Keyword to match routes belonging to the IPv4 unicast (unlabeled) address family.

label-ipv4

Keyword to match routes belonging to the IPv4 unicast (labeled) address family.

vpn-ipv4

Keyword to match routes belonging to the IPv4 VPN (SAFI 128) address family.

ipv6

Keyword to match routes belonging to the IPv6 unicast (unlabeled) address family.

label-ipv6

Keyword to match routes belonging to the IPv6 unicast (labeled) address family.

vpn-ipv6

Keyword to match routes belonging to the IPv6 VPN (SAFI 128) address family.

mcast-ipv4

Keyword to match routes belonging to the IPv4 multicast SAFI address family.

l2-vpn

Keyword to match routes belonging to the L2 VPN address family.

mvpn-ipv4

Keyword to match routes belonging to the IPv4 multicast VPN address family.

mvpn-ipv6

Keyword to match routes belonging to the IPv6 multicast VPN address family.

mdt-safi

Keyword to match routes belonging to the MDT SAFI address family.

ms-pw

Keyword to match routes belonging to the multi-segment pseudowire address family.

flow-ipv4

Keyword to match routes belonging to the IPv4 FlowSpec address family.

flow-ipv6

Keyword to match routes belonging to the IPv6 FlowSpec address family.

route-target

Keyword to match routes belonging to the address family for RT constrain routes.

mcast-vpn-ipv4

Keyword to match routes belonging to the IPv4 VPN multicast (SAFI 129) address family.

evpn

Keyword to match routes belonging to the EVPN address family.

bgp-ls

Keyword to advertise the BGP-LS address family to the associated BGP neighbors.

mcast-ipv6

Keyword to match routes belonging to the IPv6 multicast SAFI address family.

mcast-vpn-ipv6

Keyword to match routes belonging to the IPv6 multicast routes from a VPRN over the provider network. This family is only applicable in the base BGP routing context.

sr-policy-ipv4

Keyword to match routes belonging to the segment routing policy IPv4 address family (AFI1/SAFI73).

sr-policy-ipv6

Keyword to match routes belonging to the segment routing policy IPv6 address family (AFI2/SAFI73).

flow-vpn-ipv4

Keyword to match routes belonging to the FlowSpec-VPN IPv4 address family (AFI 1, SAFI 134).

flow-vpn-ipv6

Keyword to match routes belonging to the FlowSpec-VPN IPv6 address family (AFI 2, SAFI 134).

10.7 far-end

far-end

Syntax

far-end *ip-address* [**vc-id** *vc-id*] [{**ing-svc-label** *ingress-vc-label* | **tldp**}] [**icb**]

no far-end *ip-address*

Context

[Tree] (config>mirror>mirror-dest>remote-source far-end)

Full Context

configure mirror mirror-dest remote-source far-end

Description

This command is used on a destination router in a remote mirroring solution. See the description for the **remote-source** command for additional information.

When using L2TPv3, MPLS-TP or LDP IPv6 LSP SDPs in the remote mirroring solution, the destination node should be configured with **remote-src>spoke-sdp** entries. For all other types of SDPs, r**emote-source>far-end** entries are used.

Up to 50 far-end entries can be specified.

The **no** form of this command removes the IP address from the remote source configuration.

Parameters

ip-address

Specifies the service IP address (system IP address) of the remote device sending mirrored traffic to this mirror destination service. If 0.0.0.0 is specified, any remote is allowed to send to this service.

Values 1.0.0.1 to 223.255.255.254

vc-id

Specifies the virtual circuit identifier of the remote source. For mirror services, the *vc-id* defaults to the *service-id*. However, if the *vc-id* is being used by another service a unique vc-id is required to create an SDP binding. For this purpose the mirror service SDP bindings accepts *vc-ids*. This VC ID must match the VC ID used on the spoke SDP that is configured on the source router.

ingress-vc-label

Specifies the ingress service label for mirrored service traffic on the **far end** device for manually configured mirror service labels.

The defined *ing-svc-label* is entered into the ingress service label table which causes ingress packet with that service label to be handled by this mirror destination service.

The specified *ing-svc-label* must not have been used for any other service ID and must match the egress service label being used on the spoke SDP that is configured on the source router. It must be within the range specified for manually configured service labels defined on this router. It may be reused for other far end addresses on this *mirror-dest-service-id*.

Values 2048 to 18431

tldp

Specifies that the label is obtained through signaling via the LDP.

icb

Specifies that the remote source is an inter-chassis backup SDP binding.

no far-end *ip-address* | *ipv6-address*

Context

[Tree] (config>service>sdp far-end)

Full Context

configure service sdp far-end

Description

This command configures the system IP address of the far-end destination router for the service destination point (SDP) that is the termination point for a service.

The far-end IP address must be explicitly configured. The destination IP address must be that of an SR OS and for a GRE SDP it must match the system IP address of the far end router.

If the SDP uses GRE for the destination encapsulation, the IP address is checked against other GRE SDPs to verify uniqueness. If the IP address is not unique within the configured GRE SDPs, an error is generated and the IP address is not associated with the SDP. The local device may not know whether the IP address is actually a system IP interface address on the far-end device.

If the SDP uses MPLS encapsulation, the **far-end** address is used to check LSP names when added to the SDP. If the " **to** IP address" defined within the LSP configuration does not exactly match the SDP **far-end** address, the LSP will not be added to the SDP and an error will be generated. Alternatively, an SDP that uses MPLS can have an MPLS-TP node with an MPLS-TP node-id and (optionally) a global ID. In this case, the SDP must use an MPLS-TP LSP and the SDP **signaling** parameter must be set to **off**.

An SDP cannot be administratively enabled until a **far-end** *ip-address* or MPLS-TP node-id is defined. The SDP is operational when it is administratively enabled (**no shutdown**) and the **far-end** *ip-address* is contained in the IGP routing table as a host route. OSPF ABRs should not summarize host routes between areas. This can cause SDPs to become operationally down. Static host routes (direct and indirect) can be defined in the local device to alleviate this issue.

On a tunnel configured as SDP with delivery type of eth-gre-bridged, this command designates L2oGRE tunnel end points. This is the only configuration option allowed for this type of SDP.

The **no** form of this command removes the currently configured destination IP address for the SDP. The *ip-address* parameter is not specified and will generate an error if used in the **no far-end** command. The SDP must be administratively disabled using the **config service sdp shutdown** command before the **no far-end** command can be executed. Removing the far-end IP address will cause all *lsp-name* associations with the SDP to be removed.

Parameters

far-end

Specifies the far-end termination point for the GRE tunnel.

ip-address* | *ipv6-address

Specifies a IPv4 or IPv6 address of the far-end SR OS for the SDP in dotted decimal notation.

node-id

Specifies the MPLS-TP Node ID of the far-end system for the SDP, either in dotted decimal notation (a.b.c.d) or an unsigned 32-bit integer (1 to 4294967295). This parameter is mandatory for an SDP using an MPLS-TP LSP.

global-id

Specifies a MPLS-TP Global ID of the far-end system for the SDP, in an unsigned 32-bit integer (0 to 4294967295). This parameter is optional for an SDP using an MPLS-TP LSP. If not entered, a default value for the Global ID of '0' is used. A global ID of '0' indicates that the far-end node is in the same domain as the local node. The user must explicitly configure a Global ID if its value is non-zero.

configure service vpls sap igmp-snooping fast-leave

configure service vpls spoke-sdp igmp-snooping fast-leave

configure service vpls spoke-sdp mld-snooping fast-leave

configure service vpls mesh-sdp mld-snooping fast-leave

configure service vpls mesh-sdp igmp-snooping fast-leave

Description

This command enables fast leave.

When IGMP fast leave processing is enabled, the 7705 SAR Gen 2 immediately removes a SAP or SDP from the IP multicast group when it detects an IGMP leave message on that SAP or SDP. Fast leave processing allows the switch to remove a SAP or SDP that sends a leave message from the forwarding table without first sending out group-specific queries to the SAP or SDP, which speeds up the process of changing channels.

Fast leave should only be enabled when there is a single receiver present on the SAP or SDP.

When fast leave is enabled, the configured **last-member-query-interval** value is ignored.

Default

no fast-leave

Platforms

7705 SAR Gen 2

fast-leave

Syntax

[**no**] **fast-leave**

Context

[Tree] (config>service>pw-template>igmp-snooping fast-leave)

Full Context

configure service pw-template igmp-snooping fast-leave

Description

This command enables fast leave.

When IGMP fast leave processing is enabled, the 7705 SAR Gen 2 will immediately remove a SAP or SDP from the IP multicast group when it detects an IGMP **leave** on that SAP or SDP. Fast leave processing allows the switch to remove a SAP or SDP that sends a **leave** from the forwarding table without first sending out group-specific queries to the SAP or SDP, and thus speeds up the process of changing channels (zapping).

Fast leave should only be enabled when there is a single receiver present on the SAP or SDP.

When fast leave is enabled, the configured last-member-query-interval value is ignored.

Default

no fast-leave

Platforms

7705 SAR Gen 2

10.9 fast-reroute

fast-reroute

Syntax

fast-reroute [**backup-sr-tunnel**]

no fast-reroute

Context

[Tree] (config>router>ldp fast-reroute)

Full Context

configure router ldp fast-reroute

Description

This command enables LDP Fast-Reroute (FRR) procedures. When enabled, LDP uses both the primary next-hop and LFA next-hop, when available, for resolving the next-hop of an LDP FEC against the corresponding prefix in the routing table. This will result in LDP programming a primary NHLFE and a backup NHLFE into the forwarding engine for each next-hop of a FEC prefix for the purpose of forwarding packets over the LDP FEC.

When any of the following events occurs, LDP instructs in the fast path the forwarding engines to enable the backup NHLFE for each FEC next-hop impacted by this event:

- An LDP interface goes operationally down, or is admin shutdown.
- An LDP session to a peer went down as the result of the Hello or Keep-Alive timer expiring.
- The TCP connection used by a link LDP session to a peer went down, due say to next-hop tracking of the LDP transport address in RTM, which brings down the LDP session.
- A BFD session, enabled on a T-LDP session to a peer, times-out and as a result the link LDP session to the same peer and which uses the same TCP connection as the T-LDP session goes also down.
- A BFD session enabled on the LDP interface to a directly connected peer, times out and brings down the link LDP session to this peer.

The **tunnel-down-dump-time** option or the **label-withdrawal-delay** option, when enabled, does not cause the corresponding timer to be activated for a FEC as long as a backup NHLFE is still available.

Because LDP can detect the loss of a neighbor/next-hop independently, it is possible that it switches to the LFA next-hop while IGP is still using the primary next-hop. Also, when the interface for the previous primary next-hop is restored, IGP may re-converge before LDP completed the FEC exchange with it neighbor over that interface. This may cause LDP to de-program the LFA next-hop from the FEC and blackhole traffic. In order to avoid this situation, it is recommended to enable IGP-LDP synchronization on the LDP interface.

When the SPF computation determines there is more than one primary next-hop for a prefix, it will not program any LFA next-hop in RTM. Thus, the LDP FEC will resolve to the multiple primary next-hops that provide the required protection.

The **backup-sr-tunnel** option enables the use of SR tunnel, as a remote LFA or TI-LFA backup tunnel next-hop by an LDP FEC.

As a pre-requisite, the user must enable the stitching of LDP and SR in the LDP-to-SR direction. That is because the LSR must perform the stitching of the LDP ILM to SR tunnel when the primary LDP next-hop of the FEC fails. Thus LDP must listen to SR tunnels programmed by the IGP in TTM but the mapping server feature is not required.

Assuming the following:

- the **backup-sr-tunnel** option is enabled in LDP
- the {**loopfree-alternates remote-lfa**} and/or the {**loopfree-alternates ti-lfa**} option is enabled in the IGP instance
- LDP was able to resolve the primary next-hop of the LDP FEC in RTM

IGP SPF will run both the base LFA and the TI-LFA algorithms and if it does not find a backup next-hop for a prefix of an LDP FEC, it will also run the remote LFA algorithm. If IGP finds a TI-LFA or a remote LFA tunnel next-hop, LDP programs the primary next-hop of the FEC using a LDP NHLFE and programs the LFA backup next-hop using a LDP NHLFE pointing to the SR tunnel endpoint. Note that the LDP packet is not "tunneled" over the SR tunnel. The LDP label is actually stitched to the segment routing label stack. LDP points both the LDP ILM and the LTN to the backup LDP NHLFE which itself uses the SR tunnel endpoint.

The behavior of the feature is thus similar to the LDP-to-SR stitching feature, except the behavior is augmented to allow the stitching of an LDP ILM/LTN to a SR tunnel also when the primary LDP next-hop of the FEC fails.

If the LDP FEC primary next-hop failed and LDP has pre-programmed a remote LFA or TI-LFA next-hop with a LDP backup NHLFE pointing to SR tunnel, the LDP ILM/LTN switches to it. Note that if for some reason the failure impacted only the LDP tunnel primary next-hop but not the SR tunnel primary next-hop, the LDP backup NHLFE will effectively point to the primary next-hop of the SR tunnel and traffic of the LDP ILM/LTN will follow this path instead of the TI-LFA or remote LFA next-hop of the SR tunnel until the latter is activated.

This feature is limited to IPv4 /32 prefixes in both LDP and SR.

The **no** form of this command disables the use of SR tunnels as backups for LDP FECs and disables LDP FRR.

Default

no fast-reroute

Context

[Tree] (config>router>mpls>lsp fast-reroute)

[Tree] (config>router>mpls>lsp-template fast-reroute)

Full Context

configure router mpls lsp fast-reroute

configure router mpls lsp-template fast-reroute

Description

This command creates a pre-computed detour LSP from each node in the path of the LSP. In case of failure of a link or LSP between two nodes, traffic is immediately rerouted on the pre-computed detour LSP, thus avoiding packet-loss.

When **fast-reroute** is enabled, each node along the path of the LSP tries to establish a detour LSP as follows:

- Each upstream node sets up a detour LSP that avoids only the immediate downstream node, and merges back on to the actual path of the LSP as soon as possible.

  If it is not possible to set up a detour LSP that avoids the immediate downstream node, a detour can be set up to the downstream node on a different interface.

- The detour LSP may take one or more hops (see **config>router>mpls>lsp hop-limit**, **config>router>mpls>lsp>primary-p2mp-instance hop-limit**) before merging back on to the main LSP path.
- When the upstream node detects a downstream link or node failure, the ingress router switches traffic to a standby path if one was set up for the LSP.

Fast reroute is available only for the primary path. No configuration is required on the transit hops of the LSP. The ingress router will signal all intermediate routers using RSVP to set up their detours. TE must be enabled for fast-reroute to work.

If an LSP is configured with **fast-reroute** *frr-method* specified but does not enable CSPF, then global revertive will not be available for the LSP to recover.

The **no** form of the **fast-reroute** command removes the detour LSP from each node on the primary path. This command will also remove configuration information about the hop-limit and the bandwidth for the detour routes.

The **no** form of **fast-reroute hop-limit** command reverts to the default value.

Note:
A one-to-one detour backup LSP cannot be used at the PLR for ABR node protection. As a result, a PLR node does not signal a one-to-one detour LSP for ABR protection. In addition, the ABR node rejects a Path message that it has received from a third-party implementation configured with a detour object and a loose ERO next-hop. The Path message is rejected regardless of whether the **cspf-on-loose-hop** command is enabled on the node. When the router transits ABR for the detour path, the router rejects the signaling of an inter-area detour backup LSP.

Default

no fast-reroute — When fast-reroute is specified, the default fast-reroute method is one-to-one.

Parameters

frr-method

Configures the fast-reroute method.

Values **one-to-one** — In the one-to-one technique, a label switched path is established which intersects the original LSP somewhere downstream of the point of link or node failure. For each LSP which is backed up, a separate backup LSP is established.

Values **facility** — This option, sometimes called many-to-one, takes advantage of the MPLS label stack. Instead of creating a separate LSP for every backed-up LSP, a single LSP is created which serves to backup up a set of LSPs. This LSP tunnel is called a bypass tunnel.

The bypass tunnel must intersect the path of the original LSP(s) somewhere downstream of the point of local repair (PLR). Naturally, this constrains the set of LSPs being backed-up through that bypass tunnel to those that pass through a common downstream node. All LSPs which pass through the PLR and through this common node which do not also use the facilities involved in the bypass tunnel are candidates for this set of LSPs.

10.10 fc

fc

Syntax

fc *fc-name* **class-type** *ct-number*

no fc fc-name

Context

[Tree] (config>router>rsvp>diffserv-te fc)

Full Context

configure router rsvp diffserv-te fc

Description

This command maps one or more system forwarding classes to a Diff-Serv Class Type (CT). The default mapping is shown in Table 39: Forwarding Classes Mapping.

Table 39: Forwarding Classes Mapping

FC ID	FC Name	FC Designation	Class Type (CT)
7	Network Control	NC	7
6	High-1	H1	6
5	Expedited	EF	5
4	High-2	H2	4
3	Low-1	L1	3
2	Assured	AF	2
1	Low-2	L2	1
0	Best Effort	BE	0

The **no** form of this command reverts to the default mapping for the forwarding class name.

Parameters

class-type *ct-number*

The Diff-Serv Class Type number. One or more system forwarding classes can be mapped to a CT.

Values 0 to 7

Platforms

7705 SAR Gen 2

fc

Syntax

fc *fc-name*

no fc

Context

[Tree] (config>mirror>mirror-dest fc)

Full Context

configure mirror mirror-dest fc

Description

This command specifies a forwarding class for all mirrored packets transmitted to the destination SAP or SDP overriding the default (be) forwarding class. All packets are sent with the same class of service to minimize out-of-sequence issues. The mirrored packet does not inherit the forwarding class of the original packet.

When the destination is on a SAP, a single egress queue is created that pulls buffers from the buffer pool associated with the *fc-name*.

When the destination is on an SDP, the *fc-name* defines the DiffServ-based egress queue that is used to reach the destination. The *fc-name* also defines the encoded forwarding class of the encapsulation.

The FC configuration also affects how mirrored packets are treated at the ingress queuing point on the line cards. One ingress queue is used per mirror destination (service) and that is an expedited queue if the configured FC is expedited (one of nc, h1, ef or h2). The ingress mirror queues have no CIR, but a line-rate PIR.

The **no** form of this command reverts the mirror-dest service ID forwarding class to the default forwarding class.

Default

The best effort (be) forwarding class is associated with the mirror-dest service ID.

Parameters

fc-name

The name of the forwarding class with which to associate mirrored service traffic. The forwarding class name must already be defined within the system. If the *fc-name* does not exist, an error is returned and the **fc** command has no effect. If the *fc-name* does exist, the forwarding class associated with *fc-name* overrides the default forwarding class.

fc

Syntax

fc *fc-name* [**create**]

no fc *fc-name*

Context

[Tree] (config>qos>sap-ingress fc)

Full Context

configure qos sap-ingress fc

Description

The **fc** command creates a class or subclass instance of the forwarding class fc-name. When the *fc-name* is created, classification actions can be applied and the subclass can be used in match classification criteria. Attempting to use an undefined subclass in a classification command will result in an execution error and the command will fail.

The **no** form of this command removes all the explicit queue mappings for *fc-name* forwarding types. The queue mappings revert to the default queues for *fc-name*. To successfully remove a subclass, all associations with the subclass in the classification commands within the policy must first be removed or diverted to another forwarding class or subclass.

Parameters

fc-name

The parameter subclass-name is optional and must be defined using a dot separated notation with a preceding valid system-wide forwarding class name. Creating a subclass follows normal naming conventions. Up to sixteen ASCII characters may be used. If the same sub-name is used with two or more forwarding class names, each is considered a different instance of subclass. A subclass must always be specified with its preceding forwarding class name. When a forwarding class is created or specified without the optional subclass, the parent forwarding class is assumed.

Within the SAP ingress QoS policy, up to 56 subclasses may be created. Each of the 56 subclasses may be created within any of the eight parental forwarding classes. When the limit of 56 is reached, any further subclass creations will fail and the subclass will not exist.

Successfully creating a subclass places the CLI within the context of the subclass for further subclass parameter definitions. Within the subclass context, commands may be executed that define subclass priority (within the parent forwarding class queue mapping), subclass color aware profile settings, subclass in-profile and out-of-profile precedence or DSCP markings.

The *subclass-name* parameter is optional and used with the *fc-name* parameter to define a pre-existing subclass. The *fc-name* and *subclass-name* parameters must be separated by a period (.). If *subclass-name* does not exist in the context of *fc-name*, an error will occur. If *subclass-name* is removed using the **no fc** *fc-name.subclass-name* **force** command, the **default-fc** command will automatically drop the *subclass-name* and only use *fc-name* (the parent forwarding class for the subclass) as the forwarding class.

Values

fc: *class*[.*subclass*]

class: be, l2, af, l1, h2, ef, h1, nc

subclass: 29 characters max

create

Required parameter when creating a SAP QoS ingress policy forwarding class.

configure qos queue-group-templates egress queue-group fc

Description

The **fc** command is used to enter the forwarding class mapping context for the given fc-name. Each forwarding class has a default mapping depending on the egress queue group template. The system-created policer-output-queue template contains queues 1 and 2 by default with queue 1 being best-effort and queue 2 expedited. Forwarding classes be, l1, af and l2 all map to queue 1 by default. Forwarding classes h1, ef, h2 and nc all map to queue 2 by default. More queues may be created within the policer-output-queues template and the default forwarding classes may be changed to any defined queue within the template.

When all other user-defined egress queue group templates are created, only queue 1 (best-effort) exists and all forwarding classes are mapped to that queue. Other queues may be created and the forwarding classes may be changed to any defined queue within the template.

Besides the default mappings within the templates, the egress queue group template forwarding class queue mappings operate the same as the forwarding class mappings in a sap-egress QoS policy.

The template forwarding class mappings are the default mechanism for mapping egress policed traffic to a queue within an egress port queue group associated with the template. If a queue-id is explicitly specified in the QoS policy forwarding class policer mapping, and that queue exists within the queue group, the template forwarding class mapping is ignored.

Egress policed subscriber traffic works in a slightly different way. The subscriber and subscriber host support destination and organization strings are used to identify the egress port queue group. In this instance, the forwarding class mappings are always used and any queue overrides in the QoS policy are ignored. If neither string exists for the subscriber host, the egress queue group queue-id can be derived from either the QoS policy policer mapping or the template forwarding class queue mappings.

The **no** form of this command is used to return the specified forwarding class to its default template queue mapping.

Parameters

fc-name

A valid forwarding class must be specified as *fc-name* when the **fc** command is executed. When the **fc** *fc-name* command is successfully executed, the system will enter the specified forwarding class context where the **queue** *queue-id* command may be executed.

Values **be**, **l1**, **af**, **l2**, **h1**, **ef**, **h2**, **nc**

Full Context

configure service vpls fdb-table-size

configure service template vpls-template fdb-table-size

Description

This command specifies the maximum number of MAC entries in the forwarding database (FDB) for the VPLS instance on this node.

The **fdb-table-size** specifies the maximum number of forwarding database entries for both learned and static MAC addresses for the VPLS instance.

The **no** form of this command returns the maximum FDB table size to default.

Default

fdb-table-size 250

Parameters

table-size

Specifies the number of entries permitted in the forwarding database for this VPLS instance.

Values 7705 SAR Gen 2: 1 to 32767

Platforms

7705 SAR Gen 2

fdb-table-size

Syntax

fdb-table-size *table-size*

no fdb-table-size

Context

[Tree] (config>service>system fdb-table-size)

Full Context

configure service system fdb-table-size

Description

This command configures the maximum system FDB table size, which is dependent on the chassis type. CPMs with at least 16 GB of memory are required when exceeding 500k MAC addresses in a system. The table size cannot be reduced below its default value, which is also chassis-dependent.

The maximum system FDB table size also limits the maximum FDB table size of any card within the system.

The **no** version of this command sets the table size to its default.

The command default depends on the chassis type and available memory.

Parameters

table-size

Specifies the maximum system FDB table size.

Values 32767 to 32767

Platforms

7705 SAR Gen 2

10.14 fec-limit

fec-limit

Syntax

fec-limit *limit* [**log-only**] [**threshold** *percentage*]

no fec-limit

Context

[Tree] (config>router>ldp>session-params>peer fec-limit)

Full Context

configure router ldp session-parameters peer fec-limit

Description

This command configures a limit on the number of FECs which an LSR will accept from a given peer and add into the LDP label database. The limit applies to the aggregate count of all FEC types including service FEC. Once the limit is reached, any FEC received will be released back to the peer. This behavior is different from the per-peer import policy which will still accept the FEC into the label database but will not resolve it.

When the FEC limit for a peer is reached, the LSR performs the following actions:

1. Generates a trap and a syslog message.

2. Generates a LDP notification message with the LSR overload status TLV, for each LDP FEC type including service FEC, to this peer only if this peer advertised support for the LSR overload sub-TLV via the LSR Overload Protection Capability TLV at session initialization.
3. Releases, with LDP Status Code of "No_Label_Resources", any new FEC, including service FEC, from this peer which exceeds the limit.

If a legitimate FEC is released back to a peer, while the FEC limit was exceeded, the user must have a means to replay that FEC back to the router LSR once the condition clears. This is done automatically if the peer is an SR OS-based router and supports the LDP overload status TLV (SR OS 11.0R5 and higher). Third-party peer implementations must support the LDP overload status TLV or provide a manual command to replay the FEC.

The **threshold** option allows to set a threshold value when a trap and an syslog message are generated as a warning to the user in addition to when the limit is reached. The default value for the threshold when not configured is 90%.

The **log-only** option causes a trap and syslog message to be generated when reaching the threshold and limit. However, LDP labels are not released back to the peer.

If the user decreases the limit value such that it is lower than the current number of FECs accepted from the peer, the LDP LSR raises the trap for exceeding the limit. In addition, it will set overload for peers which signaled support for LDP overload protection capability TLV. However, no existing resolved FECs from the peer which does not support the overload protection capability TLV should be de-programmed or released.

A different trap is released when crossing the threshold in the upward direction, when reaching the FEC limit, and when crossing the threshold in the downward direction. However the same trap will not be generated more often than 2 minutes apart if the number of FECs oscillates around the threshold or the FEC limit.

Default

no fec-limit

Parameters

limit

Specifies the aggregate count of FECs of all types which can be accepted from this LDP peer.

log-only

Specifies that only a trap and syslog message are generated when reaching the threshold and limit. However, LDP labels are not released back to the peer.

percentage

Specifies the threshold value (as a percentage) that triggers a warning syslog message and trap to be sent.

fec-originate *ip-prefix/mask* [**advertised-label** *in-label*] **pop**

no fec-originate *ip-prefix/mask* **interface interface-name**

no fec-originate *ip-prefix/mask* **next-hop** *ip-address*

no fec-originate *ip-prefix/mask* **next-hop** *ip-address* **interface interface-name**

no fec-originate *ip-prefix/mask* **pop**

Context

[Tree] (config>router>ldp fec-originate)

Full Context

configure router ldp fec-originate

Description

This command defines a way to originate a FEC (with a swap action) for which the LSR is not egress, or to originate a FEC (with a pop action) for which the LSR is egress.

Parameters

ip-prefix/mask

Specifies information for the specified IP prefix and mask length.

Values

ipv4-prefix - a.b.c.d	
ipv4-prefix-le - [0..32]	
ipv6-prefix	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x - [0..FFFF]H
	d - [0..255]D
	ipv6-prefix-le - [0..128]

next-hop

Specifies the IP address of the next hop of the prefix.

advertised-label

Specifies the label advertised to the upstream peer. If not configured, then the label advertised should be from the label pool. If the configured static label is not available then the IP prefix is not advertised.

out-label

Specifies the LSR to swap the label. If configured, then the LSR should swap the label with the configured swap-label. If not configured, then the default action is pop if the next-hop parameter is not defined.

The next-hop, advertised-label, swap-label parameters are all optional. If next-hop is configured but no swap label specified, it will be a swap with label 3, such as, pop and forward to the next-hop. If the next-hop and swap-label are configured, then it is a regular swap. If no parameters are specified, a pop and route is performed.

Values 16 to 1048575

in-label

Specifies the number of labels to send to the peer associated with this FEC.

Values 32 to 1023

pop

Specifies to pop the label and transmit without the label.

interface *interface-name*

Specifies the name of the interface the label for the originated FEC is swapped to. For an unnumbered interface, this parameter is mandatory since there is no address for the next-hop. For a numbered interface, it is optional.

file

Syntax

file

Context

[Tree] (file)

Full Context

file

Description

Specifies the context to enter and perform file system operations. When entering the **file** context, the prompt changes to reflect the present working directory. Navigating the file system with the **cd ..** command results in a changed prompt.

The **exit all** command leaves the file system/file operation context and returns to the operational root CLI context. The state of the present working directory is maintained for the CLI session. Entering the **file** command returns the cursor to the working directory where the **exit** command was issued.

Platforms

7705 SAR Gen 2

10.21 file-id

file-id

Syntax

[**no**] **file-id** *file-id* [**name** *file-policy-name*]

Context

[Tree] (config>log file-id)

Full Context

configure log file-id

Description

This command creates the context to configure a file policy that is used as the destination for an event log or billing (accounting) file.

This command defines the file location and characteristics that are to be used as the destination for a log event message stream or accounting/billing information. The file defined in this context is subsequently specified in the **to** command under **log-id** or **accounting-policy** to direct specific logging or billing source streams to the file destination.

A file policy can only be assigned to either *one* **log-id** or *one* **accounting-policy**. It cannot be reused for multiple instances. A file policy and associated file definition must exist for each log and billing file that must be stored in the file system.

A file is created when the file policy defined in this command is selected as the destination type for a specific log or accounting record. Log files are collected in a "log" directory. Accounting files are collected in an "act" directory.

The file names for a log are created by the system as summarized in Table 40: Log File Names.

Table 40: Log File Names

File Type	File Name
Log File	log*llff-timestamp*
Accounting File	act*aaff-timestamp*

Where:

- *ll* is the *log-id*
- *aa* is the accounting *policy-id*
- *ff* is the file-id
- The *timestamp* is the actual timestamp when the file is created. The format for the timestamp is *yyyymmdd-hhmmss* where:
  - *yyyy* is the year (for example, 2006)
  - *mm* is the month number (for example, 12 for December)
  - *dd* is the day of the month (for example, 03 for the 3rd of the month)
  - *hh* is the hour of the day in 24 hour format (for example, 04 for 4 a.m.)
  - *mm* is the minutes (for example, 30 for 30 minutes past the hour)
  - *ss* is the number of seconds (for example, 14 for 14 seconds)
- The accounting file is compressed and has a gz extension.

When initialized, each file contains:

- The *log-id* description.
- The time the file was opened.
- The reason the file was created.
- If the event log file was closed properly, the sequence number of the last event stored on the log is recorded.

If the process of writing to a log file fails (for example, the compact flash card is full) and if a backup location is not specified or fails, the log file will not become operational even if the compact flash card is replaced. Enter either a **clear log** command or a **shutdown/no shutdown** command to reinitialize the file.

If the primary location fails (for example, the compact flash card fills up during the write process), a trap is sent and logging continues to the specified backup location. This can result in truncated files in different locations.

The **no** form of this command removes the file policy from the configuration. A file policy can only be removed from the configuration if the policy is not the designated output for a log destination. The actual log or accounting file remain on the file system when a file policy is deleted.

Parameters

file-id

The file identification number for the file policy, expressed as a decimal integer.

Values 1 to 99

name file-policy-name

Configures an optional file policy name, up to 64 characters, that can be used to refer to the file policy after it is created. If the name begins with a numerical digit (from 1 to 9), the name is a number from 1 to 99.

file-url

Syntax

file-url *file-url*

no file-url

Context

[Tree] (config>mirror>mirror-dest>pcap file-url)

Full Context

configure mirror mirror-dest pcap file-url

Description

This command specifies a file URL for the FTP or TFTP server, including the filename for packet capture transfer. After the file URL is entered, the system attempts to establish a connection and creates a file using the filename specified. The command prompt displays an error and rejects the file URL if the

session establishment fails, if write privilege to remote server fails, or if the session experiences a sudden termination. If the FTP or TFTP server is unreachable, the command prompt is halted for further input until the retires are timed out after 24 seconds (after four attempts of about six seconds each). This command overwrites any file on the FTP or TFTP server with the same filename.

The **no** form of this command removes the *file-url* instance and stops the packet capture and file transfer session.

Parameters

file-url

Specifies the URL for the file to direct the search.

Values [*local-url* | *remote-url*]

where:

- *local-url* — [*cflash-id/*] [*file-path*]
  180 chars max, including *cflash-id*

[Tree] (config>service>vprn>if>spoke-sdp>egress filter)

Full Context

configure service vprn network-interface egress filter

configure service vprn interface spoke-sdp ingress filter

configure service vprn interface spoke-sdp egress filter

Description

This command associates an IP filter policy with an ingress or egress Service Access Point (SAP) or IP interface. An IP filter policy can be associated with spoke SDPs. Filter policies control the forwarding and dropping of packets based on IP or MAC matching criteria.

The filter command is used to associate a filter policy with a specified ip-filter-id with an ingress or egress SAP. The ip-filter-id must already be defined before the filter command is executed. If the filter policy does not exist, the operation fails and an error message returned.

In general, filters applied to SAPs (ingress or egress) apply to all packets on the SAP. One exception is non-IP packets are not applied to IP match criteria, so the default action in the filter policy applies to these packets.

The **no** form of this command removes any configured filter ID association with the SAP or IP interface. The filter ID itself is not removed from the system unless the scope of the created filter is set to local. To avoid deletion of the filter ID and only break the association with the service object, use scope command within the filter definition to change the scope to local or global. The default scope of a filter is local.

Parameters

ip *ip-filter-id*

Specifies IP filter policy. The filter ID must already exist within the created IP filters.

Values 1 to 65535

Platforms

7705 SAR Gen 2

filter

Syntax

configure service vpls sap egress filter

configure service vpls spoke-sdp ingress filter

configure service vpls mesh-sdp ingress filter

configure service vpls mesh-sdp egress filter

Description

This command associates an IP filter policy or MAC filter policy with an ingress or egress Service Access Point (SAP) or IP interface.

Filter policies control the forwarding and dropping of packets based on IP or MAC matching criteria. There are two types of filter policies: IP and MAC. Only one type may be applied to a SAP at a time.

The **filter** command is used to associate a filter policy with a specified *filter ID* with an ingress or egress SAP. The *filter ID* must already be defined before the **filter** command is executed. If the filter policy does not exist, the operation will fail and an error message returned.

In general, filters applied to SAPs (ingress or egress) apply to all packets on the SAP. One exception is non-IP packets are not applied to IP match criteria, so the default action in the filter policy applies to these packets.

The **no** form of this command removes any configured filter ID association with the SAP or IP interface. The filter ID itself is not removed from the system unless the scope of the created filter is set to local. To avoid deletion of the filter ID and only break the association with the service object, use **scope** command within the filter definition to change the scope to **local** or **global**. The default scope of a filter is **local**.

Parameters

ip *ip-filter-id*

Specifies IP filter policy. The filter ID must already exist within the created IP filters.

Values 1 to 65535

ipv6 *ipv6-filter-id*

Specifies the IPv6 filter policy. The filter ID must already exist within the created IPv6 filters.

Values 1 to 65535

mac *mac-filter-id*

Specifies the MAC filter policy. The specified filter ID must already exist within the created MAC filters. The filter policy must already exist within the created MAC filters.

[Tree] (config>service>epipe>sap>egress filter)

Full Context

configure service epipe sap ingress filter

configure service epipe spoke-sdp ingress filter

configure service epipe spoke-sdp egress filter

configure service epipe sap egress filter

Description

This command associates an IP filter policy with an ingress or egress Service Access Point (SAP) or IP interface.

Filter policies control the forwarding and dropping of packets based on IP matching criteria. Only one filter can be applied to a SAP at a time.

The **filter** command is used to associate a filter policy with a specified *filter-id* with an ingress or egress SAP. The *filter-id* must already be defined before the **filter** command is executed. If the filter policy does not exist, the operation will fail and an error message returned.

IP filters apply only to RFC 2427-routed IP packets. Frames that do not contain IP packets will not be subject to the filter and will always be passed, even if the filter's default action is to drop.

The **no** form of this command removes any configured filter ID association with the SAP or IP interface. The filter ID itself is not removed from the system unless the scope of the created filter is set to local. To avoid deletion of the filter ID and only break the association with the service object, use **scope** command within the filter definition to change the scope to **local** or **global**. The default scope of a filter is **local**.

IPv6 filters are only supported by the 7705 SAR Gen 2 but are not supported on a Layer 2 SAP that is configured with QoS MAC criteria. Also, MAC filters are not supported on a Layer 2 SAP that is configured with QoS IPv6 criteria.

Parameters

ip-filter-id

Specifies IP filter policy. The filter ID must already exist within the created IP filters.

Values 1 to 65535

ipv6-filter-id

Specifies the IPv6 filter policy. The filter ID must already exist within the created IPv6 filters.

Values 1 to 65535

mac-filter-id

Specifies the MAC filter policy. The specified filter ID must already exist within the created MAC filters. The filter policy must already exist within the created MAC filters.

[Tree] (config>service>ies>if>spoke-sdp>egress filter)

Full Context

configure service ies interface spoke-sdp ingress filter

configure service ies interface spoke-sdp egress filter

Description

This command associates an IP filter policy filter policy with an ingress or egress spoke SDP.

Filter policies control the forwarding and dropping of packets based on matching criteria.

MAC filters are only allowed on Epipe and Virtual Private LAN Service (VPLS) SAPs.

The **filter** command is used to associate a filter policy with a specified *ip-filter-id* with an ingress or egress spoke SDP. The *ip-filter-id* must already be defined in the **config>filter** context before the **filter** command is executed. If the filter policy does not exist, the operation fails and an error message returned.

In general, filters applied to SAPs or spoke SDPs (ingress or egress) apply to all packets on the SAP or spoke SDPs. One exception is non-IP packets are not applied to IP match criteria, so the default action in the filter policy applies to these packets.

The **no** form of this command removes any configured filter ID association with the SAP or IP interface. The filter ID itself is not removed from the system unless the scope of the created filter is set to local. To avoid deletion of the filter ID and only break the association with the service object, use **scope** command within the filter definition to change the scope to **local** or **global**. The default scope of a filter is **local**.

Parameters

ip

Keyword indicating the filter policy is an IP filter.

ip-filter-id

The filter name acts as the ID for the IP filter policy. Allowed values are an integer in the range of 1 and 65535 that corresponds to a previously created IP filter policy. The filter ID must already exist within the created IP filters.

Platforms

7705 SAR Gen 2

[Tree] (config>service>vprn>if>sap>ingress filter)

Full Context

configure service vprn interface sap egress filter

configure service vprn interface sap ingress filter

Description

This command associates an IP filter policy with an ingress or egress Service Access Point (SAP) or IP interface. Filter policies control the forwarding and dropping of packets based on IP matching criteria.

The **filter** command is used to associate a filter policy with a specified filter ID with an ingress or egress SAP. The filter ID must already be defined before the **filter** command is executed. If the filter policy does not exist, the operation fails and an error message returned.

In general, filters applied to SAPs (ingress or egress) apply to all packets on the SAP. One exception is non-IP packets are not applied to IP match criteria, so the default action in the filter policy applies to these packets.

The **no** form of this command removes any configured filter ID association with the SAP or IP interface. The filter ID itself is not removed from the system unless the scope of the created filter is set to local. To avoid deletion of the filter ID and only break the association with the service object, use **scope** command within the filter definition to change the scope to **local** or **global**. The default scope of a filter is **local**.

Parameters

ip *ip-filter-id*

Specifies IP filter policy. The filter ID must already exist within the created IP filters.

Values ip-filter-id: 1 to 65535

name: up to 64 characters

ipv6 *ipv6-filter-id*

Specifies IPv6 filter policy. The filter ID must already exist within the created IP filters.

Values ip-filter-id: 1 to 65535

no filter *filter-id*

Context

[Tree] (config>service>vprn>log filter)

[Tree] (config>service>vprn>log>log-id filter)

Full Context

configure service vprn log filter

configure service vprn log log-id filter

Description

This command creates a context for an event filter. An event filter specifies whether to forward or drop an event or trap based on the match criteria.

Filters are configured in the **filter** *filter-id* context and then applied to a log in the **log-id** *log-id* context. Only events for the configured log source streams destined to the log ID where the filter is applied are filtered.

Changes made to an existing filter using any of the sub-commands are immediately applied to the destinations where the filter is applied.

By default, no event filters are defined. Event filters must be explicitly configured.

The **no** form of this command removes the filter association from log IDs, which causes those logs to forward all events.

Default

No event filters are defined.

Parameters

filter-id

Specifies the unique filter ID.

Values 1 to 1500

name filter-name

Configures an optional filter name, up to 64 characters, that can be used to refer to the filter after it is created.

Platforms

7705 SAR Gen 2

filter

Syntax

filter ip *ip-filter-id*

filter ipv6 *ipv6-filter-id*

no filter [**ip** *ip-filter-id*] [**ipv6** *ipv6-filter-id*]

Context

[Tree] (config>service>vprn>network>ingress filter)

Full Context

configure service vprn network ingress filter

Description

This command configures a network ingress filter for IPv4 or IPv6 traffic arriving over explicitly defined spokes or auto-bind network interfaces for the VPRN service.

The **no** form of this command removes an IPv4, IPv6, or both filters.

Default

no filter

Parameters

ip-filter-id/ipv6-filter-id

Specifies an existing IP/IPv6 filter policy of a scope template.

Values 1 to 65535, *name*

name: 64 characters maximum

Platforms

7705 SAR Gen 2

Context

[Tree] (config>service>pw-template>ingress filter)

[Tree] (config>service>pw-template>egress filter)

Full Context

configure service pw-template ingress filter

configure service pw-template egress filter

Description

This command associates an IP filter policy or MAC filter policy on egress or ingress. Filter policies control the forwarding and dropping of packets based on IP or MAC matching criteria. There are two types of filter policies: IP and MAC. Only one type may be applied to a SAP at a time.

The **filter** command is used to associate a filter policy with a specified *filter ID* with an ingress or egress SAP. The *filter ID* must already be defined before the **filter** command is executed. If the filter policy does not exist, the operation will fail and an error message returned.

This command is only supported in 'classic' configuration-mode (**configure system management-interface configuration-mode classic**). The **filter-name** command can be used in all configuration modes.

This command is mutually exclusive with the **filter-name** command. Only one or the other can be configured.

The **no** form of this command removes any configured filter ID association with the SAP or IP interface. The filter ID itself is not removed from the system unless the scope of the created filter is set to local. To avoid deletion of the filter ID and only break the association with the service object, use **scope** command within the filter definition to change the scope to **local** or **global**. The default scope of a filter is **local**.

Parameters

ip-filter-id

Specifies the IP filter policy.

Values 1 to 65535

ipv6-filter-id

Specifies the IPv6 filter policy.

Values 1 to 65535

mac-filter-id

Specifies the MAC filter policy.

Context

[Tree] (config>log filter)

Full Context

configure log filter

Description

This command creates a context for an event filter. An event filter specifies whether to forward or drop an event or trap based on the match criteria.

Filters are configured in the **filter** *filter-id* context and then applied to a log in the **log-id** *log-id* context. Only events for the configured log source streams destined to the log ID where the filter is applied are filtered.

Changes made to an existing filter using any of the sub-commands are immediately applied to the destinations where the filter is applied.

By default, no event filters are defined. Event filters must be explicitly configured.

The **no** form of this command removes the filter association from log IDs, which causes those logs to forward all events.

Parameters

filter-id

Specifies the unique filter ID.

Values 1 to 1500

name filter-name

Configures an optional filter name, up to 64 characters, that can be used to refer to the filter after it is created.

Platforms

7705 SAR Gen 2

filter

Syntax

filter *filter-id*

no filter

Context

[Tree] (config>log>log-id filter)

Full Context

configure log log-id filter

Description

This command adds an event filter policy with the log destination.

The **filter** command is optional. If an event filter is not configured, all events, alarms and traps generated by the source stream will be forwarded to the destination.

An event filter policy defines (limits) the events that are forwarded to the destination configured in the log-id. The event filter policy can also be used to select the alarms and traps to be forwarded to a destination **snmp-trap-group**.

The application of filters for debug messages is limited to application and subject only.

Accounting records cannot be filtered using the **filter** command.

Only one filter ID can be configured per log destination.

