and configure the required parameters.

8. Configure the Server 1 through Server 8 parameters.
9. Select the interface name for each DHCPv6 server in the Zone Index panel.

   If you have entered a Unicast address, then the Interface Name parameter is not required.

12

To configure WPP on the group interface:

1. Ensure the Enable WPP parameter is enabled on the General tab.
2. Click on the WPP tab.
3. Configure the Administrative State parameter.
4. Select a WPP site in the WPP Site panel.
5. Configure the Portal Name parameter.
6. Select an Initial Subscriber Profile.
7. Select an Initial SLA Profile.
8. Select an Initial Application Profile.
9. Configure the Restore Default Profile On Disconnection parameter.
10. Select a Local User DB.
11. Configure the Enable Triggered Hosts parameter.
12. Disable the Default check box and configure the Lease Time (Days, Hours, Minutes, and Seconds) parameters, if required.

13

To configure anti-spoofing:

1. Click on the Anti-Spoofing tab.
2. Configure the ARP Populate parameter.

14

To configure subscriber management:

1. Click on the Subscriber Management tab.
2. Configure the required parameters.

   The parameters on the SHCV panel are configurable when the SHCV Enabled parameter is configured.
3. On the Subscriber Host Connectivity Verification panel, select an IPv4/IPv6 policy, IPv4 policy, and IPv6 policy, as required.

15

To configure ICMP for the group interface:

1. Click on the ICMP tab.

2. Configure the required parameters.

16

To configure ARP for the group interface:

1. Click on the ARP tab.
2. Configure the Timeout (seconds) parameter.
3. Click on the Proxy ARP tab.
4. Configure the required parameters.

17

To configure IPv4 DHCP relay for the group interface:

1. Click on the DHCP tab.
2. Configure the required general parameters.

   When the Relay Unicast Message parameter is set to Renew or Release Update Source IP, the GI address parameter can be configured as any local configured address in the same routing instance as the GI address for the DHCP relayed messages. If the Relay Unicast Message parameter is set to None, the GI address is restricted to the IP address configured on the subscriber interface.
3. Select a subscriber authentication policy in the Subscriber Authentication panel.
4. Select a local user database in the Local User Database panel.
5. Select a filter policy in the DHCP Filter panel.
6. Click on the Server tab and configure the required parameters.

   The Number of Days, Number of Hours, Number of Minutes, Number of Seconds, and Lease Time Override parameters are configurable only when the Lease Time parameter is set to Specified Time Period.
7. Click on the Client Applications tab and configure the Client Applications parameter.

18

To configure IPoE sessions for the group interface:

1. Click on the IPoE Session tab.
2. Configure the required parameters.

   The Stateless Redundancy parameter is configurable only on a regular (not soft GRE) group interface.

   Certain conditions and restrictions apply to an IPoE session on a soft GRE group interface:
   - RADIUS Session Timeout is set to Backwards Compatible by default
   - The IPoE session policy is set to a default policy (with SAP MAC address as key); cannot be changed
   - SAP Session Limit is set to 131071; cannot be changed
   - Administrative Sate is set to Enabled; cannot be changed.

3. Select an IPoE session policy.
4. Select a local user database.

19

To configure neighbor discovery on the group interface:

Neighbor discovery is configurable when the IPv6 Allowed parameter is enabled on the group interface.

1. Click on the Neighbor Discovery tab.
2. Configure the Maximum Number of Neighbors Learned and Duplicate Address Detection parameters.

20

To configure PPP for the group interface:

1. Click on the PPP tab.
2. Configure the Description and Administrative State parameters in the PPPoE panel.
3. Select a PPPoE policy in the PPPoE panel.
4. Select a PPPoE Local User DB in the PPPoE panel.
5. Select a python policy in the PPPoE panel.
6. Configure the required parameters in the PPPoE panel.
7. Configure the Description and Administrative State parameters in the PPP panel.
8. Select a PPP policy in the PPP panel.
9. Select a PPP Local User DB in the PPP panel.
10. Configure the Session Limit parameter in the PPP panel.