The **no** form of this command removes the specified event filter from the *log-id*.

Parameters

filter-id

Specifies the event filter policy ID is used to associate the filter with the *log-id* configuration. The event filter policy ID must already be defined in **config>log>filter** *filter-id*.

Values 1 **to** 1000

Platforms

7705 SAR Gen 2

no filter-id-range

Context

[Tree] (config>filter>md-auto-id filter-id-range)

Full Context

configure filter md-auto-id filter-id-range

Description

This command specifies the range of IDs used by SR OS to automatically assign an ID to filters that are created in model-driven interfaces without an ID explicitly specified by the user or client.

A filter created with an explicitly-specified ID cannot use an ID in this range. In classic CLI and SNMP, the ID range cannot be changed while objects exist inside the previous or new range. In MD interfaces, the range can be changed, which causes any previously existing objects in the previous ID range to be deleted and re-created using a new ID in the new range.

The **no** form of this command removes the range values.

See the **config>filter md-auto-id** command for further details.

Default

no filter-id-range

Parameters

start *filter-id*

Specifies the lower value of the ID range. The value must be less than or equal to the **end** value.

Values 1 to 2147483647

end *filter-id*

Specifies the upper value of the ID range. The value must be greater than or equal to the **start** value.

configure service pw-template egress filter-name

Description

This command associates an IP filter policy or MAC filter policy on egress or ingress. Filter policies control the forwarding and dropping of packets based on IP or MAC matching criteria. There are two types of filter policies: IP and MAC. Only one type may be applied to a SAP at a time.

The **filter-name** command is used to associate a filter policy with a specified *filter name* with an ingress or egress SAP. The *filter name* must already be defined before the **filter-name** command is executed. If the filter policy does not exist, the operation will fail and an error message returned.

This command is mutually exclusive with the **filter** command. Only one or the other can be configured.

The **no** form of this command removes any configured filter name association with the SAP or IP interface. The filter name itself is not removed from the system unless the scope of the created filter is set to local. To avoid deletion of the filter name and only break the association with the service object, use **scope** command within the filter definition to change the scope to **local** or **global**. The default scope of a filter is **local**.

Parameters

ip-name

Specifies the IP filter policy. The filter name must already exist within the created IP filters, up to 64 characters.

ipv6-name

Specifies the IPv6 filter policy. The filter name must already exist within the created IPv6 filters, up to 64 characters.

mac-name

Specifies the MAC filter policy. The specified filter name must already exist within the created MAC filters. The filter policy must already exist within the created MAC filters, up to 64 characters.

10.29 flags-tlv

flags-tlv

Syntax

[no] flags-tlv

Context

[Tree] (config>router>fad>flex-algo flags-tlv)

Full Context

configure router flexible-algorithm-definitions flex-algo flags-tlv

Description

This command advertises the FAD Flags TLV to provide additional context on how the router must run a constrained SPF (cSPF). The IETF definition includes only the M-flag for use in the FAD Flags TLV. When it is set, the M-flag specifies the use of a Flex-Algorithm specific prefix metric. The M-flag is important for inter-area or inter-domain routing support with Flex-Algorithms.

When a router advertises a FAD, it is optional to advertise the FAD Flags TLV. However, when a FAD that includes the FAD Flags TLV is received, then the router must decode the flags before participating in the Flex-Algorithm.

By default, the following considerations apply to the FAD Flags TLV.

- SR OS sets the M-flag and advertises the FAD Flags TLV.
- When a FAD Flags TLV is received, SR OS decodes the flags and modifies the cSPF computation based upon the M-flag status.

The **no** form of this command prevents the advertisement of the FAD Flags TLV within a FAD.

10.30 flex-algo

flex-algo

Syntax

flex-algo *flex-algo*

no flex-algo

Context

[Tree] (config>router>static-route-entry>indirect>tunnel-next-hop flex-algo)

Full Context

configure router static-route-entry indirect tunnel-next-hop flex-algo

Description

This command instructs the tunnel towards the indirect static-route next-hop to use the specified flexible algorithm.

It is assumed that the router using this command is participating in the flexible algorithm. This command instructs the router to lookup the indirect next-hop using flexible algorithm tunnels. If flexible algorithm aware tunnel to the indirect next-hop does not exist, then the static-route is not activated.

The expected outcome of this command is that when the router receives an IP payload packet, that it is steered towards the indirect next-hop using a flexible algorithm aware segment-routing tunnel if such tunnel exists. If such tunnel does not exist, then the route is not active, and the received IP packet will be dropped, if no other Longest Prefix Match (LPM) route exists.

If the *flex-algo* parameter is specified, the resolution filter can only use matching flexible algorithm-aware segment routing tunnels created by flexible algorithm-aware routing protocols (for example, SR IS-IS).

The **no** form of this command disables flexible algorithm-aware indirect next-hop resolution.

Default

no flex-algo

Parameters

flex-algo

Configures or deconfigures tunnel-next-hop flexible algorithm for resolving indirect static-route-entry.

Values 128 to 255

Platforms

7705 SAR Gen 2

flex-algo

Syntax

flex-algo *fad-name* [**create**]

Context

[Tree] (config>router>fad flex-algo)

Full Context

configure router flexible-algorithm-definitions flex-algo

Description

This command configures the definition context for a Flexible Algorithm Definition (FAD). Parameters, including the FAD priority, metric type, links to construct a flexible algorithm topology graph, and a description of the algorithm. Up to 256 local FADs can be configured on a router.

The FAD configuration parameters are grouped using the *fad-name* as the reference anchor. When an IGP is configured to use and advertise a local configured FAD, the *fad-name* is used as the reference anchor.

The **no** form of this command deletes the configured parameters and removes the defined FAD.

Default

no flex-algo

Parameters

fad-name

Specifies the name of the flexible algorithm, up to 32 characters, that is used as reference anchor for the configured parameters.

create

Specifies the mandatory keyword to create a router instance.

Platforms

Description

This command configures the flow-label and optional mask match condition.

The **no** form of the command reverts to the default.

Default

no flow-label

Parameters

flow-label

Specifies the flow label to be used as a match criterion. Value can be expressed as a decimal integer, as well as in hexadecimal or binary format. The following value shows decimal integer format only.

Values 0 to 1048575

mask

Specifies the flow label mask value for this policy IPv6 Filter entry. Value can be expressed as a decimal integer, as well as in hexadecimal or binary format. The following value shows decimal integer format only.

Values 0 to 1048575

Platforms

7705 SAR Gen 2

flow-label

Syntax

flow-label *value*

no flow-label

Context

[Tree] (config>system>security>mgmt-access-filter>ipv6-filter>entry flow-label)

Full Context

configure system security management-access-filter ipv6-filter entry flow-label

Description

This command configures flow label match conditions. Flow labeling enables the labeling of packets belonging to particular traffic flows for which the sender requests special handling, such as non-default quality of service or real-time service.

Parameters

value

Specifies the flow identifier in an IPv6 packet header that can be used to discriminate traffic flows (See RFC 3595, *Textual Conventions for IPv6 Flow Label*.)

Values 0 to 1048575

Platforms

7705 SAR Gen 2

10.35 flr-threshold

flr-threshold

Syntax

flr-threshold *percentage*

no flr-threshold

Context

[Tree] (config>oam-pm>session>ip>twamp-light>loss flr-threshold)

Full Context

configure oam-pm session ip twamp-light loss flr-threshold

Description

This command defines the frame loss threshold used to determine whether the delta-t is available or unavailable. An individual delta-t with a frame loss threshold equal to or higher than the configured threshold is marked unavailable. An individual delta-t with a frame loss threshold lower than the configured threshold is marked as available.

The **no** form of this command restores the default value of 50%.

Default

flr-threshold 50

Parameters

percentage

Specifies the percentage of the threshold.

Values 0 to 100

Default 50

Platforms

7705 SAR Gen 2

10.36 force-l2pt-boundary

force-l2pt-boundary

Syntax

force-l2pt-boundary [**cdp**] [**dtp**] [**pagp**] [**stp**] [**udld**] [**vtp**]

no force-l2pt-boundary

Context

[Tree] (config>service>vpls>sap force-l2pt-boundary)

Full Context

configure service vpls sap force-l2pt-boundary

Description

Enabling force-l2pt-boundary will force all SAPs managed by the specified m-vpls instance on the corresponding port to have l2pt-termination enabled. This command is applicable only to SAPs created under m-vpls regardless of the flavor of STP currently active. It is not applicable to spoke-SDPs.

The execution of this command will fail as soon as at least one of the currently managed SAPs (all SAPs falling within the specified managed-vlan-range) does not have l2pt-termination enabled regardless of its admin/operational status.

If force-l2pt-boundary is enabled on a specified m-vpls SAP, all newly created SAPs falling into the specified managed-vlan-range will have l2pt-termination enabled per default.

Extending or adding new range into a managed-vlan-range declaration will fail as soon as there is at least one SAPs falling into the specified vlan-range does not have l2pt-termination enabled.

Disabling l2pt-termination on currently managed SAPs will fail as soon as the force-l2pt-boundary is enabled under corresponding m-vpls SAP.

Parameters

cdp

Specifies the Cisco discovery protocol

dtp

Specifies the dynamic trunking protocol

pagp

Specifies the port aggregation protocol

stp

Specifies all spanning tree protocols: stp, rstp, mstp, pvst (default)

udld

Specifies unidirectional link detection

vtp

Specifies the virtual trunk protocol

Platforms

7705 SAR Gen 2

10.37 force-renews

force-renews

Syntax

[**no**] **force-renews**

Context

[Tree] (config>router>dhcp>server force-renews)

Full Context

configure router dhcp local-dhcp-server force-renews

Description

This command enables the sending of sending FORCERENEW messages for DHCP.

The **no** form of this command disables the sending of FORCERENEW messages.

Platforms

7705 SAR Gen 2

10.38 force-switchover

force-switchover

Syntax

force-switchover [**now**]

Context

[Tree] (admin>redundancy force-switchover)

Full Context

admin redundancy force-switchover

Description

This command forces a switchover to the standby CPM card. The primary CPM reloads its software image and becomes the secondary CPM.

Parameters

now

Forces the switchover to the redundant CPM card immediately.

Platforms

7705 SAR Gen 2

10.39 force-vlan-vc-forwarding

force-vlan-vc-forwarding

Syntax

[**no**] **force-vlan-vc-forwarding**

Context

[Tree] (config>service>vpls>bgp-evpn>mpls force-vlan-vc-forwarding)

[Tree] (config>service>epipe>bgp-evpn>mpls force-vlan-vc-forwarding)

Full Context

configure service vpls bgp-evpn mpls force-vlan-vc-forwarding

configure service epipe bgp-evpn mpls force-vlan-vc-forwarding

Description

This command enables the system to preserve the VLAN ID and 802.1p bits of the service-delimiting qtag in a new tag, which is sent in the customer frame to the EVPN destinations.

If this configuration is used in conjunction with the **sap ingress vlan-translation** command, the configured translated VLAN ID is the VLAN ID sent to the EVPN destinations, instead of the service-delimiting tag VLAN ID. If the ingress SAP or SDP binding is null-encapsulated, the output VLAN ID and p-bits are zero.

The **no** form of this command does not preserve the VLAN ID and 802.1p bits of the service-delimiting qtag.

Default

no force-vlan-vc-forwarding

Platforms

7705 SAR Gen 2

force-vlan-vc-forwarding

Syntax

Context

[Tree] (config>filter>ip-filter>entry>action forward)

[Tree] (config>filter>ipv6-filter>entry>action forward)

Full Context

configure filter ip-filter entry action forward

configure filter ipv6-filter entry action forward

Description

This command sets the context for specific forward commands to be performed.

Parameters

connection-id

Specifies that the packet should be forwarded over the specified connection (specified by the connection ID under the bonding group interface), if that connect is available. Outside of a bonding egress context, the behavior of this filter is undefined.

Values 1, 2

esi service-id

Specifies that the packet matching the entry is forwarded to an ESI-identified first appliance in Nuage service chain using EVPN-resolved VXLAN tunnel in the specified VPLS service.

esi sf-ip vas-interface router

Specifies that the packet matching the entry is forwarded to ESI/SF-IP identified first appliance in Nuage service chain using EVPN-resolved VXLAN tunnel over the configured VAS interface in the specified VPRN service.

gre-tunnel-name

Specifies the GRE tunnel name up to 32 characters.

lsp

Specifies that the packet matching the entry is forwarded using the specified lsp.

mpls-policy

Specifies the redirection of the traffic to the programed instance of the MPLS FP specified by its endpoint IPv4 or IPv6 address. The behavior results in a simple forward if no policy exists, if no instance is programmed, and if the policy or instance is administratively down.

next-hop

Specifies that the packet matching the entry is forwarded in the routing context of the incoming interface using direct or indirect IPv4 address in the routing lookup.

next-hop router

Specifies that the packet matching the entry is forwarded in the configured routing context using direct or indirect IPv4 address in the routing lookup.

redirect-policy

Specifies that the packet matching the entry is forwarded using forward next-hop or forward next hop router and the IP address of destination selected by the configured redirect policy. If no destination is selected, packets are subject to action forward.

router

Specifies that the packet matching the entry is routed in the configured routing instance and not in the incoming interface routing instance.

sap

Specifies that the packet matching the entry is forwarded using the configured SAP.

sdp

Specifies that the packet matching the entry is forwarded using the configured SDP.

srte-policy

Specifies the redirection of the traffic to the programed instance of the SR-TE policy specified by its endpoint IPv4 address or IPv6 address and color. The behavior results

in a simple forward if no policy exists, if no instance is programmed, and if the policy or instance is administratively down.

color-id

Specifies the color identifier of the specified SR-TE policy.

Values 0 to 4294967295

vprn-target

Specifies that the packet matching the entry is redirected towards a designated BGP next-hop (**bgp-nh**). The user may specify an LSP (**lsp** *lsp-name*) to use towards that next-hop. If no LSP is specified, the system will automatically select one. The user must specify the routing context (**router** {*router-instance* | **service-name** *service-name*}) in which the system will perform the lookups in order to derive the proper VPRN service label. The user may specify an advertised prefix route (**adv-prefix** *ip-address/prefix-length*). This is needed in case label per VRF is not the label allocation method configured at the BGP peer.

esi

Specifies a 10-byte Ethernet Segment Identifier.

ip-address/mask

Specifies an IPv4 advertised route in the CIDR notation. The IPv4 address is in dotted decimal notation.

Values ip-address a.b.c.d (host bits must be 0)

mask: 0 to 32

ipv6-address/prefix-length

Specifies an IPv6 advertised route in the CIDR notation.

Values ipv6-address:

- x:x:x:x:x:x:x:x (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d, where "x" is [0..FFFF]H, and "d" is [0..255]

prefix-length: 0 to 128

bgp-nh ip-address

Specifies the IPv4 address (in dotted decimal notation) of the target BGP next-hop.

Values ip-address d.d.d.d

ipv6-address

Specifies the IPv6 address of a direct or indirect next hop to forward matching packets or of the service SID to use with the SRv6 policy.

interface-name

Specifies the (maximum 32-character) name of an egress R-VPLS IP interface used to forward the packets using ESI redirect for VPRN/IES service.

lsp-name

Specifies an existing RSVP-TE, MPLS-TP, or SR-TE LSP that supports LSP redirect.

policy-name

Specifies an IPv4 redirect policy configured in the config>filter>redirect-policy context.

sap-id

Specifies an existing VPLS Ethernet SAP.

sdp-id:vc-id

Specifies an existing VPLS SDP.

router-instance

Specifies "Base" or an existing VPRN service ID. For the **forward vprn-target bgp-nh** command, *router-instance* must specify an existing VPRN service ID.

service-name

Specifies an existing VPRN service name.

vpls-service-id

Specifies an existing VPLS service ID or service name.

[Tree] (config>service>vpls>stp forward-delay)

Full Context

configure service template vpls-template stp forward-delay

configure service vpls stp forward-delay

Description

RSTP, as defined in the IEEE 802.1D-2004 standards, will normally transition to the forwarding state via a handshaking mechanism (rapid transition), without any waiting times. If handshaking fails (foe example, on shared links, see below), the system falls back to the timer-based mechanism defined in the original STP (802.1D-1998) standard.

A shared link is a link with more than two nodes (for example, a shared 10/100BaseT segment). The port-type command is used to configure a link as point-to-point or shared.

For timer-based transitions, the 802.1D-2004 standard defines an internal variable forward-delay, which is used in calculating the default number of seconds that a SAP or spoke-SDP spends in the discarding and learning states when transitioning to the forwarding state.

The value of the forward-delay variable depends on the STP operating mode of the VPLS instance:

- in rstp or mstp mode, but only when the SAP or spoke-SDP has not fallen back to legacy STP operation, the value configured by the hello-time command is used;
- in all other situations, the value configured by the forward-delay command is used.

Default

forward-delay 15

Parameters

seconds

The forward delay timer for the STP instance in seconds

Values 4 to 30

configure oam-pm session ip forwarding

Description

This command influences the forwarding decision of the TWAMP Light packet. When this command is used, only one of the forwarding options can be enabled at any time.

The **no** form of this command removes the options and enables the default forwarding logic.

Parameters

ip-address

Specifies the IP address of the next hop on the path.

Values

ipv4-address: a.b.c.d

ipv6-address: x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x: [0 to FFFF]H

d: [0 to 255]D

interface-name

Specifies the name, up to 32 characters, to refer to the interface from which the packet is sent. The name must already exist in the **config>router>interface** context or within the appropriate **config>service** context.

bypass-routing

Specifies to send the packet to a host on a directly attached network, bypassing the routing table.

configure service vprn bgp group graceful-restart long-lived forwarding-bits-set

configure service vprn bgp group neighbor graceful-restart long-lived forwarding-bits-set

configure service vprn bgp graceful-restart long-lived forwarding-bits-set

Description

This command determines the setting of the F bits in the GR and LLGR capabilities advertised by the router. When the F bit is set for an AFI/SAFI, it indicates that the advertising router was able to preserve forwarding state for the routes of that AFI/SAFI across the last restart. If a router restarts and does not set F=1, then when the session with a peer is re-established, the peer immediately deletes all LLGR stale routes it was preserving on behalf of the restarting router for the corresponding AFI/SAFI.

This command allows the F bits for all advertised AFI/SAFI to be set to 1, or only the F bits for non-forwarding AFI/SAFI to be set to 1. Non-forwarding AFI/SAFI are the following configuration-related address families: L2-VPN, route-target, flow-IPv4, and flow-IPv6.

Default

no forwarding-bits-set

Parameters

all

Specifies that the F bit for all AFI/SAFI should be set to 1.

non-fwd

Specifies that the F bit for only non-forwarding AFI/SAFI should be set to 1. These AFI/SAFI correspond to the following families: L2-VPN, route-target, flow-IPv4, and flow-IPv6.

Platforms

7705 SAR Gen 2

forwarding-policy

Syntax

[**no**] **forwarding-policy** *name*

Context

[Tree] (config>router>mpls>fwd-policies forwarding-policy)

Full Context

configure router mpls forwarding-policies forwarding-policy

Description

This command creates an MPLS forwarding policy.

There are two types of MPLS forwarding policy:

- endpoint policy
- label-binding policy

The endpoint policy allows the user to forward unlabeled packets over a set of user-defined direct (with option to push a label stack) or indirect next hops. Routes are bound to an endpoint policy when their next hop matches the endpoint address of the policy.

The label-binding policy provides the same capability for labeled packets. In this case, labeled packets matching the ILM of the policy binding label are forwarded over the set of next hops of the policy.

The data model of a forwarding policy represents each pair of {primary next hop, backup next hop} as a group and models the ECMP set as the set of Next-Hop Groups (NHGs). Flows of prefixes can be switched on a per-NHG basis from the primary next hop, when it fails, to the backup next hop without disturbing the flows forwarded over the other NHGs of the policy. The same can be performed when reverting back from a backup next hop to the restored primary next hop of the same NHG.

The MPLS forwarding policy supports two types of NHGs on a per policy basis:

- An NHG of resolution type indirect supported with the label-binding policy and in which forwarding over the primary/backup next hop is modeled as a swap operation from the binding label to an implicit-null label over multiple outgoing interfaces (multiple NHLFEs) corresponding to the resolved next hops of the indirect route.

  Within a given NHG, the primary next hop is the preferred active path in the absence of any failure of the NHG of resolution type indirect.

  The forwarding database tracks the primary or backup next hop in the routing table. A **route delete** of the primary indirect next hop causes the CPM to program the backup indirect next hop in the data path.

A **route modify** to the indirect primary or backup next hop causes the CPM to update the resolved next hops and to update the data path if it is the active indirect next hop.

When the primary indirect next hop is restored and is added back into the routing table, CPM waits for an amount of time equal to the user-programmed revert timer before updating the data path. However, if the backup indirect next hop fails while the timer is running, CPM updates the data path immediately.

- An NHG of resolution type direct is modeled as follows:
  - For a label-binding policy, forwarding over the primary or backup next hop is modeled as a swap operation from the binding label to the configured label stack or to an implicit-null label (if the **pushed-labels** command not configured) over a single outgoing interface to the next hop.
  - For an endpoint policy, forwarding over the primary or backup next hop is modeled as a push operation from the binding label to the configured label stack or to an implicit-null label (if the **pushed-labels** command not configured) over a single outgoing interface to the next hop.
  - The labels configured by the **pushed-labels** command are not validated.

  Within a given NHG, the primary next hop is the preferred active path in the absence of any failure of the NHG of resolution type direct.

  The NHG supports uniform failover. The forwarding policy database assigns a Protect-Group ID (PG-ID) to each of the primary next hop and the backup next hop and programs both of them in data path. A failure of the active path switches traffic to the other path following the uniform failover procedures.

  The forwarding database tracks the primary or backup next hop in the routing table. A **route delete** of the primary/backup direct next hop causes CPM to send the corresponding PG-ID switch to the data path.

  A **route modify** to the direct primary or backup next hop causes CPM to update the MPLS forwarding database and to update the data path since both next hops are programmed.

  When the primary direct next hop is restored and is added back into the routing table, CPM waits for an amount of time equal to the user programmed revert timer before activating it and updating the data path. However, if the backup direct next hop fails while the timer is running, CPM activates it and updates the data path immediately. The latter failover to the restored primary next hop is performed using the uniform failover procedure.

The forwarding policy database activates the best endpoint policy among the named policies sharing the same value of the endpoint parameter by selecting the lowest preference value policy. This policy is then programmed into the TTM and into the tunnel table in data path. If this policy goes down, then the forwarding policy database performs a re-evaluation and activates the named policy with the next lowest preference value for the same endpoint value. If a more preferred policy comes back up, the forwarding policy database reverts to it and activates it.

The forwarding policy database similarly activates the best label-binding policy among the named policies sharing the same binding label by selecting the lowest preference value policy. This policy is then programmed into the label FIB table in data path. If this policy goes down, then the forwarding policy database performs a re-evaluation and activates the names policy with the next lowest preference value for the same binding label value. If a more preferred policy comes back up, the forwarding policy database reverts to it and activates it.

Ingress statistics can be enabled as is associated with binding label, that is the ILM of the forwarding policy, and provides aggregate packet and byte counters for packets matching the binding label.

The **no** form of the command deletes the named MPLS forwarding policy.

Parameters

name

Specifies the name of the MPLS forwarding policy, up to 64 characters.

Platforms

7705 SAR Gen 2

10.50 fp

fp

Syntax

fp [*fp-number*]

Context

[Tree] (config>card fp)

Full Context

configure card fp

Description

This command enables access to the configuration of the forwarding planes on a card.

The default forwarding plane is 1. When entering the FP node, if the forwarding plane number is omitted, the system will assume forwarding plane number 1.

Commands can only be configured under **card>fp** if the hardware that the FP resides on (either a card or an XMA) is provisioned. Conversely, all commands under **card>fp** of the corresponding FPs are automatically removed when that hardware is unprovisioned.

Parameters

fp-number

Specifies that the FP number parameter is optional following the **fp** command.

Values 1 to 8

Default fp 1

Platforms

7705 SAR Gen 2

10.51 fp-redirect-group

fp-redirect-group

Syntax

fp-redirect-group *policer-type policer-id*

no fp-redirect-group *policer-type*

Context

[Tree] (config>qos>network>ingress>fc fp-redirect-group)

Full Context

configure qos network ingress fc fp-redirect-group

Description

This command is used to redirect the FC of a broadcast packet received in a VPLS service over a PW or network IP interface to an ingress forwarding plane queue-group.

It defines the mapping of an FC to a policer-id and redirects the lookup of the policer of the same ID in some ingress forwarding plane queue-group instance. However, the queue-group name and instance are explicitly provided only at the time the network QoS policy is applied to the ingress context of a spoke or mesh SDP or a network IP interface.

The broadcast-policer statement is ignored when the network QoS policy is applied to any object other than a VPLS spoke or mesh SDP or a network IP interface.

The **no** form of this command removes the redirection of the FC.

Parameters

policer-type

The policer type to be used. The *policer-type* is ignored when the network QoS policy is applied to any object other than a VPLS spoke or mesh SDP or a network IP interface.

Values broadcast-policer | mcast-policer | policer | unknown-policer

policer-id

The specified *policer-id* must exist within the queue-group template applied to the ingress context of the forwarding plane.

Values 1 to 32

fragment

Syntax

fragment {**true** | **false**}

no fragment

Context

[Tree] (config>qos>sap-ingress>ip-criteria>entry>match fragment)

[Tree] (config>qos>sap-egress>ip-criteria>entry>match fragment)

Full Context

configure qos sap-ingress ip-criteria entry match fragment

configure qos sap-egress ip-criteria entry match fragment

Description

This command configures fragmented or non-fragmented IP packets as a SAP QoS policy match criterion.

The **no** form of this command removes the match criterion and matches all packets regardless of whether they are fragmented or not.

Default

no fragment

Parameters

true

Configures a match on all fragmented IP packets. A match will occur for all packets that have either the MF (more fragment) bit set or have the Fragment Offset field of the IP header set to a non-zero value.

false

Configures a match on all non-fragmented IP packets. Non-fragmented IP packets are packets that have the MF bit set to zero and have the Fragment Offset field also set to zero.

Platforms

7705 SAR Gen 2

fragment

Syntax

fragment {**true** | **false** | **first-only** | **non-first-only**}

no fragment

Context

[Tree] (config>qos>sap-ingress>ipv6-criteria>entry>match fragment)

Full Context

configure qos sap-ingress ipv6-criteria entry match fragment

Description

This command configures fragmented or non-fragmented IPv6 packets as a SAP ingress QoS policy match criterion.

The **no** form of this command removes the match criterion and matches all packets regardless of whether they are fragmented or not.

Default

no fragment

Parameters

true

Specifies to match on all fragmented IPv6 packets. A match will occur for all packets that contain an IPv6 Fragmentation Extension Header.

false

Specifies to match on all non-fragmented IP packets. Non-fragmented IPv6 packets are packets that do not contain an IPv6 Fragmentation Extension Header.

first-only

Matches if a packet is an initial fragment of the fragmented IPv6 packet.

non-first-only

Matches if a packet is a non-initial fragment of the fragmented IPv6 packet.

Platforms

7705 SAR Gen 2

fragment

Syntax

fragment {**true** | **false**}

no fragment

Context

[Tree] (config>filter>ipv6-filter>entry>match fragment)

[Tree] (config>filter>ip-filter>entry>match fragment)

Full Context

configure filter ipv6-filter entry match fragment

configure filter ip-filter entry match fragment

Description

This command specifies match criterion for fragmented packets.

Matches can be based on the presence of a fragmented packet (or otherwise) on the ingress or egress interface.

Matches can also be based on the presence of the first fragment of a packet, or on the presence of a fragment that is not the first fragment on the ingress interface.

The **no** form of the command removes the match criterion.

Default

no fragment

Parameters

true

Specifies to match on all fragmented packets.

false

Specifies to match on all non-fragmented packets.

first-only

Matches if a packet is an initial fragment of a fragmented packet.

non-first-only

Matches if a packet is a non-initial fragment of a fragmented packet.

Platforms

7705 SAR Gen 2

10.54 frame-based-accounting

frame-based-accounting

Syntax

[**no**] **frame-based-accounting**

Context

[Tree] (config>qos>scheduler-policy frame-based-accounting)

Full Context

configure qos scheduler-policy frame-based-accounting

Description

The frame-based-accounting command is used to enable frame-based accounting for both the children queues parented to the scheduling policy and for the schedulers within the scheduler policy.

When frame-based accounting is enabled on the policy, all queues associated with the scheduler (through the parent command on each queue) will have their rate and CIR values interpreted as frame-based values. When shaping, the queues will include the 12-byte Inter-Frame Gap (IFG) and 8 byte preamble for each packet scheduled out the queue. The profiling CIR threshold will also include the 20-byte frame encapsulation overhead. Statistics associated with the queue do not include the frame encapsulation overhead.

The scheduler policy’s scheduler rate and CIR values will be interpreted as frame-based values.

The configuration of **parent-location** and **frame-based-accounting** in a scheduler policy is mutually exclusive to ensure consistency between the different scheduling levels. Packet byte offset settings are not included in the applied rate when frame-based accounting is configured; however, the offsets are applied to the statistics.

The **no** form of this command is used to return all schedulers within the policy and queues associated with the policy to the default packet-based accounting mode. If **frame-based-accounting** is not currently enabled for the scheduling policy, the **no frame-based-accounting** command has no effect.

10.57 frequency

frequency

Syntax

frequency *frequency*

no frequency

Context

[Tree] (config>port>dwdm frequency)

Full Context

configure port dwdm frequency

Description

This command configures the center frequency to use for a tunable DWDM optical interface. It replaces the **configure**>**port**>**dwdm**>**channel** command (used prior to Release 22.2.R1). The **frequency** command supports any frequency in the C band, but the actual operating frequency is dependent on the installed optic module.

Provisioning rules

The provisioned MDA type must have DWDM tunable optics (for example, p1-100g-tun-b) or the MDA must support the option of tunable DWDM optic modules. The following provisioning rules apply:

- The DWDM frequency must set to a non-zero value before the port is set to **no shutdown**.
- The port must be **shutdown** before changing the DWDM frequency.
- The port must be a physical port to set the DWDM frequency.

Default

frequency 0

Parameters

frequency

Specifies the frequency in MHz.

Values 0, 191100000 to 196150000

Platforms

7705 SAR Gen 2

10.58 from

from

Syntax

no from

Context

[Tree] (config>service>vprn>log>log-id from)

Full Context

configure service vprn log log-id from

Description

This command selects the source stream to be sent to a log destination.

One or more source streams must be specified. The source of the data stream must be identified using the **from** command before you can configure the destination using the **to** command. The **from** command can identify multiple source streams in a single statement (for example: **from main change debug-trace**).

Only one **from** command may be entered for a single *log-id*. If multiple **from** commands are configured, then the last command entered overwrites the previous **from** command.

The **no** form of this command removes all previously configured source streams.

Default

No source stream is configured.

Parameters

main

Instructs all events in the main event stream to be sent to the destination defined in the **to** command for this destination *log-id*. The main event stream contains the events that are not explicitly directed to any other event stream. To limit the events forwarded to the destination, configure filters using the **filter** command.

security

Instructs all events in the security event stream to be sent to the destination defined in the **to** command for this destination *log-id*. The security event stream contains all events that pertain to attempts to breach system security. To limit the events forwarded to the destination, configure filters using the **filter** command.

change

Instructs all events in the user activity stream to be sent to the destination configured in the **to** command for this destination *log-id*. The change event stream contains all events that directly affect the configuration or operation of this node. To limit the events forwarded to the change stream destination, configure filters using the filter command.

debug-trace

Instructs all events in the debug-trace event stream to be sent to the destination defined in the **to** command for this destination *log-id*. The debug-trace event stream contains all events that pertain to trace or other debugging information. To limit the events forwarded to the destination, configure filters using the **filter** command.

from

Syntax

from *ip-address*

Context

[Tree] (config>router>mpls>lsp-template from)

[Tree] (config>router>mpls>lsp from)

Full Context

configure router mpls lsp-template from

configure router mpls lsp from

Description

This optional command specifies the IP address of the ingress router for the LSP. When this command is not specified, the system IP address is used. IP addresses that are not defined in the system are allowed. If an invalid IP address is entered, LSP bring-up fails and an error is logged.

If an interface IP address is specified as the **from** address, and the egress interface of the LSP nexthop IP address is a different interface, the LSP is not signaled. As the egress interface changes due to changes in the routing topology, it is recommended to set the **from** IP address to the system IP address or to the address of a loopback interface to ensure the LSP recovers.

Only one **from** address can be configured.

Default

The system IP address

Parameters

ip-address

Specifies the IP address of the ingress router. This can be either the interface, the system or a loopback interface IP address. If the IP address is local, the LSP must egress through that local interface which ensures local strictness. When the LSP type is **sr-te**, then an IPv6 address can be used.

Values ipv4-address — a.b.c.d

ipv6-address — x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x — 0 to FFFF (hexadecimal)

d — 0 to 255 (decimal)

Platforms

no from

Context

[Tree] (config>log>log-id from)

Full Context

configure log log-id from

Description

This command selects the source stream to be sent to a log destination.

One or more source streams must be specified. The source of the data stream must be identified using the **from** command before you can configure the destination using the **to** command. The **from** command can identify multiple source streams in a single statement (for example: **from main change debug-trace**).

Only one **from** command may be entered for a single *log-id*. If multiple **from** commands are configured, then the last command entered overwrites the previous **from** command.

The **no** form of this command removes all previously configured source streams.

Parameters

main

Instructs all events in the main event stream to be sent to the destination defined in the **to** command for this destination *log-id*. The main event stream contains the events that are not explicitly directed to any other event stream. To limit the events forwarded to the destination, configure filters using the **filter** command.

security

Instructs all events in the security event stream to be sent to the destination defined in the **to** command for this destination *log-id*. The security stream contains all events that affect attempts to breach system security such as failed login attempts, attempts to access MIB tables to which the user is not granted access or attempts to enter a branch of the CLI to which access has not been granted. To limit the events forwarded to the destination, configure filters using the **filter** command.

change

Instructs all events in the user activity stream to be sent to the destination configured in the **to** command for this destination *log-id*. The change event stream contains all events that directly affect the configuration or operation of this node. To limit the events forwarded to the change stream destination, configure filters using the **filter** command.

debug-trace

Instructs all debug-trace messages in the debug stream to be sent to the destination configured in the **to** command for this destination *log-id*. Filters applied to debug messages are limited to application and subject.

11.1 garp-flood-evpn

garp-flood-evpn

Syntax

[**no**] **garp-flood-evpn**

Context

[Tree] (config>service>vpls>proxy-arp garp-flood-evpn)

Full Context

configure service vpls proxy-arp garp-flood-evpn

Description

This command controls whether the system floods GARP-requests and GARP-replies to the EVPN. The GARPs impacted by this command are identified by the sender's IP being equal to the target's IP and the MAC DA being broadcast.

The **no** form of the command only floods to local SAPs or binds but not to EVPN destinations.

Disabling this command is only recommended in networks where CEs are routers that are directly connected to the PEs. Networks using aggregation switches between the host/routers and the PEs should flood GARP messages in the EVPN to ensure that the remote caches are updated and the BGP does not miss the advertisement of these entries.

Default

garp-flood-evpn

no gateway name *name* **tunnel-subnet** *ip-prefix/ip-prefix-length*

Context

[Tree] (debug>ipsec gateway)

Full Context

debug ipsec gateway

Description

This command enables debugging for dynamic IPsec tunnels that terminate on the specified IPsec gateway.

The tunnel to be debugged can be specified by either its source address or source subnet. If a subnet is specified, the system will enable debugging for all tunnels with source addresses in the specified subnet.

Parameters

name

Specifies the name of the IPsec gateway up to 32 characters.

ip-address:port

Specifies the tunnel IP address of the remote peer and, optionally, the remote UDP port of IKE.

nat-ip:port

Specifies the inside IP address of the NAT tunnel and, optionally, the port.

detail

Specifies to display detailed debug information.

no-dpd-debug

Specifies to stop logging IKEv1 and IKEv2 DPD events during debug in order to produce less noise.

ip-prefix/ip-prefix-length

Specifies the subnet of the peer’s tunnel address.

display-keys

Specifies the IKE-SA and CHILD-SA keys for inclusion in the debug output.

gen-keypair *url-string* [**size** *key-size*] [**type** {**rsa** | **dsa**}]

Context

[Tree] (admin>certificate gen-keypair)

Full Context

admin certificate gen-keypair

Description

This command generates RSA, DSA, or ECDSA private key or public key pairs at the specified location.

Parameters

url-string

Specifies the path of the key file.

Values		
	url-string	<local-url> [up to 99 characters]
	local-url	<cflash-id>/<file-path>
	cflash-id	cf1: | cf2: | cf3:

curve

Generates an ECDSA key with a specified curve.

Values secp256r1, secp384r1, secp521r1

key-size

Specifies the key size in bits.

Values 512 to 8192

Default 2048

type

Specifies the type of key.

Values rsa, dsa

Default rsa

Platforms

7705 SAR Gen 2

11.4 gen-local-cert-req

gen-local-cert-req

Syntax

gen-local-cert-req keypair *url-string* **subject-dn** *subject-dn* [**domain-name** *name*] [**ip-addr** *ip-address*] **file** *cert-req-file-url* [**hash-alg hash-algorithm**]

Context

[Tree] (admin>certificate gen-local-cert-req)

Full Context

admin certificate gen-local-cert-req

Description

This command generates a PKCS#10 formatted certificate request by using a local existing key pair file.

Parameters

url-string

Specifies the name of the keyfile in cf3:\system-pki\key that is used to generate a certificate request.

Values

url-string	<local-url> [up to 99 characters]
local-url	<cflash-id>/<file-path>
cflash-id	cf1: | cf2: | cf3:

subject-dn

Specifies the distinguish name that is used as the subject in a certificate request, including:

- C-Country

- ST-State
- O-Organization name
- OU-Organization Unit name
- CN-common name

This parameter is formatted as a text string including any of the above attributes. The attribute and its value is linked by using "=", and "," is used to separate different attributes.

For example: C=US,ST=CA,O=ALU,CN=SR12

Values attr1=val1,attr2=val2... where: attrN={C| ST| O| OU| CN}, 256 chars max

domain-name

Specifies a domain name string can be specified and included as the dNSName in the Subject Alternative Name extension of the certificate request.

ip-address

Specifies an IPv4 address string can be specified and included as the ipAddress in the Subject Alternative Name extension of the certificate request.

cert-req-file-url

Specifies the certificate URL. This URL could be either a local CF card path and filename to save the certificate request; or an FTP URL to upload the certificate request.

hash-algorithm

Specifies the hash algorithm to be used in a certificate request.

Values sha1, sha224, sha256, sha384, sha512

Platforms

7705 SAR Gen 2

configure system snmp general-port

Description

This command configures the port number used to receive SNMP request messages and send replies.

For the port used for SNMP notifications, configure the **configure log snmp-trap-group trap-target port** command.

The **no** form of the command reverts to the default value.

Default

general-port 161

Parameters

port-number

Specifies the port number used to send SNMP traffic other than traps.

Values 1 to 65535

Platforms

7705 SAR Gen 2

11.6 generate-icmp

generate-icmp

Syntax

[**no**] **generate-icmp**

Context

[Tree] (config>service>vprn>static-route-entry>black-hole generate-icmp)

Full Context

configure service vprn static-route-entry black-hole generate-icmp

Description

This optional command causes the ICMP unreachable messages to be sent when received packets match the associated static route. By default, the ICMP unreachable messages for those types of static routes are not generated.

This command can only be associated with a static route that has a black-hole next-hop

The **no** form of this command removes the black-hole next-hop from static route configuration.

Default

no generate-icmp

Platforms

7705 SAR Gen 2

generate-icmp

Syntax

[**no**] **generate-icmp**

Context

[Tree] (config>router>static-route-entry>black-hole generate-icmp)

Full Context

configure router static-route-entry black-hole generate-icmp

Description

This optional command causes the ICMP unreachable messages to be sent when received packets match the associated static route. By default, the ICMP unreachable messages for those types of static routes are not generated.

This command can only be associated with a static route that has a blackhole next-hop

The **no** form of this command removes the black-hole nexthop from the static route configuration.

Default

no generate-icmp

Platforms

7705 SAR Gen 2

11.7 generate-traps

generate-traps

Syntax

[**no**] **generate-traps**

Context

[Tree] (config>system>network-element-discovery generate-traps)

Full Context

configure system network-element-discovery generate-traps

Description

This command configures whether traps are generated every time a node is updated, added, or removed from the OSPF opaque database (using LSA type 10 opaque update).

The **no** form of causes traps to not be generated for database changes.

Platforms

7705 SAR Gen 2

11.8 get

get

Syntax

[**no**] **get**

Context

[Tree] (configure>system>security>profile>netconf>base-op-authorization get)

Full Context

configure system security profile netconf base-op-authorization get

Description

This command enables the NETCONF <get> RPC.

The **no** form of this command disables the RPC.

Default

no get

Note:
The operation is enabled by default in the built-in system-generated administrative profile.

Platforms

7705 SAR Gen 2

11.9 get-config

get-config

Syntax

[**no**] **get-config**

Context

[Tree] (configure>system>security>profile>netconf>base-op-authorization get-config)

Full Context

configure system security profile netconf base-op-authorization get-config

Description

This command enables the NETCONF <get-config> RPC.

The **no** form of this command disables the RPC.

Default

no get-config

Note:
The operation is enabled by default in the built-in system-generated administrative profile.

Platforms

7705 SAR Gen 2

11.10 get-data

get-data

Syntax

[**no**] **get-data**

Context

[Tree] (configure>system>security>profile>netconf>base-op-authorization get-data)

Full Context

configure system security profile netconf base-op-authorization get-data

Description

This command enables the NETCONF <get-data> RPC.

The **no** form of this command disables the RPC.

Default

no get-data

Note:
The operation is enabled by default in the built-in system-generated administrative profile.

Platforms

7705 SAR Gen 2

11.11 get-schema

get-schema

Syntax

[**no**] **get-schema**

Context

[Tree] (configure>system>security>profile>netconf>base-op-authorization get-schema)

Full Context

configure system security profile netconf base-op-authorization get-schema

Description

This command enables the NETCONF <get-schema> RPC.

The **no** form of this command disables the RPC.

Default

no get-schema

Note:
The operation is enabled by default in the built-in system-generated administrative profile.

Platforms

7705 SAR Gen 2

11.12 gi-address

gi-address

Syntax

gi-address *ip-address*

no gi-address

Context

[Tree] (config>subscr-mgmt>loc-user-db>ipoe>host gi-address)

Full Context

configure subscriber-mgmt local-user-db ipoe host gi-address

Description

This command allows selection of GI addresses based on the host entry in LUDB.

The gi-address must be a valid address (associated with an interface) within the routing context that received the DHCP message on the access side.

The **no** form of this command reverts to the default.

Parameters

ip-address

Specifies the IPv4 gi-address.

Values a.b.c.d

Platforms

7705 SAR Gen 2

gi-address

Syntax

gi-address *ip-address* [**src-ip-address**]

no gi-address

Context

[Tree] (config>service>vprn>if>dhcp gi-address)

[Tree] (config>service>ies>if>dhcp gi-address)

Full Context

configure service vprn interface dhcp gi-address

configure service ies interface dhcp gi-address

Description

This command configures the gateway interface address for the DHCP relay. A subscriber interface can include multiple group interfaces with multiple SAPs. The GI address is needed, when the router functions as a DHCP relay, to distinguish between the different subscriber interfaces and potentially between the group interfaces defined.

By default, the GI address used in the relayed DHCP packet is the primary IP address of a normal IES interface. Specifying the GI address allows the user to choose a secondary address. For group interfaces a GI address must be specified under the group interface DHCP context or subscriber-interface DHCP context in order for DHCP to function.

The **no** form of this command reverts to the default.

Parameters

ip-address

Specifies the host IP address to be used for DHCP relay packets.

Values a.b.c.d

src-ip-address

Specifies that this GI address is to be the source IP address for DHCP relay packets. This parameter is not applicable for PPPoE DHCP client messages (**dhcp client-applications ppp**).