21

To configure IPoE linkage for the group interface:

1. Click on the IPoE Linkage tab.
2. Configure the required parameters.

22

To configure the ARP host for the group interface:

1. Click on the ARP Host Configuration tab.
2. Configure the required parameters.

23

To configure local address assignment for the group interface:

1. Click on the Local Address Assignment tab.

2. Configure the required parameters.
3. In the IPv4 Options panel, configure the PPP-v4 parameter and select a local DHCP server.
4. In the IPv6 Options panel, configure the IPoE SLAAC, IPoE WAN, and PPP SLAAC parameters and select a local DHCPv6 server.

24

To configure GTP for the group interface:

1. Ensure the Specific Type parameter is set to GTP on the General tab.
2. Click on the GTP tab.
3. Configure the Administrative State parameter.
4. Select a forward path extension.

25

To configure BRG for the group interface:

1. Click on the BRG Configuration tab.
2. Configure the Administrative State parameter.
3. Select a default BRG profile.
4. Enable the Authenticate BRG Only parameter, if only authenticated BRGs are permitted on the group interface.

26

To configure LNS for the group interface:

After you create an LNS group interface, you must configure the L2TP tunnel group profile or tunnel profile to terminate sessions for the LNS group interface that you just created; see 28.89 “To configure L2TP on a routing instance” (p. 989) . You can also configure the termination of sessions on a group interface using a RADIUS server.

1. Ensure that the LNS parameter is enabled on the General tab.
2. Click on the LNS tab.
3. Configure the Description parameter.
4. Select a subscriber profile in the Default Subscriber Profile panel.
5. Select an SLA profile in the Default SLA Profile panel.
6. Select a subscriber identification policy in the Subscriber Identification Policy panel.
7. Select an application profile in the Default Application Profile panel.
8. Configure the Default Subscriber Identification String parameter.

27

To configure SRRP for the group interface:

1. Click on the SRRP tab.

2. Configure the parameters in the Routing panel.
3. Click Create in the SRRP Instance panel. The SRRP Instance (Create) form opens.
4. Configure the required parameters in the SRRP Instance Information panel.
5. Select an operational group in the Operational Group panel.
6. Configure the Priority Step parameter.
7. Click on the Behavior tab.
8. Configure the required general parameters.
9. Select the SAP you need to use for the in-band messaging between the sites in the Message Path panel.
10. Select a policy pointer in the Policy Pointer 1 and Policy Pointer 2 panels.
11. Save the changes and close the form.

28

Save the changes and close the forms.

END OF STEPS

79.38 To create a bonding group interface on a VPRN

79.38.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites→Routing Instance→Subscriber Interfaces, right-click on a subscriber interface and choose Create VPRN Group Interface. The VPRN Group Interface (Create) form opens.

4

Configure the Name and Description parameters.

5

Select a redundant interface.

6

Select a diameter application policy.

7

Select a diameter authentication policy.

8

To configure bonding for the group interface:

1. Click on the Bonding tab.
2. On the General tab, configure the required parameters.
3. Select an FPE with subscriber management extensions enabled.
4. Click on the Connections tab.
5. Click Create. The Bonding Connection Object (Create) form opens.
6. Configure the required parameters, setting the Connection ID parameter to 1.
7. Save you changes and close the form.
8. Create a second bonding connection object, setting the Connection ID parameter to 2.

9

On the VPRN Group Interface, General tab set the Specific Type parameter to Bonding.

10

Save your changes and close the forms.

END OF STEPS

79.39 To configure a SAP on a VPRN group interface

79.39.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites→Routing Instance→Subscriber Interfaces→*subscriber_interface*, right-click on a group interface and choose Properties. The VPRN Group Interface (Edit) form opens.

4

Click on the Service Access Points tab.

5

Click Create. The VPRN Service Access Point (Create) form opens.

6

Configure the required general parameters.

7

Select a host lockout policy in the Host Lockout panel.

8

Configure a port:

1. Click on the Port tab.
2. Select a port for the L3 access interface from the Select Terminating Port form.

   Note:

   The form lists only ports in access or hybrid mode. To choose a port that is not listed, you must set the Mode parameter for the port to Access or Hybrid. After you do this, the port is listed when you click Search.
3. Configure the required parameters.

   The Auto-Assign ID parameter is configurable if the port uses dot1q encapsulation. When the parameter is enabled, the NFM-P automatically configures the Outer Encapsulation Value parameter using the lowest unassigned value.