Platforms

7705 SAR Gen 2

gi-address

Syntax

gi-address *ip-address*

no gi-address

Context

[Tree] (config>service>ies>if>sap>ipsec-gw>dhcp gi-address)

[Tree] (config>service>vprn>if>sap>ipsec-gw>dhcp gi-address)

Full Context

configure service ies interface sap ipsec-gw dhcp gi-address

configure service vprn interface sap ipsec-gw dhcp gi-address

Description

This command specifies the gateway IP address of the DHCPv4 packets sent by the system. IPsec DHCP Relay uses only the **gi-address** configuration found under the IPsec gateway and does not take into account **gi-address** with **src-ip-addr** configuration below other interfaces.

Default

no gi-address

Parameters

ip-address

Specifies the host IP address to be used for DHCP relay packets.

Platforms

7705 SAR Gen 2

gi-address

Syntax

gi-address *ip-address* [**src-ip-addr**]

no gi-address

Context

[Tree] (config>router>if>dhcp gi-address)

Full Context

configure router interface dhcp gi-address

Description

This command configures the gateway interface address for the DHCP relay. The GI address is needed, when the router functions as a DHCP relay, to distinguish between the different subscriber interfaces and potentially between the group interfaces defined.

Default

no gi-address

Parameters

ip-address

Specifies the host IP address to be used for DHCP relay packets.

src-ip-addr

Uses the GI address as the source IP.

Platforms

7705 SAR Gen 2

11.13 global

global

Syntax

global *file-url*

no global

Context

[Tree] (config>system>login-control>login-scripts global)

Full Context

configure system login-control login-scripts global

Description

This command enables an operator to define a common CLI script that executes when any user logs into a CLI session. This login exec script is executed when any user (authenticated by any means including local user database, TACACS+, or RADIUS) opens a CLI session. This allows a user, for example, to define a common set of CLI aliases that are made available on the router for all users. This global login exec script is executed before any user-specific login exec files that may be configured.

This CLI script executes in the context of the user who opens the CLI session. Any commands in the script that the user is not authorized to execute will fail.

The **no** form of this command disables the execution of a global login-script.

Default

no global

Parameters

file-url

The path or directory name.

Platforms

7705 SAR Gen 2

11.14 global-timeouts

global-timeouts

Syntax

global-timeouts

Context

[Tree] (config>system>management-interface>ops global-timeouts)

Full Context

configure system management-interface operations global-timeouts

Description

Commands in this context configure system timeout parameters for operational commands.

Timeout parameters provide default system-level control for various types of operational commands in model-driven interfaces. The timeout values are used when specific execution and retention timeouts are not requested for a specific operation.

Platforms

7705 SAR Gen 2

11.15 global-variables

global-variables

Syntax

global-variables

no global-variables

Context

[Tree] (config>router>policy-options global-variables)

Full Context

configure router policy-options global-variables

Description

This command enables the **global-variables** configuration context.

The **no** form of this command removes all global variables.

Platforms
7705 SAR Gen 2

11.16 gnmi

gnmi

Syntax
gnmi

Context
[Tree] (config>system>grpc gnmi)

Full Context
configure system grpc gnmi

Description
Commands in this context configure a gNMI service on gRPC.

Platforms
7705 SAR Gen 2

11.17 gnmi-capabilities

gnmi-capabilities

Syntax
gnmi-capabilities {**permit** | **deny**}

Context
[Tree] (config>system>security>profile>grpc>rpc-authorization gnmi-capabilities)

Full Context
configure system security profile grpc rpc-authorization gnmi-capabilities

Description
This command permits the use of Capability RPC for a user associated with the given format.

The **no** form of this command reverts to the default value.

Default

gnmi-capabilities permit

Parameters

permit

Specifies that the use of the Capability RPC is permitted.

deny

Specifies that the use of the Capability RPC is denied.

Platforms

7705 SAR Gen 2

11.18 gnmi-get

gnmi-get

Syntax

gnmi-get {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization gnmi-get)

Full Context

configure system security profile grpc rpc-authorization gnmi-get

Description

This command permits the use of Get RPC.

The **no** form of this command reverts to the default value.

Default

gnmi-get permit

Parameters

permit

Specifies that the use of the Get RPC is permitted.

deny

Specifies that the use of the Get RPC is denied.

Platforms
7705 SAR Gen 2

11.19 gnmi-set

gnmi-set

Syntax
gnmi-set {**permit** | **deny**}

Context
[Tree] (config>system>security>profile>grpc>rpc-authorization gnmi-set)

Full Context
configure system security profile grpc rpc-authorization gnmi-set

Description
This command permits the use of Set RPC.

The **no** form of this command reverts to the default value.

Default
gnmi-set permit

Parameters
permit
Specifies that the use of the Set RPC is permitted.

deny
Specifies that the use of the Set RPC is denied.

Platforms
7705 SAR Gen 2

11.20 gnmi-subscribe

gnmi-subscribe

Syntax
gnmi-subscribe {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization gnmi-subscribe)

Full Context

configure system security profile grpc rpc-authorization gnmi-subscribe

Description

This command permits the use of Subscribe RPC.

The **no** form of this command reverts to the default value.

Default

gnmi-subscribe permit

Parameters

permit

Specifies that the use of the Subscribe RPC is permitted.

deny

Specifies that the use of the Subscribe RPC is denied.

Platforms

7705 SAR Gen 2

11.21 gnoi-cert-mgmt-cangenerate

gnoi-cert-mgmt-cangenerate

Syntax

gnoi-cert-mgmt-cangenerate {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization gnoi-cert-mgmt-cangenerate)

Full Context

configure system security profile grpc rpc-authorization gnoi-cert-mgmt-cangenerate

Description

This command permits the use of gNOI CanGenerateCSR RPCs for the user profile.

The **no** form of this command reverts to the default value.

Default

gnoi-cert-mgmt-cangenerate deny

Parameters

permit

Specifies that the use of the gNOI CanGenerateCSR RPCs for the user profile is permitted.

deny

Specifies that the use of the gNOI CanGenerateCSR RPCs for the user profile is denied.

Platforms

7705 SAR Gen 2

11.22 gnoi-cert-mgmt-getcert

gnoi-cert-mgmt-getcert

Syntax

gnoi-cert-mgmt-getcert {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization gnoi-cert-mgmt-getcert)

Full Context

configure system security profile grpc rpc-authorization gnoi-cert-mgmt-getcert

Description

This command permits the use of gNOI GetCertificate RPCs for the user profile.

The **no** form of this command reverts to the default value.

Default

gnoi-cert-mgmt-getcert deny

Parameters

permit

Specifies that the use of the gNOI GetCertificate RPCs for the user profile is permitted.

deny

Specifies that the use of the gNOI GetCertificate RPCs for the user profile is denied.

Platforms
7705 SAR Gen 2

11.23 gnoi-cert-mgmt-install

gnoi-cert-mgmt-install

Syntax
gnoi-cert-mgmt-install {**permit** | **deny**}

Context
[Tree] (config>system>security>profile>grpc>rpc-authorization gnoi-cert-mgmt-install)

Full Context
configure system security profile grpc rpc-authorization gnoi-cert-mgmt-install

Description
This command permits the use of gNOI Install RPCs for the user profile.

The **no** form of this command reverts to the default value.

Default
gnoi-cert-mgmt-install deny

Parameters
permit
Specifies that the use of the gNOI Install RPCs for the user profile is permitted.

deny
Specifies that the use of the gNOI Install RPCs for the user profile is denied.

Platforms
7705 SAR Gen 2

11.24 gnoi-cert-mgmt-revoke

gnoi-cert-mgmt-revoke

Syntax
gnoi-cert-mgmt-revoke {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization gnoi-cert-mgmt-revoke)

Full Context

configure system security profile grpc rpc-authorization gnoi-cert-mgmt-revoke

Description

This command permits or denies the use of gNOI RevokeCertificates RPCs for the user profile.

The **no** form of this command reverts to the default value.

Default

gnoi-cert-mgmt-revoke deny

Parameters

permit

Specifies that the use of gNOI RevokeCertificates RPCs for the user profile is permitted.

deny

Specifies that the use of gNOI RevokeCertificates RPCs for the user profile is denied.

Platforms

7705 SAR Gen 2

11.25 gnoi-cert-mgmt-rotate

gnoi-cert-mgmt-rotate

Syntax

gnoi-cert-mgmt-rotate {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization gnoi-cert-mgmt-rotate)

Full Context

configure system security profile grpc rpc-authorization gnoi-cert-mgmt-rotate

Description

This command permits the use of gNOI Rotate RPCs for the user profile.

Default

gnoi-cert-mgmt-rotate deny

Parameters

permit

Specifies that the use of the gNOI Rotate RPCs for the user profile is permitted.

deny

Specifies that the use of the gNOI Rotate RPCs for the user profile is denied.

Platforms

7705 SAR Gen 2

11.26 gnoi-file-get

gnoi-file-get

Syntax

gnoi-file-get {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization gnoi-file-get)

Full Context

configure system security profile grpc rpc-authorization gnoi-file-get

Description

This command permits the use of gNOI File Get RPC for a file from a target location.

Default

gnoi-file-get permit

Parameters

permit

Specifies that the use of the gNOI File Get RPC is permitted.

deny

Specifies that the use of the gNOI File Get RPC is denied.

Platforms

7705 SAR Gen 2

11.27 gnoi-file-put

gnoi-file-put

Syntax

gnoi-file-put {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization gnoi-file-put)

Full Context

configure system security profile grpc rpc-authorization gnoi-file-put

Description

This command permits the use of gNOI File Put RPC to write to a file on a target location.

Default

gnoi-file-put permit

Parameters

permit

Specifies that the use of the gNOI File Put RPC is permitted.

deny

Specifies that the use of the gNOI File Put RPC is denied.

Platforms

7705 SAR Gen 2

11.28 gnoi-file-remove

gnoi-file-remove

Syntax

gnoi-file-remove {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization gnoi-file-remove)

Full Context

configure system security profile grpc rpc-authorization gnoi-file-remove

Description

This command permits the use of gNOI File Remove RPC to remove a file from the specified target location.

Default

gnoi-file-remove permit

Parameters

permit

Specifies that the use of the gNOI File Remove RPC is permitted.

deny

Specifies that the use of the gNOI File Remove RPC is denied.

Platforms

7705 SAR Gen 2

11.29 gnoi-file-stat

gnoi-file-stat

Syntax

gnoi-file-stat {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization gnoi-file-stat)

Full Context

configure system security profile grpc rpc-authorization gnoi-file-stat

Description

This command permits the use of gNOI File Stat RPC to retrieve metadata for a file from the specified target location.

Default

gnoi-file-stat permit

Parameters

permit

Specifies that the use of the gNOI File Stat RPC is permitted.

deny

Specifies that the use of the gNOI File Stat RPC is denied.

Platforms

7705 SAR Gen 2

11.30 gnoi-file-transfertoremote

gnoi-file-transfertoremote

Syntax

gnoi-file-transfertoremote {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization gnoi-file-transfertoremote)

Full Context

configure system security profile grpc rpc-authorization gnoi-file-transfertoremote

Description

This command permits the use of the gNOI File TransferToRemote RPC to transfer the file from the target node to a specified remote location.

Default

gnoi-file-transfertoremote permit

Parameters

permit

Specifies that the use of the gNOI File TransferToRemote RPC is permitted.

deny

Specifies that the use of the gNOI File TransferToRemote RPC is denied.

Platforms

7705 SAR Gen 2

11.31 gnoi-system-cancelreboot

gnoi-system-cancelreboot

Syntax

gnoi-system-cancelreboot {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization gnoi-system-cancelreboot)

Full Context

configure system security profile grpc rpc-authorization gnoi-system-cancelreboot

Description

This command permits the use of gNOI System CancelReboot RPC for a user-given profile.

Default

gnoi-system-cancelreboot deny

Parameters

permit

Specifies that the use of gNOI System CancelReboot RPC is permitted.

deny

Specifies that the use of gNOI System CancelReboot RPC is denied.

Platforms

7705 SAR Gen 2

11.32 gnoi-system-ping

gnoi-system-ping

Syntax

gnoi-system-ping {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization gnoi-system-ping)

Full Context

configure system security profile grpc rpc-authorization gnoi-system-ping

Description

This command permits the use of the gNOI Ping RPC to execute the ping command on the target node and stream back the results.

Default

gnoi-system-ping permit

Parameters

permit

Specifies that the use of the gNOI Ping RPC is permitted.

deny

Specifies that the use of the gNOI Ping RPC is denied.

Platforms

7705 SAR Gen 2

11.33 gnoi-system-reboot

gnoi-system-reboot

Syntax

gnoi-system-reboot {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization gnoi-system-reboot)

Full Context

configure system security profile grpc rpc-authorization gnoi-system-reboot

Description

This command permits the use of gNOI System Reboot RPC for a user-given profile.

The **no** form of this command reverts to the default value.

Default

gnoi-system-reboot deny

Parameters

permit

Specifies that the use of gNOI System Reboot RPC is permitted.

deny

Specifies that the use of gNOI System Reboot RPC is denied.

Platforms

7705 SAR Gen 2

11.34 gnoi-system-rebootstatus

gnoi-system-rebootstatus

Syntax

gnoi-system-rebootstatus {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization gnoi-system-rebootstatus)

Full Context

configure system security profile grpc rpc-authorization gnoi-system-rebootstatus

Description

This command permits the use of gNOI System RebootStatus RPC for a user-given profile.

The **no** form of this command reverts to the default value.

Default

gnoi-system-rebootstatus deny

Parameters

permit

Specifies that the use of gNOI System RebootStatus RPC is permitted for a user-given profile.

deny

Specifies that the use of gNOI System RebootStatus RPC is denied.

Platforms

7705 SAR Gen 2

11.35 gnoi-system-setpackage

gnoi-system-setpackage

Syntax

gnoi-system-setpackage {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization gnoi-system-setpackage)

Full Context

configure system security profile grpc rpc-authorization gnoi-system-setpackage

Description

This command permits the use of gNOI System SetPackage RPC for a user-given profile.

The **no** form of this command reverts to the default value.

Default

gnoi-system-setpackage deny

Parameters

deny

Specifies that the use of gNOI System SetPackage RPC is denied.

permit

Specifies that the use of gNOI System SetPackage RPC is permitted.

Platforms

7705 SAR Gen 2

11.36 gnoi-system-switchcontrolprocessor

gnoi-system-switchcontrolprocessor

Syntax

gnoi-system-switchcontrolprocessor {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization gnoi-system-switchcontrolprocessor)

Full Context

configure system security profile grpc rpc-authorization gnoi-system-switchcontrolprocessor

Description

This command permits the use of gNOI System SwitchControlProcessor RPC for a user-given profile.

The **no** form of this command reverts to the default value.

Default

gnoi-system-switchcontrolprocessor deny

Parameters

deny

Specifies that the use of gNOI System SwitchControlProcessor RPC is denied.

permit

Specifies that the use of gNOI System SwitchControlProcessor RPC is permitted.

Platforms

7705 SAR Gen 2

11.37 gnoi-system-time

gnoi-system-time

Syntax

gnoi-system-time {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization gnoi-system-time)

Full Context

configure system security profile grpc rpc-authorization gnoi-system-time

Description

This command permits the use of the gNOI Time RPC to return the current time on the target node.

Default

gnoi-system-time permit

Parameters

permit

Specifies that the use of the gNOI Time RPC is permitted.

deny

Specifies that the use of the gNOI Time RPC is denied.

Platforms

7705 SAR Gen 2

11.38 gnoi-system-traceroute

gnoi-system-traceroute

Syntax

gnoi-system-traceroute {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization gnoi-system-traceroute)

Full Context

configure system security profile grpc rpc-authorization gnoi-system-traceroute

Description

This command permits the use of the gNOI Traceroute RPC to execute the traceroute command on the target node and stream back the results.

Default

gnoi-system-traceroute permit

Parameters

permit

Specifies that the use of the gNOI Traceroute RPC is permitted.

deny

Specifies that the use of the gNOI Traceroute RPC is denied.

Platforms

7705 SAR Gen 2

11.39 goto

goto

Syntax

goto *line*

Context

[Tree] (candidate goto)

Full Context

candidate goto

Description

This command changes the edit point of the candidate configuration. The edit point is the point after which new commands are inserted into the candidate configuration as an operator navigates the CLI and issues commands in edit-cfg mode.

Parameters

line

Indicates which line to change starting at the point indicated by the following options.

Values line, offset, **first**, **edit-point**, **last**

line	absolute line number
offset	relative line number to current edit point. Prefixed with '+' or '-'
first	keyword - first line
edit-point	keyword - current edit point
last	keyword - last line that is not 'exit'

Platforms

7705 SAR Gen 2

11.40 gr-helper

gr-helper

Syntax

gr-helper [**enable** | **disable**]

Context

[Tree] (config>router>rsvp>if gr-helper)

Full Context

configure router rsvp interface gr-helper

Description

This command enables the RSVP Graceful Restart Helper feature.

The RSVP-TE Graceful Restart helper mode allows the SR OS based system (the helper node) to provide another router that has requested it (the restarting node) a grace period, during which the system will continue to use RSVP sessions to neighbors requesting the grace period. This is typically used when another router is rebooting its control plane but its forwarding plane is expected to continue to forward traffic based on the previously available Path and Resv states.

The user can enable Graceful Restart helper on each RSVP interface separately. When the GR helper feature is enabled on an RSVP interface, the node starts inserting a new Restart_Cap Object in the Hello packets to its neighbor. The restarting node does the same and indicates to the helper node the desired Restart Time and Recovery Time.

The GR Restart helper consists of a couple of phases. Once it loses Hello communication with its neighbor, the helper node enters the Restart phase. During this phase, it preserves the state of all RSVP sessions to its neighbor and waits for a new Hello message.

Once the Hello message is received indicating the restarting node preserved state, the helper node enters the recovery phase in which it starts refreshing all the sessions that were preserved. The restarting node will activate all the stale sessions that are refreshed by the helper node. Any Path state which did not get a Resv message from the restarting node once the Recovery Phase time is over is considered to have expired and is deleted by the helper node causing the proper Path Tear generation downstream.

The duration of the restart phase (recovery phase) is equal to the minimum of the neighbor’s advertised Restart Time (Recovery Time) in its last Hello message and the locally configured value of the max-restart (max-recovery) parameter.

When GR helper is enabled on an RSVP interface, its procedures apply to the state of both P2P and P2MP RSVP LSP to a neighbor over this interface.

Default

disable

Platforms

7705 SAR Gen 2

11.41 gr-helper-time

gr-helper-time

Syntax

gr-helper-time max-recovery *recovery-interval* **max-restart** *restart-interval*

no gr-helper-time

Context

[Tree] (config>router>rsvp gr-helper-time)

Full Context

configure router rsvp gr-helper-time

Description

This command configures the local values for the max-recovery and the max-restart intervals used in the RSVP Graceful Restart Helper feature.

The values are configured globally in RSVP but separate instances of the timers are applied to each RSVP interface that has the RSVP Graceful Restart Helper enabled.

The **no** version of this command re-instates the default value for the delay timer.

Default

gr-helper-time max-recovery 300 max-restart 120

Parameters

recovery-interval

Specifies the max recovery interval value in seconds.

Values 1 to 1800

restart-interval

Specifies the max restart interval value in seconds.

Values 1 to 300

Platforms

7705 SAR Gen 2

11.42 graceful-restart

graceful-restart

Syntax

[**no**] **graceful-restart**

Context

[Tree] (config>service>vprn>bgp>group graceful-restart)

[Tree] (config>service>vprn>bgp graceful-restart)

[Tree] (config>service>vprn>bgp>group>neighbor graceful-restart)

Full Context

configure service vprn bgp group graceful-restart

configure service vprn bgp graceful-restart

configure service vprn bgp group neighbor graceful-restart

Description

This command enables BGP graceful restart helper procedures (the "receiving router" role defined in the standard) for address families included in the GR capabilities of both peers. In a VPRN, SR OS can support GR helper functionality for IPv4, IPv6, label-ipv4, flow-ipv4 (IPv4 FlowSpec) and flow-ipv6 (IPv6 FlowSpec) routes.

When a neighbor covered by the GR helper mode restarts its control plane, forwarding can continue uninterrupted while the session is re-established and routes are re-learned.

The **no** form of this command disables graceful restart.

Platforms

7705 SAR Gen 2

graceful-restart

Syntax

[**no**] **graceful-restart**

Context

[Tree] (config>service>vprn>isis graceful-restart)

Full Context

configure service vprn isis graceful-restart

Description

This command enables IS-IS graceful restart (GR) to minimize service interruption. When the control plane of a GR-capable router fails or restarts, the neighboring routers (GR helpers) temporarily preserve IS-IS forwarding information. Traffic continues to be forwarded to the restarting router using the last known forwarding tables. If the control plane of the restarting router becomes operationally and administratively up within the grace period, the restarting router resumes normal IS-IS operation. If the grace period expires, then the restarting router is presumed inactive and the IS-IS topology is recalculated to route traffic around the failure.

The **no** form of this command disables graceful restart and removes the graceful restart configuration from the IS-IS instance.

Default

no graceful-restart

debug router bgp graceful-restart

Description

This command enables debugging for BGP graceful restart.

The **no** form of this command disables the debugging.

Parameters

neighbor *ip-address*

Debugs only events affecting the specified BGP neighbor.

Values ipv4-address:

- a.b.c.d (host bits must be 0)

ipv6-address:

- x:x:x:x:x:x:x:x [-interface] (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d [-interface]
- x: [0 to FFFF]H
- d: [0 to 255]D

- interface: up to 32 characters for link local addresses

group *name*

Debugs only events affecting the specified peer group name, up to 64 characters, and associated neighbors.

11.43 graceful-shutdown

graceful-shutdown

Syntax

[**no**] **graceful-shutdown**

Context

[Tree] (config>router>rsvp graceful-shutdown)

[Tree] (config>router>rsvp>interface graceful-shutdown)

Full Context

configure router rsvp graceful-shutdown

configure router rsvp interface graceful-shutdown

Description

This command initiates a graceful shutdown of the specified RSVP interface or all RSVP interfaces on the node if applied at the RSVP level. These are referred to as maintenance interface and maintenance node, respectively.

To initiate a graceful shutdown the maintenance node generates a PathErr message with a specific error sub-code of Local Maintenance on TE Link required for each LSP that is exiting the maintenance interface.

The node performs a single make-before-break attempt for all adaptive CSPF LSPs it originates and LSP paths using the maintenance interfaces. If an alternative path for an affected LSP is not found, then the LSP is maintained on its current path. The maintenance node also tears down and re-signals any detour LSP path using listed maintenance interfaces as soon as they are not active.

The maintenance node floods an IGP TE LSA/LSP containing Link TLV for the links under graceful shutdown with TE metric set to 0xffffffff and Unreserved Bandwidth parameter set to zero (0).

A head-end LER node, upon receipt of the PathErr message performs a single make-before-break attempt on the affected adaptive CSPF LSP. If an alternative path is not found, then the LSP is maintained on its current path.

A node does not take any action on the paths of the following originating LSPs after receiving the PathErr message:

a. An adaptive CSPF LSP for which the PathErr indicates a node address in the address list and the node corresponds to the destination of the LSP. In this case, there are no alternative paths which can be found.

b. An adaptive CSPF LSP whose path has explicit hops defined using the listed maintenance interface(s)/ node(s).

c. A CSPF LSP with the adaptive option disabled and which current path is over the listed maintenance interfaces in the PathErr message. These are not subject to make-before-break.

d. A non CSPF LSP which current path is over the listed maintenance interfaces in the PathErr message.

The head-end LER node upon receipt of the updates IPG TE LSA/LSP for the maintenance interfaces updates the TE database. This information will be used at the next scheduled CSPF computation for any LSP which path may traverse any of the maintenance interfaces.

The **no** form of this command disables the graceful shutdown operation at the RSVP interface level or at the RSVP level. The configured TE parameters of the maintenance links are restored and the maintenance node floods the links.

configure service vpls spoke-sdp mld-snooping static group

configure service vpls mesh-sdp igmp-snooping static group

configure service vpls sap igmp-snooping static group

Description

Commands in this context add a static multicast group as a (*, G) or as one or more (S,G) records. When a static MLD or IGMP group is added, multicast data for that (*,G) or (S,G) is forwarded to the specific SAP or SDP without receiving any membership report from a host.

Parameters

grp-ip-address

Specifies an IGMP multicast group address that receives data on an interface. The IP address must be unique for each static group.

grp-ipv6-address

Specifies an MLD multicast group address that receives data on an interface. The IP address must be unique for each static group.

Values ipv6-address:

- x:x:x:x:x:x:x:x (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d
- x: [0 to FFFF]H
- d: [0 to 255]D

no group *name*

Context

[Tree] (config>service>vprn>bgp group)

Full Context

configure service vprn bgp group

Description

This command creates a context to configure a BGP peer group.

The **no** form of this command deletes the specified peer group and all configurations associated with the peer group. The group must be shut down before it can be deleted.

Parameters

name

Specifies the peer group name. Allowed values is a string up to 64 characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed between double quotes.

esm-dynamic-peer

Specifies that the given BGP group is used by BGP peers created dynamically based on subscriber-hosts pointing to corresponding BGP peering policy. There can be only one BGP group with this flag set in any given VPRN. No BGP neighbors can be manually configured in a BGP group with this flag set.

Default disabled

Platforms

7705 SAR Gen 2

group

Syntax

[**no**] **group** *grp-ip-address*

[**no**] **group start** *grp-ip-address* **end** *grp-ip-address* [**step** *ip-address*]

Context

[Tree] (config>service>vprn>igmp>if>static group)

Full Context

configure service vprn igmp interface static group

Description

This command adds a static multicast group either as a (*,G) or one or more (S,G) records. Use IGMP static group memberships to test multicast forwarding without a receiver host. When IGMP static groups are enabled, data is forwarded to an interface without receiving membership reports from host members.

When static IGMP group entries on point-to-point links that connect routers to a rendezvous point (RP) are configured, the static IGMP group entries do not generate join messages toward the RP.

Parameters

grp-ip-address

Specifies an IGMP multicast group address that receives data on an interface. The IP address must be unique for each static group. The address must be in dotted decimal notation.

start *grp-ip-address*

Specifies the start multicast group address.

end *grp-ip-address*

Specifies the end multicast group address.

step *ip-address*

Specifies the step increment.

Platforms

[**no**] **group start** *grp-ipv6-address* **end** *grp-ipv6-address* [**step** *ipv6-address*]

Context

[Tree] (config>service>vprn>mld>if>static group)

Full Context

configure service vprn mld interface static group

Description

Commands in this context add a static multicast group either as a (*,G) or one or more (S,G) records. Use MLD static group memberships to test multicast forwarding without a receiver host. When MLD static groups are enabled, data is forwarded to an interface without receiving membership reports from host members.

When static MLD group entries on point-to-point links that connect routers to a rendezvous point (RP) are configured, the static MLD group entries do not generate join messages toward the RP.

The **no** form of this command removes the IPv6 address from the configuration.

Parameters

grp-ipv6-address

Specifies an MLD multicast group address that receives data on an interface. The IP address must be unique for each static group.

Values ipv6-address:

- x:x:x:x:x:x:x:x (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d
- x: [0 to FFFF]H
- d: [0 to 255]D

start *grp-ipv6-address*

Specifies the start multicast group address.

Values ipv6-address:

- x:x:x:x:x:x:x:x (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d
- x: [0 to FFFF]H
- d: [0 to 255]D

end *grp-ipv6-address*

Specifies the end multicast group address.

Values ipv6-address:

- x:x:x:x:x:x:x:x (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d
- x: [0 to FFFF]H

Full Context

configure router mld interface static group

Description

Commands in this context add a static multicast group either as a (*,G) or one or more (S,G) records. Use MLD static group memberships to test multicast forwarding without a receiver host. When MLD static groups are enabled, data is forwarded to an interface without receiving membership reports from host members.

When static MLD group entries on point-to-point links that connect routers to a rendezvous point (RP) are configured, the static MLD group entries do not generate join messages toward the RP.

The **no** form of this command removes the IPv6 address from the configuration.

Parameters

grp-ipv6-address

Specifies an MLD multicast group address that receives data on an interface. The IP address must be unique for each static group.

Values ipv6-address:

- x:x:x:x:x:x:x:x (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d
- x: [0 to FFFF]H
- d: [0 to 255]D

start *grp-ipv6-address*

Specifies the start multicast group address.

Values ipv6-address:

- x:x:x:x:x:x:x:x (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d
- x: [0 to FFFF]H
- d: [0 to 255]D

end *grp-ipv6-address*

Specifies the end multicast group address.

Values ipv6-address:

- x:x:x:x:x:x:x:x (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d
- x: [0 to FFFF]H
- d: [0 to 255]D

step *ipv6-address*

Specifies the step increment.

group

Syntax

group *group-name*

no group

Context

[Tree] (config>system>security>user>snmp group)

Full Context

configure system security user snmp group

Description

This command associates (or links) a user to a group name. The group name must be configured with the **config>system>security>user >snmp>group** command. The **config>system>security>user access** command links the group with one or more views, security model (s), security level (s), and read, write, and notify permissions.

Parameters

group-name

Enter the group name (between 1 and 32 alphanumeric characters) that is associated with this user. A user can be associated with one group-name per security model.

Platforms

7705 SAR Gen 2

group

Syntax

[**no**] **group** *group-name*

Context

[Tree] (config>router>rip group)

[Tree] (config>router>ripng group)

Full Context

configure router rip group

configure router ripng group

Description

This command creates a context for configuring a RIP group of neighbor interfaces.

RIP groups are a way of logically associating RIP neighbor interfaces to facilitate a common configuration for RIP interfaces.

The **no** form of the command deletes the RIP neighbor interface group. Deleting the group will also remove the RIP configuration of all the neighbor interfaces currently assigned to this group.

Default

no group

Parameters

group-name

Specifies the RIP group name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

Platforms

7705 SAR Gen 2

group

Syntax

group down *time* | **no group down**

group up *time* | **no group up**

Context

[Tree] (config>service>oper-group>hold-time group)

Full Context

configure service oper-group hold-time group

Description

The **group down** form of the command configures the number of seconds to wait before notifying clients monitoring this group when its operational status transitions from up to down.

The **group up** form of the command configures the number of seconds to wait before notifying clients monitoring this group when its operational status transitions from down to up. A value of zero indicates that transitions are reported immediately to monitoring clients. The up time option is a must to achieve fast convergence: when the group comes up, the monitoring MH site that tracks the group status may wait without impacting the overall convergence; there is usually a pair MH site that is already handling the traffic.

The **no** form of the command sets the values back to the default.

Default

group down 0

group up 4

Parameters

time

Specifies the group up or group down time value.

Values 0 to 3600

Platforms

7705 SAR Gen 2

11.48 group-address

group-address

Syntax

group-address *prefix-list-name*

no group-address

Context

[Tree] (config>router>policy-options>policy-statement>entry>from group-address)

Full Context

configure router policy-options policy-statement entry from group-address

Description

This command specifies the multicast group-address prefix list containing multicast group-addresses that are embedded in the join or prune packet as a filter criterion. The prefix list must be configured prior to entering this command. Prefix lists are configured in the **config>router>policy-options>prefix-list** context.

The **no** form of this command removes the criterion from the configuration.

Default

no group-address

Parameters

prefix-list-name

Specifies the prefix-list name. Allowed values are any string up to 64 characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

The *prefix-list-name* is defined in the **config>router>policy-options>prefix-list** context.

11.53 group-name

group-name

Syntax

group-name *group-name* **value** *group-value*

no group-name *group-name*

Context

[Tree] (config>service>sdp-group group-name)

Full Context

configure service sdp-group group-name

Description

This command defines SDP administrative groups, referred to as SDP admin groups.

SDP admin groups provide a way for services using a pseudowire template to automatically include or exclude specific provisioned SDPs. SDPs sharing a specific characteristic or attribute can be made members of the same admin group. When users configure a pseudowire template, they can include and/or exclude one or more admin groups. When the service is bound to the pseudowire template, the SDP selection rules will enforce the admin group constraints specified in the **sdp-include** and **sdp-exclude** commands.

A maximum of 32 admin groups can be created. The group value ranges from zero (0) to 31. It is uniquely associated with the group name at creation time. If the user attempts to configure another group name for a group value that is already assigned to an existing group name, the SDP admin group creation is failed. The same happens if the user attempts to configure an SDP admin group with a new name but associates it to a group value already assigned to an existing group name.

The **no** option of this command deletes the SDP admin group but is only allowed if the group-name is not referenced in a PW template or SDP.

Parameters

group-name

Specifies the name of the SDP admin group. A maximum of 32 characters can be entered.

group-value

Specifies the group value associated with this SDP admin group. This value is unique within the system.

Values 0 to 31

Platforms

[Tree] (config>router>pim>rp>static>address group-prefix)

Full Context

configure router pim rp ipv6 static address group-prefix

configure router pim rp static address group-prefix

Description

This command specifies the range of multicast group addresses which should be used by the router as the Rendezvous Point (RP). The **config**>**router**>**pim**>**rp**>**static**> **address** *a.b.c.d* implicitly defaults to deny all for all multicast groups (224.0.0.0/4). A group-prefix must be specified for that static address. This command does not apply to the whole group range.

The **no** form of this command removes the group-prefix from the configuration.

Parameters

grp-ipv6-address

Specifies the multicast group IPv6 address expressed in dotted decimal notation.

Values grp-ipv6-address x:x:x:x:x:x:x:x (eight 16-bit pieces)
x:x:x:x:x:x:d.d.d.d
x [0..FFFF]H
d [0..255]D

prefix-length

Specifies the prefix length of the IPv6 address.

Values 8 to 128

12 h Commands

12.1 half-life

half-life

Syntax

half-life *half-life* **max-suppress-time** *max-time*

Context

[Tree] (config>port>ethernet>dampening half-life)

Full Context

configure port ethernet dampening half-life

Description

This command configures the half-life decay time and the maximum period of time for which the port up state can be suppressed.

The *half-life* and *max-time* values must be set at the same time; the ratio of *max-time*/ *half-life* must be less than or equal to 49 and greater than or equal to 1.

Parameters

half-life

Specifies the required elapsed time, in seconds, before penalties decay to one-half the initial amount.

Values 1 to 2000

Default 5

max-time

Specifies the maximum suppression time, in seconds, which is the time it can take after the physical link comes up before the worst case accumulated penalties have decayed to the reuse threshold. The maximum penalty is derived from the maximum suppression time, half-life, and reuse threshold, using the following equation:

maximum penalty = (reuse threshold) X 2 expo:(max-time/half-life)

Values 1 to 43200

Default 20

Platforms

7705 SAR Gen 2

half-life

Syntax

half-life *minutes*

no half-life

Context

[Tree] (config>router>policy-options>damping half-life)

Full Context

configure router policy-options damping half-life

Description

This command configures the **half-life** parameter for the route damping profile.

The half-life value is the time, expressed in minutes, required for a route to remain stable in order for the Figure of Merit (FoM) value to be reduced by one half; for example, if the half-life value is 6 (minutes) and the route remains stable for 6 minutes, then the new FoM value is 3 (minutes). After another 3 minutes pass and the route remains stable, the new FoM value is 1.5 (minutes).

When the FoM value falls below the **config>router>policy-options>damping reuse** threshold, the route is once again considered valid and can be reused or included in route advertisements.

The **no** form of this command removes the half life parameter from the damping profile.

Default

no half-life

Parameters

minutes

Specifies the half-life in minutes expressed as a decimal integer.

Values 1 to 45

Platforms

7705 SAR Gen 2

12.2 handler

handler

Syntax

[**no**] **handler** *event-handler-name*

Context

[Tree] (config>log>event-handling handler)

Full Context

configure log event-handling handler

Description

This command configures an EHS handler.

The **no** form of this command removes the specified EHS handler.

Parameters

event-handler-name

Specifies the name of the EHS handler, up to 32 characters maximum.

Platforms

7705 SAR Gen 2

handler

Syntax

handler *name* **[create]**

no handler *name*

Context

[Tree] (config>system>grpc-tunnel>tunnel handler)

Full Context

configure system grpc-tunnel tunnel handler

Description

Commands in this context configure tunnel handler parameters. There can be multiple handlers created for any tunnel.

The **no** form of this command removes the specified tunnel handler.

Parameters

name

Specifies the handler name, up to 32 characters.

create

Keyword used to create a tunnel.

Platforms

7705 SAR Gen 2

configure system security pki certificate-update-profile hash-algorithm

Description

This command configures the hash algorithm used to generate a certificate request.

Default

hash-algorithm sha256

Parameters

algorithm

Specifies the hash option.

Values md5, sha1, sha224, sha256, sha384, sha512

Platforms

7705 SAR Gen 2

12.4 hash-label

hash-label

Syntax

hash-label

hash-label [**signal-capability**]

no hash-label

Context

[Tree] (config>service>pw-template hash-label)

[Tree] (config>service>epipe>spoke-sdp hash-label)

Full Context

configure service pw-template hash-label

configure service epipe spoke-sdp hash-label

Description

This command enables the use of the hash label on a VLL, VPRN or VPLS service bound to any MPLS type encapsulated SDP, as well as to a VPRN service that is using the **auto-bind-tunnel** with the **resolution-filter** set to any MPLS tunnel type. This feature is not supported on a service bound to a GRE SDP or for a VPRN service using the autobind mode with the gre option. This feature is also not supported on multicast packets forwarded using RSVP P2MP LSP or mLDP LSP in both the base router instance and in the multicast VPN (mVPN) instance. It is, however, supported when forwarding multicast packets using an IES/VPRN spoke-interface.

When this feature is enabled, the ingress data path is modified such that the result of the hash on the packet header is communicated to the egress data path for use as the value of the label field of the hash label. The egress data path appends the hash label at the bottom of the stack (BoS) and sets the S-bit to one (1).

To allow applications where the egress LER infers the presence of the hash label implicitly from the value of the label, the Most Significant Bit (MSB) of the result of the hash is set before copying into the Hash Label. This means that the value of the hash label will always be in the range [524,288 - 1,048,575] and will not overlap with the signaled/static LSP and signaled/static service label ranges. This also guarantees that the hash label will not match a value in the reserved label range.

The (unmodified) result of the hash continues to be used for the purpose of ECMP and LAG spraying of packets locally on the ingress LER. Note, however, that for VLL services, the result of the hash is overwritten and the ECMP and LAG spraying will be based on service-id when ingress SAP shared queuing is not enabled. However, the hash label will still reflect the result of the hash such that an LSR can use it to perform fine grained load balancing of VLL pseudowire packets.

Packets generated in CPM and that are forwarded labeled within the context of a service (for example, OAM packets) must also include a Hash Label at the BoS and set the S-bit accordingly.

The TTL of the hash label is set to a value of 0.

The user enables the signaling of the hash-label capability under a VLL spoke-sdp, a VPLS spoke-sdp or mesh SDP, or an IES/VPRN spoke interface by adding the **signal-capability** option. In this case, the decision whether to insert the hash label on the user and control plane packets by the local PE is solely determined by the outcome of the signaling process and can override the local PE configuration. The following are the procedures:

- The local PE will insert the flow label interface parameters sub-TLV with F=1 in the PW ID FEC element in the label mapping message for that spoke SDP or mesh SDP.
- If the remote PE includes this sub-TLV with F=1 or F=0, then local PE must insert the hash label in the user and control plane packets.

- If remote PE does not include this sub-TLV (for example, it does not support it, or it is supported but the user did not enable the **hash-label** option or the **signal-capability** option), then the local PE establishes the PW but must not insert the hash label in the user and control packets over that spoke SDP or mesh SDP. If the remote PE does not support the **signal-capability** option, then there are a couple of possible outcomes:
  - If the **hash-label** option was enabled on the local configuration of the spoke SDP or mesh SDP at the remote PE, the PW packets received by the local PE will have the hash label included. These packets must be dropped. The only way to solve this is to disable the signaling capability option on the local node which will result in the insertion of the hash label by both PE nodes.
  - If the **hash-label** option is not supported or was not enabled on the local configuration of the spoke SDP or mesh SDP at the remote PE, the PW received by the local PE will not have the hash label included.
- The user can enable or disable the signal-capability option in CLI as needed. When doing so, the 7705 SAR Gen 2 must withdraw the label it sent to its peer and send a new label mapping message with the new value of the F bit in the flow label interface parameters sub-TLV of the PW ID FEC element.

The **no** form of this command disables the use of the hash label.

Default

no hash-label

Parameters

signal-capability

Enables the signaling and negotiation of the use of the hash label between the local and remote PE nodes. The **signal-capability** option is not supported on a VPRN spoke-sdp.

Platforms

7705 SAR Gen 2

hash-label

Syntax

hash-label signal-capability

[Tree] (config>service>vpls>spoke-sdp hash-label)

Full Context

configure service vpls mesh-sdp hash-label

configure service vpls spoke-sdp hash-label

Description

This command enables the use of the hash label on a VLL, VPRN, or VPLS service bound to any MPLS type encapsulated SDP, as well as to a VPRN service using the **auto-bind-tunnel** with the **resolution-filter** set to any MPLS tunnel type. This feature is not supported on a service bound to a GRE SDP or for a VPRN service using the autobind mode with the gre option. This feature is also not supported on multicast packets forwarded using RSVP P2MP LSP or mLDP LSP in both the base router instance and in the multicast VPN (mVPN) instance. It is, however, supported when forwarding multicast packets using an IES/VPRN spoke-interface.

When this feature is enabled, the ingress data path is modified such that the result of the hash on the packet header is communicated to the egress data path for use as the value of the label field of the hash label. The egress data path appends the hash label at the bottom of the stack (BoS) and sets the S-bit to one (1).

To allow applications where the egress LER infers the presence of the hash label implicitly from the value of the label, the Most Significant Bit (MSB) of the result of the hash is set before copying into the Hash Label. This means that the value of the hash label will always be in the range [524,288 - 1,048,575] and will not overlap with the signaled/static LSP and signaled/static service label ranges. This also guarantees that the hash label will not match a value in the reserved label range.

The (unmodified) result of the hash continues to be used for the purpose of ECMP and LAG spraying of packets locally on the ingress LER. Note, however, that for VLL services, the result of the hash is overwritten and the ECMP and LAG spraying will be based on service-id when ingress SAP shared queuing is not enabled. However, the hash label will still reflect the result of the hash such that an LSR can use it to perform fine grained load balancing of VLL pseudowire packets.

Packets generated in CPM and that are forwarded labeled within the context of a service (for example, OAM packets) must also include a Hash Label at the BoS and set the S-bit accordingly.

The TTL of the hash label is set to a value of 0.

The user enables the signaling of the hash-label capability under a VLL spoke-sdp, a VPLS spoke-sdp or mesh-sdp, or an IES/VPRN spoke interface by adding the **signal-capability** option. In this case, the decision whether to insert the hash label on the user and control plane packets by the local PE is solely determined by the outcome of the signaling process and can override the local PE configuration. The following are the procedures:

- The 7705 SAR Gen 2 local PE will insert the flow label interface parameters sub-TLV with F=1 in the pseudowire ID FEC element in the label mapping message for that spoke-sdp or mesh-sdp.
- If the remote PE includes this sub-TLV with F=1 or F=0, then local PE must insert the hash label in the user and control plane packets.
- If remote PE does not include this sub-TLV (for example, it does not support it, or it is supported but the user did not enable the **hash-label** option or the **signal-capability** option), then the local PE establishes the pseudowire but must not insert the hash label in the user and control packets over that spoke-sdp or mesh-sdp. If the remote PE does not support the **signal-capability** option, then there are a couple of possible outcomes:
  - If the **hash-label** option was enabled on the local configuration of the spoke-sdp or mesh-sdp at the remote PE, the pseudowire packets received by the local PE will have the hash label included. These packets must be dropped. The only way to solve this is to disable the signaling capability option on the local node which will result in the insertion of the hash label by both PE nodes.
  - If the **hash-label** option is not supported or was not enabled on the local configuration of the spoke-sdp or mesh-sdp at the remote PE, the pseudowire received by the local PE will not have the hash label included.

- The user can enable or disable the signal-capability option in CLI as needed. When doing so, the 7705 SAR Gen 2 must withdraw the label it sent to its peer and send a new label mapping message with the new value of the F bit in the flow label interface parameters sub-TLV of the pseudowire ID FEC element.

The **no** form of this command disables the use of the hash label.

Default

no hash-label

Parameters

signal-capability

Enables the signaling and negotiation of the use of the hash label between the local and remote PE nodes. The **signal-capability** option is not supported on a VPRN spoke-sdp.