   You can set the Auto-Assign ID parameter to be the default parameter for dot1q encapsulation by enabling the Access Interface Encap Value (Dot1q only) parameter on the User Preferences form. Choose Application→ User Preferences from the main menu.

   The Inner Encapsulation Value is configurable only when the port is an Ethernet or frame relay port with QinQ encapsulation.

   The Outer Encapsulation Value (VPI) and Inner Encapsulation Value (VCI) parameters are configurable only for ATM ports.

9

To assign ingress and egress QoS policies to the SAP:

Items such as policies, schedulers, and filters can be applied later to multiple service components at once. Choose and right-click the components in the service navigation tree, choose Properties, and configure the parameters on the appropriate tab.

1. Click on the QoS tab.
2. Configure the required parameters.

   The Ingress Match QinQ Dot1P and Egress Mark QinQ Top Bits Only parameters are configurable only when the encapsulation type of the port is BCP dot1q, dot1q, or QinQ.
3. Select a policy in the Ingress Policy and Egress policy panels.

   Note:

If you select an ingress or egress policy which has a forwarding class mapped to an ingress or egress queue group, you must ensure that the port you selected in Step 8 has the access ingress or egress queue group with the same name created on it.

See 16.24 “To configure Ethernet ports” (p. 599) for more information about how to configure Ethernet ports. See Chapter 49, “Policies overview” for more information about queue group template policies.

4. Select an HS secondary shaper in the HS Overrides panel, if required.

10

To specify that an aggregation scheduler policy is not applied to the interface:

1. Set the Aggregation parameter to Off.

   Note:

   The Aggregation parameter is not configurable if the port you selected in Step 8 is an HSMDA port.

2. Configure the required parameters.

   The Aggregate Rate Limit (kbps), Frame-Based Accounting, and Limit Unused Bandwidth parameters are configurable only when there is no scheduler specified in the Egress Scheduler panel.

   The Frame-Based Accounting parameter is not configurable if the port you selected is an HSMDA port.

   You cannot specify an egress scheduler when the Aggregate Rate Limit (kbps) parameter is set to a value greater than zero.

3. Select an ingress scheduler in the Ingress Scheduler panel.
4. Select an ingress policer control policy in the Ingress Policer Control Policy panel.
5. If the port you selected in Step 8 is an HSMDA port, save the changes and close the forms.
6. Select an egress scheduler in the Egress Scheduler panel.
7. Select an egress policer control policy in the Egress Policer Control Policy panel.

11

To specify that an aggregation scheduler policy is applied to the interface:

1. Set the Aggregation parameter to On.

   Note:

   You cannot specify an access scheduler policy if the port you selected in Step 8 is an HSMDA port.

2. Select an aggregation scheduler in the Aggregation Scheduler panel.

12

To assign ingress and egress ACL filters to the SAP:

1. Click on the ACL tab.

2. Select an ingress ACL filter in the Ingress Filter panel.
3. Select an egress ACL filter in the Egress Filter panel.

13

To assign an accounting policy to the SAP:

1. Click on the Accounting tab.
2. Configure the Collect Accounting Statistics parameter.
3. Select an accounting policy.

14

To assign a virtual port to the SAP:

1. Click on the Virtual Port Name tab.
2. Configure the required parameters.

15

To configure anti-spoofing for the SAP, click on the Anti-Spoofing tab. Configure the Anti-Spoofing parameter and static hosts, as described in 74.24 “To create a static host for residential subscriber management on a SAP” (p. 2045) .

16

To assign a DoS protection policy or DDoS protection policy to the SAP:

Note: A default DoS protection policy is automatically assigned to the SAP.

1. Click on the Security tab.
2. Select a DoS protection policy in the NE DoS Protection panel.
3. Select an NE DDoS protection policy.
4. Configure the required parameters.

17

To define the levels of the ETH-CFM PDUs that are discarded on ingress into the SAP or to configure LMM or ETH-LMM frame loss measurement statistics collection:

1. Click on the OAM tab, then on the ETH-CFM tab.
2. Configure the parameters in the Squelch Ingress Level panel.

   Levels must be assigned contiguously from Level 0. If you select a level greater than 0, then all levels lower than the one you chose will automatically be selected.
3. Configure the required parameters in the LMM Session Stats Collection panel.