Platforms

7705 SAR Gen 2

hash-label

Syntax

hash-label [**signal-capability**]

no hash-label

Context

[Tree] (config>service>ies>if>spoke-sdp hash-label)

Full Context

configure service ies interface spoke-sdp hash-label

Description

This command enables the use of the hash label on a VLL, VPLS, or VPRN service bound to any MPLS-type encapsulated SDP, as well as to a VPRN service using **auto-bind-tunnel** with the **resolution-filter** configures as any MPLS tunnel type. This feature is not supported on a service bound to a GRE SDP or for a VPRN service using the autobind mode with the gre option.

When this feature is enabled, the ingress data path is modified such that the result of the hash on the packet header is communicated to the egress data path for use as the value of the label field of the hash label. The egress data path appends the hash label at the bottom of the stack (BoS) and sets the S-bit to 1 to indicate that.

In order to allow for applications whereby the egress LER infers the presence of the hash label implicitly from the value of the label, the Most Significant Bit (MSB) of the result of the hash is set before copying into the hash label. This means that the value of the hash label will always be in the range [524,288 to 1,048,575] and will not overlap with the signaled/static LSP and signaled/static service label ranges. This also guarantees that the hash label will not match a value in the reserved label range.

The (unmodified) result of the hash continues to be used for the purpose of ECMP and LAG spraying of packets locally on the ingress LER. For VLL services, the result of the hash is overwritten and the ECMP and LAG spraying will be based on service-id when ingress SAP shared queuing is not enabled. However, the hash label will still reflect the result of the hash such that an LSR can use it to perform fine grained load balancing of VLL pseudowire packets.

Packets that are generated in CPM and forwarded labeled within the context of a service (for example, OAM packets) must also include a hash label at the BoS and set the S-bit accordingly.

The TTL of the hash label is set to a value of 0.

The user enables the signaling of the hash-label capability under a VLL spoke-sdp, a VPLS spoke-sdp or mesh-sdp, or an IES/VPRN spoke interface by adding the **signal-capability** option. In this case, the decision whether to insert the hash label on the user and control plane packets by the local PE is solely determined by the outcome of the signaling process and can override the local PE configuration. The following are the procedures:

- The local PE will insert the flow label interface parameters sub-TLV with F=1 in the PW ID FEC element in the label mapping message for that spoke-sdp or mesh-sdp.
- If the remote PE includes this sub-TLV with F=1 or F=0, then local PE must insert the hash label in the user and control plane packets.
- If remote PE does not include this sub-TLV (for example, it does not support it, or it is supported but the user did not enable the **hash-label** option or the **signal-capability** option), then the local PE establishes the PW but must not insert the hash label in the user and control packets over that spoke-sdp or mesh-sdp. If the remote PE does not support the **signal-capability** option, then there are a couple of possible outcomes:
  - If the **hash-label** option was enabled on the local configuration of the spoke-sdp or mesh-sdp at the remote PE, the PW packets received by the local PE will have the hash label included. These packets must be dropped. The only way to solve this is to disable the signaling capability option on the local node which will result in the insertion of the hash label by both PE nodes.
  - If the **hash-label** option is not supported or was not enabled on the local configuration of the spoke-sdp or mesh-sdp at the remote PE, the PW received by the local PE will not have the hash label included.
- The user can enable or disable the signal-capability option in CLI as needed. When doing so, the router must withdraw the label it sent to its peer and send a new label mapping message with the new value of the F bit in the flow label interface parameters sub-TLV of the PW ID FEC element.

The **no** form of this command disables the use of the hash label.

Default

no hash-label

Parameters

signal-capability

Enables the signaling and negotiation of the use of the hash label between the local and remote PE nodes. The **signal-capability** option is not supported on a VPRN spoke-sdp.

[Tree] (config>service>vprn hash-label)

Full Context

configure service vprn interface spoke-sdp hash-label

configure service vprn hash-label

Description

This command enables the use of the hash label on a VLL, VPLS, or VPRN service bound to any MPLS-type encapsulated SDP as well as to a VPRN service using **auto-bind-tunnel** with the **resolution-filter** configured as any MPLS tunnel type. This feature is not supported on a service bound to a GRE SDP or for a VPRN service using the autobind mode with the gre option.

When this feature is enabled, the ingress data path is modified such that the result of the hash on the packet header is communicated to the egress data path for use as the value of the label field of the hash label. The egress data path appends the hash label at the bottom of the stack (BoS) and sets the S-bit to 1 to indicate that.

In order to allow for applications whereby the egress LER infers the presence of the Hash Label implicitly from the value of the label, the Most Significant Bit (MSB) of the result of the hash is set before copying into the Hash Label. This means that the value of the hash label will always be in the range [524,288 - 1,048,575] and will not overlap with the signaled/static LSP and signaled/static service label ranges. This also guarantees that the hash label will not match a value in the reserved label range.

The (unmodified) result of the hash continues to be used for the purpose of ECMP and LAG spraying of packets locally on the ingress LER. For VLL services, the result of the hash is overwritten and the ECMP and LAG spraying will be based on service-id when ingress SAP shared queuing is not enabled. However, the hash label will still reflect the result of the hash such that an LSR can use it to perform fine grained load balancing of VLL pseudowire packets.

Packets that are generated in CPM and forwarded labeled within the context of a service (for example, OAM packets) must also include a Hash Label at the BoS and set the S-bit accordingly.

The TTL of the hash label is set to a value of 0.

The **no** form of this command disables the use of the hash label.

Default

no hash-label

Parameters

signal-capability

Specifies whether the service should send the Stack Capability and check whether the capability is received from the peer via LDP interface parameters.

Platforms

7705 SAR Gen 2

hash-label

Syntax

[**no**] **hash-label**

Context

[Tree] (config>service>vpls>bgp-evpn>mpls hash-label)

Full Context

configure service vpls bgp-evpn mpls hash-label

Description

This command pushes the hash label based on the following:

- If the **no incl-mcast-l2-attributes-advertisement** command is configured, the hash label is pushed to a unicast EVPN destination.
- If the **incl-mcast-l2-attributes-advertisement** command is configured, the F bit is set to 1 in the Layer 2 Attributes Extended Community of the EVPN IMET route for the service. The hash label is pushed only if the remote PE signaled support for hash label (received F bit is set to 1).

The hash label is never used for BUM packets.

The **no** form of this command disables the push of the hash label.

Default

no hash-label

configure router pim rp ipv6 bsr-candidate hash-mask-len

Description

This command configures the length of a mask that is to be combined with the group address before the hash function is called. All groups with the same hash map to the same RP. For example, if this value is 24, only the first 24 bits of the group addresses matter. This mechanism is used to map one group or multiple groups to an RP.

The **no** form of this command reverts to the default value.

Default

hash-mask-len 30 — for **config**>**router**>**pim**>**rp**>**bsr-candidate**

hash-mask-len 126 — for **config**>**router**>**pim**>**rp**>**ipv6**> **bsr-candidate**

Parameters

hash-mask-length

Specifies the hash mask length.

Values 0 to 32 (v4)
0 to 128 (v6)

Platforms

7705 SAR Gen 2

12.6 hash-weight-threshold

hash-weight-threshold

Syntax

hash-weight-threshold *weight* [**action** *action*] [**cost** *static-cost*]

no hash-weight-threshold

Context

[Tree] (config>lag hash-weight-threshold)

Full Context

configure lag hash-weight-threshold

Description

This command controls the operational status of the LAG or the IGP cost based on the sum of the **hash-weight** values for the active links in the LAG.

The **no** form of this command disables the hash weight threshold.

Parameters

weight

Specifies the value for the sum of all the active LAG ports **hash-weight** at or below which the configured action is invoked. If the sum of **hash-weight** for operational LAG links exceeds the **hash-weight-threshold** value, then no action is taken.

Values 1 to 6400000

action

Specifies the action to take if the sum of the **hash-weight** for active links in the LAG is equal or below the threshold value.

Values **down —** Specifies that the LAG is operationally DOWN. The LAG is only considered as UP once the number of **hash-weight** for the active links exceeds the configured threshold value.

dynamic-cost — Specifies that dynamic cost is activated. The LAG remains operationally UP with a link cost relative to the number of operational links. The link is only considered as operationally DOWN when all links in the LAG are down.

static-cost — Specifies that static cost is activated. The LAG remains operationally UP with the configured cost, regardless of the number of operational links. The link is only considered as operationally DOWN when all links in the LAG are down. If this parameter is used with an IGP, its **reference-bandwidth** must also be configured.

static-cost

Specifies the decimal integer static cost of the LAG.

Values 1 to 16777215

Platforms

7705 SAR Gen 2

configure system security password hashing

Description

This command configures the password hashing algorithm.

Default

hashing bcrypt

Parameters

bcrypt

Keyword to indicate that the command configures the bcrypt algorithm.

sha2-pbkdf2

Keyword to indicate that the command configures the PBKDF2 algorithm hashed via SHA2.

sha3-pbkdf2

Keyword to indicate that the command configures the PBKDF2 algorithm hashed via SHA3.

Platforms

7705 SAR Gen 2

12.8 head-end

head-end

Syntax

head-end local

head-end *ipv4-address*

no head-end

Context

[Tree] (conf>router>segment-routing>sr-policies>policy head-end)

Full Context

configure router segment-routing sr-policies static-policy head-end

Description

This command associates a head-end location with a statically-defined segment-routing policy. The head-end identifies the router that is the target to install the policy. This is a mandatory parameter and configuration command for enabling the segment-routing policy; if the head-end parameter value is not configured, the execution of the **no shutdown** command on the static segment routing policy fails.

To associate a static policy with the local router as head-end, the keyword **local** must be specified. The static policy is associated with another (non-local) router, if the head-end parameter is set to any IPv4 address. When a non-local, static segment routing policy that originates as a BGP route is imported into BGP, the configured head-end address is converted to an IPv4-address specific route-target extended community that is automatically added to the route.

The **no** form of this command removes the head-end association.

Default

no head-end

Parameters

local

Keyword indicating that the policy is intended to be used by the local router and not advertised to other BGP routers.

ipv4-address

Specifies the IP address of the target head-end router.

Values ipv4-address: a.b.c.d

7705 SAR Gen 2

health-check

Syntax

[**no**] **health-check** [**interval** *interval*]

Context

[Tree] (config>system>security>password health-check)

Full Context

configure system security password health-check

Description

This command enables health check monitoring of the RADIUS, TACACS+, and LDAP servers by sending authentication requests for an unknown user at regular intervals. If a response is not received, the operational status of the server is changed to down. The operational status is changed to up when responses are received.

When RADIUS over TLS is configured, Status-Server packets are sent at 30-second intervals as specified in *RFC 3539*, regardless of whether health checks are enabled.

The **no** form of this command disables health monitoring of RADIUS, TACACS+, and LDAP servers. In this case, the operational status for the server is up if a response was received for the last user request.

Default

health-check interval 30

Parameters

interval

Specifies the polling interval for RADIUS, TACACS+, and LDAP servers.

Values 6 to 1500

Default 30

Platforms

7705 SAR Gen 2

configure router ldp interface-parameters ipv6 hello

configure router ldp targeted-session ipv4 hello

configure router ldp interface-parameters interface ipv4 hello

configure router ldp targeted-session peer hello

configure router ldp targeted-session peer-template hello

Description

This command configures the time interval to wait before declaring a neighbor down. The **factor** parameter derives the Hello interval.

Hold time is local to the system and sent in the Hello messages to the neighbor. Hold time cannot be less than three times the Hello interval. The hold time can be configured globally (applies to all LDP interfaces) or per interface. The most specific value is used.

When LDP session is being set up, the hold down time is negotiated to the lower of the two peers. Once an operational value is agreed upon, the Hello factor is used to derive the value of the Hello interval.

The **no** form of the command at the interface-parameters and targeted-session level sets the **hello timeout** and the **hello factor** to the default values.

The **no** form of the command, at the interface level, sets the **hello timeout** and the **hello factor** to the value defined under the interface-parameters level.

The **no** form of this command, at the peer level, sets the **hello timeout** and the **hello factor** to the value defined under the targeted-session level.

The session must be flapped for the new settings to operate.

Default

Table 41: Hello Timeout Factors lists the default values.

Table 41: Hello Timeout Factors

Context	Timeout	Factor
config>router>ldp>if-params	15	3

Context	Timeout	Factor
config>router>ldp>targ-session	45	3
config>router>ldp>if-params>if	Inherits values from interface-parameters context.	
config>router>ldp>targ-session>peer	Inherits values from targeted-session context.	

Parameters

timeout

Configures the time interval, in seconds, that LDP waits before a neighbor down.

Values 1 to 65535

factor

Specifies the number of keepalive messages that should be sent on an idle LDP session in the Hello timeout interval.

Values 1 to 255

Full Context

configure service vprn isis interface hello-authentication-key

configure service vprn isis interface level hello-authentication-key

Description

This command configures the authentication key (password) for Hello PDUs. Neighboring routers use the password to verify the authenticity of Hello PDUs sent from this interface. Both the Hello authentication key and the Hello authentication type on a segment must match. The **hello-authentication-type** must be specified.

To configure the Hello authentication key in the interface context use the **hello-authentication-key** in the **config>router>isis>if** context.

To configure or override the Hello authentication key for a specific level, configure the **hello-authentication-key** in the **config>router>isis>if>level** context.

If both IS-IS and hello-authentication are configured, Hello messages are validated using Hello authentication. If only IS-IS authentication is configured, it will be used to authenticate all IS-IS (including Hello) protocol PDUs.

When the Hello authentication key is configured in the **config>router>isis>if** context, it applies to all levels configured for the interface.

The **no** form of this command removes the authentication-key from the configuration.

Default

no hello-authentication-key — No Hello authentication key is configured.

Parameters

authentication-key

The Hello authentication key (password). The key can be any combination of ASCII characters up to 254 characters in length (un-encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

hash-key

The hash key. The key can be any combination of ASCII characters up to 342 characters in length (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided.

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be

in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

custom

Specifies the custom encryption to management interface.

Platforms

7705 SAR Gen 2

configure router isis interface hello-authentication-key

configure router isis interface level hello-authentication-key

Description

This command configures the authentication key (password) for Hello PDUs. Neighboring routers use the password to verify the authenticity of Hello PDUs sent from this interface. Both the Hello authentication key and the Hello authentication type on a segment must match. The **hello-authentication-type** must be specified.

To configure the Hello authentication key in the interface context, use the **hello-authentication-key** in the **config>router>isis>interface** context.

To configure or override the Hello authentication key for a specific level, configure the **hello-authentication-key** in the **config>router>isis>interface>level** context.

If both IS-IS and hello-authentication are configured, Hello messages are validated using Hello authentication. If only IS-IS authentication is configured, it will be used to authenticate all IS-IS (including Hello) protocol PDUs.

When the Hello authentication key is configured in the **config>router>isis>interface** context, it applies to all levels configured for the interface.

The **no** form of this command removes the authentication-key from the configuration.

Parameters

authentication-key

Specifies the Hello authentication key (password). The key can be any combination of ASCII characters, up to 254 characters (un-encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ”).

hash-key

Specifies the hash key. The key can be any combination of ASCII characters, up to 342 characters (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided.

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

custom

Specifies the custom encryption to management interface.

configure service vprn isis interface hello-authentication-type

Description

This command enables Hello authentication at either the interface or level context. Both the Hello authentication key and the Hello authentication type on a segment must match. The hello **authentication-key** statement must also be included.

To configure the Hello authentication type at the interface context, use **hello-authentication-type** in the **config>router>isis>if** context.

To configure or override the Hello authentication setting for a given level, configure the **hello-authentication-type** in the **config>router>isis>if>level** context.

The **no** form of this command disables Hello authentication.

Default

no hello-authentication-type — Hello authentication is disabled

Parameters

password

Specifies simple password (plain text) authentication is required.

message-digest

Specifies MD5 authentication in accordance with RFC 2104 (HMAC: Keyed-Hashing for Message Authentication) is required.

Platforms

7705 SAR Gen 2

hello-authentication-type

Syntax

hello-authentication-type {**password** | **message-digest**}

no hello-authentication-type

Context

12.15 hello-interval

hello-interval

Syntax

hello-interval *seconds*

no hello-interval

Context

[Tree] (config>service>vprn>isis>if>level hello-interval)

[Tree] (config>router>isis>if>level hello-interval)

Full Context

configure service vprn isis interface level hello-interval

configure router isis interface level hello-interval

Description

This command configures the interval between IS-IS Hello PDUs issued on the interface at this level. The **hello-interval**, along with the **hello-multiplier**, is used to calculate a hold time, which is communicated to a neighbor in a Hello PDU.

Note:
The neighbor hold time is (hello multiplier X hello interval) on non-designated intermediate system broadcast interfaces and point-to-point interfaces and is (hello multiplier X hello interval / 3) on

designated intermediate system broadcast interfaces. Hello values can be adjusted for faster convergence, but the hold time should always be > 3 to reduce routing instability.

The **no** form of this command reverts to the default value.

Default

3 – for designated intermediate system interfaces

9 – for non-designated intermediate system interfaces and point-to-point interfaces

Parameters

seconds

The Hello interval in seconds expressed as a decimal integer.

Values 1 to 20000

Platforms

7705 SAR Gen 2

hello-interval

Syntax

hello-interval *seconds*

no hello-interval

Context

configure service vprn ospf3 area virtual-link hello-interval

configure service vprn ospf3 area interface hello-interval

configure service vprn ospf area virtual-link hello-interval

configure service vprn ospf area interface hello-interval

Description

This command configures the interval between OSPF Hello messages issued on the interface, virtual link, or sham-link.

The Hello interval, in combination with the dead-interval, is used to establish and maintain the adjacency. Use this parameter to edit the frequency that Hello packets are sent.

Reducing the interval, in combination with an appropriate reduction in the associated **dead-interval**, allows for faster detection of link and/or router failures at the cost of higher processing costs.

The **no** form of this command reverts to the default value.

Default

hello-interval 10 — a 10-second Hello interval

Parameters

seconds

The Hello interval in seconds expressed as a decimal integer.

Values 1 to 65535

Platforms

7705 SAR Gen 2

hello-interval

Syntax

hello-interval *hello-interval*

no hello-interval

Context

[Tree] (config>service>vprn>pim>if hello-interval)

Full Context

configure service vprn pim interface hello-interval

Description

This command configures the frequency at which PIM Hello messages are transmitted on this interface.

The **no** form of this command resets the configuration to the default value.

Default

hello-interval 30

Parameters

hello-interval

Specifies the Hello interval in seconds. A 0 (zero) value disables the sending of Hello messages (the PIM neighbor will never timeout the adjacency).

Values 0 to 255 seconds

Platforms

7705 SAR Gen 2

hello-interval

Syntax

hello-interval *milli-seconds*

no hello-interval

Context

[Tree] (config>router>rsvp>interface hello-interval)

Full Context

configure router rsvp interface hello-interval

Description

This command configures the time interval between RSVP Hello messages.

RSVP Hello packets are used to detect loss of RSVP connectivity with the neighboring node. Hello packets detect the loss of neighbor far quicker than it would take for the RSVP session to time out based on the refresh interval. After the loss of the of number keep-multiplier consecutive Hello packets, the neighbor is declared to be in a down state.

The **no** form of this command reverts to the default value of the hello-interval. To disable sending hello messages, set the value to zero.

Default

hello-interval 3000

Parameters

milli-seconds

Specifies the RSVP Hello interval (in ms), in multiples of 1000. A 0 (zero) value disables the sending of RSVP Hello messages.

Values 0 to 60000 ms (in multiples of 1000)

Platforms

7705 SAR Gen 2

configure router ospf area virtual-link hello-interval

configure router ospf3 area interface hello-interval

configure router ospf area interface hello-interval

configure router ospf3 area virtual-link hello-interval

Description

This command configures the interval between OSPF Hellos issued on the interface or virtual link.

The Hello interval, in combination with the dead-interval, is used to establish and maintain the adjacency. Use this parameter to edit the frequency that Hello packets are sent.

Reducing the interval, in combination with an appropriate reduction in the associated **dead-interval ,** allows for faster detection of link and/or router failures at the cost of higher processing costs.

The **no** form of this command reverts to the default value.

Default

hello-interval 10

Parameters

seconds

Specifies the Hello interval, in seconds, expressed as a decimal integer.

Values 1 to 65535

Platforms

7705 SAR Gen 2

hello-interval

Syntax

hello-interval *number*

no hello-interval

Context

[Tree] (config>system>management-interface>remote-management hello-interval)

Full Context

configure system management-interface remote-management hello-interval

Description

This command configures the time interval between Hello messages sent from the SR OS node to the remote manager.

Default

hello-interval 10

Parameters

number

Specifies the Hello interval, in minutes.

Values 10 to 3600

Platforms

7705 SAR Gen 2

12.16 hello-multiplier

hello-multiplier

Syntax

hello-multiplier *multiplier*

no hello-multiplier

Context

[Tree] (config>service>vprn>isis>if>level hello-multiplier)

Full Context

configure service vprn isis interface level hello-multiplier

Description

This command configures the number of missing Hello messages from a neighbor before the router declares the adjacency down.

Note:
The neighbor hold time is (hello multiplier X hello interval) on point-to-point interfaces, and (hello multiplier X hello interval / 3) on broadcast interfaces. Hello values can be adjusted for faster convergence, but the hold-time should always be > 3 to reduce routing instability.

The **no** form of this command reverts to the default value.

Default

hello-multiplier 3

Parameters

multiplier

The multiplier for the Hello interval expressed as a decimal integer.

Values 2 to 100

Platforms

7705 SAR Gen 2

hello-multiplier

Syntax

hello-multiplier *deci-units*

no hello-multiplier

Context

[Tree] (config>service>vprn>pim>if hello-multiplier)

Full Context

configure service vprn pim interface hello-multiplier

Description

This command configures the multiplier to determine the hold time for a PIM neighbor on this interface.

The **hello-multiplier** in conjunction with the **hello-interval** determines the holdtime for a PIM neighbor.

Default

hello-multiplier 35

Parameters

deci-units

Specify the value, specified in multiples of 0.1, for the formula used to calculate the holdtime based on the **hello-multiplier**:

(**hello-interval** X **hello-multiplier**) / 10

This allows the PIMv2 default **hello-multiplier** of 3.5 and the default timeout of 105 seconds to be supported.

Values 20 to 100

Platforms

7705 SAR Gen 2

hello-multiplier

Syntax

hello-multiplier *deci-units*

no hello-multiplier

Context

[Tree] (config>router>pim>interface hello-multiplier)

Full Context

configure router pim interface hello-multiplier

Description

This command configures the multiplier to determine the holdtime for a PIM neighbor on this interface.

The **hello-multiplier** in conjunction with the **hello-interval** determines the holdtime for a PIM neighbor.

The **no** form of this command reverts to the default value.

Default

hello-multiplier 35

Parameters

deci-units

Specifies the value, in multiples of 0.1, for the formula used to calculate the holdtime based on the **hello-multiplier**:

(**hello-interval** X **hello-multiplier**) / 10

This allows the PIMv2 default **hello-multiplier** of 3.5 and the default timeout of 105 seconds to be supported.

Values 20 to 100

Default 35

Platforms

7705 SAR Gen 2

hello-multiplier

Syntax

hello-multiplier *multiplier*

no hello-multiplier

Context

[Tree] (config>router>isis>if>level hello-multiplier)

Full Context

configure router isis interface level hello-multiplier

Description

This command configures a Hello multiplier. The **hello-multiplier**, along with the **hello-interval**, is used to calculate a hold time, which is communicated to a neighbor in a Hello PDU.

The hold time is the time in which the neighbor expects to receive the next Hello PDU. If the neighbor receives a Hello within this time, the hold time is reset. If the neighbor does not receive a Hello within the hold time, it brings the adjacency down.

Note:
The neighbor hold time is (hello multiplier X hello interval) on non-designated intermediate system broadcast interfaces and point-to-point interfaces and is (hello multiplier X hello interval / 3) on designated intermediate system broadcast interfaces. Hello values can be adjusted for faster convergence, but the hold time should always be > 3 to reduce routing instability.

The **no** form of this command reverts to the default value.

Default

hello-multiplier 3

Parameters

multiplier

Specifies the multiplier for the Hello interval expressed as a decimal integer.

Values 2 to 100

Platforms

7705 SAR Gen 2

12.17 hello-padding

hello-padding

Syntax

hello-padding {**none** | **adaptive** | **loose** | **strict**}

no hello-padding

Context

[Tree] (config>service>vprn>isis hello-padding)

[Tree] (config>service>vprn>isis>if hello-padding)

[Tree] (config>service>vprn>isis>if>level hello-padding)

[Tree] (config>service>vprn>isis>level hello-padding)

Full Context

configure service vprn isis hello-padding

configure service vprn isis interface hello-padding

configure service vprn isis interface level hello-padding

configure service vprn isis level hello-padding

Description

This command enables the IS-IS Hello (IIH) message padding to ensure that IS-IS LSPs can traverse the link. When this option is enabled, IS-IS Hello messages are padded to the maximum LSP MTU value, which can be set with the **lsp-mtu-size** command. If link MTU is greater than the maximum LSP MTU value, padding to the link MTU is applied.

The **no** form of this command disables IS-IS Hello message padding at this level. However, the router may still perform Hello padding if it was set at a higher level in the configuration. To ensure that Hello message padding is disabled, set all levels of configuration to **no hello-padding**.

Default

no hello-padding

Parameters

adaptive

Specifies the adaptive padding option; this option is able to detect MTU asymmetry from one side of the connection but uses more overhead than loose padding.

- point-to-point interface—Hello PDUs are padded until the sender declares an adjacency on the link to be in the state up. If the implementation supports RFC 3373/5303, *Three-Way Handshake for IS-IS Point-to-Point Adjacencies*, then this is when the three-way state is up. If the implementation uses the "classic" algorithm described in ISO 10589, this is when the adjacency state is up. If the neighbor does not support the adjacency state TLV, then padding continues.
- broadcast interface—Padding starts until at least one adjacency is up on the interface.

loose

Specifies the loose padding option; the loose padding may not be able to detect certain conditions such as asymmetrical MTUs between the routing devices.

- point-to-point interface—the Hello packet is padded from the initial detection of a new neighbor until the adjacency transitions to the INIT state
- broadcast interface—padding starts until at least one adjacency (broadcast only has up/down) is up on the interface

none

Specifies that the Hello message padding is not enabled at this level, even if it is configured at one of the parent levels.

strict

Specifies the strict padding option.

- point-to-point interface—padding is done for all adjacency states, and is continuous. Strict padding has the most overhead but detects MTU issues on both sides of a link
- broadcast interface—padding is done for all adjacency states, and is continuous. Strict padding has the most overhead but detects MTU issues on both sides of a link

Platforms

7705 SAR Gen 2

hello-padding

Syntax

[**no**] **hello-padding** {**none** | **adaptive** | **loose** | **strict**}

Context

[Tree] (config>router>isis hello-padding)

Full Context

configure router isis level hello-padding

configure router isis interface level hello-padding

configure router isis interface hello-padding

configure router isis hello-padding

Description

This command enables IS-IS Hello (IIH) message padding to ensure that IS-IS LSPs can traverse the link. When this option is enabled, IS-IS Hello messages are padded to the maximum LSP MTU value, which can be set with the **lsp-mtu-size** command. If link MTU is greater than the maximum LSP MTU value, padding to the link MTU is applied.

The **no** form of this command disables IS-IS Hello padding at this level. However, the router may still perform Hello padding if it was set at a higher level in the configuration. To ensure that Hello message padding is disabled, set all levels of configuration to **no hello-padding**.

Default

no hello-padding

Parameters

none

Specifies that the Hello message padding is not enabled at this level, even if it is configured at one of the parent levels.

adaptive

Specifies the adaptive padding option; this option is able to detect LSP MTU asymmetry from one side of the connection but uses more overhead than loose padding.

1. point-to-point interface—Hello PDUs are padded until the sender declares an adjacency on the link to be in state up. If the implementation supports RFC 3373/5303, "Three-Way Handshake for IS-IS Point-to- Point Adjacencies” then this is when the three-way state is Up. If the implementation use the "classic” algorithm described in ISO 10589, this is when adjacency state is Up. If the neighbor does not support the adjacency state TLV, then padding continues.

2. broadcast interface—Padding starts until at least one adjacency is up on the interface.

loose

Specifies the loose padding option; the loose padding may not be able to detect certain situations such as asymmetrical LSP MTUs between the routing devices.

1. point-to-point interface—The Hello packet is padded from the initial detection of a new neighbor until the adjacency transitions to the INIT state.
2. broadcast interface—Padding starts until there is at least one adjacency (broadcast only has up/down) is up on the interface.

strict

Specifies the strict padding option; this option is the most overhead-intensive but detects LSP MTU issues on both sides of a link.

1. point-to-point interface—Padding is done for all adjacency states, and is continuous.
2. broadcast interface—Padding is done for all adjacency states, and is continuous.

12.18 hello-reduction

hello-reduction

Syntax

hello-reduction {**enable** *factor* | **disable**}

no hello-reduction

Context

[Tree] (config>router>ldp>targ-session>peer-template hello-reduction)

[Tree] (config>router>ldp>targ-session>ipv6 hello-reduction)

[Tree] (config>router>ldp>targ-session>ipv4 hello-reduction)

[Tree] (config>router>ldp>targ-session>peer hello-reduction)

Full Context

configure router ldp targeted-session peer-template hello-reduction

configure router ldp targeted-session ipv6 hello-reduction

configure router ldp targeted-session ipv4 hello-reduction

configure router ldp targeted-session peer hello-reduction

Description

This command enables the suppression of periodic targeted Hello messages between LDP peers once the targeted LDP session is brought up.

When this feature is enabled, the target Hello adjacency is brought up by advertising the Hold-Time value the user configured in the " **hello** timeout" parameter for the targeted session. The LSR node will then start advertising an exponentially increasing Hold-Time value in the Hello message as soon as the targeted LDP session to the peer is up. Each new incremented Hold-Time value is sent in a number of Hello messages equal to the value of the argument *factor*, which represents the dampening factor, before the next exponential value is advertised. This provides time for the two peers to settle on the new value. When the Hold-Time reaches the maximum value of 0xffff (binary 65535), the two peers will send Hello messages at a frequency of every [(65535-1)/local helloFactor] seconds for the lifetime of the targeted-LDP session (for example, if the local Hello Factor is three (3), then Hello messages will be sent every 21844 seconds.

The LSR node continues to compute the frequency of sending the Hello messages based on the minimum of its local Hold-time value and the one advertised by its peer as in RFC 5036. Thus for the targeted LDP session to suppress the periodic Hello messages, both peers must bring their advertised Hold-Time to the maximum value. If one of the LDP peers does not, the frequency of the Hello messages sent by both peers will continue to be governed by the smaller of the two Hold-Time values.

When the user enables the Hello reduction option on the LSR node while the targeted LDP session to the peer is operationally up, the change will take effect immediately. In other words, the LSR node will start advertising an exponentially increasing Hold-Time value in the Hello message, starting with the current configured Hold-Time value.

When the user disables the Hello reduction option while the targeted LDP session to the peer is operationally up, the change in the Hold-Time from 0xffff (binary 65535) to the user configured value for this peer will take effect immediately. The local LSR will immediately advertise the value of the user configured Hold-Time value and will not wait until the next scheduled time to send a Hello to make sure the peer adjusts its local hold timeout value immediately.

In general, any configuration change to the parameters of the T-LDP Hello adjacency (modifying the Hello adjacency Hello Timeout or factor, enabling/disabling Hello reduction, or modifying Hello reduction factor) will cause the LSR node to trigger immediately an updated Hello message with the updated Hold Time value without waiting for the next scheduled time to send a Hello.

The **no** form of this command disables the Hello reduction feature.

Default

no hello-reduction

Parameters

factor

Specifies the integer that specifies the Hello reduction dampening factor.

Values 3 to20

[Tree] (config>service>vpls>stp hello-time)

[Tree] (config>service>template>vpls-template>stp hello-time)

Full Context

configure service vpls stp hello-time

configure service template vpls-template stp hello-time

Description

This command configures the Spanning Tree Protocol (STP) Hello time for the Virtual Private LAN Service (VPLS) STP instance.

The Hello time parameter defines the default timer value that controls the sending interval between BPDU configuration messages by this bridge, on ports where this bridge assumes the designated role.

The active Hello time for the spanning tree is determined by the root bridge (except when the STP is running in RSTP mode, then the Hello time is always taken from the locally configured parameter).

The configured **hello-time** can also be used to calculate the forward delay. See **auto-edge** (**config>service>vpls>sap>stp auto-edge, config>service>template>vpls-sap-template>stp auto-edge, config>service>vpls>spoke-sdp>stp auto-edge**).

The **no** form of this command returns the Hello time to the default value.

Default

hello-time 2

Parameters

hello-time

The Hello time for the STP instance in seconds.

Values 1 to 10

Platforms

7705 SAR Gen 2

hello-time

configure router ospf3 graceful-restart helper-disable

configure router ospf graceful-restart helper-disable

Description

This command disables helper support for OSPF graceful restart (GR).

When **graceful-restart** is enabled, the router can be a helper (that is, the router is helping a neighbor to restart), a restarting router, or both. The router only supports the helper mode. It will not act as a restarting router because the high availability feature set already preserves OSPF forwarding information so that this functionality is not needed.

Note:
This command is a historical command and should not be disabled. Configuring **helper-disable** has the effect of disabling graceful restart, because the router only supports helper mode.

The **no** form of this command enables helper support and is the default when **graceful-restart** is enabled.

Default

no helper-disable

12.22 helper-override-restart-time

helper-override-restart-time

Syntax

helper-override-restart-time *seconds*

no helper-override-restart-time

Context

[Tree] (config>service>vprn>bgp>group>neighbor>graceful-restart>long-lived helper-override-restart-time)

[Tree] (config>service>vprn>bgp>group>graceful-restart>long-lived helper-override-restart-time)

[Tree] (config>service>vprn>bgp>graceful-restart>long-lived helper-override-restart-time)

Full Context

configure service vprn bgp group neighbor graceful-restart long-lived helper-override-restart-time

configure service vprn bgp group graceful-restart long-lived helper-override-restart-time

configure service vprn bgp graceful-restart long-lived helper-override-restart-time

Description

This command overrides the restart-time advertised by a peer (in its GR capability) with a locally-configured value. This override applies only to AFI/SAFI that were included in the GR capability of the peer. The restart-time is always zero for AFI/SAFI not included in the GR capability. This command is useful if the local router wants to force LLGR phase to begin after a set time for all protected AFI/SAFI.

By default, the restart time for all AFI/SAFI in the GR capability is the value signaled by the peer.

Default

no helper-override-restart-time

Parameters

seconds

The locally-imposed restart time for all AFI/SAFI included in the peer's GR capability.

Values 0 to 4095

Platforms

7705 SAR Gen 2

configure service vprn bgp group graceful-restart long-lived family helper-override-stale-time

configure service vprn bgp graceful-restart long-lived family helper-override-stale-time

Description

This command overrides the LLGR stale-time advertised by a peer (in its LLGR capability) with a locally-configured value. When configured in the long-lived configuration context, **helper-override-stale-time** applies to all AFI/SAFI in the advertised LLGR capability except for any AFI/SAFI with a family-specific override. A family-specific override is configured with the **helper-override-stale-time** command in a family context.

By default, the LLGR stale-time for an AFI/SAFI is the value signaled by the peer in the corresponding AFI/SAFI part of the LLGR capability.

Default

no helper-override-stale-time

Parameters

seconds

Specifies the locally imposed LLGR stale time in seconds.

Values 0 to 16777215

Platforms

7705 SAR Gen 2

12.33 hli-event

hli-event

Syntax

hli-event {**forward** | **backward** | **aggregate**} **threshold** *raise-threshold* [**clear** *clear-threshold*]

no hli-event {**forward** | **backward** | **aggregate**}

Context

[Tree] (config>oam-pm>session>ip>twamp-light>loss-events hli-event)

Full Context

configure oam-pm session ip twamp-light loss-events hli-event

Description

This command sets the high loss interval (HLI) threshold to be monitored and the associated thresholds using the counter of the specified direction. The aggregate is a function of summing forward and backward. This value is only used as a threshold mechanism and is not part of the stored statistics. If the optional **clear** *clear-threshold* parameter is not specified, the traffic crossing alarm is stateless. Stateless means the state is not carried forward to other measurement intervals. Each measurement interval is analyzed independently and regardless of any previous window. Each unique event can only be raised once within measurement interval. If the optional **clear** *clear-threshold* parameter is specified, the traffic crossing alarm uses stateful behavior. Stateful means each unique previous event state is carried forward to following measurement intervals. If a threshold crossing event is raised another is raised until a measurement

interval completes and the clear threshold has not been exceeded. A clear event is raised under that condition.

The **no** form of this command removes the event threshold for frame loss ratio. The direction must be included with the **no** command.

Default

no hli-event forward

no hli-event backward

no hli-event aggregate

Parameters

forward

Specifies the threshold is applied to the forward direction count.

backward

Specifies the threshold is applied to the backward direction count.

aggregate

Specifies the threshold is applied to the aggregate count (sum of forward and backward).

raise-threshold

Specifies the rising threshold that determines when the event is to be generated, when the percentage of loss value is reached.

Values 1 to 864000

clear-threshold

Specifies an optional value used for stateful behavior that allows the operator to configure a percentage of loss value lower than the rising percentage to indicate when the clear event should be generated.

Values 0 to 863999

A value of zero means that the HLI counter must be 0.

Platforms

7705 SAR Gen 2

12.34 hli-force-count

hli-force-count

Syntax

[**no**] **hli-force-count**

Context

[Tree] (config>oam-pm>session>ip>twamp-light>loss hli-force-count)

Full Context

configure oam-pm session ip twamp-light loss hli-force-count

Description

This command allows High Loss Interval (HLI) and Consecutive High Loss Interval (CHLI) counters to increment regardless of availability. Without this command, HLI and CHLI counters can only increment during times of availability, which includes undetermined availability. During times of complete packet loss, the forward direction HLI is marked as high loss. The backward direction is not marked as high loss during times of complete packet loss.

The **no** form of this command configures HLI and CHLI counters to increment during times of availability only.

configure vrrp policy priority-event route-unknown hold-clear

configure vrrp policy priority-event port-down hold-clear

configure vrrp policy priority-event mc-ipsec-non-forwarding hold-clear

configure vrrp policy priority-event host-unreachable hold-clear

Description

This command configures the hold clear time for the event. The *seconds* parameter specifies the hold-clear time, the amount of time in seconds by which the effect of a cleared event on the associated virtual router instance is delayed.

The hold-clear time is used to prevent black hole conditions when a virtual router instance advertises itself as a master before other conditions associated with the cleared event have had a chance to enter a forwarding state.

Default

no hold-clear

Parameters

seconds

Specifies the amount of time in seconds by which the effect of a cleared event on the associated virtual router instance is delayed.

Values 0 to 86400

Platforms

7705 SAR Gen 2

12.36 hold-count

Description

This command configures the peak number of BPDUs that can be transmitted in a period of one second.

The **no** form of this command returns the hold count to the default value

Default

hold-count 6

Parameters

BPDU tx hold count

The hold count for the STP instance in seconds

Values 1 to 10

Platforms

7705 SAR Gen 2

12.37 hold-down-time

hold-down-time

Syntax

hold-down-time [**sec** *seconds*] [**min** *minutes*] [**hrs** *hours*] [**days** *days*]

no hold-down-time

Context

[Tree] (config>aaa>radius-srv-plcy>servers hold-down-time)

Full Context

configure aaa radius-server-policy servers hold-down-time

Description

This command determines the interval during which no new communication attempts are made to a RADIUS server that is marked down to prevent immediately overloading the server when it is starting up. The only exception is when all servers in the authentication policy are marked down; in that case, they will all be used again to prevent failures on new client connections.

The **no** form of this command reverts to the default.

Default

hold-down-time sec 30

Parameters

days

Specifies the hold time in days before re-using a RADIUS server that was down.

Values 1 to 1

hours

Specifies the hold time in hours before re-using a RADIUS server that was down.

Values 1 to 23

minutes

Specifies the hold time in minutes before re-using a RADIUS server that was down.

Values 1 to 59

seconds

Specifies the hold time in seconds before re-using a RADIUS server that was down.

Values 1 to 59

Platforms

7705 SAR Gen 2

hold-down-time

Syntax

hold-down-time *seconds*

no hold-down-time

Context

[Tree] (config>service>sdp>keep-alive hold-down-time)

Full Context

configure service sdp keep-alive hold-down-time

Description

This command configures the minimum time period the SDP will remain in the operationally down state in response to SDP keepalive monitoring.

This parameter can be used to prevent the SDP operational state from "flapping" by rapidly transitioning between the operationally up and operationally down states based on keepalive messages.

When an SDP keepalive response is received that indicates an error condition or the **max-drop-count** keepalive messages receive no reply, the *sdp-id* will immediately be brought operationally down. If a keepalive response is received that indicates the error has cleared, the *sdp-id* will be eligible to be put into the operationally up state only after the **hold-down-time** interval has expired.

The **no** form of this command reverts the **hold-down-time seconds** *value* to the default setting.

Default

hold-down-time 10

Parameters

seconds

Specifies time, in seconds, expressed as a decimal integer. The SDP ID will remain in the operationally down state before it is eligible to enter the operationally up state. A value of 0 indicates that no **hold-down-time** will be enforced for SDP ID.

Values 0 to 3600

Platforms

7705 SAR Gen 2

12.38 hold-down-timer

hold-down-timer

Syntax

hold-down-timer *hold-down-timer*

no hold-down-timer

Context

[Tree] (config>router>segment-routing>maintenance-policy hold-down-timer)

Full Context

configure router segment-routing maintenance-policy hold-down-timer

Description

This command configures the hold down timer for SR policy candidate paths.

This command is intended to prevent bouncing of the SR policy path state if one or more S-BFD sessions associated with segment lists flap and therefore cause the threshold to be repeatedly crossed in a short period of time. It is started when the number of up S-BFD sessions drops below the threshold. The SR policy path is not considered to be up again until the hold down timer has expired and the number of up S-BFD sessions equals or exceeds the threshold and the internal hold timer is not running.

Note:
If the revert timer is also configured, the revert timer is not started until after the number of S-BFD sessions that are up ≥ threshold and the hold down timer for the primary candidate path has expired.

The **no** form of this command reverts to the default.

Default

hold-down-timer 0

Parameters

hold-down-timer

Specifies the hold-down timer, in deciseconds, in 10ms steps.

Values 0 to 5000

Platforms

7705 SAR Gen 2

12.39 hold-on-neighbor-failure

hold-on-neighbor-failure

Syntax

hold-on-neighbor-failure *multiplier*

no hold-on-neighbor-failure

Context

[Tree] (config>redundancy>multi-chassis>peer>mc-lag hold-on-neighbor-failure)

Full Context

configure redundancy multi-chassis peer mc-lag hold-on-neighbor-failure

Description

This command specifies the interval that the standby node will wait for packets from the active node before assuming a redundant-neighbor node failure. This delay in switch-over operation is required to accommodate different factors influencing node failure detection rate, such as IGP convergence, or HA switch-over times and to prevent the standby node to act prematurely.

The **no** form of this command reverts to the default.

Default

hold-on-neighbor-failure 3

Parameters

multiplier

Specifies the time interval that the standby node waits for packets from the active node before assuming a redundant-neighbor node failure.

Values 2 to 25

Platforms

7705 SAR Gen 2

hold-on-neighbor-failure

Syntax

hold-on-neighbor-failure *multiplier*

no hold-on-neighbor-failure

Context

[Tree] (config>redundancy>multi-chassis>peer>mc-ep hold-on-neighbor-failure)

Full Context

configure redundancy multi-chassis peer mc-endpoint hold-on-neighbor-failure

Description

This command specifies the number of keep-alive intervals that the local node will wait for packets from the MC-EP peer before assuming failure. After this time interval passed the all the mc-endpoints configured under services will revert to single chassis behavior, activating the best local pseudowire.

The **no** form of this command sets the multiplier to default value

Default

no hold-on-neighbor-failure

Parameters

multiplier

Specifies the hold time applied on neighbor failure.

Values 2 to 25

Platforms

7705 SAR Gen 2

hold-on-neighbor-failure

Syntax

hold-on-neighbor-failure *multiplier*

no hold-on-neighbor-failure

Context

configure vrrp policy priority-event lag-port-down hold-set

configure vrrp policy priority-event port-down hold-set

configure vrrp policy priority-event route-unknown hold-set

Description

This command specifies the amount of time that must pass before the set state for a VRRP priority control event can transition to the cleared state to dampen flapping events. A flapping event continually transitions between clear and set.

The **hold-set** command is used to dampen the effect of a flapping event. The **hold-set** value is loaded into a hold-set timer that prevents a set event from transitioning to the cleared state until it expires.

Each time an event transitions between cleared and set, the timer is loaded and begins a countdown to zero. When the timer reaches zero, the event is allowed to enter the cleared state. Entering the cleared state is dependent on the object controlling the event, conforming to the requirements defined in the event itself. It is possible, on some event types, to have another set action reload the hold-set timer. This extends the amount of time that must expire before entering the cleared state.

Once the hold-set timer expires and the event meets the cleared state requirements or is set to a lower threshold, the current set effect on the virtual router instances in-use priority can be removed. As with **lag-port-down** events, this may be a decrease in the set effect if the *clearing* amounts to a lower set threshold.

The **hold-set** command can be executed at any time. If the hold-set timer value is configured larger than the new *seconds* setting, the timer is loaded with the new **hold-set** value.

The **no** form of the command disables the hold timer so that event transitions are processed immediately.

Default

no hold-set

Parameters

seconds

The number of seconds that the hold-set timer waits after an event enters a set state or enters a higher threshold set state, depending on the event type.

The value of 0 disables the hold-set timer, preventing any delay in processing lower set thresholds or cleared events.

Values 0 to 86400

hold-time

Syntax

hold-time {[**up** *hold-time-up*] [**down** *hold-time-down*] [**seconds** | **centiseconds**]}

no hold-time

Context

[Tree] (config>port>ethernet hold-time)

Full Context

configure port ethernet hold-time

Description

This command configures port link dampening timers which reduce the number of link transitions reported to upper layer protocols. The **hold-time** value dampens interface transitions.

When an interface transitions from an up state to a down state, it is immediately advertised to the rest of the system if the hold-time down interval is zero, but if the hold-time down interval is greater than zero, interface down transitions are not advertised to upper layers until the hold-time down interval has expired. Likewise, an interface is immediately advertised as up to the rest of the system if the hold-time up interval is zero, but if the hold-time up interval is greater than zero, up transitions are not advertised until the hold-time up interval has expired.

For ESM SRRP setup, MCS synchronizes subscriber information between the two chassis. After a chassis recovers from a power reset/down, MCS immediately synchronizes all subscriber information at once. The longer the host list, the longer it will take to synchronize the chassis. In a fully populated chassis, it is recommended to allow at least 45 minutes for MCS synchronization. It is also recommended to hold the port down, facing the subscriber, on the recovering chassis for 45 minutes before it is allowed to forward traffic again.

The **no** form of this command reverts to the default values.

Default

down 0 seconds — No port link down dampening is enabled; link down transitions are immediately reported to upper layer protocols.

up 0 seconds — No port link up dampening is enabled; link up transitions are immediately reported to upper layer protocols.

Parameters

hold-time-up

The delay, in seconds or centiseconds, after which to notify the upper layers when an interface transitions from a down state to an up state.

Values 0 to 36000 seconds, 0 or 10 to 3600000 centiseconds in 5 centisecond increments

hold-time-down

The delay, in seconds or centiseconds, after which to notify the upper layers when an interface transitions from an up state to a down state.

Values 0 to 36000 seconds, 0 or 10 to 3600000 centiseconds in 5 centisecond increments

seconds | centiseconds

Specifies the hold time units as **seconds** or **centiseconds**.

7705 SAR Gen 2

hold-time

Syntax

hold-time down *hold-down-time*

no hold-time

Context

[Tree] (config>lag hold-time)

Full Context

configure lag hold-time

Description

This command specifies the timer, in tenths of seconds, which controls the delay between detecting that a LAG is down (all active ports are down) and reporting it to the higher levels.

A non-zero value can be configured, for example, when active/standby signaling is used in a 1:1 fashion to avoid informing higher levels during the small time interval between detecting that the LAG is down and the time needed to activate the standby link.

Default

no hold-time

Parameters

hold-down-time

Specifies the hold-time for event reporting.

Values 0 to 2000

Platforms

[Tree] (config>service>vprn>bgp>group>neighbor hold-time)

Full Context

configure service vprn bgp hold-time

configure service vprn bgp group hold-time

configure service vprn bgp group neighbor hold-time

Description

This command configures the BGP hold time, expressed in seconds.

The BGP hold time specifies the maximum time BGP waits between successive messages (either keepalive or update) from its peer, before closing the connection. This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in group) or neighbor level (only applies to specified peer). The most specific value is used.

Even though the router OS implementation allows setting the **keepalive** (**config>service>vprn>bgp keepalive**, **config>service>vprn>bgp>group keepalive**, **config>service>vprn>bgp>group>neighbor keepalive**) time separately, the configured **keepalive** timer is overridden by the **hold-time** value under the following circumstances:

- If the specified hold-time is less than the configured **keepalive** time, then the operational **keepalive** time is set to a third of the **hold-time**; the configured **keepalive** time is not changed.
- If the **hold-time** is set to zero, then the operational value of the **keepalive** time is set to zero; the configured **keepalive** time is not changed. This means that the connection with the peer is up permanently and no **keepalive** packets are sent to the peer.

The **no** form of this command used at the global level reverts to the default value.

The **no** form of this command used at the group level reverts to the value defined at the global level.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Default

hold-time 90

Parameters

seconds

Specifies the hold-time, in seconds, expressed as a decimal integer. A value of 0 indicates the connection to the peer is up permanently.

Values 0, 3 to 65535

seconds2

Specifies the minimum hold-time that is accepted for the session. If the peer proposes a hold-time lower than this value the session attempt is rejected.

[Tree] (config>system>security>user-template home-directory)

Full Context

configure system security user home-directory

configure system security user-template home-directory

Description

This command configures the home directory of the user for file access. Files can be accessed locally by CLI **file** commands and output modifiers such as **>** (file redirect), or remotely via FTP and SCP. If the home directory does not exist, a warning message is displayed when the user logs in.

When **restricted-to-home** is configured, file access is denied unless the **home-directory** is configured and the directory is created by an administrator.

The **no** form of this command removes the configured home directory of the user. The directory must be also removed by the administrator.

Default

no home-directory

Parameters

url-prefix [directory] [directory/directory ..]

Specifies the local home directory URL prefix of the user and directory structure, up to 200 characters.

Platforms

7705 SAR Gen 2

12.46 hop

hop

Syntax

hop *hop-index ip-address* {**strict** | **loose**}

hop *hop-index* **sid-label** *sid-value*

no hop *hop-index*

Context

[Tree] (config>router>mpls>path hop)

Full Context

configure router mpls path hop

Description

This command specifies the hops that the LSP should traverse on its way to the egress router. When specified, the IP address can be the interface IP address, a loopback interface address, or the system IP address. If a loopback interface or the system IP address is specified then the LSP can choose the best available interface.

When an IPv6 hop is specified, the interface IP address must be a global unicast IPv6 address. A link-local address is not allowed and is rejected in the configuration if attempted.

Optionally, the LSP ingress and egress IP address can be included as the first and the last hop. A hop list can include the ingress interface IP address, the system IP address, and the egress IP address of any of the hops being specified.

When the **sid-label** parameter is specified, this command specifies an MPLS label value for a hop in the path of an SR-TE LSP. The label value implied by the SID is only used when the path is used by an SR-TE LSP.

The **no** form of this command deletes hop list entries for the path. All the LSPs currently using this path are affected. Additionally, all services actively using these LSPs are affected. The path must be shutdown first in order to delete the hop from the hop list. The **no hop** *hop-index* command will not result in any action except a warning message on the console indicating that the path is administratively up.

Parameters

hop-index

Specifies the hop index is used to order the hops specified. The LSP always traverses from the lowest hop index to the highest. The hop index does not need to be sequential.

Values 1 to 1024

ip-address

Specifies a loopback interface, the system or network interface IP address of the transit router. An interface IPv6 address must be a global unicast address.

Values ipv4-address — a.b.c.d

ipv6-address — x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x — 0 to FFFF (hexadecimal)

d — 0 to 255 (decimal)

loose

This keyword specifies that the route taken by the LSP from the previous hop to this hop can traverse through other routers. Multiple hop entries with the same IP address are flagged as errors. Either the **loose** *or* **strict** keyword must be specified.

strict

This keyword specifies that the LSP must take a direct path from the previous hop router to this router. No transit routers between the previous router and this router are allowed. If the IP address specified is the interface address, then that is the interface the LSP must use.

If there are direct parallel links between the previous router and this router and if system IP address is specified, then any one of the available interfaces can be used by the LSP. The user must ensure that the previous router and this router have a direct link. Multiple hop entries with the same IP address are flagged as errors. Either the **loose** *or* **strict** keyword must be specified.

sid-value

Specifies the SID value. The *sid-value* can be any valid MPLS/SR label value. It is not restricted by any locally-defined label ranges since these may be different on the remote node or adjacency for which the SID is defined.

Values 32 to 1048575

Platforms

7705 SAR Gen 2

hop

Syntax

hop *hop-index ip-address*

no hop *hop-index*

Context

[Tree] (config>service>pw-routing>path hop)

Full Context

configure service pw-routing path hop

Description

This command configures each hop on an explicit path that can be used by one or more dynamic MS-PWs. It specifies the IP addresses of the hops that the MS-PE should traverse. These IP addresses can correspond to the system IP address of each S-PE, or the IP address on which the T-LDP session to a given S-PE terminates.

The **no** form of this command deletes hop list entries for the path. All the MS-PWs currently using this path are unaffected. Additionally, all services actively using these MS-PWs are unaffected. The path must be shutdown first in order to delete the hop from the hop list. The ' **no hop hop-index**' command will not result in any action, except for a warning message on the console indicating that the path is administratively up.

Default

no hop

Parameters

hop-index

Specifies a locally significant numeric identifier for the hop. The hop index is used to order the hops specified. The LSP always traverses from the lowest hop index to the highest. The hop index does not need to be sequential.

Values 1 to 1024

ip-address

Specifies the system IP address or terminating IP address for the T-LDP session to the S-PE corresponding to this hop. For a given IP address on a hop, the system will choose the appropriate SDP to use.

Platforms

7705 SAR Gen 2

hop-by-hop-opt

Syntax

hop-by-hop-opt {**true** | **false**}

no hop-by-hop-opt

Context

[Tree] (config>filter>ipv6-filter>entry>match hop-by-hop-opt)

Full Context

configure filter ipv6-filter entry match hop-by-hop-opt

Description

This command enables match on existence of Hop-by-Hop Options Extension Header in the IPv6 filter policy.

The **no** form of this command ignores Hop-by-Hop Options Extension Header presence/absence in a packet when evaluating match criteria of a given filter policy entry.

Default

no hop-by-hop-opt

Parameters

true

Matches a packet with a Hop-by-Hop Options Extension header.

false

Matches a packet without a Hop-by-Hop Options Extension header.

Platforms

7705 SAR Gen 2

12.48 hop-limit

hop-limit

Syntax

hop-limit *limit*

no hop-limit

Context

[Tree] (config>router>mpls>lsp>fast-reroute hop-limit)

[Tree] (config>router>mpls>lsp-template>fast-reroute hop-limit)

Full Context

configure router mpls lsp fast-reroute hop-limit

configure router mpls lsp-template fast-reroute hop-limit

Description

For fast reroute, how many more routers a detour is allowed to traverse compared to the LSP itself. For example, if an LSP traverses four routers, any detour for the LSP can be no more than ten router hops, including the ingress and egress routers.

The **no** form of this command reverts to the default value.

Default

hop-limit 16

Parameters

limit

Specify the maximum number of hops.

Values 0 to 255

Platforms

7705 SAR Gen 2

hop-limit

Syntax

hop-limit *number*

no hop-limit

Context

[Tree] (config>router>mpls>lsp hop-limit)

Full Context

configure router mpls lsp hop-limit

Description

This command specifies the maximum number of hops that an LSP can traverse, including the ingress and egress routers. An LSP is not set up if the hop limit is exceeded. This value can be changed dynamically for an LSP that is already set up with the following implications.

If the new value is less than the current number of hops of the established LSP, the LSP is brought down. The software then tries to re-establish the LSP within the new **hop-limit** number. If the new value is equal to or greater than the current number hops of the established LSP, the LSP is not affected.

The **no** form of this command returns the parameter to the default value.

Default

hop-limit 255

Parameters

number

Specifies the number of hops the LSP can traverse, expressed as an integer.

Values 2 to 255

Platforms

7705 SAR Gen 2

hop-limit

Syntax

hop-limit *number*

no hop-limit

Context

[Tree] (config>router>mpls>lsp>primary hop-limit)

[Tree] (config>router>mpls>lsp>secondary hop-limit)

Full Context

configure router mpls lsp primary hop-limit

configure router mpls lsp secondary hop-limit

Description

This optional command overrides the **config>router>mpls>lsp** *lsp-name***>hop-limit** command. This command specifies the total number of hops that an LSP traverses, including the ingress and egress routers.

This value can be changed dynamically for an LSP that is already set up with the following implications:

If the new value is less than the current hops of the established LSP, the LSP is brought down. MPLS then tries to re-establish the LSP within the new hop-limit number. If the new value is equal or more than the current hops of the established LSP then the LSP will be unaffected.

The **no** form of this command reverts the values defined under the LSP definition using the **config>router>mpls>lsp** *lsp-name***>hop-limit** command.

Default

no hop-limit

Parameters

number

Specifies the number of hops the LSP can traverse, expressed as an integer.

Values 2 to 255

Platforms

7705 SAR Gen 2

12.49 host

host

Syntax

host *host-name* [**create**]

no host *host-name*

Context

[Tree] (config>subscr-mgmt>loc-user-db>ipoe host)

Full Context

configure subscriber-mgmt local-user-db ipoe host

Description

This command creates an IPoE or PPP host entry in the local user database. A host entry in the local user database is matched based on the specified match-list criteria and an optional mask that is applied to the host-identification parameters.

A default host entry can be created without host-identification parameters which is used when no other host entries match. Note that creating a default host entry also requires a match-list to be specified.

The **no** form of this command removes the host entry from the local user database.

Parameters

host-name

Specifies a unique host name, up to 32 characters. The *host-name* **default** creates a special match-all host entry that should not have host-identification parameters and is used when no other host entries match.

create

Keyword used to create the host name. The **create** keyword requirement can be enabled or disabled in the **environment>create** context.

Platforms

7705 SAR Gen 2

host

Syntax

[**no**] **host** [*ip-address*]

[**no**] **host** [**fwd-service** *service-id*] **group-interface** *ip-int-name*

Context

[Tree] (debug>router>igmp host)

Full Context

debug router igmp host

Description

This command enables debugging for the IGMP host.

The **no** form of the command disables debugging.

Parameters

ip-address

Debugs the information associated with the specified IP address.

service-id

Debugs information associated with the service ID.

Values service-id: 1 to 2148278386

svc-name: up to 64 characters.

group-interface ***ip-int-name***

Debugs the information associated with the specified IP interface name.

Values IP interface address

12.53 host-unreachable

host-unreachable

Syntax

[**no**] **host-unreachable** *ip-address*

[**no**] **host-unreachable** *ipv6-address*

Context

[Tree] (config>vrrp>policy>priority-event host-unreachable)

Full Context

configure vrrp policy priority-event host-unreachable

Description

This command creates the context to configure a host unreachable priority control event to monitor the ability to receive ICMP echo reply packets from an IP host address.

A host unreachable priority event creates a continuous ICMP echo request (ping) probe to the specified *ip-address*. If a ping fails, the event is considered to be set. If a ping is successful, the event is considered to be cleared.

Multiple unique (different *ip-address*) **host-unreachable** event nodes can be configured within the **priority-event** node to a maximum of 32 events.

The **host-unreachable** command can reference any valid local or remote IP address. The ability to ARP a local IP address or find a remote IP address within a route prefix in the route table is considered part of the monitoring procedure. The **host-unreachable** priority event operational state tracks ARP or route table entries dynamically appearing and disappearing from the system. The operational state of the **host-unreachable** event are listed in Table 42: Host Unreachable Operational States.

Table 42: Host Unreachable Operational States

Host Unreachable Operational State	Description
Set – no ARP	No ARP address found for *ip-addr* for **drop-count** consecutive attempts; only applies when IP address is considered local
Set – no route	No route exists for *ip-addr* for **drop-count** consecutive attempts; only when IP address is considered remote
Set – host unreachable	ICMP host unreachable message received for **drop-count** consecutive attempts
Set – no reply	ICMP echo request timed out for **drop-count** consecutive attempts
Set – reply received	Last ICMP echo request attempt received an echo reply but historically not able to clear the event
Cleared – no ARP	No ARP address found for *ip-addr* - not enough failed attempts to set the event
Cleared – no route	No route exists for *ip-addr* - not enough failed attempts to set the event
Cleared – host unreachable	ICMP host unreachable message received - not enough failed attempts to set the event
Cleared – no reply	ICMP echo request timed out - not enough failed attempts to set the event
Cleared – reply received	Event is cleared - last ICMP echo request received an echo reply

Unlike other priority event types, the **host-unreachable** priority event monitors a repetitive task. A historical evaluation is performed on the success rate of receiving ICMP echo reply messages. The operational state takes its cleared and set orientation from the historical success rate. The informational portion of the operational state is derived from the last attempt's result. It is possible for the previous attempt to fail while the operational state is still cleared due to an insufficient number of failures to cause it to become set. It is also possible for the state to be set while the previous attempt was successful.

When an event transitions from clear to set, the set is processed immediately and must be reflected in the associated virtual router instances in-use priority value. As the event transitions from clear to set, a hold-set timer is loaded with the value configured by the events **hold-set** command. This timer prevents the event from clearing until it expires, damping the effect of event flapping. If the event clears and becomes set again before the hold-set timer expires, the timer is reset to the **hold-set** value, extending the time before another clear can take effect.

The hold-set timer be expired and the historical success rate must be met prior to the event operational state becoming cleared.

The **no** form of the command deletes the specific IP host monitoring event. The event may be deleted at any time. When the event is deleted, the in-use priority of all associated virtual router instances must be reevaluated. The event's **hold-set** timer has no effect on the removal procedure.

Default

no host-unreachable — No host unreachable priority events are created.

Parameters

ip-address

The IP address of the host for which the specific event will monitor connectivity. The *ip-addr* can only be monitored by a single event in this policy. The IP address can be monitored by multiple VRRP priority control policies. The IP address can be used in one or multiple **ping** requests. Each VRRP priority control **host-unreachable** and **ping** destined to the same *ip-addr* is uniquely identified on a per message basis. Each session originates a unique identifier value for the ICMP echo request messages it generates. This allows received ICMP echo reply messages to be directed to the appropriate sending application.

Values

ipv4-address:	a.b.c.d	
ipv6-address:	x:x:x:x:x:x:x:x[-interface]	
	x:	[0..FFFF]H
	interface:	32 chars maximum, mandatory for link local addresses

The link-local IPv6 address must have an interface name specified. The global IPv6 address must not have an interface name specified.

12.54 host-unsolicited-na-flood-evpn

host-unsolicited-na-flood-evpn

Syntax

[**no**] **host-unsolicited-na-flood-evpn**

Context

[Tree] (config>service>vpls>proxy-nd host-unsolicited-na-flood-evpn)

Full Context

configure service vpls proxy-nd host-unsolicited-na-flood-evpn

Description

This command controls whether the system floods host unsolicited Neighbor Advertisements to the EVPN. The NA messages impacted by this command are NA messages with the following flags: S=0 and R=0.

The **no** form of the command will only flood to local SAPs/binds but not to the EVPN destinations. This is only recommended in networks where CEs are routers that are directly connected to the PEs. Networks using aggregation switches between the host/routers and the PEs should flood unsolicited NA messages in the EVPN to ensure that the remote caches are updated and the BGP does not miss the advertisement of these entries.

Default

host-unsolicited-na-flood-evpn

Platforms

12.55 hostname

hostname

Syntax

hostname {**use-system-name** | **value** *value-string*}

no hostname

Context

[Tree] (config>log>syslog hostname)

Full Context

configure log syslog hostname

Description

This command controls how the HOSTNAME field of syslog messages is populated.

The **no** form of this command causes the HOSTNAME to be populated with an IP address.

Default

no hostname

Parameters

use-system-name

Keyword used to specify the HOSTNAME uses the system name as configured by the **configure system name** command. Do not use any spaces in the system name if it is used for the syslog HOSTNAME.

value-string

Specifies a string, up to 255 characters with no spaces, that is used as the HOSTNAME of syslog messages.

Platforms

7705 SAR Gen 2

hostname

Syntax

hostname {**use-system-name** | **use-vprn-name** | **value** *value-string*}

no hostname

Context

[Tree] (config>service>vprn>log>syslog hostname)

Full Context

configure service vprn log syslog hostname

Description

This command controls how the HOSTNAME field of syslog messages is populated.

The **no** form of this command causes the HOSTNAME to be populated with an IP address.

Default

no hostname

Parameters

use-system-name

Keyword used to specify the HOSTNAME uses the system name as configured by the **configure system name** command. Do not use any spaces in the system name if it is used for the syslog HOSTNAME.

use-vprn-name

Keyword used to specify the HOSTNAME uses the VPRN name as configured by the **configure service vprn name** command. Do not use any spaces in the VPRN name if it is used for the syslog HOSTNAME.

value-string

Specifies a string, up to 255 characters with no spaces, that is used as the HOSTNAME of syslog messages.

12.56 hour

hour

Syntax

hour *hour-number* [*..hour-number*] | **all**}

no hour

Context

[Tree] (config>system>cron>sched hour)

Full Context

configure system cron schedule hour

Description

This command specifies which hour to schedule a command. Multiple hours of the day can be specified. When multiple hours are configured, each of them will cause the schedule to trigger. **Day-of-month** or **weekday** must also be specified. All days of the month or weekdays can be specified. If an hour is configured without configuring month, weekday, day-of-month, and minute, the event will not execute.

The **no** form of this command removes the specified hour from the configuration.

Default

no hour

Parameters

hour-number

Specifies the hour to schedule a command.

Values 0 to 23 (maximum 24 hour-numbers)

all

Specifies all hours.

Platforms

7705 SAR Gen 2

12.57 http-auth

http-auth

Syntax

http-auth password *password* [**hash | hash2**]

http-auth username *user-name*

http-auth username *user-name* **password** *password* [**hash | hash2**]

no http-auth

Context

[Tree] (config>system>security>pki>est-profile http-auth)

Full Context

configure system security pki est-profile http-auth

Description

This command configures HTTP authentication parameters. HTTP authentication is used by a client when requested by the server. When disabled, there is no HTTP-level client authentication.

The **no** form of the command reverts to the default value.

Default

no http-auth

Parameters

password

Specifies a text string containing the password. Allowed values are any string up to 64 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

user-name

Specifies the name of the user to authenticate, up to 32 characters.

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

12.58 http-connections

http-connections

Syntax

http-connections [*ip-address/prefix-length*]

http-connections any

http-connections [*ipv6-address/prefix-length*]

no http-connections

Context

[Tree] (debug>system http-connections)

Full Context

debug system http-connections

Description

This command displays HTTP connections debug information.

Parameters

ip-address/prefix-length

Displays information for the specified host IP address and prefix length.

Values ip-address: a.b.c.d

prefix-length: 0 to 32

any

Specifies that any address can be used.

ipv6-address/prefix-length

Displays information for the specified host IPv6 address and prefix length.

Values ipv6-address:

- x:x:x:x:x:x:x:x: (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d
- x [0 to FFFFF] H
- d [0 to 255] D

prefix-length: 0 to 128

http-response-timeout

Syntax

http-response-timeout *timeout*

no http-response-timeout

Context

[Tree] (config>system>security>pki>ca-profile>cmpv2 http-response-timeout)

Full Context

configure system security pki ca-profile cmpv2 http-response-timeout

Description

This command specifies the timeout value for HTTP response that is used by CMPv2.

The **no** form of this command reverts to the default.

Default

http-response-timeout 30

Parameters

timeout

Specifies the HTTP response timeout, in seconds.

Values 1 to 3600

Platforms

7705 SAR Gen 2

http-response-timeout

Syntax

http-response-timeout *timeout*

no http-response-timeout

Context

[Tree] (config>system>security>pki>ca-profile>cmpv2 http-response-timeout)

Full Context

configure system security pki ca-profile cmpv2 http-response-timeout

Description

This command specifies the timeout value for HTTP response that is used by CMPv2.

The **no** form of this command reverts to the default.

Default

http-response-timeout 30

Parameters

timeout

Specifies the HTTP response timeout in seconds.

Values 1 to 3600

Platforms

7705 SAR Gen 2

12.60 http-version

http-version

Syntax

http-version [**1.0** | **1.1**]

Context

[Tree] (config>system>security>pki>ca-profile>cmpv2 http-version)

Full Context

configure system security pki ca-profile cmpv2 http-version

Description

This command configures the HTTP version for CMPv2 messages.

Default

http-version 1.1

13.4 icmp-code

icmp-code

Syntax

icmp-code *icmp-code*

no icmp-code

Context

[Tree] (config>filter>ip-exception>entry>match icmp-code)

[Tree] (config>filter>ipv6-filter>entry>match icmp-code)

[Tree] (config>filter>ipv6-exception>entry>match icmp-code)

[Tree] (config>filter>ip-filter>entry>match icmp-code)

Full Context

configure filter ip-exception entry match icmp-code

configure filter ipv6-filter entry match icmp-code

configure filter ipv6-exception entry match icmp-code

configure filter ip-filter entry match icmp-code

Description

Configures matching on /ICMPv6 code field in the /ICMPv6 header of an IPv4 or IPv6 packet as a filter match criterion or configures matching on the ICMP code field in the ICMP header of an IPv4 packet as an exception filter match criterion. An entry containing Layer 4 non-zero match criteria will not match non-initial (for example, 2nd, 3rd) fragments of a fragmented packet because only the first fragment contains the Layer 4 information. Similarly an entry containing " **icmp-code** 0" match criterion, may match non-initial fragments when the Layer 4 header is not present in a packet fragment and other match criteria are also met.

The **no** form of the command removes the criterion from the match entry.

Default

no icmp-code

Parameters

icmp-code

Specifies the /ICMPv6 code value that must be present to match. Value can be expressed as a decimal integer, as well as in hexadecimal or binary format, or even using keywords. The following value shows decimal integer only.

Values 0 to 255

Platforms

7705 SAR Gen 2

13.5 icmp-echo-reply

icmp-echo-reply

Syntax

[**no**] **icmp-echo-reply**

Context

[Tree] (config>service>vprn>nat>outside>pool icmp-echo-reply)

[Tree] (config>router>nat>outside>pool icmp-echo-reply)

Full Context

configure service vprn nat outside pool icmp-echo-reply

configure router nat outside pool icmp-echo-reply

Description

IPv4 addresses in a NAT pool can be configured to respond to ICMP Echo Requests (PINGs). The configuration can be toggled online while the pool is in use.

In L2-aware NAT when **port-block-extensions** is disabled, the reply from an outside IP address is generated only when this IP address has at least one host (binding) behind it.

In L2-aware NAT when **port-block-extensions** is enabled, the reply from an outside IP address is generated regardless if a binding is present.

In LSN, the reply from an outside IP address is generated regardless if a binding is present.

The **no** form of the command disables ICMP echo replies.

Default

no icmp-echo-reply

Platforms

7705 SAR Gen 2

13.6 icmp-generation

[Tree] (config>ipsec>tunnel-template icmp-generation)

Full Context

configure service vprn interface sap ipsec-tunnel icmp-generation

configure router interface ipsec ipsec-tunnel icmp-generation

configure service vprn interface sap ip-tunnel icmp-generation

configure service ies interface sap ip-tunnel icmp-generation

configure ipsec tunnel-template icmp-generation

Description

This command enables the context to configure ICMP generation information.

Platforms

7705 SAR Gen 2

13.7 icmp-ping

icmp-ping

Syntax

icmp-ping {*ip-address* | *dns-name*} [{**bypass-routing** | {**interface** *interface-name*} | {**next-hop** *ip-address*}}] [**count** *requests*] [**do-not-fragment**] [**fc** *fc-name*] [**interval** { *centisecs* | *secs*}] [**pattern** *pattern*] [**rapid**] [{ **router** *router-or-service* | **router-instance** *router-instance* | **service-name** *service-name*}] [**size** *bytes*] [**source** *ip-address*] [**timeout** *timeout*] [**tos** *type-of-service*] [**ttl** *time-to-live*]

Context

[Tree] (config>saa>test>type icmp-ping)

Full Context

configure saa test type icmp-ping

Description

This command configures an ICMP traceroute test.

Parameters

ip-address* | *dns-name

Specifies the far-end IP address or DNS name to which to send the **svc-ping** request message in dotted-decimal notation.

Values

ipv4-address:	a.b.c.d	
ipv6-address:	x:x:x:x:x:x:x:x	
	x:x:x:x:x:x:d.d.d.d	
	x:	[0 to FFFF]H
	d:	[0 to 255]D
	interface	up to 32 characters. This is mandatory for link local addresses.
dns-name	up to 128 characters	

bypass-routing

Specifies whether to send the ping request to a host on a directly attached network bypassing the routing table.

interface-name

Specifies the name used to refer to the interface, up to 32 characters. The name must already exist in the **config>router>interface** context.

next-hop *ip-address*

Displays only static routes with the specified next-hop IP address.

Values

ipv4-address:	a.b.c.d (host bits must be 0)
ipv6-address:	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x: [0 to FFFF]H
	d: [0 to 255]D

requests

Specifies the number of times to perform an OAM ping probe operation. Each OAM echo message request must either time out or receive a reply before the next message request is sent.

Values 1 to 100000

Default 5

do-not-fragment

Sets the DF (Do Not Fragment) bit in the ICMP ping packet (does not apply to ICMPv6).

fc-name

Specifies the forwarding class of the SAA.

Values be, l2, af, l1, h2, ef, h1, nc

Default nc

interval {*centisecs* | *secs*}

Specifies the minimum amount of time, in seconds, that must expire before the next message request is sent. If the **rapid** parameter is configured, this value is measured in centiseconds (hundredths of a second) instead of seconds.

Values 1 to 10000

Default 1

pattern

Specifies the date portion in a ping packet is filled with the pattern value specified. If not specified, a system-generated sequential pattern is used.

Values 0 to 65535

rapid

Configures the *interval* parameter to use centiseconds (hundredths of a second) instead of seconds.

router-or-service

Specifies the numerical reference to the router instance or service. Well known router names "Base", "management", "vpm-vr-name", and " vpls-management" are allowed for convenience, but are mapped numerically.

Values {*router-name* | *vprn-svc-id*}

router-name: Base, management, cmp-vr-name, vpls-management

vprn-svc-id: 1 to 2147483647

cpm-vr-name: Up to 32 characters

The parameter *router-instance* is preferred for specifying the router or service.

Default Base

router-instance

Specifies the preferred method for entering a service name. Stored as the service name. Only the service linking function is allowed for both mixed-mode and model-driven configuration modes.

Values *router-name*, *vprn-svc-name*

router-name: Base, management, vpls-management, *cpm-vr-name*

vprn-svc-name: up to 64 characters

cpm-vr-name: up to 32 characters

service-name

Specifies the alias function that allows the service name to be used, converted and stored as a service ID, up to 64 characters.

The *router-instance* parameter is preferred for specifying the router or service.

bytes

Specifies the request packet size in bytes, expressed as a decimal integer.

Values 0 to 16384

Default 56

source *ip-address*

Specifies the IP address to be used.

Values

ipv4-address:	a.b.c.d	
ipv6-address:	x:x:x:x:x:x:x:x	
	x:x:x:x:x:x:d.d.d.d	
	x:	[0 to FFFF]H
	d:	[0 to 255]D

timeout

Specifies the override time that the router waits for a message reply after sending the last probe for a specific test. Upon the expiration of the time out, the test is marked complete and no more packets are processed for any of those request probes.

Values 1 to 10

Default 5

type-of-service

Specifies the service type.

Values 0 to 255

Default 0

time-to-live

Specifies the TTL value for the MPLS label, expressed as a decimal integer.

Values 1 to 128

Default 64

Platforms

7705 SAR Gen 2

13.8 icmp-query

icmp-query

Syntax

icmp-query [**min** *minutes*] [**sec** *seconds*]

no icmp-query

Context

[Tree] (config>service>nat>nat-policy>timeouts icmp-query)

Full Context

configure service nat nat-policy timeouts icmp-query

Description

This command configures the timeout applied to an ICMP query session.

Default

icmp-query min 1

Parameters

min *minutes*

Specifies the timeout, in minutes, applied to an ICMP query session.

Values 1 to 4

Default 1

sec *seconds*

Specifies the timeout, in seconds, applied to an ICMP query session.

Values 1 to 59

Platforms

7705 SAR Gen 2

13.9 icmp-tunneling

icmp-tunneling

Syntax

[**no**] **icmp-tunneling**

Context

[Tree] (config>router icmp-tunneling)

Full Context

configure router icmp-tunneling

Description

This command enables the tunneling of ICMP reply packets over MPLS LSP at a LSR node as per RFC 3032.

The LSR part of this feature consists of crafting the reply ICMP packet of type=11- 'time exceeded', with a source address set to a local address of the LSR node, and appending the IP header and leading payload octets of the original datagram. The system skips the lookup of the source address of the sender of the label TTL expiry packet, which becomes the destination address of the ICMP reply packet. Instead, CPM injects the ICMP reply packet in the forward direction of the MPLS LSP the label TTL expiry packet was received from. The TTL of pushed labels should be set to 255.

The source address of the ICMP reply packet is determined as follows. The LSR uses the address of the outgoing interface for the MPLS LSP. With LDP LSP or BGP LSP multiple ECMP next-hops can exist and in such a case the first outgoing interface is selected. If that interface does not have an address of the same family (IPv4 or IPv6) as the ICMP packet, then the system address of the same family is selected. If one is not configured, the packet is dropped.

When the packet is received by the egress LER, it performs a regular user packet lookup in the data path in the GRT context for BGP shortcut, 6PE, and BGP label route prefixes, or in VPRN context for VPRN and 6VPE prefixes. It then forwards it to the destination, which is the sender of the original packet which TTL expired at the LSR.

If the egress LER does not have a route to the destination of the ICMP packet, it drops the packets.

The rate of the tunneled ICMP replies at the LSR can be directly or indirectly controlled by the existing IOM level and CPM levels mechanisms. Specifically, the rate of the incoming UDP traceroute packets received with a label stack can be controlled at ingress IOM using the distributed CPU protection feature. The rate of the ICMP replies by CPM can also be directly controlled by configuring a system wide rate limit for packets ICMP replies to MPLS expired packets which are successfully forwarded to CPM using

the command 'configure system security vprn-network-exceptions'. While this command's name refers to VPRN service, this feature rate limits ICMP replies for packets received with any label stack, including VPRN and shortcuts.

The 7705 SAR Gen 2 implementation supports appending to the ICMP reply of type Time Exceeded the MPLS label stack object defined in RFC 4950. It does not include it in the ICMP reply type of Destination unreachable.

The new MPLS Label Stack object permits an LSR to include label stack information including label value, EXP, and TTL field values, from the encapsulation header of the packet that expired at the LSR node. The ICMP message continues to include the IP header and leading payload octets of the original datagram.

In order to include the MPLS Label Stack object, SR OS implementation adds support of RFC 4884 which defines extensions for a multi-part ICMPv4/v6 message of type Time Exceeded.

The **no** form of command disables the tunneling of ICMP reply packets over MPLS LSP at a LSR node.

Default

no icmp-tunneling

Platforms

7705 SAR Gen 2

13.10 icmp-type

icmp-type

Syntax

icmp-type *icmp-type*

no icmp-type

Context

[Tree] (config>filter>ip-exception>entry>match icmp-type)

[Tree] (config>filter>ipv6-filter>entry>match icmp-type)

[Tree] (config>filter>ip-filter>entry>match icmp-type)

Full Context

configure filter ip-exception entry match icmp-type

configure filter ipv6-filter entry match icmp-type

configure filter ipv6-exception entry match icmp-type

configure filter ip-filter entry match icmp-type

Description

This command configures matching on the /ICMPv6 type field in the /ICMPv6 header of an IPv4 or IPv6 packet as a filter match criterion or configures matching on the ICMP type field in the ICMP header of an IPv4 packet as an exception filter match criterion. An entry containing Layer 4 non-zero match criteria will not match non-initial (2nd, 3rd, etc.) fragments of a fragmented packet because only the first fragment contains the Layer 4 information. Similarly an entry containing " **icmp-type** 0" match criterion, may match non-initial fragments when the Layer 4 header is not present in a packet fragment and other match criteria are also met.

The **no** form of the command removes the criterion from the match entry.

Default

no icmp-type

Parameters

icmp-type

Specifies the /ICMPv6 type value that must be present to match. Value can be expressed as a decimal integer, as well as in hexadecimal or binary format, or even using keywords. The following value shows decimal integer only.

Values 0 to 255

Platforms

7705 SAR Gen 2

configure qos network egress ip-criteria entry match icmp-type

Description

This command configures matching on the ICMP or ICMPv6 type field in the ICMP or ICMPv6 header of an IPv4 or IPv6 packet as a network QoS match criterion.

An entry containing Layer 4 non-zero match criteria will not match non-initial (2nd, 3rd, etc.) fragments of a fragmented packet since only the first fragment contains the Layer 4 information. Similarly, an entry

containing " **icmp-type** 0" match criterion, may match non-initial fragments when the Layer 4 header is not present in a packet fragment and other match criteria are also met.

The **no** form of the command removes the criterion from the match entry.

Default

no icmp-type

Parameters

icmp-type

Specifies the ICMP or ICMPv6 type value that must be present to match. Value can be expressed as a decimal integer, or in hexadecimal or binary format, or even using keywords.

Values 0 to 255 (Decimal)

0 to FF (Hexadecimal)

0 to 11111111 (Binary)

no idi

Context

[Tree] (config>ipsec>client-db>client>client-id idi)

Full Context

configure ipsec client-db client client-identification idi

Description

This command specifies a match criteria that uses the peer's identification initiator (IDi) as the input, only one IDi criteria can be configured for a given client entry. This command supports the following matching methods:

- **idi any**: Matches any type of IDi with any value.
- **idi ipv4-prefix**: Matches an IDi with the type ID_IPV4_ADDR. If the **any** parameter is specified, then it will match any IPv4 address. If an IPv4 prefix is specified, then it will match an IPv4 address that is within the specified prefix.
- **idi ipv6-prefix**: Matches an IDi with the type ID_IPV6_ADDR. If the **any** parameter is specified, then it will match any IPv6 address. If an IPv6 prefix is specified, then it will match an IPv6 address that is within the specified prefix.
- **idi string-type**: Supports following type of IDi:
  - FQDN: Either a full match or a suffix match
  - RFC822: Either a full match or a suffix match

The **no** form of this command reverts to the default.

Default

no idi

Parameters

any

Matches any type of IDi with any value.

ipv4-prefix/ipv4-prefix-length

Matches any IPv4 address and prefix.

ipv6-prefix/ipv6-prefix-length

Matches any IPv6 address and prefix.

string-type

Matches the type of IDi value for this IPsec client entry.

Values fqdn, fqdn-suffix, rfc822, rfc822-suffix

string-value

Matches the IDi value within the client ID for this IPsec client entry up to 256 characters.

Platforms

7705 SAR Gen 2

idi

Syntax

[**no**] **idi**

Context

configure system grpc tcp-keepalive idle-time

configure system telemetry destination-group tcp-keepalive idle-time

Description

This command configures the amount of time, in seconds, that the connection must remain idle before TCP keepalive probes are sent.

The **no** form of this command reverts to the default value.

Default

idle-time 600

Parameters

idle

Specifies the number of seconds before the first TCP keepalive probe is sent.

Values 1 to 100000

Default 600

Platforms

7705 SAR Gen 2

13.16 idle-timeout

idle-timeout

Syntax

idle-timeout {*minutes* | **disable**}

no idle-timeout

Context

[Tree] (config>system>login-control idle-timeout)

Full Context

configure system login-control idle-timeout

Description

This command configures the idle timeout for console, FTP, Telnet, and SSH sessions before the session is terminated by the system.

By default, each idle console, FTP, Telnet, and SSH session times out after 30 minutes of inactivity.

The **no** form of this command reverts to the default value.

Default

idle-timeout 30

Parameters

minutes

Specifies the idle timeout in minutes. Allowed values are 1 to 1440.

Values 1 to 1440

disable

When the **disable** option is specified, a session will never timeout. To re-enable idle timeout, enter the command without the disable option.

13.17 ies

ies

Syntax

ies *service-id* [**customer** *customer-id*] [**create**] [**vpn** *vpn-id*] [**name** *name*]

no ies *service-id*

Context

[Tree] (config>service ies)

Full Context

configure service ies

Description

This command creates or edits an IES service instance.

The **ies** command creates or maintains an Internet Ethernet Service (IES). If the *service-id* does not exist, a context for the service is created. If the *service-id* exists, the context for editing the service is entered.

IES services allow the creation of customer facing IP interfaces in the same routing instance used for service network core routing connectivity. IES services require that the IP addressing scheme used by the subscriber must be unique between it and other addressing schemes used by the provider and potentially the entire Internet.

IP interfaces defined within the context of an IES service ID must have a SAP created as the access point to the subscriber network. This allows a combination of bridging and IP routing for redundancy purposes.

When a service is created, the **customer** keyword and *customer-id* must be specified and associates the service with a customer. The *customer-id* must already exist having been created using the **customer** command in the service context. Once a service has been created with a customer association, it is not possible to edit the customer association. The service must be deleted and recreated with a new customer association.

Once a service is created, the use of the **customer** *customer-id* is optional for navigating into the service configuration context. Attempting to edit a service with the incorrect *customer-id* specified results in an error.

Multiple IES services are created to separate customer owned IP interfaces. More than one IES service may be created for a single customer ID. More than one IP interface may be created within a single IES service ID. All IP interfaces created within an IES service ID belongs to the same customer.

By default, no IES service instances exist until they are explicitly created.

The **no** form of this command deletes the IES service instance with the specified *service-id*. The service cannot be deleted until all the IP interfaces defined within the service ID have been shut down and deleted.

Parameters

service-id

Specifies the unique service identification number identifying the service in the service domain. This ID must be unique to this service and may not be used for any other service of any type. The *service-id* must be the same number used for every router on which this service is defined.

Values *service-id*: 1 to 214748364

svc-name: A string up to 64 characters

customer-id

Specifies the customer ID number to be associated with the service. This parameter is required on service creation and optional for service editing or deleting.

Values 1 to 2147483647

vpn-id

Specifies the VPN ID number used to identify virtual private networks (VPNs) by a VPN identification number.

Values 1 to 2147483647

Default **null** (0)

create

Keyword used to create the service ID. The **create** keyword requirement can be enabled or disabled in the **environment>create** context.

name

This parameter configures an optional service name, up to 64 characters, which adds a name identifier to a given service to then use that service name in configuration references as well as display and use service names in show commands throughout the system. This helps the service provider or administrator to identify and manage services within the SR OS platforms.

All services are required to assign a service ID to initially create a service. However, either the service ID or the service name can be used to identify and reference a given service once it is initially created.

If a name is not specified at creation time, then SR OS assigns a string version of the service-id as the name.

Service names may not begin with an integer (0 to 9).

Values *name*: up to 64 characters

igmp

Syntax

[**no**] **igmp**

Context

[Tree] (config>router igmp)

Full Context

configure router igmp

Description

This command enables the Internet Group Management Protocol (IGMP) context. When the context is created, the IGMP protocol is enabled.

The Internet Group Management Protocol (IGMP) is used by IPv4 systems (hosts and routers) to report their IP multicast group memberships to neighboring multicast routers. An IP multicast router can be a member of one or more multicast groups, in which case it performs both the "multicast router part" of

the protocol which collects the membership information needed by its multicast routing protocol, and the "group member part" of the protocol which informs itself and other neighboring multicast routers of its memberships.

The **no** form of the command disables the IGMP instance. To start or suspend execution of IGMP without affecting the configuration, use the **no shutdown** command.

configure service vprn dhcp local-dhcp-server failover ignore-mclt-on-takeover

configure service vprn dhcp6 local-dhcp-server failover ignore-mclt-on-takeover

Description

With this flag enabled, the remote IP address or prefix can be taken over immediately upon entering the PARTNER-DOWN state of the intercommunication link, without having to wait for the Maximum Client Lead Time (MCLT) to expire. By setting this flag, the lease times of the existing DHCP clients, while the intercommunication link is in the PARTNER-DOWN state, will still be reduced to the MCLT over time and all new lease times are set to MCLT. This behavior remains the same as originally intended for MCLT.