18

To configure residential subscriber management on the SAP:

1. Click on the Subscriber Management tab, then on the IGMP Host Tracking tab.
2. Select the import policy used to filter IGMP packets.
3. Configure the required parameters.
4. You can click on the Host Tracking Info tab to view a list of hosts that are being tracked on this service access point.
5. Click on the Profiles tab.
6. Configure the required general parameters.
7. Select a default subscriber profile, subscriber authentication policy, and default application profile in the Policies panel.
8. Configure the Profiled Traffic Only parameter in the Single Subscriber Configuration panel.
9. Select a non-subscriber subscriber profile for the SAP in the Non-Subscriber Traffic Subscriber Profile panel.
10. Select a non-subscriber traffic SLA profile for the SAP in the Non-Subscriber Traffic SLA Profile panel.
11. Select a non-subscriber traffic application profile for the SAP in the Non-Subscriber Traffic Application Profile panel.
12. To view active hosts for the subscriber instance, click on the Subscriber Hosts tab.

19

To configure a default host in cases where the associated DHCP filter policy is configured with the Bypass Host Creation action:

1. Click on the Default Hosts tab.
2. Depending on the required addressing format, click on either the IPv4 or IPv6 tab.
3. Click Create. The (IPv4|IPv6) Default Host (Create) form opens.
4. In the Default Host Configuration panel, Select an (IPv4|IPv6) address to associate with the subscriber interface SAP.

   The address must be one of the addresses on the subscriber interface that the SAP belongs to, and not another default host.
5. Configure the Next Hop (IPv4|IPv6) Address parameter.

   The next hop address can be duplicated on the same SAP, but not on another SAP default host on the same routing instance.
6. Save your changes and close the form.

   Default host configuration settings cannot be changed once the default host is created.

20

To assign an ANCP policy to the SAP:

1. Click on the ANCP Static Map tab.
2. Click Create. The ANCP Static Map (Create) form opens.
3. Configure the ANCP String parameter.
4. Select an ANCP policy in the ANCP Policy panel.
5. Save the changes and close the forms.

21

To configure ATM on the SAP:

1. Click on the ATM tab.
2. Configure the required parameters.
3. Select an ingress ATM policy in the Ingress ATM Policy panel.
4. Select an egress ATM policy in the Egress ATM Policy panel.

22

Save the changes and close the forms.

END OF STEPS

79.40 To configure LAG per-link hashing on a VPRN group interface SAP

79.40.1 Purpose

You can configure weighted per-link hashing on a SAP on a VPRN group interface if the terminating port has LAG per-link hashing enabled. The interface must be a LAG member.

79.40.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites→Routing Instance→Subscriber Interfaces→*subscriber_interface*→Service Access Points, right-click on a SAP and choose Properties. The VPRN Service Access Point (Edit) form opens.

4

Click on the LAG Per Link Hash tab.

5

Configure the Class and Weight parameters.

6

Save the changes and close the forms.

END OF STEPS

79.41 To add an IGMP interface to a VPRN

79.41.1 Prerequisites

Before an IGMP interface can be configured, the following prerequisites must be met:

- The VPRN routing instance must be configured for IGMP; see 79.24 “To configure IGMP on a VPRN routing instance” (p. 2560) .
- The VPRN routing instance must be configured with an L3 interface; see 79.83 “To configure an L3 access interface on a VPRN site” (p. 2656) .

79.41.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites→Routing Instance→Routing Instance→Routing Instance→Protocols→*IGMP instance*.

4

Right-click on the IGMP instance and choose Create IGMP Interface. The IGMP Interface, Routing Instance (Create) form opens.

5

Configure the required parameters.

6

To assign an L3 access interface to the IGMP interface:

1. Click Select in the Interface panel and choose a L3 access interface
2. Configure the required parameters.

7

Click on the Behavior tab and configure the required parameters.

8

To configure multicast CAC, click on the Multicast CAC tab, select a multicast CAC policy and configure the required parameters.

9

To add a static multicast group or source:

1. Click on the Static Group/Source tab.
2. Click Create. The Static Grp Src, Interface routing instance (Create) form opens.
3. Configure the required parameters.
4. Save the changes and close the form.

10

Save the changes and close the forms.