Some deployments require that the remote IP address/prefix range starts delegating new IP addresses and prefixes upon the failure of the intercommunication link, without waiting for the intercommunication link to transition from the COMM-INT state into the PARTNER-DOWN state and the MCLT to expire while in PARTNER-DOWN state.

This can be achieved by enabling the **ignore-mclt-on-takeover** flag and by configuring the **partner-down-delay** to 0.

Enabling this functionality must be exercised with caution. One needs to keep in mind that the partner-down-delay and MCLT timers were originally introduced to prevent IP address duplication in cases where DHCP redundant nodes transition out-of-sync due to the failure of intercommunication link. These timers (**partner-down-delay** and MCLT) would ensure that during their duration, the new IP addresses and prefixes are delegated only from one node, the one with local IP address-range/prefix. This causes the new IP address delegation to be delayed and the service is impacted.

If it can be assured that the intercommunication link is always available, then the DHCP nodes would stay in sync and the two timers would not be needed. Therefore, it is important that in this mode of operation, the intercommunication link is well protected by providing multiple paths between the two DHCP nodes. The only event that should cause intercommunication link to fail is the entire nodal failure. This failure is acceptable since in this case only one DHCP node is available to provide new IP addresses and prefixes.

The **no** form of this command reverts to the default.

Full Context

configure service vprn ignore-nh-metric

configure service vprn bgp best-path-selection ignore-nh-metric

configure router bgp best-path-selection ignore-nh-metric

Description

This command instructs BGP to disregard the resolved distance to the BGP next-hop in its decision process for selecting the best route to a destination. When configured in the config>router>bgp>best-path-selection context, this command applies to the comparison of two BGP routes with the same NLRI learned from base router BGP peers. When configured in the config>service>vprn context, this command applies to the comparison of two BGP-VPN routes for the same IP prefix imported into the VPRN from the base router BGP instance. When configured in the config>service>vprn>bgp>best-path-selection context, this command applies to the comparison of two BGP routes for the same IP prefix learned from VPRN BGP peers.

The **no** form of this command (no ignore-nh-metric) restores the default behavior whereby BGP factors distance to the next-hop into its decision process.

Default

no ignore-nh-metric

ignore-router-id

Syntax
ignore-router-id include-internal *family* [*family*]
[**no**] **ignore-router-id**

Context
[Tree] (config>router>bgp>best-path-selection ignore-router-id)

[Tree] (config>service>vprn>bgp>best-path-selection ignore-router-id)

Full Context

configure router bgp best-path-selection ignore-router-id

configure service vprn bgp best-path-selection ignore-router-id

Description

When the **ignore-router-id** command is present, and the current best path to a destination was learned from EBGP peer X with BGP identifier x and a new path is received from EBGP peer Y with BGP identifier y, the best path remains unchanged if the new path is equivalent to the current best path up to the BGP identifier comparison – even if y is less than x.

The **no** form of this command restores the default behavior of selecting the route with the lowest BGP identifier (y) as best.

Default

no ignore-router-id

Parameters

family

Specifies up to two internal families to be included in this configuration.

Values mvpn-ipv4, mvpn-ipv6

include-internal

Specifies to ignore the router ID value even when comparing two IGBP paths or an EBGP and an IBGP path.

[Tree] (config>service>vpls>spoke-sdp ignore-standby-signaling)

Full Context

configure service vpls endpoint ignore-standby-signaling

configure service vpls spoke-sdp ignore-standby-signaling

Description

When this command is enabled, the node ignores the standby-bit received from the TLDP peers for the specific spoke-SDP and performs internal tasks without taking it into account.

This command is present at the endpoint level and the spoke-SDP level. If the spoke-SDP is part of the explicit-endpoint, this setting cannot be changed at the spoke-SDP level. The existing spoke-SDP will become part of the explicit-endpoint only if the setting is not conflicting. The newly created spoke-SDP, which is a part of the specified explicit-endpoint, will inherit this setting from the endpoint configuration.

Default

no ignore-standby-signaling

[Tree] (config>router>mpls>lsp igp-shortcut)

Full Context

configure router mpls lsp-template igp-shortcut

configure router mpls lsp igp-shortcut

Description

This command enables the use of a specific RSVP LSP by IS-IS and OSPF routing protocols as a shortcut or as a forwarding adjacency for resolving IGP routes.

When the **igp-shortcut** or the **advertise-tunnel-link** option is enabled at the IGP instance level, all RSVP LSPs originating on this node are eligible by default as long as the destination address of the LSP, as configured in **config>router>mpls>lsp>to**, corresponds to a router-id of a remote node.

The **lfa-protect** option allows an LSP to be included in both the main SPF and the Loop-Free Alternate (LFA) SPF. For a given prefix, the LSP can be used either as a primary next-hop or as an LFA next-hop, but not both. If the main SPF computation selected a tunneled primary next-hop for a prefix, the LFA SPF will not select an LFA next-hop for this prefix and the protection of this prefix will rely on the RSVP LSP

FRR protection. If the main SPF computation selected a direct primary next-hop, then the LFA SPF will select an LFA next-hop for this prefix but will prefer a direct LFA next-hop over a tunneled LFA next-hop.

The **lfa-only** option allows an LSP to be included in the LFA SPF only such that the introduction of IGP shortcuts does not impact the main SPF decision. For a given prefix, the main SPF always selects a direct primary next-hop. The LFA SPF selects an LFA next-hop for this prefix but will prefer a direct LFA next-hop over a tunneled LFA next-hop.

When the **relative-metric** option is enabled, IGP will apply the shortest IGP cost between the endpoints of the LSP plus the value of the offset (instead of the LSP operational metric) when computing the cost of a prefix which is resolved to the LSP. The offset value is optional and it defaults to zero. The minimum net cost for a prefix is one (1) after applying the offset. The TTM continues the show the LSP operational metric as provided by MPLS. In other words, applications such as LDP-over-RSVP (when IGP shortcut is disabled) and BGP and static route shortcuts will continue to use the LSP operational metric.

The **relative-metric** option is mutually exclusive with the **lfa-protect** or the **lfa-only** options. In other words, an LSP with the **relative-metric** option enabled cannot be included in the LFA SPF, and vice-versa, when the **igp-shortcut** option is enabled in the IGP.

Finally, the **relative-metric** option is ignored when forwarding adjacency is enabled in IS-IS or OSPF. In this case, IGP advertises the LSP as a point-to-point unnumbered link along with the LSP operational metric as returned by MPLS and capped to maximum link metric allowed in that IGP. Both the main SPF and the LFA SPFs will use the local IGP database to resolve the routes.

When the router performs local SPF, the SR-TE LSP is used as an eligible IGP shortcut for SRv4 or SRv6 only if the LSP is explicitly allowed using the **allow-sr-over-srte** option when the top SID in the SR-TE LSP is an adjacency SID.

The **no** form of this command disables the use of a specific RSVP LSP by IS-IS and OSPF routing protocols as a shortcut or a forwarding adjacency for resolving IGP routes.

Default

igp-shortcut. All RSVP LSPs originating on this node are eligible by default as long as the destination address of the LSP corresponds to a router-id of a remote node.

Parameters

lfa-protect

Specifies an LSP is included in both the main SPF and the LFA SPF.

lfa-only

Specifies an LSP is included in the LFA SPF only.

relative-metric [*offset*]

Specifies the shortest IGP cost between the endpoints of the LSP plus the configured offset, instead of the LSP operational metric returned by MPLS, is used when calculating the cost of prefix resolved to this LSP. The offset parameter is an integer and is optional. An offset value of zero is used when the relative-metric option is enabled without specifying the offset parameter value.

Values [-10, +10]

allow-sr-over-srte

Specifies that the LSP or LSP template is eligible as an IGP shortcut.

Platforms

7705 SAR Gen 2

igp-shortcut

Syntax

igp-shortcut

Context

[Tree] (config>router>isis igp-shortcut)

Full Context

configure router isis igp-shortcut

Description

This command enables the use of an RSVP-TE or SR-TE shortcut for resolving IGP routes by OSPF or IS-IS routing protocols.

This command instructs IGP to include RSVP LSPs and SR-TE LSPs originating on this node and terminating on the router ID of a remote node as direct links with a metric equal to the metric provided by MPLS.

During the IP reach calculation to determine the reachability of nodes and prefixes, LSPs are overlaid and the LSP metric is used to determine the subset of paths that are equal lowest cost to reach a node or a prefix. If the user enabled the **relative-metric** option for this LSP, IGP will apply the shortest IGP cost between the endpoints of the LSP plus the value of the offset, instead of the LSP operational metric, when computing the cost of a prefix that is resolved to the LSP.

When a prefix is resolved to a tunnel next-hop, the packet is sent labeled with the label stack corresponding to the NHLFE of the RSVP-TE or SR-TE LSP, as well as the explicit-null IPv6 label at the bottom of the stack in the case of an IPv6 prefix. Any network event causing one or more IGP shortcuts to go down will trigger a full SPF computation, which may result in installing a new route over an updated set of tunnel next-hops and IP next-hops.

When **igp-shortcut** is enabled at the IGP instance level, all RSVP-TE and SR-TE LSPs originating on this node are eligible by default as long as the destination address of the LSP, as configured in **config>router>mpls>lsp>to**, corresponds to a router ID of a remote node. LSPs with a destination corresponding to an interface address or any other loopback interface address of a remote node are automatically not considered by IGP. The user can, however, exclude a specific RSVP-TE or SR-TE LSP from being used as a shortcut for resolving IGP routes by entering the **config>router>mpls>lsp>no igp-shortcut** command.

The SPF in IGP only uses RSVP LSPs as forwarding adjacencies, IGP shortcuts, or as endpoints for LDP-over-RSVP. These applications of RSVP LSPs are mutually exclusive at the IGP instance level. If two or more options are enabled in the same IGP instance, then forwarding adjacency takes precedence over the shortcut application, which takes precedence over the LDP-over-RSVP application.

The SPF in IGP uses SR-TE LSPs as IGP shortcuts only.

When ECMP is enabled on the system and multiple equal-cost paths exist for a prefix, the following selection criteria are used to pick up the set of tunnel and IP next-hops to program in the data path.

- Where a destination is a tunnel-endpoint (including external prefixes with tunnel-endpoint as the next-hop), the tunnel with lowest tunnel-index is selected (the IP next-hop is never used in this case).
- Where a destination is not a tunnel-endpoint:
  - LSPs with metric higher than underlying IGP cost between the endpoint of the LSP are excluded
  - Tunnel next-hops are preferred over IP next-hops
  - Within tunnel next-hops, the following priority applies to selection:
    1. The lowest endpoint-to-destination cost is selected
    2. If the endpoint-to-destination costs are the same, the lowest endpoint node router ID is selected
    3. If the router IDs are the same, the lowest tunnel index is selected
  - Within IP next-hops, the following priority applies to selection:
    1. The lowest downstream router ID is selected
    2. If the downstream router IDs are the same, the lowest interface-index is selected

Note:
Although ECMP is not performed across both the IP and tunnel next-hops, the tunnel endpoint may lie in one of the shortest IGP paths for that prefix. In that case, the tunnel next-hop is always selected as long as the prefix cost using the tunnel is equal to or lower than the IGP cost.

When both RSVP-TE and SR-TE IGP shortcuts are available, the IP reach calculation, in the unicast routing table, will first follow the above ECMP tunnel and IP next-hop selection rules when resolving a prefix over IGP shortcuts. After the set of ECMP tunnel and IP next-hops have been selected, the preference of tunnel type is then applied based on the user setting for prefix family resolution. If the user enabled resolution of the prefix family to both RSVP-TE and SR-TE tunnel types, the TTM tunnel preference value is used to select one type for the prefix. In other words, an RSVP-TE LSP type is preferred to an SR-TE LSP type on a per-prefix basis.

The ingress IOM sprays the packets for this prefix over the set of tunnel next-hops and IP next-hops based on the hashing routine currently supported for IPv4 packets.

This feature provides IGP with the capability to populate the multicast RTM with the prefix IP next-hop when both the **igp-shortcut** and the **multicast-import** options are enabled in IGP. The unicast RTM can still use the tunnel next-hop for the same prefix. The SPF keeps track of both the direct first hop and the tunneled first hop of a node, which is added to the Dijkstra tree.

Full Context

configure router ospf3 igp-shortcut

configure router ospf igp-shortcut

Description

This command enables the use of an RSVP-TE or SR-TE shortcut for resolving IGP routes by OSPF or IS-IS routing protocols.

This command instructs IGP to include RSVP LSPs and SR-TE LSPs originating on this node and terminating on the router ID of a remote node as direct links with a metric equal to the metric provided by MPLS.

During the IP reach calculation to determine the reachability of nodes and prefixes, LSPs are overlaid and the LSP metric is used to determine the subset of paths that are equal lowest cost to reach a node or a prefix. If the user enabled the **relative-metric** option for this LSP, IGP will apply the shortest IGP cost between the endpoints of the LSP plus the value of the offset, instead of the LSP operational metric, when computing the cost of a prefix that is resolved to the LSP.

When a prefix is resolved to a tunnel next hop, the packet is sent labeled with the label stack corresponding to the NHLFE of the RSVP-TE or SR-TE LSP, as well as the explicit-null IPv6 label at the bottom of the stack in the case of an IPv6 prefix. Any network event causing one or more IGP shortcuts to go down will trigger a full SPF computation, which may result in installing a new route over an updated set of tunnel next-hops and IP next-hops.

When **igp-shortcut** is enabled at the IGP instance level, all RSVP-TE and SR-TE LSPs originating on this node are eligible by default as long as the destination address of the LSP, as configured in **config>router>mpls>lsp>to**, corresponds to a router ID of a remote node. LSPs with a destination corresponding to an interface address or any other loopback interface address of a remote node are automatically not considered by IGP. The user can, however, exclude a specific RSVP-TE or SR-TE LSP from being used as a shortcut for resolving IGP routes by entering the **config>router>mpls>lsp>no igp-shortcut** command.

The SPF in IGP only uses RSVP LSPs as forwarding adjacencies, IGP shortcuts, or as endpoints for LDP-over-RSVP. These applications of RSVP LSPs are mutually exclusive at the IGP instance level. If two or more options are enabled in the same IGP instance, then forwarding adjacency takes precedence over the shortcut application, which takes precedence over the LDP-over-RSVP application.

The SPF in IGP uses SR-TE LSPs as IGP shortcuts only.

When ECMP is enabled on the system and multiple equal-cost paths exist for a prefix, the following selection criteria are used to pick up the set of tunnel and IP next-hops to program in the data path.

- Where a destination is a tunnel-endpoint (including external prefixes with tunnel-endpoint as the next hop), the tunnel with lowest tunnel-index is selected (the IP next hop is never used in this case).
- Where a destination is not a tunnel-endpoint:
  - LSPs with metric higher than underlying IGP cost between the endpoint of the LSP are excluded
  - Tunnel next-hops are preferred over IP next-hops
  - Within tunnel next-hops:
    1. The lowest endpoint-to-destination cost is selected
    2. If the endpoint-to-destination costs are the same, the lowest endpoint node router ID is selected
    3. If the router IDs are the same, the lowest tunnel index is selected

– Within IP next-hops:

1. The lowest downstream router ID is selected
2. If the downstream router IDs are the same, the lowest interface-index is selected

Note:
Although ECMP is not performed across both the IP and tunnel next-hops, the tunnel endpoint may lie in one of the shortest IGP paths for that prefix. In that case, the tunnel next hop is always selected as long as the prefix cost using the tunnel is equal or lower than the IGP cost.

When both RSVP-TE and SR-TE IGP shortcuts are available, the IP reach calculation, in the unicast routing table, will first follow the above ECMP tunnel and IP next hop selection rules when resolving a prefix over IGP shortcuts. After the set of ECMP tunnel and IP next-hops have been selected, the preference of tunnel type is then applied based on the user setting of the resolution of the family of the prefix. If the user enabled resolution of the prefix family to both RSVP-TE and SR-TE tunnel types, the TTM tunnel preference value is used to select one type for the prefix. In other words, the RSVP-TE LSP type is preferred to an SR-TE LSP type on a per-prefix basis.

The ingress IOM sprays the packets for this prefix over the set of tunnel next-hops and IP next-hops based on the hashing routine currently supported for IPv4 packets.

This feature provides IGP with the capability to populate the multicast RTM with the prefix IP next hop when both the **igp-shortcut** and the **multicast-import** options are enabled in IGP. The unicast RTM can still make use of the tunnel next hop for the same prefix. This change is made possible with the enhancement by which SPF keeps track of both the direct first hop and the tunneled first hop of a node which is added to the Dijkstra tree.

Full Context

configure ipsec ike-transform ike-auth-algorithm

Description

This command specifies the IKE authentication algorithm for the IKE transform

Default

ike-auth-algorithm sha1

Parameters

auth-algorithm

Specifies the values used to identify the hashing algorithm

Values

md5 — Configures the use of the hmac-md5 algorithm for authentication

sha1 — Configures the use of the hmac-sha1 algorithm for authentication

sha256 — Configures the use of the hmac-sha256 algorithm for authentication.

sha384 — Configures the use of the hmac-sha384 algorithm for authentication

sha512 — Configures the use of the hmac-sha512 algorithm for authentication.

aes-xcbc — Configures the use of aes-xcbc (RFC 3566, *The AES-XCBC-MAC-96 Algorithm and Its Use With IPsec*) algorithm for authentication.

Platforms

7705 SAR Gen 2

13.39 ike-encryption-algorithm

ike-encryption-algorithm

Syntax

ike-encryption-algorithm {**des** | **3des** | **aes128** | **aes192** | **aes256** | **aes128-gcm8** | **aes128-gcm16** | **aes256-gcm8** | **aes256-gcm16**}

Context

[Tree] (config>ipsec>ike-transform ike-encryption-algorithm)

Full Context

configure ipsec ike-transform ike-encryption-algorithm

Description

This command specifies the IKE encryption algorithm to be used in the IKE transform instance.

Default

ike-encryption-algorithm aes128

Parameters

encryption-algorithm

Specifies the IKE encryption algorithm.

Values **des** — Configures the 56-bit des algorithm for encryption. This is an older algorithm with relatively weak security. While better than nothing, it should only be used where a strong algorithm is not available on both ends at an acceptable performance level.

3des — Configures the 3-des algorithm for encryption. This is a modified application of the des algorithm which uses multiple des operations to make information more secure.

aes128 — Configures the aes algorithm with a block size of 128 bits. This is a mandatory implementation size for aes. This is a very strong algorithm choice.

aes192 — Configures the aes algorithm with a block size of 192 bits. This is a stronger version of aes.

aes256 — Configures the aes algorithm with a block size of 256 bits. This is the strongest available version of aes.

aes128-gcm8 - Configures ESP to use aes-gcm with a 128-bit key size and an 8-byte ICV for encryption and authentication.

aes128-gcm16 - Configures ESP to use aes-gcm with a 128-bit key size and a 16-byte ICV for encryption and authentication.

aes256-gcm8 - Configures ESP to use aes-gcm with a 256-bit key size and an 8-byte ICV for encryption and authentication.

aes256-gcm16 - This parameter configures ESP to use aes-gcm with a 256-bit key size and a 16-byte ICV for encryption and authentication.

Full Context

configure ipsec ike-transform ike-prf-algorithm

Description

This command specifies the PRF algorithm to use for IKE security association.

Note:
If an authenticated encryption algorithm like AES-GCM is used for IKE encryption algorithm, **same-as-auth** cannot be used for **ike-prf-algorithm**.

Default

ike-prf-algorithm same-as-auth

Parameters

md5

This parameter configures IKE to use the **hmac-md5** algorithm for PRF.

sha1

This parameter configures IKE to use the **hmac-sha1** algorithm for PRF.

sha256

This parameter configures IKE to use the **hmac-sha256** algorithm for PRF.

sha384

This parameter configures IKE to use the **hmac-sha384** algorithm for PRF.

sha512

This parameter configures IKE to use the **hmac-sha512** algorithm for PRF.

aes-xcbc

This parameter configures IKE to use the **aes128-xcbc** algorithm for PRF.

same-as-auth

This parameter configures the same algorithm as IKE authentication algorithm.

Platforms

ike-transform

Syntax

ike-transform *ike-transform-id* [*ike-transform-id* ...(up to 4 max)]

no ike-transform

Context

[Tree] (config>ipsec>ike-policy ike-transform)

Full Context

configure ipsec ike-policy ike-transform

Description

This command specifies the IKE transform to be used in the IKE policy. Up to four IKE transforms can be specified. If multiple IDs are specified, the system selects an IKE transform based on the peer's proposal. If the system is a tunnel initiator, it uses the configured IKE transform to generate the SA payload.

Default

no ike-transform

Parameters

ike-transform-id

Specifies up to four existing IKE transform instances to be associated with this IKE policy.

Values 1 to 4096

Platforms

7705 SAR Gen 2

ike-transform

Syntax

ike-transform *ike-transform-id* [**create**]

no ike-transform *ike-transform-id*

Context

[Tree] (config>ipsec ike-transform)

Full Context

configure ipsec ike-transform

Description

This commands creates a new or enters an existing IKE transform instance. The IKE transform include following configuration for IKE SA:

- DH Group
- IKE authentication algorithm
- IKE encryption algorithm
- IKE SA lifetime

The *ike-transform-id* is referenced in the **ike-policy** configuration.

Parameters

ike-transform

Specifies a number used to uniquely identify an IKE transform instance.

Values 1 to 4096

create

Keyword used to create the ike-transform instance. The **create** keyword requirement can be enabled or disabled in the **environment>create** context.

Full Context

configure router ldp implicit-null-label

Description

This command enables the use of the implicit null label. Use this command to signal the implicit null option for all LDP FECs for which this node is the egress LER.

The **no** form of this command disables the signaling of the implicit null label.

Default

no implicit-null-label

Platforms

7705 SAR Gen 2

implicit-null-label

Syntax

[**no**] **implicit-null-label**

Context

[Tree] (config>router>rsvp implicit-null-label)

Full Context

configure router rsvp implicit-null-label

Description

This command enables the use of the implicit null label.

Signaling the IMPLICIT NULL label value for all RSVP LSPs can be enabled for which this node is the egress LER. RSVP must be shut down before being able to change this configuration option.

The egress LER does not signal the implicit null label value on P2MP RSVP LSPs. However, the Penultimate Hop Popping (PHP) node can honor a Resv message with the label value set to the implicit null.

The **no** form of this command disables the signaling of the implicit null label.

Default

no implicit-null-label

Platforms

7705 SAR Gen 2

implicit-null-label

Syntax

implicit-null-label [**enable** | **disable**]

no implicit-null-label

Context

[Tree] (config>router>rsvp>interface implicit-null-label)

Full Context

configure router rsvp interface implicit-null-label

Description

This command enables the use of the implicit null label over a specific RSVP interface.

All LSPs for which this node is the egress LER and for which the path message is received from the previous hop node over this RSVP interface will signal the implicit null label. This means that if the egress LER is also the merge-point (MP) node, then the incoming interface for the path refresh message over the bypass dictates if the packet will use the implicit null label or not. The same for a 1-to-1 detour LSP.

The user must shut down the RSVP interface before being able to change the implicit null configuration option.

The **no** form of this command returns the RSVP interface to use the RSVP level configuration value.

Default

no implicit-null-label

Parameters

enable

Enables the implicit null label.

disable

Disables the implicit null label.

Description

This command specifies the import routing policy to be used for IGMP packets to be used on this SAP or SDP. Only a single policy can be imported on a SAP at any time.

The **no** form of this command removes the policy association from the SAP or SDP.

Default

no import

Parameters

policy-name

Specifies the routing policy name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters excluding double quotes. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes. Routing policies are configured in the **config>router>policy-options** context The router policy must be defined before it can be imported.

Full Context

configure service vprn bgp import

configure service vprn bgp group neighbor import

configure service vprn bgp group import

Description

This command is used to specify route policies that control the handling of inbound routes received from certain peers. Route policies are configured in the **config>router>policy-options** context.

This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in a peer-group) or neighbor level (only applies to the specified peer). The most specific level is used

The **import** command can reference up to 15 objects, where each object is either a policy logical expression or the name of a single policy. The objects are evaluated in the specified order to determine the modifications of each route and the final action to accept or reject the route.

Only one of the 15 objects referenced by the **import** command can be a policy logical expression consisting of policy names (enclosed in square brackets) and logical operators (AND, OR, NOT). The first of the 15 objects has a maximum length of 255 characters while the remaining 14 objects have a maximum length of 64 characters each.

When multiple **import** commands are issued, the last command entered overrides the previous command.

When an import policy is not specified, BGP routes are accepted by default.

The **no** form of this command removes the policy association.

Default

no import

Parameters

plcy-or-long-expr

Specifies the route policy name (up to 64 characters) or a policy logical expression (up to 255 characters).

plcy-or-expr

Specifies the route policy name (up to 64 characters) or a policy logical expression (up to 255 characters).

Full Context

configure service vprn pim import

Description

This command specifies the import route policy to be used for determining which routes are accepted from peers. Route policies are configured in the **config>router>policy-options** context. When an import policy is not specified, BGP routes are accepted by default.

The **no** form of this command removes the policy association from the IGMP instance.

Default

no import join-policy

no import register-policy

Parameters

join-policy

Use this command to filter PIM join messages which prevents unwanted multicast streams from traversing the network.

register-policy

This keyword filters register messages. PIM register filters prevent register messages from being processed by the RP. This filter can only be defined on an RP. When a match is found, the RP immediately sends back a register-stop message.

policy-name

Specifies the route policy name. Allowed values are any string up to 32 characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed between double quotes. Route policies are configured in the **config>router>policy-options** context.

Syntax

import type {**cert** | **key** | **crl**} **input** *url-string* **output** *filename* **format** *input-format* [**password** [*32 chars max*]]

Context

[Tree] (admin>certificate import)

Full Context

admin certificate import

Description

This command converts an input file (key/certificate/CRL) to a system format file. The following list summarizes the formats supported by this command:

- Certificate
  - PKCS #12
  - PKCS #7 PEM encoded
  - PKCS #7 DER encoded
  - PEM
  - DER
- Key
  - PKCS #12
  - PEM
  - DER
- CRL
  - PKCS #7 PEM encoded
  - PKCS #7 DER encoded
  - PEM
  - DER

Note:
If there are multiple objects with the same type in the input file, only the first object is extracted and converted.

Parameters

input *url-string*

Specifies the URL for the input file. This URL could be either a local CF card URL file or a FP URL to download the input file.

Values

url-string	<local-url> up to 99 characters
local-url	<cflash-id>/<file-path>
cflash-id	cf1:| cf2:| cf3:

output *filename*

Specifies the name of output file up to 95 characters. The output directory depends on the file type like following:

- Key: cf3:\system-pki\key
- Cert: cf3:\system-pki\cert
- CRL: cf3:\system-pki\CRL

type

The type of input file.

Values cert, key, crl

format

Specifies the format of input file.

Values pkcs12, pkcs7-der, pkcs7-pem, pem, der

password

Specifies the password to decrypt the input file in case that it is an encrypted PKCS#12 file.

configure router bgp group neighbor import

configure router bgp group import

configure router bgp import

Description

This command specifies route policies that control the handling of inbound routes received from certain peers. Route policies are configured in the **config>router>policy-options** context.

This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). The most specific level is used.

The **import** command can reference up to 15 objects, where each object is either a policy logical expression or the name of a single policy. The objects are evaluated in the specified order to determine the modifications of each route and the final action to accept or reject the route.

Only one of the 15 objects referenced by the **import** command is allowed to be a policy logical expression consisting of policy names (enclosed in square brackets) and logical operators (AND, OR, NOT). The first of the 15 objects has a maximum length of 255 characters; the remaining 14 objects have a maximum length of 64 characters each.

When multiple **import** commands are issued, the last command entered overrides the previous command.

When an import policy is not specified, BGP routes are accepted by default.

The **no** form of this command removes the policy association.

Default

no import

Parameters

plcy-or-long-expr

Specifies the route policy name (up to 64 characters long) or a policy logical expression (up to 255 characters long). Allowed values are any string up to 255 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

plcy-or-expr

Specifies the route policy name (up to 64 characters long) or a policy logical expression (up to 64 characters long). Allowed values are any string up to 64 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

Platforms

7705 SAR Gen 2

import

Syntax

import {**ignore** | **accept** | **drop**}

Context

[Tree] (config>service>vprn>bgp-ipvpn>attribute-set import)

Full Context

configure service vprn bgp-ipvpn attribute-set import

Description

This command configures the reception behavior for ATTR_SETs in received VPN-IP routes.

Default

import ignore

Parameters

accept

Keyword to configure BGP to accept and process ATTR_SETs in received unicast VPN-IP routes (MPLS or SRv6) when they are imported into the VPRN. The path attributes contained inside the ATTR_SET are used for best-path selection within the VPRN, instead of the outer-path attributes attached to the imported VPN-IP route. The path attributes inside the ATTR_SET determine the path attributes of BGP routes advertised to PE-CE peers of the VPRN. However, the ATTR_SET is removed at the time of advertisement. VPRN BGP routes with attributes derived from **accept** processing are only advertised to EBGP peers and IBGP route reflector client peers. VPRN BGP routes are not advertised to BGP confederation peers. If the origin AS in the ATTR_SET attribute does not match the configured ASN, VPRN BGP routes with attributes derived from **accept** processing are advertised to IBGP peers that are not covered by a cluster configuration.

drop

Keyword to configure BGP to ignore and silently discard ATTR_SETs in received VPN-IP routes when they are imported into the VPRN. The path attributes contained inside the ATTR_SET are not used for best path selection within the VPRN. If a VPRN is not involved in an independent domain Layer 3 VPN service, Nokia recommends configuring the **import** command to **drop**.

ignore

Keyword to configure BGP to ignore ATTR_SETs in received VPN-IP routes when they are imported into the VPRN. The path attributes contained inside the ATTR_SET are not used for best-path selection within the VPRN. With the **ignore** parameter, the ATTR_SET attribute is transmitted unchanged to the CE. Nokia does not recommend configuring the **import** command to **ignore** in most deployments.

13.49 import-grt

import-grt

Syntax

import-grt *plcy-or-long-expr* [*plcy-or-expr*]

no import-grt

Context

[Tree] (config>service>vprn>grt import-grt)

Full Context

configure service vprn grt-lookup import-grt

Description

This command associates policies to control the leaking of GRT routes into the associated VPRN.

The GRT route must have first been leaked by a **leak-export** policy defined under the **config>router** context. Then the route must match a route entry in the specified **import-grt** policy with an accept action.

The **no** form of this command removes route leaking policy associations and disables the leaking of GRT routes into the local VPRN.

Parameters

plcy-or-long-expr

Specifies route policy names, up to 64 characters, or a policy logical expression, up to 255 characters.

Values *plcy-or-long-expr*: *policy-name* | *long-expr*

policy-name: up to 64 characters

long-expr: up to 255 characters

plcy-or-expr

Specifies up to four route policy names, up to 64 characters, or a policy logical expression, up to 64 characters.

Values *plcy-or-expr*: *policy-name* | *expr*

policy-name: up to 64 characters

expr: up to 64 characters

13.50 import-pmsi-routes

import-pmsi-routes

Syntax

import-pmsi-routes

Context

[Tree] (config>router>ldp import-pmsi-routes)

Full Context

configure router ldp import-pmsi-routes

Description

Commands in this context configure import-pmsi-routes.

For option B, the leafs or ABR/ASBR that are not directly connected to the root have no visibility of the root. As such, for LDP to build the recursive FEC it needs to cache the MVPN PMSI AD routes, this command gives the user the ability to manually enable caching of MVPN PMSI AD routes internally in LDP for EVPN or MVPN inter-as or **mvpn_no_export_community** intra-as.

Platforms

13.51 import-prefixes

import-prefixes

Syntax

[**no**] **import-prefixes** *policy-name*

Context

[Tree] (config>router>ldp>session-params>peer import-prefixes)

Full Context

configure router ldp session-parameters peer import-prefixes

Description

This command configures the import FEC prefix policy to determine which prefixes received from this LDP peer are imported and installed by LDP on this node. If resolved these FEC prefixes are then re-distributed to other LDP and T-LDP peers. A FEC prefix that is filtered out (deny) will not be imported. A FEC prefix that is filtered in (accept) will be imported.

If no import policy is specified, the node will import all prefixes received from this LDP/T-LDP peer. This policy is applied in addition to the global LDP policy and targeted session policy.

Policies are configured in the **config>router>policy-options** context. A maximum of five policy names can be specified. Peer address has to be the peer LSR-ID address.

The **no** form of the command removes the policy from the configuration.

Default

no import-prefixes - no import route policy is specified

Parameters

policy-name

Specifies up to five import-prefix route policy names. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters excluding double quotes. If the string contains spaces, use double quotes to delimit the start and end of the string. The specified name(s) must already be defined.

Platforms

7705 SAR Gen 2

import-prefixes

Syntax

import-prefixes *policy-name* [*policy-name*]

no import-prefixes

Context

[Tree] (config>router>ldp>targeted-session import-prefixes)

Full Context

configure router ldp targeted-session import-prefixes

Description

This command configures the import route policy to determine which FEC prefix label bindings are accepted from targeted LDP neighbors into this node. A label binding that is filtered out (deny) will not be imported. A route that is filtered in (accept) will be imported.

If no import policy is specified, this node session will accept all bindings from configured targeted LDP neighbors. This policy is applied in addition to the global LDP policy.

Policies are configured in the **config>router>policy-option**s context. A maximum of five policy names can be specified.

The **no** form of this command removes the policy from the configuration.

Parameters

policy-name

Specifies up to five import policy names. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

Platforms

7705 SAR Gen 2

13.52 import-tunnel-table

import-tunnel-table

Syntax

import-tunnel-table *policy-name* [*policy-name*]

no import-tunnel-table

Context

[Tree] (config>router>ldp import-tunnel-table)

Full Context

configure router ldp import-tunnel-table

Description

This command controls the import, in the tunnel table, of LDP tunnels to non-host prefixes. This command is only intended for importing tunnels; it cannot be used for preventing the import of any specific prefix and only non-host prefixes will be considered when evaluating this policy in this context. The LDP tunnels to these non-host prefixes must be created before they can be imported.

This command does not affect the automatic import of LDP tunnels to host prefixes.

The **no** version of this command removes all of the import policies and, by consequence, any tunnels to non-host prefixes from the tunnel table. If a non-host prefix tunnel is currently being used for forwarding, disabling this command may be service-impacting.

Default

no import-tunnel-table

Parameters

policy-name

Specifies up to five import route policy names. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

The specified policy names must already be defined.

7705 SAR Gen 2

13.54 improved-assert

improved-assert

Syntax

[**no**] **improved-assert**

Context

[Tree] (config>service>vprn>pim>if improved-assert)

Full Context

configure service vprn pim interface improved-assert

Description

This command enables improved assert processing on this interface. The PIM assert process establishes a forwarder for a LAN and requires interaction between the control and forwarding planes.

The assert process is started when data is received on an outgoing interface. This could impact performance if data is continuously received on an outgoing interface.

When enabled, the PIM assert process is done entirely on the control-plane with no interaction between the control and forwarding plane.

Default

improved-assert

Platforms

7705 SAR Gen 2

improved-assert

Syntax

[**no**] **improved-assert**

Context

[Tree] (config>router>pim>interface improved-assert)

Full Context

configure router pim interface improved-assert

Description

This command enables improved assert processing. The PIM assert process establishes a forwarder for a LAN and requires interaction between the control and forwarding planes. The assert process is started when data is received on an outgoing interface meaning that duplicate traffic is forwarded to the LAN until the forwarder is negotiated among the routers.

When the **improved-assert** command is enabled, the PIM assert process is done entirely in the control plane. The advantages are that it eliminates duplicate traffic forwarding to the LAN. It also improves performance since it removes the required interaction between the control and data planes.

Note:
improved-assert is still fully interoperable with the RFC 4601, *Protocol Independent Multicast - Sparse Mode (PIM-SM): Protocol Specification (Revised)* and RFC 2362, *Protocol Independent Multicast-Sparse Mode (PIM-SM)*, implementations. However, there may be conformance tests that may fail if the tests expect control-data plane interaction in determining the assert winner. Disabling the **improved-assert** command when performing conformance tests is recommended.

13.67 in-remark

in-remark

Syntax

in-remark {**dscp** *dscp-name* | **prec** *ip-prec-value*}

no in-remark

Context

[Tree] (config>qos>sap-ingress>fc in-remark)

Full Context

configure qos sap-ingress fc in-remark

Description

This command is used in a SAP ingress QoS policy to define an explicit in-profile remark action for a forwarding class or subclass. While the SAP ingress QoS policy may be applied to any SAP, the remarking functions are only enforced when the SAP is associated with an IP or subscriber interface (in an IES or VPRN). When the policy is applied to a Layer 2 SAP (i.e., Epipe or VPLS), the remarking definitions are silently ignored.

In the case where the policy is applied to a Layer 3 SAP, the in-profile remarking definition will be applied to packets that have been classified to the forwarding class or subclass. It is possible for a packet to match a classification command that maps the packet to a particular forwarding class or subclass, only to have a more explicit (higher priority match) override the association. Only the highest priority match forwarding class or subclass association will drive the in-profile marking.

The in-remark command is only applicable to ingress IP routed packets that are considered in-profile. The profile of a SAP ingress packet is affected by either the explicit in-profile/out-of-profile definitions or the ingress policing function applied to the packet. Table 43: Effect of In-Remark Command on Received SAP Ingress Packets shows the effect of the in-remark command on received SAP ingress packets. Within the in-profile IP packet's ToS field, either the six DSCP bits or the three precedence bits are remarked.

Table 43: Effect of In-Remark Command on Received SAP Ingress Packets

SAP Ingress Packet State	in-remark Command Effect
Non-Routed, Policed In-Profile	No Effect (non-routed packet)
Non-Routed, Policed Out-of-Profile	No Effect (non-routed packet)
Non-Routed, Explicit In-Profile	No Effect (non-routed packet)
Non-Routed, Explicit Out-of-Profile	No Effect (non-routed packet)
IP Routed, Policed In-Profile	in-remark value applied to IP header ToS field
IP Routed, Policed Out-of-Profile	No Effect (out-of-profile packet)
IP Routed, Explicit In-Profile	in-remark value applied to IP header ToS field
IP Routed, Explicit Out-of-Profile	No Effect (out-of-profile packet)

The **no** form of this command disables ingress remarking of in-profile packets classified to the forwarding class or subclass.

Parameters

dscp *dscp-name*

Specifies that the matching packet's DSCP bits should be overridden with the value represented by dscp-name.

The *dscp-name* parameter is a 6-bit value. It must be one of the predefined DSCP names defined on the system.

Values be, cp1, cp2, cp3, cp4, cp5, cp6, cp7, cs1, cp9, af11, cp11, af12, cp13, af13, cp15, cs2, cp17, af21, cp19, af22, cp21, af23, cp23, cs3, cp25, af31, cp27, af32, cp29, af33, cp31, cs4, cp33, af41, c p35, af42, cp37, af43, cp39, cs5, cp41, cp42, cp43, cp44, cp45, ef, cp47, nc1, cp49, cp50, cp51, cp52, cp53, cp54, cp55, nc2, cp57, cp58, cp59, cp60, cp61, cp62, cp63

prec *ip-prec-value*

Specifies that the matching packet's precedence bits should be overridden with the value represented by *ip-prec-value*.

Values 0 to 7

Description

This command configures the length of time to maintain stale state on the session reflector. Stale state is test data that has not been refreshed or updated by newly arriving probes for that specific test in a predetermined length of time. Any single reflector can maintain up state for a maximum of 12000 tests. If the maximum value is exceeded, the session reflector lacks memory to allocate to new tests.

The **no** form of this command returns the value to the default.

Default

inactivity-timeout 100

Parameters

seconds

Specifies the value in seconds for maintaining stale state.

Values 10 to 100

Default 100

Platforms

7705 SAR Gen 2

13.69 inband

inband

Syntax

inband *service-id*

no inband

Context

[Tree] (config>system>security>vprn-aaa-server inband)

Full Context

configure system security vprn-aaa-server inband

Description

This command configures TACACS+ or RADIUS servers in a VPRN to be used for AAA by that VPRN and by sessions in the Base routing instance.

The **no** form of this command disables the use of servers for in-band management.

Default

no inband

Parameters

service-id

Specifies the VPRN server for AAA to use for in-band sessions.

Values *service-id*: 1 to 2147483648

svc-name: 64 characters maximum

Platforms

7705 SAR Gen 2

13.70 inbound-max-sessions

inbound-max-sessions

Syntax

inbound-max-sessions *number-of-sessions*

no inbound-max-sessions

Context

[Tree] (config>system>login-control>ftp inbound-max-sessions)

Full Context

configure system login-control ftp inbound-max-sessions

Description

This command configures the maximum number of concurrent inbound FTP sessions.

This value is the combined total of inbound and outbound sessions.

The **no** form of this command reverts to the default value.

Default

inbound-max-sessions 3

Parameters

value

Specifies the maximum number of concurrent FTP sessions on the node.

Values 0 to 5

Platforms

7705 SAR Gen 2

inbound-max-sessions

Syntax

inbound-max-sessions *number-of-sessions*

no inbound-max-sessions

Context

[Tree] (config>system>login-control>telnet inbound-max-sessions)

[Tree] (config>system>login-control>ssh inbound-max-sessions)

Full Context

configure system login-control telnet inbound-max-sessions

configure system login-control ssh inbound-max-sessions

Description

This parameter limits the number of inbound Telnet and SSH sessions. A maximum of 30 telnet and ssh connections can be established to the router. The local serial port cannot be disabled.

Telnet and SSH maximum sessions can also use the combined total of both inbound sessions (SSH +Telnet). While it is acceptable to continue to internally limit the combined total of SSH and Telnet sessions to N, either SSH or Telnet sessions can use the inbound maximum sessions, if so required by the Operator.

The **no** form of this command reverts to the default value.

Default

inbound-max-sessions 5

Parameters

number-of-sessions

The maximum number of concurrent inbound Telnet sessions, expressed as an integer.

Values 0 **to** 50 (default = 5) or 0 **to** N where N is the new total number of SSH +Telnet sessions if they are scaled

Platforms

7705 SAR Gen 2

13.71 incl-mcast-l2-attributes-advertisement

incl-mcast-l2-attributes-advertisement

Syntax

[**no**] **incl-mcast-l2-attributes-advertisement**

Context

[Tree] (config>service>vpls>bgp-evpn incl-mcast-l2-attributes-advertisement)

Full Context

configure service vpls bgp-evpn incl-mcast-l2-attributes-advertisement

Description

This command triggers the advertisement of the Layer 2 attributes extended community including:

- the service MTU in the Layer 2 MTU field
- the F bit, which is set to 1 if the **hash-label** command is set to true (in the **configure service vpls bgp-evpn mpls** context); otherwise, the F bit is set to 0
- the C bit, which is set to 1 if the **control-word** command is set to true (in the **configure service vpls bgp-evpn mpls** context); otherwise, the C bit is set to 0

The router compares the received Layer 2 MTU from a peer with the local service MTU. If there is a mismatch, the operation state of the EVPN destination is set to down, except if the **configure service vpls bgp-evpn ignore-mtu-mismatch** command is enabled.

A mismatch between the received C bit and the local **control-word** setting (in the **configure service vpls bgp-evpn mpls** context) results in the operational state of the EVPN destination being set to down.

A mismatch between the received F bit and the local F bit (via the hash label configuration) results in the operational state of the EVPN destination being set to down.

The **no** form of this command prevents the router from advertising the Layer 2 attributes extended community along with the IMET route for the service.

Default

no incl-mcast-l2-attributes-advertisement

Platforms

7705 SAR Gen 2

13.72 incl-mcast-orig-ip

incl-mcast-orig-ip

Syntax

incl-mcast-orig-ip *ip-address*

no incl-mcast-orig-ip

Context

[Tree] (config>service>vpls>bgp-evpn incl-mcast-orig-ip)

Full Context

configure service vpls bgp-evpn incl-mcast-orig-ip

Description

The IP address configured by the user in the **incl-mcast-orig-ip** command is encoded in the **originating-ip** field of EVPN Inclusive Multicast Routes with tunnel type Ingress Replication (value 6), mLDP (2), and Composite IR and mLDP (130).

The configured address does not need to be reachable in the base router or have an interface in the base router. The originating-ip address is used solely for BGP route-key selection.

The originating-ip is never changed for Inclusive Multicast Routes with tunnel type AR (Assisted Replication, value 10).

The **no** version of the command withdraws the affected Inclusive Multicast Routes and re-advertises it with the default system-ip address in the originating-ip field.

Default

incl-mcast-orig-ip 1

Parameters

ip-address

Specifies the IPv4 address value.

Values a.b.c.d

Platforms

7705 SAR Gen 2

13.73 include

include

Syntax

include *group-name* [*group-name*]

no include [*group-name* [*group-name*]]

Context

[Tree] (config>router>mpls>lsp>secondary include)

[Tree] (config>router>mpls>lsp include)

[Tree] (config>router>mpls>lsp>primary include)

[Tree] (config>router>mpls>lsp-template include)

Full Context

configure router mpls lsp secondary include

configure router mpls lsp include

configure router mpls lsp primary include

configure router mpls lsp-template include

Description

This command specifies the admin groups to be included when an LSP is set up. Up to five groups per operation can be specified, up to 32 maximum. The **include** statement instructs the CSPF algorithm to pick TE links among the links which belong to one or more of the specified admin groups. A link that does not belong to at least one of the specified admin groups is excluded and thus pruned from the TE database before the CSPF computation. However, a link can still be selected if it belongs to one of the groups in a **include** statement but also belongs to other groups which are not part of any **include** statement in the LSP or primary/secondary path configuration. In other words, the **include** statements implements the "include-any" behavior.

The **no** form of this command deletes the specified groups in the specified context.

Default

no include

Parameters

group-name

Specifies admin groups to be included when an LSP is set up.

Platforms

7705 SAR Gen 2

include

Syntax

[**no**] **include** *tag*

Context

[Tree] (config>router>admin-tags>route-admin-tag-policy include)

Full Context

configure router admin-tags route-admin-tag-policy include

Description

This configures an admin tag to be included when matching a route against an LSP.

Up to eight inclusion statements are supported per policy.

The **no** form of this command removes the admin tag from the include statement.

Parameters

tag

Specifies the value of the admin tag, up to 32 characters.

Platforms

7705 SAR Gen 2

13.74 include-all

include-all

Syntax

include-all

Context

[Tree] (config>router>fad>flex-algo include-all)

Full Context

configure router flexible-algorithm-definitions flex-algo include-all

Description

Commands in this context configure administrative groups to include in the flexible algorithm topology graph. Administrative groups are attributes associated with a link and are generally referred to as link colors.

Flexible algorithms provide the possibility to restrict inclusion into the topology graph to links that have a pre-defined combination of associated administrative groups. The **include-all** command requires that all configured administrative groups must be present in a link before the link can be included in the topology graph.

Platforms

7705 SAR Gen 2

13.75 include-any

include-any

Syntax

include-any

Context

[Tree] (config>router>fad>flex-algo include-any)

Full Context

configure router flexible-algorithm-definitions flex-algo include-any

Description

Commands in this context configure administrative groups to include in the flexible algorithm topology graph. Administrative groups are attributes associated with a link and are generally referred to as link colors.

Flexible algorithms provide the possibility to restrict inclusion into the topology graph to links that have a pre-defined combination of associated administrative groups. The **include-any** command requires that one of the configured administrative groups must be present on a link before the link can be included in the topology graph.

Description

This command enables the Recursive DNS Server (RDNSS) Option in router advertisements. This must be enabled for each interface on which the RDNSS option is required in router advertisement messages.

The **no** form of this command disables the RDNSS option in router advertisements.

Default

include-dns

Platforms

7705 SAR Gen 2

13.77 include-group

include-group

Syntax

include-group *ip-admin-group-name* [**pref** *preference*]

no include-group *ip-admin-group-name*

Context

[Tree] (config>router>route-next-hop-policy>template include-group)

Full Context

configure router route-next-hop-policy template include-group

Description

This command configures the admin group constraint into the route next-hop policy template.

Each group is entered individually. The **include-group** statement instructs the LFA SPF selection algorithm to pick up a subset of LFA next-hops among the links which belong to one or more of the specified admin groups. A link which does not belong to at least one of the admin-groups is excluded. However, a link can still be selected if it belongs to one of the groups in a include-group statement but also belongs to other groups which are not part of any include-group statement in the route next-hop policy.

The **pref** option is used to provide a relative preference for the admin group to select. A lower preference value means that LFA SPF will first attempt to select a LFA backup next-hop which is a member of the corresponding admin group. If none is found, then the admin group with the next higher preference value is evaluated. If no preference is configured for a given admin group name, then it is supposed to be the least preferred, that is, numerically the highest preference value.

When evaluating multiple **include-group** statements within the same preference, any link which belongs to one or more of the included admin groups can be selected as an LFA next-hop. There is no relative preference based on how many of those included admin groups the link is a member of.

The **exclude-group** statement simply prunes all links belonging to the specified admin group before making the LFA backup next-hop selection for a prefix.

If the same group name is part of both include and exclude statements, the exclude statement will win. It other words, the exclude statement can be viewed as having an implicit preference value of 0.

The admin-group criteria are applied before running the LFA next-hop selection algorithm.

The **no** form deletes the admin group constraint from the route next-hop policy template.

Parameters

ip-admin-group-name

Specifies the name of the group, up to 32 characters.

preference

An integer specifying the relative preference of a group.

Values	1 to 255
Default	255

Platforms

7705 SAR Gen 2

13.80 incremental-spf-wait

incremental-spf-wait

Syntax

incremental-spf-wait *incremental-spf-wait*

no incremental-spf-wait

Context

[Tree] (config>router>ospf>timers incremental-spf-wait)

[Tree] (config>router>ospf3>timers incremental-spf-wait)

Full Context

configure router ospf timers incremental-spf-wait

configure router ospf3 timers incremental-spf-wait

Description

This command sets the delay before an incremental SPF calculation is performed when LSA types 3, 4, 5, or 7 are received. This allows multiple updates to be processed in the same SPF calculation. Type 1 or type 2 LSAs are considered a topology change and will always trigger a full SPF calculation.

The **no** form of this command resets the timer value back to the default value.

Note:
The timer granularity is 10 ms if the value is less than 500 ms, and 100 ms if the value is ≥ 500 ms. Timer values are rounded down to the nearest granularity, for example a configured value of 550 ms is internally rounded down to 500 ms.

Default

incremental-spf-wait 1000

Parameters

incremental-spf-wait

Specifies the OSPF incremental SPF calculation delay, in milliseconds.

Values 0 to 1000

Platforms

7705 SAR Gen 2

13.81 indirect

indirect

Syntax

[**no**] **indirect** *ip-address*

Context

[Tree] (config>service>vprn>static-route-entry indirect)

Full Context

configure service vprn static-route-entry indirect

Description

This command specifies that the route is indirect and specifies the next hop IP address used to reach the destination.

The configured *ip-addr*ess is not directly connected to a network configured on this node. The destination can be reached via multiple paths. The indirect address can only be resolved from dynamic routing protocol. Another static route cannot be used to resolve the indirect address.

The *ip-address* configured here can be either on the network side or the access side and is typically at least one hop away from this node.

Default

no indirect

Parameters

ip-address

The IP address of the IP interface.

Values

ipv4-address	a.b.c.d
ipv6-address	x:x:x:x:x:x:x:x-[interface]

Platforms

7705 SAR Gen 2

indirect

Syntax

[**no**] **indirect** *ip-address*

Context

[Tree] (config>router>static-route-entry indirect)

Full Context

configure router static-route-entry indirect

Description

This command specifies that the route is indirect and specifies the next hop IP address used to reach the destination.

The configured *ip-addr*ess is not directly connected to a network configured on this node. The destination can be reached via multiple paths. The indirect address can only be resolved from dynamic routing protocol. Another static route cannot be used to resolve the indirect address.

The *ip-address* configured here can be either on the network side or the access side and is typically at least one hop away from this node.

Default

no indirect

Parameters

ip-address

Specifies the IP address of the IP interface.

Values

ipv4-address	a.b.c.d
ipv6-address	x:x:x:x:x:x:x:x-[interface]

7705 SAR Gen 2

13.82 info

info

Syntax

info [**detail**] [**objective**]

info [**detail**] [**objective**] **operational**

Context

[Tree] (info)

Full Context

info

Description

This command displays the running configuration for the configuration context where it is entered and all branches below that context level. It can be used in any branch under configure, but not with **configure** itself.

By default, the command only enters the configuration parameters that vary from the default values.

The **detail** keyword causes all configuration parameters to be displayed. The **include-dynamic** objective keyword includes configuration parameters from dynamic sources such as dynamic data services Python scripts. These dynamic configuration parameters are not saved in the configuration file.

The **operational** keyword is available in edit-cfg mode only, in which case the keyword is mandatory when using the **info** command.