END OF STEPS

79.42 To add an IGMP group interface to a VPRN

79.42.1 Prerequisites

Before an IGMP group interface can be configured, the following prerequisites must be met:

- The VPRN routing instance must be configured for IGMP; see 79.24 “To configure IGMP on a VPRN routing instance” (p. 2560) .
- A VPRN group interface must be configured; see 79.37 “To configure a group interface on a VPRN” (p. 2586) .

79.42.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites→Routing Instance→Routing Instance→Routing Instance→Protocols→*IGMP instance*.

4

Configure the required parameters.

5

Right-click on the IGMP instance and choose Create IGMP Group Interface. The IGMP Group Interface, Routing Instance (Create) form opens.

6

To assign a VPRN group interface to the IGMP group interface:

1. Click Select in the Interface panel and choose a VPRN group interface.
2. Configure the required parameters.

7

Click on the Behavior tab and configure the required parameters.

8

To configure multicast CAC, click on the Multicast CAC tab, select a multicast CAC policy and configure the required parameters.

9

Save the changes and close the forms.

END OF STEPS

79.43 To add an IP mirror interface to a VPRN

79.43.1 Purpose

Perform this procedure to configure an IP mirror interface in a VPRN service. This is a spoke terminated interface used to receive mirrored packets from a remote source.

79.43.2 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites→Routing Instance, right-click on IP Mirror Interfaces and choose Create IP Mirror Interface. The IP Mirror Interface (Create) form opens.

4

Configure the required parameters.

The Name value for an IP mirror interface must be unique in VPRN site. There cannot be another L3 access interface, subscriber interface, or group interface with the same name on the VPRN site.

5

Save the changes and close the forms.

END OF STEPS

79.44 To configure a network interface on a VPRN site

Note: You cannot configure a network interface on a VPRN service if there are any pre-existing interfaces configured on the service. Once a network interface is configured on a VPRN service, no other interface types can be configured on the service.

79.44.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

Click on the Sites tab, choose a VPRN site, and click Properties. The VPRN Site (Edit) form opens.

4

Click on the Routing tab and configure the Carrier Carrier VPN parameter.

The Carrier Carrier VPN parameter is configurable only if there are no other interfaces configured on the site.

5

Close the form.

6

On the VPRN Service (Edit) form, click on the Interfaces tab, then on the Network Interfaces tab and click Create. The Network Interface (Create) form opens.

7

Configure the required general parameters.

8

Configure the parameters in the Unicast RPF panel.

9

Configure the parameters in the NTP panel.

10

To configure Cflowd sampling:

1. Click Create in the Cflowd Sampling panel. The Cflowd Sampling (Create) form opens.
2. Configure the required parameters and click Apply. The Cflowd sampling object appears in the Cflowd Sampling panel.
3. To associate a service template with the Cflowd sampling object, select the newly created Cflowd sampling object and click Properties. The Cflowd Sampling (Edit) form opens.
4. Save your changes.

11

Configure the port.

1. Click on the Port tab.
2. Choose a terminating port for the interface in the Terminating Port panel and configure the required parameters.

   Note:

   If the Loopback Enabled parameter is selected on the General tab, the Port port tab does not appear.

   If you Clear or change the port associated with an existing Network Interface, the Network Policy associated to the Network interface remains but all the redirect information is cleared. This includes the Egress Queue Group Template Policy and its Egress Queue Group Instance ID, as well as the Ingress Queue Group Template Policy and its Ingress Queue Group Instance ID. These will subsequently need to be reconfigured if required.

12

Click on the Policies tab to select the network policy, the queue group template policies for the ingress forwarding plane redirect and egress port redirect, and the ingress and egress IP and IPv6 ACL policies.

Network policies are used to determine QoS settings based on the packet DSCP bits on the ingress and egress of the network.

Only global Ingress Queue Group Template Policies that have already been defined can be chosen. Queue group template policies allow SAP or IP interface forwarding classes to be redirected from the typical queue mapping to a shared queue.

Only local Egress Queue Group Template Policies which have a Network Egress Queue Group Instance defined on the associated port can be chosen.

Note: If you select a network policy with a forwarding class mapped to a queue group queue ID, you must ensure that the mapping queue group queue ID is in the selected Queue Group Template Policy.
If you need to add or remove a Port Redirect Group (queue or policer) to or from any of the Ingress or Egress Forwarding Classes in the global copy of the Network Policy, you must first define or remove the queue or policer in the global copy of the Egress Queue Group Template Policy.
You must ensure that the port you selected has a network egress queue group with the same name as the Queue Group Template policy created on it.
If the Network Policy you selected has Port Redirect Groups on its Ingress or Egress Forwarding Classes, you must specify both an Ingress or Egress Queue Group Template Policy and Instance ID. The Port Redirect Groups must already be defined within the Ingress or Egress Queue Group Template Policy you select. The default policy does not contain any redirects.
Queue Group Template policies are not applicable to L3 interfaces associated with HSMDA ports.
See 16.24 “To configure Ethernet ports” (p. 599) for more information about how to configure Ethernet ports. See Chapter 49, “Policies overview” for more information about queue group template policies.

13

To assign a non-default DoS protection policy or DDoS protection policy to the interface, click on the Security tab and select a DOS policy and NE DDos protection policy in the NE Protection panel.

14

To configure BFD for the interface, click on the BFD tab and configure the required parameters.

Note: You cannot configure BFD for the interface if BFD is disabled. See Chapter 28, “Routing protocol configuration” for information about enabling and disabling BFD for routing protocols.

15

To view local and remote session peers that are managed by the NFM-P, click on the BFD Session tab, choose a session and click Properties. View the following and close the form:

- BFD status
- protocol used
- local address
- remote address
- operational status and statistics

16

To configure ARP, click on the ARP tab and configure the Timeout (seconds) parameter.

1. Click Create to statically associate an IP or MAC address to the interface, and configure the required parameters.
2. Close the form.

17

Click on the Addresses tab to assign IP addresses to the interface:

1. Click Create. The IP Address, routing instance (Create) form opens.
2. Configure the required parameters.
3. Save the changes and close the form.

18

Click on the ICMP tab and configure the required ICMP parameters.

19

Save the changes and close the forms.

END OF STEPS

79.45 To add a PIM interface to a VPRN

79.45.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

On the service navigation tree, expand Sites→Routing Instance→Routing Instance→Routing Instance→Protocols→*PIM instance*, right-click on an instance and choose Create PIM Interface. The PIM Interface, Routing Instance (Create) form opens.

4

To assign an L3 access interface to the PIM interface:

1. Select an L3 access interface in the Interface panel.
2. Configure the required parameters.

5

Click on the Behavior tab and configure the required parameters.

The Sticky DR Priority parameter is configurable when the Sticky DR parameter is enabled.

6

To configure multicast CAC, click on the Multicast CAC tab, select a multicast CAC policy and configure the required parameters.

7

Save the changes and close the forms.

END OF STEPS

79.46 To implement dual homing using SRRP

79.46.1 Steps

1

Choose Manage→Service→Services from the NFM-P main menu. The Manage Services form opens.

2

Choose a VPRN service and click Properties. The VPRN Service (Edit) form opens.

3

Create the redundant interface used for SRRP out-of-band messaging between the two NEs:

Note: The two sites that participate in the dual homing configuration do not have to be part of the same service.

Ensure that the pair of sites each contains a properly configured subscriber interface and SAPs underneath the group interface that are participating in the redundant configuration.

Ensure that all subscriber interface IP addresses have a gateway address configured on them.

1. On the service navigation tree, click on the site to which you need to add the redundant pair; expand the entries for that site.
2. Right-click on Redundant Interfaces for one site of the redundant pair, and choose Create Redundant Interface. The Redundant Interface (Create) form opens.
3. Configure the required parameters.
4. Click on the Addresses tab.
5. Click Create. The IP Address (Create) form opens.
6. To specify IP addresses for the redundant interface on the current and remote sites, configure the required parameters.

   The remote IP address must be on the same subnet as the redundant interface IP address of the current site. For example, if the IP address of the current site is 7.7.7.7, with a prefix length of 24, then the redundant interface IP address of the remote site must be 7.7.7.d, where d is a value from 0 to 255, excluding 7.
7. Save the changes and close the forms.

4

Create an SDP spoke binding between the current and remote sites. The Source Interface is the Redundant Interface you created in Step 3 and the Tunnel Termination Site is the remote site. The Return Tunnel must come from the remote site. See 79.68 “To configure a VPRN spoke SDP binding” (p. 2635) for more information.

5