Example:

```
A:ALA-48>config>router>if-attr# info

13.85 ingress-rate

ingress-rate

Syntax

ingress-rate *sub-rate*

no ingress-rate

Context

[Tree] (config>port>ethernet ingress-rate)

Full Context

configure port ethernet ingress-rate

Description

This command configures the maximum amount of ingress bandwidth that this port can receive with the configured sub-rate using packet-based accounting.

The **no** form of this command returns the value to the default.

Default

no ingress-rate

Parameters

sub-rate

Specifies the ingress rate, in Mb/s.

Values 1 to 400000

Platforms

7705 SAR Gen 2

13.86 ingress-repl-inc-mcast-advertisement

ingress-repl-inc-mcast-advertisement

Syntax

[**no**] **ingress-repl-inc-mcast-advertisement**

Context

[Tree] (config>service>vpls>bgp-evpn ingress-repl-inc-mcast-advertisement)

Full Context

configure service vpls bgp-evpn ingress-repl-inc-mcast-advertisement

Description

This command enables and disables the advertisement of the Inclusive Multicast Ethernet Tag route (IMET route) with tunnel-type Ingress-Replication in the PMSI Tunnel Attribute, or with the tunnel-type Composite Point-to-Multipoint and Ingress-Replication (P2MP+IR) in the root-and-leaf nodes. The following must be considered:

- When **no ingress-repl-inc-mcast-advertisement** is configured, no IMET routes will be sent for the service unless the **provider-tunnel** is configured with **owner bgp-evpn-mpls** and **root-and-leaf**, in which case, an IMET-P2MP route is sent.
- When **ingress-repl-inc-mcast-advertisement** and **provider-tunnel** are configured for **bgp-evpn-mpls** with **root-and-leaf**, the system will send an IMET-P2MP-IR route, that is, an IMET route with a composite P2MP+IR tunnel type.
- When **no ingress-repl-inc-mcast-advertisement** and **assisted-replication replicator** are configured, the system will send IMET-AR routes, but IMET-IR routes will not be sent.

Default

ingress-repl-inc-mcast-advertisement

Platforms

7705 SAR Gen 2

13.87 ingress-replication-bum-label

ingress-replication-bum-label

Syntax

[**no**] **no-ingress-replication-bum-label**

Context

[Tree] (config>service>vpls>bgp-evpn>mpls ingress-replication-bum-label)

Full Context

configure service vpls bgp-evpn mpls ingress-replication-bum-label

Description

This command allows the user to configure the system so that a separate label is sent for BUM (Broadcast, Unknown unicast and Multicast) traffic in a specified service. By default (**no ingress-replication-bum-label**), the same label is used for unicast and flooded BUM packets when for-warding traffic to remote PEs.

When saving labels, this might cause transient traffic duplication for all-active multi-homing. By enabling **ingress-replication-bum-label**, the system will advertise two labels per EVPN VPLS instance, one for unicast and one for BUM traffic. The ingress PE will use the BUM label for flooded traffic to the advertising egress PE, so that the egress PE can determine if the unicast traffic has been flooded by the ingress PE. Depending on the scale required in the network, the user may choose between saving label space or avoiding transient packet duplication sent to an all-active multi-homed CE for certain macs.

Default

no ingress-replication-bum-label

Platforms

7705 SAR Gen 2

13.88 ingress-statistics

ingress-statistics

Syntax

[**no**] **ingress-statistics**

Context

[Tree] (config>router>mpls>fwd-policies>fwd-policy ingress-statistics)

Full Context

configure router mpls forwarding-policies forwarding-policy ingress-statistics

Description

This command configures ingress statistics in an MPLS forwarding policy.

The ingress statistics are associated with a binding label, that is the ILM of the forwarding policy, and provides aggregate packet and byte counters for packets matching the binding label.

The **no** form of this command removes the statistics from the MPLS forwarding policy.

Platforms

7705 SAR Gen 2

13.89 init

init

Syntax

init [**detail**]

no init

Context

[Tree] (debug>router>ldp>peer>packet init)

Full Context

debug router ldp peer packet init

Description

This command enables debugging for LDP Init packets.

The **no** form of the command disables the debugging output.

Parameters

detail

Displays detailed information.

13.91 init-extract-prio-mode

init-extract-prio-mode

Syntax

init-extract-prio-mode {**uniform** | **l3-classify**}

Context

[Tree] (config>card>fp init-extract-prio-mode)

Full Context

configure card fp init-extract-prio-mode

Description

This command determines the scheme used to select the initial drop priority of extracted control plane traffic. The initial drop priority of extracted packets can be either low or high priority. The drop priority of the extracted packets can be subsequently altered by mechanisms such as CPU protection. High-priority traffic receives preferential treatment in control plane congestion situations over low-priority traffic.

Default

init-extract-prio-mode uniform

Parameters

uniform

Initializes the drop priority of all extracted control traffic as high priority. Drop priority can then be altered (marked low priority) by distributed CPU protection (DCP) or centralized CPU protection rate-limiting functions in order to achieve protocol and interface isolation.

l3-classify

Initializes the drop priority of Layer 3 extracted control traffic (BGP and OSPF) based on the QoS classification of the packets. This is useful in networks where the DSCP and EXP markings can be trusted as the primary method to distinguish, protect, and isolate good terminating protocol traffic from unknown or potentially harmful protocol traffic instead of using the rate-based DCP and centralized CPU protection traffic marking/coloring mechanisms (for example, **out-profile-rate** and **exceed-action low-priority**).

For network interfaces, the QoS classification profile result selects the drop priority (in = high priority, out = low priority) for extracted control traffic, and the default QoS classification maps different DSCP and EXP values to different in/out profile states.

For access interfaces, the QoS classification priority result typically selects the drop priority for extracted control traffic. The default access QoS classification (**default-priority**) maps all traffic to **low**. If the queues in the access QoS policy are configured as **profile-mode** queues (rather than the default **priority-mode**) extracted traffic will use the QoS classification profile value configured against the associated FC (rather than the priority result) to select the drop priority.

Layer 2 extracted control traffic (ARP or ETH-CFM) and protocols that cannot always be QoS-classified, such as IS-IS, are initialized as low drop priority in order to protect Layer 2 protocol traffic on uniform interfaces (which would typically be subject to centralized CPU protection). Alternately, DCP can be used (by configuring a non-zero rate with **exceed-action** of **low-priority** for the **all-unspecified** protocol) to mark some of this traffic as high priority.

7705 SAR Gen 2

13.92 initial-registration

initial-registration

Syntax

initial-registration ca *ca-profile-name* **key-to-certify** *key-filename* **protection-alg** {**password** *password* **reference** *ref-number* | **signature** [**cert** *cert-file-name* [**send-chain** [**with-ca** *ca-profile-name*]]] [**protection-key** *key-file-name*] [**hash-alg** {**md5** | **sha1** | **sha224** | **sha256** | **sha384** | **sha512**}]} **subject-dn** *dn* [**domain-name** *domain-names*] [**ip-addr** *ip-address* | *ipv6-address*] **save-as** *save-path-of-result-cert*

Context

[Tree] (admin>certificate>cmpv2 initial-registration)

Full Context

admin certificate cmpv2 initial-registration

Description

This command request initial certificate from CA by using CMPv2 initial registration procedure.

The **ca** parameter specifies a CA-profile which includes CMP server information.

The **key-to-certify** is an imported key file to be certified by the CA.

The protection-key is an imported key file used to for message protection if protection-alg is signature.

The request is authenticated either of following methods:

- A password and a reference number that pre-distributed by CA via out-of-band means.
- The specified password and reference number are not necessarily in the cmp-keylist configured in the corresponding CA-Profile
- A signature signed by the protection-key or key-to-certify, optionally along with the corresponding certificate. If the protection-key is not specified, system will use the key-to-certify for message protection. The hash algorithm used for signature is depends on key type:
- DSA key: SHA1
- RSA key: MD5/SHA1/SHA224 | SHA256 | SHA384 | SHA512, by default is SHA1

Optionally, the system could also send a certificate or a chain of certificates in extraCerts field. Certificate is specified by the "cert” parameter, it must include the public key of the key used for message protection.

Sending a chain is enabled by specify the **send-chain** parameter.

subject-dn specifies the subject of the requesting certificate.

save-as specifies full path name of saving the result certificate.

In some cases, CA may not return certificate immediately, due to reason like request processing need manual intervention. In such cases, the **admin certificate cmpv2** poll command could be used to poll the status of the request. If key-list is not configured in the corresponding **ca-profile**, then the system will use the existing password to authenticate the CMPv2 packets from server if it is in password protection.

If key-list is configured in the corresponding **ca-profile** and server does not send SenderKID, then the system will use lexicographical first key in the key-list to authenticate the CMPv2 packets from server in case it is in password protection.

Parameters

ca-profile-name

Specifies a ca-profile name which includes CMP server information up to 32 characters.

key-filename

Specifies the file name of the key to certify up to 95 characters.

password

Specifies an ASCII string up to 64 characters.

ref-number

Specifies the reference number for this CA initial authentication key up to 64 characters.

cert-file-name

specifies the certificate file up to 95 characters.

ca-profile-name

Specifies to send the chain.

key-file-name

Specifies the protection key associated with the action on the CA profile.

hash-algorithm

Specifies the hash algorithm for RSA key.

Values md5,sha1,sha224,sha256,sha384,sha512

dn

Specifies the subject of the requesting certificate up to 256 characters.

Values attr1 equals val1

attr2 equals val2 where: attrN equals {C | ST | O | OU | CN}

save-path-of-result-cert

Specifies the save full path name of saving the result certificate up to 200 characters.

domain-name *domain-names*

Specifies FQDNs for SubjectAltName of the requesting certificate, separated by commas, up to 512 characters.

ip-address* | *ipv6-address

Specifies an IPv4 or IPv6 address for SubjectAtName of the requesting certificate.

Platforms

7705 SAR Gen 2

13.93 initial-send-delay-zero

initial-send-delay-zero

Syntax

[**no**] **initial-send-delay-zero**

Context

[Tree] (config>service>vprn>bgp>group initial-send-delay-zero)

[Tree] (config>service>vprn>bgp>group>neighbor initial-send-delay-zero)

[Tree] (config>service>vprn>bgp initial-send-delay-zero)

Full Context

configure service vprn bgp group initial-send-delay-zero

configure service vprn bgp group neighbor initial-send-delay-zero

configure service vprn bgp initial-send-delay-zero

Description

This command configures BGP to send UPDATE messages announcing reachability information to a peer or set of peers immediately after the sessions come up (become established) with these peers.

The default behavior, provided by the **no** form of this command, is to wait for min-route-advertisement time after each session is established before sending the first set of UPDATE messages.

Platforms

7705 SAR Gen 2

initial-send-delay-zero

Syntax

[**no**] **initial-send-delay-zero**

Context

[Tree] (config>router>bgp initial-send-delay-zero)

[Tree] (config>router>bgp>group initial-send-delay-zero)

[Tree] (config>router>bgp>group>neighbor initial-send-delay-zero)

Full Context

configure router bgp initial-send-delay-zero

configure router bgp group initial-send-delay-zero

configure router bgp group neighbor initial-send-delay-zero

Description

This command configures BGP to send UPDATE messages announcing reachability information to a peer or set of peers immediately after the sessions become established with these peers.

The **no** form of this command waits for **min-route-advertisement** time after each session is established before sending the first set of UPDATE messages.

Platforms

7705 SAR Gen 2

13.94 inner-tag

inner-tag

Syntax

inner-tag *value* [*vid-mask*]

no inner-tag

Context

[Tree] (config>qos>sap-ingress>mac-criteria>entry>match inner-tag)

Full Context

configure qos sap-ingress mac-criteria entry match inner-tag

Description

This command configures the matching of the second tag that is carried transparently through the service. The inner tag on ingress is the second tag on the frame if there are no service delimiting tags. The inner tag is the second tag before any service delimiting tags on egress but is dependent in the ingress configuration and may be set to 0 even in cases where additional tags are on the frame. This allows matching VLAN tags for explicit filtering or QoS setting when using default or null encapsulations.

The inner tag is not applicable in ingress on dot1Q SAPs. The inner tag may be populated on egress depending on the ingress SAP type.

On QinQ SAPs of null and default that do not strip tags, the inner-tag will contain the second tag (which is still the second tag carried transparently through the service.) On ingress SAPs that strip any tags, the inner tag will contain 0 even if there are more than two tags on the frame.

The optional vid_mask is defaulted to 4095 (exact match) but may be specified to allow pattern matching. The masking operation is ((value and vid-mask) = = (tag and vid-mask)). A value of 6 and a mask of 7 would match all VIDs with the lower 3 bits set to 6.

For QoS, the VID type cannot be specified on the default QoS policy.

The default vid-mask is set to 4095 for exact match.

Platforms

7705 SAR Gen 2

13.95 insert

insert

Syntax

insert [*line*]

Context

[Tree] (candidate insert)

Full Context

candidate insert

Description

This command inserts the contents of the temporary buffer (populated by a previous copy or delete command) into the candidate configuration. The contents are inserted by default after the current edit point. Optional parameters allow the insertion after some other point of the candidate. The contents of the temporary buffer are deleted when the operator exits candidate edit mode.

Insertions are context-aware. The temporary buffer always stores the CLI context (such as the current CLI branch) for each line deleted or copied. If the lines to be inserted are supported at the context of the insertion point then the lines are simply inserted into the configuration. If the lines to be inserted are not supported at the context of the insertion point, then the context at the insertion point is first closed using multiple exit statements, the context of the lines to be inserted is built (added) into the candidate at the insertion point, then the lines themselves are added, the context of the inserted lines is closed using exit statements and finally the context from the original insertion point is built again leaving the context at the same point as it was before the insertion.

Parameters

line

Indicates where to insert the line starting at the point indicated by the following options.

Values line, offset, **first**, **edit-point**, **last**

line	absolute line number
offset	relative line number to current edit point. Prefixed with '+' or '-'
first	keyword - first line
edit-point	keyword - current edit point
last	keyword - last line that is not 'exit'

13.97 install-backup-path

install-backup-path

Syntax
install-backup-path
no install-backup-path

Context
[Tree] (config>router>policy-options>policy-statement>default-action install-backup-path)
[Tree] (config>router>policy-options>policy-statement>entry>action install-backup-path)

Full Context
configure router policy-options policy-statement default-action install-backup-path

configure router policy-options policy-statement entry action install-backup-path

Description

When the best BGP route for an IPv4 or IPv6 prefix is matched by a policy entry or policy default action with this command, BGP attempts to find and install a preprogrammed backup path for the prefix in order to provide BGP fast reroute protection.

The **install-backup-path** command overrides and has no dependency on commands such as the BGP instance **backup-path** command or the VPRN-level **enable-bgp-vpn-backup** command, which enable BGP fast reroute for an entire address family. The **install-backup-path** command provides more precise control over which IP prefixes are supported with preprogrammed backup paths.

In VPRN, if the best path for an IP prefix is provided by a VPRN BGP route, the backup path can be provided by another VPRN BGP route or an imported VPN-IP route. If the best path for an IP prefix is provided by an imported VPN-IP route, the backup path can be provided by another VPN-IP route.

The **install-backup-path** command is supported only in BGP and VRF import policies and has no effect on other types. The **install-backup-path** command applies only to the following types of matched routes: IPv4, IPv6, label-IPv4, label-IPv6, VPN-IPv4, and VPN-IPv6.

The **no** form of this command disables the install-backup-path functionality.

Default

no install-backup-path

Platforms

7705 SAR Gen 2

13.98 instant-prune-echo

instant-prune-echo

Syntax

[**no**] **instant-prune-echo**

Context

[Tree] (config>service>vprn>pim>if instant-prune-echo)

Full Context

configure service vprn pim interface instant-prune-echo

Description

This command enables PIM to send an instant prune echo when the router starts the prune pending timer for a group on the interface. All downstream routers will see the prune message immediately, and can send a join override if they are interested in receiving the group. Configuring instant-prune-

echo is recommended on broadcast interfaces with more than one PIM neighbor to optimize multicast convergence.

The **no** form of this command disables instant Prune Echo on the PIM interface.

Default

no instant-prune-echo

Platforms

7705 SAR Gen 2

instant-prune-echo

Syntax

13.99 interactive-authentication

interactive-authentication

Syntax

[**no**] **interactive-authentication**

Context

[Tree] (config>system>security>radius interactive-authentication)

[Tree] (config>service>vprn>aaa>rmt-srv>radius interactive-authentication)

Full Context

configure system security radius interactive-authentication

configure service vprn aaa remote-servers radius interactive-authentication

Description

This command enables RADIUS interactive authentication for the system. Enabling interactive-authentication forces RADIUS to fall into challenge/response mode.

Default

no interactive-authentication

Platforms

7705 SAR Gen 2

interactive-authentication

Syntax

[**no**] **interactive-authentication**

Context

[Tree] (config>system>security>tacplus interactive-authentication)

[Tree] (config>service>vprn>aaa>rmt-srv>tacplus interactive-authentication)

Full Context

configure system security tacplus interactive-authentication

configure service vprn aaa remote-servers tacplus interactive-authentication

Description

This configuration instructs the SR OS to send no username nor password in the TACACS+ start message, and to display the *server_msg* in the GETUSER and GETPASS response from the TACACS+ server. Interactive authentication can be used to support a One Time Password scheme (such as an S/Key). An example flow (such as with a telnet connection) is as follows:

- The SR OS sends an authentication start request to the TACACS+ server with no username nor password.
- TACACS+ server replies with TAC_PLUS_AUTHEN_STATUS_GETUSER and a *server_msg*.
- The SR OS displays the *server_msg*, and collects the username.
- The SR OS sends a continue message with the username.
- TACACS+ server replies with TAC_PLUS_AUTHEN_STATUS_GETPASS and a *server_msg*.

- The SR OS displays the *server_msg* (which may contain, for example, an S/Key for One Time Password operation), and collects the password.
- The SR OS sends a continue message with the password.
- TACACS+ server replies with PASS or FAIL.

When interactive-authentication is disabled, the SR OS will send the username and password in the *tacplus* start message. An example flow (such as with a telnet connection) is as follows:

- TAC_PLUS_AUTHEN_TYPE_ASCII.
  - the login username in the "user" field.
  - the password in the *user_msg* field (while this is non-standard, it does not cause interoperability problems).
- TACACS+ server ignores the password and replies with TAC_PLUS_AUTHEN_STATUS_GETPASS.
- The SR OS sends a continue packet with the password in the *user_msg* field.
- TACACS+ server replies with PASS or FAIL.

When interactive-authentication is enabled, tacplus must be the first method specified in the authentication-order configuration.

Default

no interactive-authentication

no interface *ip-int-name*

Context

[Tree] (config>service>vprn interface)

[Tree] (config>service>ies interface)

Full Context

configure service vprn interface

configure service ies interface

Description

This command creates a logical IP routing interface. Once created, attributes like an IP address and service access point (SAP) can be associated with the IP interface.

The **interface** command, under the context of services, is used to create and maintain IP routing interfaces within service IDs. The **interface** command can be executed in the context of a service ID. The IP interface created is associated with the service core network routing instance and default routing table. The typical use for IP interfaces created in this manner is for subscriber Internet access. An IP address cannot be assigned to an IES interface. Multiple SAPs can be assigned to a single group interface.

Interface names are case sensitive and must be unique within the group of defined IP interfaces defined for **config>router>interface**, **config>service>ies>interface** and **config>service>vprn>interface** (that is, the network core router instance). Interface names must not be in the dotted decimal notation of an IP address. For example, the name "1.1.1.1" is not allowed, but "int-1.1.1.1" is allowed. Show commands for router interfaces use either interface names or the IP addresses. Use unique IP address values and IP address names to maintain clarity. It could be unclear to the user if the same IP address and IP address name values are used. Although not recommended, duplicate interface names can exist in different router instances.

When a new name is entered, a new logical router interface is created. When an existing interface name is entered, the user enters the router interface context for editing and configuration.

By default, there are no default IP interface names defined within the system. All IP interfaces must be explicitly defined. Interfaces are created in an enabled state.

The **no** form of this command removes IP the interface and all the associated configuration. The interface must be administratively shut down before issuing the **no interface** command.

The IP interface must be shut down before the SAP on that interface may be removed. IES and VPRN services do not have the **shutdown** command in the SAP CLI context. The service SAPs rely on the interface status to enable and disable them.

Parameters

ip-int-name

Specifies the name of the IP interface. Interface names must be unique within the group of defined IP interfaces for **config router interface** and config service vprn interface commands. An interface name cannot be in the form of an IP address. Interface names can be from 1 to 32 alphanumeric characters. If the string contains special characters (#, ?, space), the entire string must be enclosed between double quotes.

If *ip-int-name* already exists within the service ID, the context will be changed to maintain that IP interface. If *ip-int-name* already exists within another service ID or is an IP interface defined within the **config router** commands, an error will occur and context will not be changed to that IP interface. If *ip-int-name* does not exist, the interface is created and context is changed to that interface for further command processing.

tunnel

Specifies that the interface is configured as tunnel interface, which could be used to terminate IPsec or GRE runnels in the private service.

create

Creates the IPsec interface instance. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

Platforms

7705 SAR Gen 2

interface

Syntax

[**no**] **interface** *ip-int-name*

Context

[Tree] (config>router>igmp interface)

Full Context

configure router igmp interface

Description

Commands in this context configure an IGMP interface. The interface is a local identifier of the network interface on which reception of the specified multicast address is to be enabled or disabled.

The **no** form of the command deletes the IGMP interface. The **shutdown** command in the **config>router>igmp>interface** context can be used to disable an interface without removing the configuration for the interface.

Default

no interface

Parameters

ip-int-name

The IP interface name. Interface names must be unique within the group of defined IP interfaces for **config router interface** and **config service ies interface** commands. An interface name cannot be in the form of an IP address. Interface names can be any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

If the IP interface name does not exist or does not have an IP address configured an error message will be returned.

If the IP interface exists in a different area it will be moved to this area.

Platforms

7705 SAR Gen 2

interface

Syntax

[**no**] **interface** *ip-int-name*

Context

[Tree] (config>router>mld interface)

Full Context

configure router mld interface

Description

Commands in this context configure an Multicast Listener Discovery (MLD) interface. The interface is a local identifier of the network interface on which reception of the specified multicast address is to be enabled or disabled.

The **no** form of this command deletes the MLD interface. The **shutdown** command in the **config>router>mld>interface** context can be used to disable an interface without removing the configuration for the interface.

Default

no interface — No interfaces are defined.

Parameters

ip-int-name

Specifies the IP interface name. Interface names must be unique within the group of defined IP interfaces for **config>router>interface** and **config>service>ies>interface** commands. An interface name cannot be in the form of an IP address. Interface names can be any string up to 32 characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

If the IP interface name does not exist or does not have an IP address configured an error message will be returned.

If the IP interface exists in a different area it will be moved to this area.

Platforms

7705 SAR Gen 2

interface

Syntax

[**no**] **interface** *ip-int-name*

Context

[Tree] (config>service>vpls interface)

Full Context

configure service vpls interface

Description

This command creates a logical IP routing interface for a VPLS service. Once created, attributes such as IP address and service access points (SAP) can be associated with the IP interface.

The interface command, under the context of services, is used to create and maintain IP routing interfaces within the VPLS service IDs. The IP interface created is associated with the VPLS management routing instance. This instance does not support routing.

Interface names are case-sensitive and must be unique within the group of defined IP interfaces defined for the network core router instance. Interface names in the dotted decimal notation of an IP address are not allowed. For example, the name "1.1.1.1” is not allowed, but "int-1.1.1.1” is allowed. Show commands for router interfaces use either interface names or the IP addresses. Use unique IP address values and IP address names to maintain clarity. Duplicate interface names can exist in different router instances.

Enter a new name to create a logical router interface. When an existing interface name is entered, the user enters the router interface context for editing and configuration.

By default, no default IP interface names are defined within the system. All VPLS IP interfaces must be explicitly defined in an enabled state.

The no form of this command removes the IP interface and the entire associated configuration. The interface must be administratively shut down before issuing the no interface command.

For VPLS services, the IP interface must be shut down before the SAP on that interface is removed.

For VPLS service, ping and traceroute are the only applications supported.

Parameters

ip-int-name

Specifies the name of the IP interface. Interface names must be unique within the group of defined IP.

An interface name:

- Should not be in the form of an IP address.
- Can be from 1 to 32 alphanumeric characters.
- If the string contains special characters (such as #,$,spaces), the entire string must be enclosed within double quotes.

If ip-int-name already exists within the service ID, the context changes to maintain that IP interface. If ip-int-name already exists within another service ID, an error occurs and the context does not change to that IP interface. If ip-int-name does not exist, the interface is created and the context is changed to that interface for further command processing.

[Tree] (config>service>vprn>ospf>area interface)

[Tree] (config>service>vprn>ospf3>area interface)

Full Context

configure service vprn ospf area interface

configure service vprn ospf3 area interface

Description

This command creates a context to configure an OSPF interface.

By default interfaces are not activated in any interior gateway protocol, such as OSPF, unless explicitly configured.

The **no** form of this command deletes the OSPF interface configuration for this interface. The **shutdown** command in the **config>router>ospf>if** context can be used to disable an interface without removing the configuration for the interface.

Default

no interface

Parameters

ip-int-name

Specifies the IP interface name. Interface names must be unique within the group of defined IP interfaces for **config router interface** and **config service vprn interface** commands. An interface name cannot be in the form of an IP address. Interface names can be any string up to 32 characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed between double quotes.

If the IP interface name does not exist or does not have an IP address configured an error message will be returned.

If the IP interface exists in a different area it will be moved to this area.

secondary

Keyword used to allow multiple secondary adjacencies, in addition to the primary adjacency, to be established over a single IP interface. This keyword can also be applied to the system interface and to loopback interfaces to allow them to participate in multiple areas, although no adjacencies are formed over these types of interfaces.

7705 SAR Gen 2

interface

Syntax

[**no**] **interface** *ip-int-name*

Context

[Tree] (config>service>vprn>pim interface)

Full Context

configure service vprn pim interface

Description

This command enables PIM on an interface and enables the context to configure interface-specific parameters. By default interfaces are activated in PIM based on the **apply-to** command, and do not have to be configured on an individual basis unless the default values must be changed.

The **no** form of this command deletes the PIM interface configuration for this interface. If the **apply-to** command parameter is configured, then the **no interface** form must be saved in the configuration to avoid automatic (re)creation after the next **apply-to** is executed as part of a reboot.

The **shutdown** command can be used to disable an interface without removing the configuration for the interface.

Default

Interfaces are activated in PIM based on the apply-to command.

Parameters

ip-int-name

Specifies the interface name. If the string contains special characters (#, ?, space), the entire string must be enclosed between double quotes.

7705 SAR Gen 2

interface

Syntax

[**no**] **interface** *ip-int-name* [**dual-stack**]

Context

[Tree] (config>router>ldp>interface-parameters interface)

Full Context

configure router ldp interface-parameters interface

Description

This command enables LDP on the specified IP interface.

The **no** form of the command deletes the LDP interface and all configuration information associated with the LDP interface.

The LDP interface must be disabled using the **shutdown** command before it can be deleted.

The user can configure different parameters for IPv4 and IPv6 LDP interfaces by entering **ipv4** or **ipv6** as the next command.

Parameters

ip-int-name

Specifies the name of an existing interface. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

dual-stack

This optional keyword allows the user to explicitly indicate if this interface should create the IPv4 context automatically or not. With the introduction of LDP IPv6, the creation of the interface does not automatically mean it is to be used for IPv4 like with legacy IPv4 only LDP interface. Thus the dual-stack keyword is an indication to the system that user will manually enable the IPv4, IPv6, or the dual-stack IPv4/IPv6 contexts manually.

The following are some of the key points for this keyword:

- If the keyword is provided, then IPv4 interface context will not be created automatically. If it is not provided, the IPv4 interface context will be created like in the legacy single stack LDP IPv4 interface behavior.
- This new keyword will always show in a configuration.
- When entering an already configured interface, there is no need to provide the keyword, but it will be ignored if provided.
- When deleting a configured interface, the keyword will not be accepted in the **no** version of the **interface** command.

Full Context

configure router mpls srlg-database router-id interface

Description

This command allows the operator to manually enter the SRLG membership information for any link in the network, including links on this node, into the user SRLG database.

An interface can be associated with up to five SRLG groups for each execution of this command. The operator can associate an interface with up to 64 SRLG groups by executing the command multiple times.

CSPF will not use entered SRLG membership if an interface is not validated as part of a router ID in the routing table.

The **no** form of this command deletes a specific interface entry in this user SRLG database. The *group-name* must already exist in the config>router>if-attribute>srlg-group context.

Parameters

ip-address

Specifies the IPv4 address in a.b.c.d

srlg-group group-name

Specifies the SRLG group name. Up to 1024 group names can be defined in the config>router>if-attribute context. The SRLG group names must be identical across all routers in a single domain.

configure router pim interface

Description

This command creates a PIM interface.

Interface names are case-sensitive and must be unique within the group of defined IP interfaces defined for **config>router>interface**, **config>service>ies>interface**, and **config>service>ies>subscriber-interface>group-interface**. Interface names must not be in the dotted decimal notation of an IP address. For example, the name "1.1.1.1" is not allowed, but "int-1.1.1.1" is allowed. Show commands for router interfaces use either the interface names or the IP addresses. Ambiguity can exist if an IP address is used as an IP address and an interface name. Duplicate interface names can exist in different router instances, although this is not recommended because it may be confusing.

By default, no interfaces or names are defined within PIM.

The **no** form of this command removes the IP interface and all the associated configurations.

Parameters

ip-int-name

Specifies the name of the IP interface, up to 32 characters. Interface names must be unique within the group of defined IP interfaces for **config router interface**, **config service ies interface**, and **config service ies subscriber-interface group-interface** commands. An interface name cannot be in the form of an IP address. If the string contains special characters (#, $, spaces, and so on.), the entire string must be enclosed within double quotes.

If the *ip-int-name* already exists, the context is changed to maintain that IP interface. If *ip-int-name* does not exist, the interface is created and the context is changed to that interface for further command processing.

Context

[Tree] (config>router interface)

Full Context

configure router interface

Description

This command creates a logical IP routing or unnumbered MPLS-TP interface. Once created, attributes like IP address, port, or system can be associated with the IP interface.

Interface names are case-sensitive and must be unique within the group of IP interfaces defined for **config router interface** and **config service ies interface**. Interface names must not be in the dotted decimal notation of an IP address.; for example, the name "1.1.1.1" is not allowed, but "int-1.1.1.1" is allowed. Show commands for router interfaces use either the interface names or the IP addresses. Ambiguity can exist if an IP address is used as an IP address and an interface name. Duplicate interface names can exist in different router instances, although this is not recommended because it is confusing. Nokia recommends that names are meaningful and unique to remove ambiguity when displaying the state associated with IP interfaces through show commands.

When a new name is entered, a new logical router interface is created. When an existing interface name is entered, the user enters the router interface context for editing and configuration.

Although not a keyword, the ip-int-name "**system**" is associated with the network entity (such as a specific router), not a specific interface. The system interface is also referred to as the loopback address.

An unnumbered MPLS-TP interface is a special type of interface that is only intended for MPLS-TP LSPs. IP routing protocols are blocked on interfaces of this type. If an interface is configured as unnumbered-mpls-tp, then it can only be associated with an Ethernet port or VLAN, using the port command, then either a unicast, multicast, or broadcast remote MAC address may be configured. Only static ARP is supported.

The control-tunnel parameter creates a loopback interface representing a GRE tunnel. One IP tunnel can be created in this interface.

Only the primary IPv4 interface address and only one IP tunnel per interface are allowed. Multiple tunnels can be configured using up to four controlTunnel loopback interfaces. A static route can take the new controlTunnel interface as a next hop.

The **no** form of this command removes the IP interface and all the associated configurations. The interface must be administratively shut down before issuing the **no interface** command.

Parameters

interface-name

Specifies the name of the IP interface. Interface names must be unique within the group of defined IP interfaces for **config router interface** and **config service ies interface** commands. An interface name cannot be in the form of an IP address. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

Values 1 to 32 alphanumeric characters

If the *ip-int-name* already exists, the context is changed to maintain that IP interface. If *ip-int-name* already exists within another service ID or is an IP interface defined within the **config router** commands, an error will occur and the context will not be changed to that IP interface. If *ip-int-name* does not exist, the interface is created and the context is changed to that interface for further command processing.

unnumbered-mpls-tp

Specifies that an interface is an unnumbered MPLS-TP. An unnumbered MPLS-TP interface is a special type of interface that is only intended for MPLS-TP LSPs. IP routing protocols are blocked on interfaces of this type. If an interface is configured as **unnumbered-mpls-tp**, then it can only be associated with an Ethernet port or VLAN, using the **port** command. A unicast, multicast, or broadcast remote MAC address can be configured using the **static-arp** command. Only static ARP is supported.

pdn

Specifies that the interface is a PDN.

[Tree] (config>router>policy-options>policy-statement>entry>from interface)

Full Context

configure router policy-options policy-statement entry from interface

Description

This command specifies the router interface, specified either by name or address, as a filter criterion.

The **no** form of this command removes the criterion from the configuration.

Default

no interface

Parameters

ip-int-name

Specifies the name of the interface as a match criterion for this entry. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

Platforms

7705 SAR Gen 2

interface

Syntax

[**no**] **interface** *ip-int-name*

Context

[Tree] (config>router>bgp>group>dynamic-neighbor interface)

Full Context

configure router bgp group dynamic-neighbor interface

Description

Commands in this context configure an unnumbered base router network interface for dynamic neighbors.

If this interface connects to a network with other BGP routers, sessions with the other routers can be set up automatically without explicitly configuring them as BGP neighbors. The interface must be IPv6 enabled, but because the interface is considered unnumbered, it does not require an IPv4 address or a global-unicast IPv6 address. The sessions are set up using IPv6 link-local addresses.

The BGP unnumbered feature supports all address families that allow IPv6 link-local BGP next-hop addresses. This includes IPv4 with the use of RFC 8950 extensions.

When an interface is added to the list of dynamic-neighbor interfaces, an outgoing connection attempt is initiated toward any directly connected router on the interface that announces itself using an ICMPv6 router advertisement message. The session attempt is unsuccessful if the peer type is not EBGP, the reported AS number of the peer does not match one of the allowed values, or the maximum session limit of the interface would be exceeded.

The **no** form of this command removes the interface from the list of dynamic-neighbor interfaces.

Parameters

ip-int-name

Specifies the name of a base router IP interface, up to 32 characters.

Platforms

7705 SAR Gen 2

interface

Syntax

[**no**] **interface** *ip-int-name*

Context

[Tree] (config>service>vprn>bgp>group>dynamic-neighbor interface)

Full Context

configure service vprn bgp group dynamic-neighbor interface

Description

Commands in this context configure an unnumbered VPRN access IP interface for dynamic neighbors.

If this interface connects to a network with other BGP routers, sessions with the other routers can be set up automatically without explicitly configuring them as BGP neighbors. The interface must be IPv6 enabled, but because the interface is considered unnumbered, it does not require an IPv4 address or a global-unicast IPv6 address. The sessions are set up using IPv6 link-local addresses.

The BGP unnumbered feature supports all address families that allow IPv6 link-local BGP next-hop addresses. This includes IPv4 with the use of RFC 8950 extensions.

When an interface is added to the list of dynamic-neighbor interfaces, an outgoing connection attempt is initiated toward any directly connected router on the interface that announces itself using an ICMPv6 router advertisement message. The session attempt is unsuccessful if the peer type is not EBGP, the reported AS number of the peer does not match one of the allowed values, or the maximum session limit of the interface would be exceeded.

The **no** form of this command removes the interface from the list of dynamic-neighbor interfaces.

Parameters

ip-int-name

Specifies the name of a VPRN access IP interface, up to 32 characters.

Platforms

7705 SAR Gen 2

13.101 interface-ful

interface-ful

Syntax

interface-ful

Context

[Tree] (config>service>system>bgp-evpn>ip-prefix-routes interface-ful)

Full Context

configure service system bgp-evpn ip-prefix-routes interface-ful

Description

13.102 interface-id

interface-id

Syntax

interface-id [**ascii-tuple**]

interface-id ifindex

interface-id sap-id

interface-id string *string*

no interface-id

Context

[Tree] (config>service>vprn>if>ipv6>dhcp6>option interface-id)

[Tree] (config>service>ies>if>ipv6>dhcp6>option interface-id)

Full Context

configure service vprn interface ipv6 dhcp6-relay option interface-id

configure service ies interface ipv6 dhcp6-relay option interface-id

Description

This command enables the sending of interface ID options in the DHCPv6 relay packet.

The **no** form of this command disables the sending of interface ID options in the DHCPv6 relay packet.

Parameters

ascii-tuple

Specifies that the ASCII-encoded concatenated tuple is used which consists of the access-node-identifier, service-id, and interface-name, separated by "| ".

ifindex

Specifies that the interface index is used. The If Index of a router interface can be displayed using the **show>router>interface>detail** command.

sap-id

Specifies that the SAP identifier is used.

string

Specifies that a string is used.

string

Specifies a string of up to 80 characters long, composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

Platforms

7705 SAR Gen 2

interface-id

Syntax

interface-id [**ascii-tuple**]

interface-id [**vlan-ascii-tuple**]

no interface-id

Context

[Tree] (config>service>vpls>sap>dhcp6>ldra>options interface-id)

Full Context

configure service vpls sap dhcp6 ldra options interface-id

Description

This command enables the sending of interface ID options in the DHCPv6 LDRA.

The **no** form of this command disables the sending of interface ID options in the DHCPv6 LDRA.

Parameters

ascii-tuple

Specifies the use of the ASCII-encoded concatenated tuple, which consists of the *system name*, *service-id*, and *sap-id* separated by "| ".

vlan-ascii-tuple

Specifies the use of the ASCII-encoded concatenated tuple enhanced with VLAN ID and dot1p bits, consisting of the *system name*, *service-id*, *sap-id*, *dot1p-inner-vlan*, and *inner-vplan-id*, separated by "| ".

7705 SAR Gen 2

13.103 interface-id-mapping

interface-id-mapping

Syntax

[**no**] **interface-id-mapping**

Context

[Tree] (config>router>dhcp6>server interface-id-mapping)

[Tree] (config>service>vprn>dhcp6>server interface-id-mapping)

Full Context

configure router dhcp6 local-dhcp-server interface-id-mapping

configure service vprn dhcp6 local-dhcp-server interface-id-mapping

Description

This command enables the behavior where unique /64 prefix is allocated per interface-id, and all clients having the same interface-id get an address allocated out of this /64 prefix for DHCP6. This is relevant for bridged clients behind the same local-loop (and same SAP), where sharing the same prefix allows communication between bridged clients behind the same local-loop to stay local. For SLAAC based assignment, downstream neighbor-discovery is automatically enabled to resolve the assigned address.

The **no** form of this command reverts to the default.

Platforms

7705 SAR Gen 2

13.104 interface-parameters

interface-parameters

Syntax

interface-parameters

Context

[Tree] (config>router>ldp interface-parameters)

Full Context

configure router ldp interface-parameters

Description

Commands in this context configure LDP interfaces and parameters applied to LDP interfaces. The user can configure different default parameters for IPv4 and IPv6 LDP interfaces by entering **ipv4** or **ipv6** as the next command.

Platforms

7705 SAR Gen 2

13.105 interface-subnets

interface-subnets

Syntax

interface-subnets [**service** *service-id*] *interface-name*

no interface-subnets

Context

[Tree] (config>router>policy-options>policy-statement>entry>from interface-subnets)

Full Context

configure router policy-options policy-statement entry from interface-subnets

Description

This command configures the applied router instance and interfaces that are used as matching condition within each policy-statement entry. A maximum of 10 *interface-name* entries is supported, and all entries must belong to the same routing context (either **base** or **service**). The interface subnet policy-statement match criterion is applied to the following unicast use case contexts:

- **export**, when used with OSPFv2, OSPFv3, IS-IS, RIP, RIPng, and BGP
- **route-table-import**, when used with BGP
- **vrf-export**, when used with MP-BGP

The **no** form of this command removes all policies from the configuration.

Default

no interface-subnets

Parameters

service

Specifies the context in which the configured interface exists. By default, the base routing instance is assumed. However, the configured service context is used only when the service is configured.

service-id

Specifies the service ID of the service to match.

Values *service-id* — 1 to 2147483647

svc-name — 64 characters maximum

interface-name

Specifies the interface name, up to 32 characters, to match when exporting the IP address of the associated interface to a routing protocol.

13.106 interface-type

interface-type

Syntax

interface-type {**broadcast** | **point-to-point**}

no interface-type

Context

[Tree] (config>service>vprn>isis>if interface-type)

Full Context

configure service vprn isis interface interface-type

Description

This command configures the IS-IS interface type as either broadcast or point-to-point.

Use this command to set the interface type of an Ethernet link to point-to-point to avoid having to carry the designated IS-IS overhead if the link is used as a point-to-point.

If the interface type is not known at the time the interface is added to IS-IS and subsequently the IP interface is bound (or moved) to a different interface type, then this command must be entered manually.

The **no** form of this command reverts to the default value.

Default

point-to-point — For IP interfaces on SONET channels.

broadcast — For IP interfaces on Ethernet or unknown type physical interfaces.

Parameters

broadcast

Configures the interface to maintain this link as a broadcast network.

point-to-point

Configures the interface to maintain this link as a point-to-point link.

Platforms

7705 SAR Gen 2

interface-type

Syntax

interface-type {**broadcast** | **point-to-point** | **non-broadcast** | **p2mp-nbma**}

no interface-type

Context

[Tree] (config>service>vprn>ospf3>area>if interface-type)

[Tree] (config>service>vprn>ospf>area>if interface-type)

Full Context

configure service vprn ospf3 area interface interface-type

configure service vprn ospf area interface interface-type

Description

This command configures the interface type to:

- broadcast

- non-broadcast
- point-to-point
- point-to-multipoint on a link without broadcast or multicast support

Use this command to set the interface type of an Ethernet link to point-to-point to avoid having to carry the broadcast adjacency maintenance overhead if the Ethernet link provided the link is used as a point-to-point.

For subscriber interfaces, configure the adjacent interface (CPE) with interface type point-to-point. For subscriber interfaces, when the interface is configured as P2MP-NBMA, the subscriber interface becomes an active OPSF interface, allowing it to both send and receive OSPF LSAs. For all other interface types, subscriber interfaces remain as passive OSPF interfaces by default.

The **no** form of this command reverts to the default value.

Default

point-to-point — If the physical interface is SONET.

broadcast — If the physical interface is Ethernet or unknown.

Parameters

broadcast

Specifies the interface as a broadcast network. To significantly improve adjacency forming and network convergence, configure the network as point-to-point if only two routers are connected, even if the network is a broadcast media such as Ethernet.

point-to-point

Specifies the interface as a point-to-point link. Set the interface type of an Ethernet link to point-to-point to avoid having to carry the broadcast adjacency maintenance overhead if the Ethernet link provided is used as a point-to-point.

non-broadcast

Specifies the interface as a non-broadcast network.

p2mp-nbma

Specifies the interface as a point-to-multipoint on a link without broadcast or multicast support. No designated router or backup designated router is elected on this type of interface and all OSPF neighbors connect through individual point-to-point links. Only VPRN and IES services interfaces support this interface type.

Platforms

7705 SAR Gen 2

interface-type

Syntax

interface-type {**broadcast** | **point-to-point**}

no interface-type

Context

[Tree] (config>router>isis>interface interface-type)

Full Context

configure router isis interface interface-type

Description

This command configures the IS-IS interface type as either broadcast or point-to-point.

Use this command to set the interface type of an Ethernet link to point-to-point to avoid having to carry the designated IS-IS overhead if the link is used as a point-to-point.

If the interface type is not known at the time the interface is added to IS-IS and subsequently the IP interface is bound (or moved) to a different interface type, then this command must be entered manually.

The **no** form of this command reverts to the default value.

Default

interface-type point-to-point — For IP interfaces on SONET channels.

interface-type broadcast — For IP interfaces on Ethernet or unknown type physical interfaces.

Parameters

broadcast

Configures the interface to maintain this link as a broadcast network.

point-to-point

Configures the interface to maintain this link as a point-to-point link.

Platforms

7705 SAR Gen 2

interface-type

[Tree] (config>router>ospf3>area>interface interface-type)

Full Context

configure router ospf area interface interface-type

configure router ospf3 area interface interface-type

Description

This command configures the interface type to:

- broadcast
- non-broadcast
- point-to-point
- point-to-multipoint on a link without broadcast or multicast support

Use this command to set the interface type of an Ethernet link to point-to-point to avoid having to carry the broadcast adjacency maintenance overhead of the Ethernet link provided the link is used as point-to-point.

For subscriber interfaces, configure the adjacent interface (CPE) with interface type point-to-point. For subscriber interfaces, when the interface is configured as P2MP-NBMA, the subscriber interface becomes an active OPSF interface, allowing it to both send and receive OSPF LSAs. For all other interface types, subscriber interfaces remain as passive OSPF interfaces by default.

The **no** form of this command returns the setting to the default value.

Default

interface-type point-to-point (if the physical interface is SONET)

interface-type broadcast (if the physical interface is Ethernet or unknown)

Parameters

broadcast

Specifies the interface as a broadcast network. To significantly improve adjacency forming and network convergence, configure a network as point-to-point if only two routers are connected, even if the network is a broadcast media such as Ethernet.

point-to-point

Specifies the interface as a point-to-point link. Set the interface type of an Ethernet link to point-to-point to avoid having to carry the broadcast adjacency maintenance overhead if the Ethernet link provided is used as a point-to-point.

non-broadcast

Specifies the interface as a non-broadcast network.

p2mp-nbma

Specifies the interface as a point-to-multipoint on a link without broadcast or multicast support. No designated router or backup designated router is elected on this type of interface and all OSPF neighbors connect through individual point-to-point links. Only VPRN and IES services interfaces support this interface type.

Platforms

7705 SAR Gen 2

interface-type

Syntax

interface-type {**client-facing** | **network-facing**}

no interface-type

Context

[Tree] (config>service>vpls>sap>dhcp6>ldra interface-type)

Full Context

configure service vpls sap dhcp6 ldra interface-type

Description

This command configures LDRA interface type as either client or network facing.

The **no** form of this command reverts to the default value.

Default

no interface-type

Parameters

client-facing

Configures the SAP as an untrusted client-facing interface. Only DHCPv6 client messages are accepted and encapsulated in a Relay-Forward message. It is mandatory to configure an interface ID for client-facing SAPs. Relay-Forward, Relay-Reply, and DHCPv6 server messages are silently dropped when received on a client-facing SAP

network-facing

Configures the SAP as a network-facing interface. Only Relay-Reply messages are accepted: the server message is extracted from the Relay-Reply message and forwarded in the VPLS. All other DHCPv6 message types are silently dropped when received on a network-facing SAP.

[Tree] (config>oam-pm>session>meas-interval intervals-stored)

Full Context

configure oam-pm session meas-interval intervals-stored

Description

This command defines the number of completed measurement intervals per session to be stored in volatile system memory. The entire block of memory is allocated for the measurement interval when the test is active (**no shutdown**) to ensure memory is available. The numbers are increasing from 1 to the configured value + 1. The active pm data is stored in the interval number 1 and older runs are stored, in

order, to the upper most number with the oldest rolling off when the number of completed measurement intervals exceeds the configured value+1. As new test measurement intervals complete for the session, the stored intervals are renumbered to maintain the described order. Use caution when setting this value. There must be a balance between completed runs stored in volatile memory and the use of the write-to-flash function of the accounting policy.

The **5-mins** and **15-mins** measurement intervals share the same (1 to 96) retention pool. In the event that both intervals are required, the sum total of both intervals cannot exceed 96. The **1-hour** and **1-day** measurement intervals utilize their own ranges.

If this command is omitted when configuring the measurement interval, the default value is used.

The **no** form of the command reverts to the default.

Default

intervals-stored 1

Parameters

intervals

Specifies the number of measurement intervals.

Values **5-mins**: 1 to 96
15-mins: 1 to 96
1-hour: 1 to 24
1-day: 1

Default **5-mins**: 32
15-mins: 32
1-hour: 8
1-day: 1

ip

Syntax

[**no**] **ip** *ip-filter-id*

Context

[Tree] (config>filter>system-filter ip)

Full Context

configure filter system-filter ip

Description

This command activates an IPv4 system filter policy. Once activated, all IPv4 ACL filter policies that chain to the system filter (**config>filter>ip-filter>chain-to-system-filter**) will automatically execute system filter policy rules first.

The **no** form of the command deactivates the system filter policy.

Parameters

ip-filter-id

Specifies the existing IPv4 filter policy with scope **system**. This parameter can either be expressed as a decimal integer, or as an ASCII string of up to 64 characters.

Values 1 to 65535 or the filter policy name (*filter-name*, 64 char max)

13.117 ip-criteria

ip-criteria

Syntax

[**no**] **ip-criteria**

Context

[Tree] (config>qos>sap-ingress ip-criteria)

[Tree] (config>qos>sap-egress ip-criteria)

Full Context

configure qos sap-ingress ip-criteria

configure qos sap-egress ip-criteria

Description

IP criteria-based SAP ingress or egress policies are used to select the appropriate ingress or egress queue or policer and corresponding forwarding class and packet profile for matched traffic.

This command is used to enter the context to create or edit policy entries that specify IP criteria such as IP quintuple lookup or DiffServ code point.

The software implementation will exit on the first match found and execute the actions in accordance with the accompanying action command. For this reason, entries must be sequenced correctly from most to least explicit.

The **no** form of this command deletes all the entries specified under this node. When IP criteria entries are removed from a SAP ingress or egress policy, the IP criteria is removed from all services where that policy is applied.

Platforms

7705 SAR Gen 2

ip-criteria

Syntax

[**no**] **ip-criteria**

Context

[Tree] (config>qos>network>ingress ip-criteria)

[Tree] (config>qos>network>egress ip-criteria)

Full Context

configure qos network ingress ip-criteria

configure qos network egress ip-criteria

Description

IP criteria-based network ingress and egress policies are used to select the appropriate ingress or egress queue or policer, and the corresponding forwarding class and packet profile for matched traffic. This command is used to enter the context to create or edit policy entries that specify IP criteria such as IP quintuple lookup or DSCP.

The SR OS implementation will exit on the first match found and execute the actions in accordance with the accompanying action command. Entries must be sequenced correctly from most to least explicit.

The ingress classification only applies to the outer IP header of non-tunneled traffic. The only exception is for traffic received on a Draft Rosen tunnel, for which only classification on the outer IP header is supported.

Attempting to apply a network QoS policy containing an **ip-criteria** statement to any object except a network IP interface will result in an error.

The **no** form of this command deletes all entries specified under this node. When IP criteria entries are removed from a network policy, the IP criteria are removed from all network interfaces to which that policy is applied.

[Tree] (config>router>if>ipsec ip-exception)

Full Context

configure service ies interface ipsec ip-exception

configure service vprn interface ipsec ip-exception

configure router interface ipsec ip-exception

Description

This command configures the IP exception filter for the secured interface. All ingress traffic matching by the specified filter bypasses IPsec processing.

The **no** form of this command removes the policy from the configuration.

Default

no ip-exception

Parameters

filter-id

Specifies IP filter policy that will be used to bypass encryption.

Platforms

7705 SAR Gen 2

ip-exception

Syntax

ip-exception *filter-id* [**create**]

no ip-exception *filter-id*

Context

[Tree] (config>filter ip-exception)

Full Context

configure filter ip-exception

Description

Commands in this context configure the specified IPv4 exception filter.

The **no** form of the command deletes the IPv4 exception filter.

Parameters

filter-id

Specifies the IPv4 filter policy ID expressed as a decimal integer.

Values 1 to 65535

create

This keyword is required to create the configuration context. Once it is created, the context can be enabled with or without the **create** keyword.

Platforms

7705 SAR Gen 2

ip-exception

Syntax

ip-exception *filter-id* **direction** {**inbound** | **outbound**}

no ip-exception direction {**inbound** | **outbound**}

Context

[Tree] (config>router>if>group-encryption ip-exception)

Full Context

configure router interface group-encryption ip-exception

Description

This command associates an IP exception filter policy with an NGE-enabled router interface to allow packets matching the exception criteria to transit the NGE domain as clear text.

When an exception filter is added for inbound traffic, packets matching the criteria in the IP exception filter policy are allowed to be received in clear text even if an inbound key group is configured. If no inbound key group is configured, then associated inbound IP exception filter policies will be ignored.

When an exception filter is added for outbound traffic, packets matching the criteria in the IP exception filter policy are not encrypted when sent out of the router interface even if an outbound key group is configured. If no outbound key group is configured, then associated outbound IP exception filter policies will be ignored.

The **no** form of this command removes the IP exception filter policy from the specified direction.

Default

no ip-exception direction inbound

no ip-exception direction outbound

Parameters

filter-id

Specifies the IP exception filter policy. The IP exception ID or exception name must have already been created.

Values 1 to 6553, *filter-name* (64 characters maximum)

inbound

Binds the exception filter policy in the inbound direction.

outbound

Binds the exception filter policy in the outbound direction.

Platforms

7705 SAR Gen 2

13.119 ip-filter

ip-filter

Syntax

ip-filter *ip-filter-id* **entry** *entry-id* [*entry-id*]

no ip-filter *ip-filter-id* [**entry** *entry-id*]

Context

[Tree] (config>mirror>mirror-source ip-filter)

Full Context

configure mirror mirror-source ip-filter

Description

This command enables mirroring of packets that match specific entries in an existing IP filter.

The **ip-filter** command directs packets which match the defined list of entry IDs to be mirrored to the mirror destination referenced by the *mirror-dest-service-id* of the **mirror-source**.

The IP filter must already exist in order for the command to execute. Filters are configured in the **config>filter** context. If the IP filter does not exist, an error will occur. If the filter exists but has not been associated with a SAP or IP interface, an error is not generated but mirroring will not be enabled (there are no packets to mirror). Once the IP filter is defined to a SAP or IP interface, mirroring is enabled.

If the IP filter is defined as ingress, only ingress packets are mirrored. Ingress mirrored packets are mirrored to the mirror destination prior to any ingress packet modifications.

If the IP filter is defined as egress, only egress packets are mirrored. Egress mirrored packets are mirrored to the mirror destination after all egress packet modifications.

An *entry-id* within an IP filter can only be mirrored to a single mirror destination. If the same *entry-id* is defined multiple times, an error occurs and only the first **mirror-source** definition is in effect.

By default, no packets matching any IP filters are mirrored. Mirroring of IP filter entries must be explicitly defined.

The **no ip-filter** command, without the **entry** keyword, removes mirroring on all *entry-id*'s within the *ip-filter-id*.

When the **no** command is executed with the **entry** keyword and one or more *entry-id*'s, mirroring of that list of *entry-id*'s is terminated within the *ip-filter-id*. If an *entry-id* is listed that does not exist, an error will occur

and the command will not execute. If an *entry-id* is listed that is not currently being mirrored, no error will occur for that *entry-id* and the command will execute normally.

Parameters

ip-filter-id

Specifies the IP filter ID whose entries are mirrored. If the *ip-filter-id* does not exist, an error will occur and the command will not execute. Mirroring of packets will commence once the *ip-filter-id* is defined on a SAP or IP interface.

Values 1 to 65535

name, up to 64 characters

entry-id

Specifies the IP filter entries to use as match criteria for packet mirroring. The **entry** keyword begins a list of *entry-id*'s for mirroring. Multiple *entry-id* entries may be specified with a single command. Each *entry-id* must be separated by a space.

If an *entry-id* does not exist within the IP filter, an error occurs and the command will not execute.

If the filter's *entry-id* is renumbered within the IP filter definition, the old *entry-id* is removed but the new *entry-id* must be manually added to the configuration to include the new (renumbered) entry's criteria.

Values 1 to 2097151

Platforms

7705 SAR Gen 2

ip-filter

Syntax

ip-filter *ip-filter-id* **entry** *entry-id* [*entry-id*]

no ip-filter *ip-filter-id* [**entry** *entry-id*]

Context

[Tree] (debug>mirror-source ip-filter)

Full Context

debug mirror-source ip-filter

Description

This command enables mirroring of packets that match specific entries in an existing IP filter.

The **ip-filter** command directs packets which match the defined list of entry IDs to be mirrored to the mirror destination referenced by the *mirror-dest-service-id* of the **mirror-source**.

The IP filter must already exist in order for the command to execute. Filters are configured in the **config>filter** context. If the IP filter does not exist, an error will occur. If the filter exists but has not been associated with a SAP or IP interface, an error is not generated but mirroring will not be enabled (there are no packets to mirror). Once the IP filter is defined to a SAP or IP interface, mirroring is enabled.

If the IP filter is defined as ingress, only ingress packets are mirrored. Ingress mirrored packets are mirrored to the mirror destination prior to any ingress packet modifications.

If the IP filter is defined as egress, only egress packets are mirrored. Egress mirrored packets are mirrored to the mirror destination after all egress packet modifications.

An *entry-id* within an IP filter can only be mirrored to a single mirror destination. If the same *entry-id* is defined multiple times, an error occurs and only the first **mirror-source** definition is in effect.

By default, no packets matching any IP filters are mirrored. Mirroring of IP filter entries must be explicitly defined.

The **no ip-filter** command, without the **entry** keyword, removes mirroring on all *entry-id*'s within the *ip-filter-id*.

When the **no** command is executed with the **entry** keyword and one or more *entry-id*'s, mirroring of that list of *entry-id*'s is terminated within the *ip-filter-id*. If an *entry-id* is listed that does not exist, an error will occur and the command will not execute. If an *entry-id* is listed that is not currently being mirrored, no error will occur for that *entry-id* and the command will execute normally.

Parameters

ip-filter-id

The IP filter ID whose entries are mirrored. If the *ip-filter-id* does not exist, an error will occur and the command will not execute. Mirroring of packets will commence once the *ip-filter-id* is defined on a SAP or IP interface.

entry-id

The IP filter entries to use as match criteria for packet mirroring. The **entry** keyword begins a list of *entry-id*'s for mirroring. A maximum of eight *entry-id* entries may be specified with a single command. Each *entry-id* must be separated by a space.

If an *entry-id* does not exist within the IP filter, an error occurs and the command will not execute.

If the filter's *entry-id* is renumbered within the IP filter definition, the old *entry-id* is removed but the new *entry-id* must be manually added to the configuration to include the new (renumbered) entry's criteria.

Platforms

7705 SAR Gen 2

ip-filter

Syntax

ip-filter *filter-id* [**name**] [**create**]

no ip-filter {*filter-id* | *filter-name*}

Context

[Tree] (config>filter ip-filter)

Full Context

configure filter ip-filter

Description

Commands in this context configure the specified IPv4 filter policy.

The **no** form of the command deletes the IPv4 filter policy. A filter policy cannot be deleted until it is removed from all objects where it is applied.

Parameters

filter-id

Specifies the IPv4 filter policy ID expressed as a decimal integer.

Values 1 to 65535

name

Configures an optional filter name, up to 64 characters in length, to a given filter. This filter name can then be used in configuration references, display, and show commands throughout the system. A defined filter name can help the service provider or administrator to identify and manage filters within the SR OS platforms.

To create a filter, you must assign a filter ID, however, after it is created, either the filter ID or filter name can be used to identify and reference a filter.

If a name is not specified at creation time, then SR OS assigns a string version of the *filter-id* as the name.

Filter names may not begin with an integer (0 to 9).

filter-name

Specifies a string, up to 64 characters, uniquely identifying this IPv4 filter policy.

create

This keyword is required to create the configuration context. Once it is created, the context can be enabled with or without the **create** keyword.

ip-filter

Syntax

ip-filter *src-filter-id* [**src-entry** *src-entry-id*] **to** *dst-filter-id* [**dst-entry** *dst-entry-id*] [**overwrite**]

Context

[Tree] (config>filter>copy ip-filter)

Full Context

configure filter copy ip-filter

Description

This command copies an existing filter entry for a specific filter ID to another filter ID. The command is a configuration level maintenance tool used to create new entries using an existing filter policy. If **overwrite** is not specified, an error will occur if the destination filter entry exists.

Parameters

src-filter-id

Identifies the source filter policy from which the copy command will attempt to copy. The filter policy must exist within the context of the preceding keyword (**ip-filter**).

dst-filter-id

Identifies the destination filter policy to which the copy command will attempt to copy. If the **overwrite** keyword is not specified, the filter entry ID cannot already exist in the destination filter policy. If the **overwrite** keyword is present, the destination entry ID may or may not exist.

overwrite

Specifies that the destination filter entry may exist. If it does, everything in the existing destination filter entry will be completely overwritten with the contents of the source filter entry. If the destination filter entry exists, either **overwrite** must be specified or an error message will be returned. If **overwrite** is specified, the function of copying from source to destination occurs in a "break before make" manner and therefore should be handled with care.

13.122 ip-mirror-interface

ip-mirror-interface

Syntax

ip-mirror-interface *ip-int-name* [**create**]

no ip-mirror-interface *ip-int-name*

Context

[Tree] (config>service>vprn ip-mirror-interface)

Full Context

configure service vprn ip-mirror-interface

Description

This command is used for remote mirroring, where the mirror source is a separate system then the mirror destination. The mirror source can only be of IP type and is only supported for the following services: IES, VPRN, VPLS and Ipipe. The mirror destination on a remote system will configure an interface on a VPRN as **ip-mirror-interface**. This interface only supports spoke sdp termination. The IP mirror interface requires PBR to determine the next outgoing interface for the mirror packet to be delivered to.

The **no** form of this command removes the interface name from the configuration.

Parameters

ip-int-name

Specifies the name of the IP interface, up to 32 characters. An interface name cannot be in the form of an IP address.

create

Keyword used to create an IP mirror interface.

Platforms

7705 SAR Gen 2

13.123 ip-mtu

ip-mtu

Syntax

ip-mtu *octets*

no ip-mtu

Context

[Tree] (config>service>vprn>if ip-mtu)

Full Context

configure service vprn interface ip-mtu

Description

This command specifies the maximum size of IP packets on this group interface. Packets larger than this are fragmented.

The **ip-mtu** applies to all IPoE host types (DHCP, ARP, or static). For PPP/L2TP sessions, the **ip-mtu** is not considered for the MTU negotiation. The **ppp-mtu** in the PPP policy should be used instead.

The **no** form of this command reverts to the default.

Default

no ip-mtu

Parameters

octets

Specifies the largest frame size (in octets) that this interface can handle.

Values 512 to 9000

Platforms

7705 SAR Gen 2

ip-mtu

Syntax

ip-mtu *octets*

no ip-mtu

Context

[Tree] (config>service>ies>if ip-mtu)

[Tree] (config>service>ies>if>sap>ip-tunnel ip-mtu)

Full Context

configure service ies interface ip-mtu

configure service ies interface sap ip-tunnel ip-mtu

Description

This command configures the IP maximum transmit unit (packet) for this interface.

Because this connects a Layer 2 to a Layer 3 service, this parameter can be adjusted under the IES interface.

The MTU that is advertised from the IES size is:

MINIMUM((SdpOperPathMtu - EtherHeaderSize), (Configured ip-mtu))

By default (for Ethernet network interface) if no ip-mtu is configured it is (1568 - 14) = 1554.

The **no** form of this command returns the default value.

Default

no ip-mtu

Parameters

octets

Specifies the maximum number of octets that can be transmitted.

Values 512 to 9786 (for IES interface)
512 to 9000 (for ip-tunnel interface)

Platforms

7705 SAR Gen 2

ip-mtu

configure service ies interface ipsec ipsec-tunnel ip-mtu

configure router interface ipsec ipsec-tunnel ip-mtu

configure service vprn interface sap ipsec-tunnel ip-mtu

configure service vprn interface ipsec ipsec-tunnel ip-mtu

configure service vprn interface sap ip-tunnel ip-mtu

Description

This command configures the IP maximum transmit unit (packet) for this interface.

Because this connects a Layer 2 to a Layer 3 service, this parameter can be adjusted under the IES interface.

The MTU that is advertised from the IES size is:

MINIMUM((SdpOperPathMtu - EtherHeaderSize), (Configured ip-mtu))

By default (for the Ethernet network interface), if no ip-mtu is configured it is (1568 - 14) equals 1554.

The **ip-mtu** command instructs the MS-ISA to perform IP packet fragmentation, prior to IPsec encryption and encapsulation, based on the configured MTU value. In particular:

If the length of a payload IP packet (including its header) exceeds the configured MTU value and the DF flag is clear (due to the presence of the clear-df-bit command or because the original DF value was 0) then the MS-ISA fragments the payload packet as efficiently as possible (i.e. it creates the minimum number of fragments each less than or equal to the configured MTU size); in each created fragment the DF bit shall be 0.

If the length of a payload IP packet (including its header) exceeds the configured MTU value and the DF flag is set (because the original DF value was 1 and the tunnel has no clear-df-bit in its configuration) then the MS-ISA discards the payload packet without sending an ICMP type 3/code 4 message back to the packet's source address.

The effective MTU for packets entering a tunnel is the minimum of the private tunnel SAP interface IP MTU value (used by the IOM) and the tunnel IP MTU value (configured using the above command and used

by the MS-ISA). To fragment IP packets larger than X bytes with DF set, rather than discarding them, the tunnel IP MTU should be set to X and the private tunnel SAP interface IP MTU should be set to a value larger than X.

The **no ip-mtu** command, corresponding to the default behavior, disables fragmentation of IP packets by the MS-ISA; all IP packets, regardless of size or DF bit setting, are allowed into the tunnel.

Default

no ip-mtu

Parameters

bytes

Specifies the IP maximum transmit unit (packet) for this interface.

Values 512 to 9000

Platforms

7705 SAR Gen 2

ip-mtu

Syntax

ip-mtu *octets*

no ip-mtu

Context

[Tree] (config>service>vprn>nw-if ip-mtu)

Full Context

configure service vprn network-interface ip-mtu

Description

This command configures the IP maximum transmit unit (packet) for the associated router IP interface.

The configured IP-MTU cannot be larger than the calculated IP MTU based on the port MTU configuration.

The MTU that is advertised from the IES size is:

MINIMUM((SdpOperPathMtu - EtherHeaderSize), (Configured ip-mtu))

The **no** form of this command returns the associated IP interfaces MTU to its default value, which is calculated based on the port MTU setting. For Ethernet ports this will typically be 1554.

Default

no ip-mtu

Parameters

octets

Specifies the octets.

Values 512 to 9786

Platforms

7705 SAR Gen 2

Description

This command configures the template IP MTU.

Default

no ip-mtu

Parameters

octets

Specifies the maximum size in octets.

Values 512 to 9000

Platforms

7705 SAR Gen 2

ip-mtu

Syntax

ip-mtu *octets*

no ip-mtu

Context

[Tree] (config>router>if ip-mtu)

Full Context

configure router interface ip-mtu

Description

This command configures the IP maximum transmit unit (packet) for the associated router IP interface.

The operational IP MTU that is used for the interface is determined based on both the configured IP MTU and the port MTU of the port bound to this interface.

The MTU that is used is:

MINIMUM((Port_MTU - EthernetHeaderSize), (configured ip-mtu))

The **no** form of this command returns the associated IP interfaces MTU to its default value, which is calculated based on the port MTU setting. (For Ethernet ports the default IP MTU is 1500 octets.)

Default

no ip-mtu

Parameters

octets

Specifies the IP MTU value associated with the IP interface, specified in octets. If the interface supports IPv6 packets, the IP-MTU must be set to a value greater than or equal to (≥) 1280 in accordance with RFC 2460 *Internet Protocol, Version 6 (IPv6) Specification*.

Values 512 to 9786

Platforms

7705 SAR Gen 2

ip-mtu

Syntax

ip-mtu *octets*

no ip-mtu

Context

[Tree] (bof ip-mtu)

Full Context

bof ip-mtu

Description

This command configures the IP maximum transmit unit (packet) for the management router instance.

The operational IP MTU that is used for the interface is determined based on both the configured IP MTU and the port MTU of the port bound to this interface.

The MTU that is used is:

MINIMUM((Port_MTU - EthernetHeaderSize), (configured ip-mtu))

For the management port, the port MTU is fixed at 1514 and the EthernetHeaderSize is 14 so the first element of the equation above is 1500 octets.

The **no** form of this command returns the associated IP interfaces MTU to its default value, which is calculated based on the port MTU setting. (For the management port the default IP MTU is 1500 octets.)

Default

ip-mtu 1500

Parameters

octets

Specifies the IP MTU value associated with the IP interface, specified in octets. If the interface supports IPv6 packets, the IP-MTU must be set to a value greater than or equal to (≥) 1280 in accordance with RFC 2460 *Internet Protocol, Version 6 (IPv6) Specification*.

Values 512 to 9786

Platforms

7705 SAR Gen 2

13.124 ip-prefix-list

ip-prefix-list

Syntax

ip-prefix-list *ip-prefix-list-name* [**create**]

no ip-prefix-list *ip-prefix-list-name*

Context

[Tree] (config>qos>match-list ip-prefix-list)

Full Context

configure qos match-list ip-prefix-list

Description

This command creates a list of IPv4 prefixes for match criteria in QoS policies.

An IP prefix list must contain only IPv4 address prefixes created using the prefix command and cannot be deleted if it is referenced by a QoS policy.

The **no** form of this command deletes the specified list.

Parameters

ip-prefix-list-name

A string of up to 32 characters of printable ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes. The name **default** (case insensitive) is reserved by the system.

Platforms

7705 SAR Gen 2

ip-prefix-list

Syntax

ip-prefix-list *ip-prefix-list-name* [**create**]

no ip-prefix-list *ip-prefix-list-name*

Context

[Tree] (config>filter>match-list ip-prefix-list)

Full Context

configure filter match-list ip-prefix-list

Description

This command creates a list of IPv4 prefixes for match criteria in IPv4 ACL and CPM filter policies.

The **no** form of this command deletes the specified list.

Operational Notes:

An **ip-prefix-list** must contain only IPv4 address prefixes.

An IPv4 prefix match list cannot be deleted if it is referenced by a filter policy.

See general description related to match-list usage in filter policies.

Parameters

ip-prefix-list-name

Specifies a string of up to 32 printable ASCII characters. If special characters are used, the string must be enclosed within double quotes.

Platforms

7705 SAR Gen 2

13.125 ip-prefix-routes

ip-prefix-routes

Syntax

ip-prefix-routes

Context

[Tree] (config>service>system>bgp-evpn ip-prefix-routes)

Full Context

configure service system bgp-evpn ip-prefix-routes

Description

Commands in this context configure attribute uniform propagation and BGP path selection.

Platforms

7705 SAR Gen 2

13.126 ip-route-advertisement

ip-route-advertisement

Syntax

ip-route-advertisement [**incl-host**] [**domain-id** *global-field*:*local-field*]

no ip-route-advertisement

Context

[Tree] (config>service>vpls>bgp-evpn ip-route-advertisement)

Full Context

configure service vpls bgp-evpn ip-route-advertisement

Description

This command enables and disables the advertisement of IP prefixes in EVPN. If enabled, any active route in the R-VPLS VPRN route table are advertised in EVPN using the VPLS BGP configuration. The interface host addresses are not advertised in EVPN unless the **ip-route-advertisement incl-host** command is enabled.

The **no** form of this command disables IP prefixes advertisement in EVPN.

Default

no ip-route-advertisement

Parameters

incl-host

Specifies to advertise the interface host addresses in EVPN.

global-field:local-field

Specifies the domain ID.

Values *4byte-GlobalAdminValue:2byte-LocalAdminValue*

4byte-GlobalAdminValue:	0 to 4294967295
2byte-LocalAdminValue	0 to 65535

Platforms

7705 SAR Gen 2

Full Context

configure service vpls bgp-evpn ip-route-link-bandwidth

Description

Commands in this context configure the IP route link bandwidth.

Platforms

7705 SAR Gen 2

13.128 ip-tunnel

ip-tunnel

Syntax

ip-tunnel *name* [**create**]

no ip-tunnel *name*

Context

[Tree] (config>service>vprn>if>sap ip-tunnel)

[Tree] (config>service>ies>if>sap ip-tunnel)

Full Context

configure service vprn interface sap ip-tunnel

configure service ies interface sap ip-tunnel

Description

This command is used to configure an IP-GRE or IP-IP tunnel and associate it with a private tunnel SAP within an IES or VPRN service.

The **no** form of this command deletes the specified IP/GRE or IP-IP tunnel from the configuration. The tunnel must be administratively shutdown before issuing the **no ip-tunnel** command.

Default

no-ip tunnel *name*

Parameters

name

Specifies the name of the IP tunnel. Tunnel names can be from 1 to 32 alphanumeric characters. If the string contains special characters (for example, #, $, spaces), the entire string must be enclosed within double quotes.

Platforms

7705 SAR Gen 2

[Tree] (config>service>vprn ipsec)

Full Context

configure router interface ipsec

configure service ies interface ipsec

configure service vprn ipsec

Description

Commands in this context configure IPsec policies.

Parameters

ipsec-group-id

Specifies the IPsec group ID used for the IPsec tunnels configured under this context.

Values 1 to 16

public-sap

Specifies the public SAP ID used for the IPsec tunnels configured under this context.

Values 0 to 4096

Platforms

7705 SAR Gen 2

13.131 ipsec-domain

ipsec-domain

Syntax

ipsec-domain *ipsec-domain-id* [**create**]

no ipsec-domain *ipsec-domain-id*

Context

[Tree] (config>redundancy>multi-chassis ipsec-domain)

Full Context

configure redundancy multi-chassis ipsec-domain

Description

Commands in this context configure parameters for the multi-chassis IPsec domain configured on this system.

The **no** form of this command removes the ID from the configuration.

Parameters

ipsec-domain-id

Specifies IPsec domain ID.

Values 1 to 255

create

Keyword used to create the command instance.

Platforms

7705 SAR Gen 2

13.132 ipsec-gw

ipsec-gw

Syntax

ipsec-gw *name*

no ipsec-gw

Context

[Tree] (config>service>vprn>if>sap ipsec-gw)

[Tree] (config>service>ies>if>sap ipsec-gw)

Full Context

configure service vprn interface sap ipsec-gw

configure service ies interface sap ipsec-gw

Description

This command configures an IPsec gateway.

Platforms

7705 SAR Gen 2

13.133 ipsec-lifetime

ipsec-lifetime

Syntax

ipsec-lifetime *ipsec-lifetime*

no ipsec-lifetime

Context

[Tree] (config>ipsec>ike-policy ipsec-lifetime)

Full Context

configure ipsec ike-policy ipsec-lifetime

Description

This command specifies the lifetime of the Phase 2 IKE key.

The **no** form of this command reverts to the default, which is 3600 seconds.

Default

no ipsec-lifetime

Parameters

ipsec-lifetime

Specifies the Phase 2 lifetime for this IKE policy in seconds.

Values 1200 to 31536000

Platforms

7705 SAR Gen 2

ipsec-lifetime

Syntax

ipsec-lifetime *seconds*

ipsec-lifetime inherit

Context

[Tree] (config>ipsec>ipsec-transform ipsec-lifetime)

Full Context

configure ipsec ipsec-transform ipsec-lifetime

Description

This command specifies the CHILD_SA. If the **inherit** parameter is specified, then the system uses the IPsec lifetime configuration in the corresponding IKE policy configured in the same IPsec gateway or IPsec tunnel.

Default

ipsec-lifetime inherit

Parameters

seconds

Specifies the lifetime of the Phase 2 IKE key in seconds.

Values 1200 to 31536000

inherit

Specifies that the system uses the **ipsec-lifetime** configuration in the corresponding IKE policy that is configured for the same IPsec gateway or IPsec tunnel.

Platforms

7705 SAR Gen 2

13.134 ipsec-responder-only

ipsec-responder-only

Syntax

[**no**] **ipsec-responder-only**

Context

[Tree] (config>isa>tunnel-group ipsec-responder-only)

Full Context

configure isa tunnel-group ipsec-responder-only

Description

With this command configured, system will only act as IKE responder except for the automatic CHILD_SA re-key upon MC-IPsec switchover.

Default

no ipsec-responder-only

Platforms

7705 SAR Gen 2

13.135 ipsec-transform

ipsec-transform

Syntax

ipsec-transform *transform-id* [**create**]

no ipsec-transform *transform-id*

Context

[Tree] (config>ipsec ipsec-transform)

Full Context

configure ipsec ipsec-transform

Description

Commands in this context create an **ipsec-transform** policy. IPsec transforms policies can be shared. A change to the ipsec-transform is allowed at any time. The change will not impact tunnels that have been established until they are renegotiated. If the change is required immediately the tunnel must be cleared (reset) for force renegotiation.

IPsec transform policy assignments to a tunnel require the tunnel to be shutdown.

The **no** form of this command removes the ID from the configuration.

Parameters

transform-id

Specifies a policy ID value to identify the IPsec transform policy.

Values 1 to 2048

create

This keyword is mandatory when creating an ipsec-transform policy. The **create** keyword requirement can be enabled or disabled in the **environment>create** context.

Platforms

7705 SAR Gen 2

13.136 ipsec-transport-mode-profile

ipsec-transport-mode-profile

Syntax

ipsec-transport-mode-profile *name* [**create**]

no ipsec-transport-mode-profile *name*

Context

[Tree] (config>ipsec ipsec-transport-mode-profile)

Full Context

configure ipsec ipsec-transport-mode-profile

Description

Commands in this context configure an IPsec transport mode profile.

The **no** form of this command removes the name from the configuration.

Parameters

name

Specifies the name of the IPsec transport mode profile, up to 32 characters.

create

Keyword used to create the IPsec transport mode profile instance.

Platforms

7705 SAR Gen 2

ipsec-transport-mode-profile

Syntax

ipsec-transport-mode-profile *name*

no ipsec-transport-mode-profile

Context

[Tree] (config>service>ies>if>sap>ip-tunnel ipsec-transport-mode-profile)

[Tree] (config>service>vprn>if>sap>ip-tunnel ipsec-transport-mode-profile)

Full Context

configure service ies interface sap ip-tunnel ipsec-transport-mode-profile

configure service vprn interface sap ip-tunnel ipsec-transport-mode-profile

Description

This command specifies an IPsec transport mode profile name to the SAP.

The **no** form of this command removes the profile name from the service configuration.

Parameters

name

Specifies the name of an existing IPsec transport mode profile, up to 32 characters

Platforms

7705 SAR Gen 2

13.137 ipsec-tunnel

ipsec-tunnel

Syntax

ipsec-tunnel *ipsec-tunnel-name*

no ipsec-tunnel [*ipsec-tunnel-name*]

Context

[Tree] (config>service>vprn>static-route-entry ipsec-tunnel)

Full Context

configure service vprn static-route-entry ipsec-tunnel

Description

This command creates a static route in a VPRN service context that points to the global routing context (base router). This is primarily used to allow traffic that ingress through a VPRN service to be routed out of the global routing context.

This **next-hop** type cannot be used in conjunction with any other next-hop types.

Default

no ipsec-tunnel

Parameters

ipsec-tunnel-name

IPsec tunnel name; maximum length up to 32 characters.

Platforms

7705 SAR Gen 2

ipsec-tunnel

Syntax

ipsec-tunnel *name* [**private-sap** [*0..4094*]] [**private-service-name** *private-service-name*] [**create**]

no ipsec-tunnel *ipsec-tunnel-name*

Context

[Tree] (config>service>vprn>if>sap ipsec-tunnel)

[Tree] (config>router>if>ipsec ipsec-tunnel)

[Tree] (config>service>ies>if>ipsec ipsec-tunnel)

Full Context

configure service vprn interface sap ipsec-tunnel

configure router interface ipsec ipsec-tunnel

configure service ies interface ipsec ipsec-tunnel

Description

This command configures a secured interface IPsec tunnel. If the **private-service-name** is not specified, the private service is the secured interface service.

The **no** form of this command removes the IPsec tunnel from the configuration.

Parameters

name

Specifies the name of the IPsec tunnel.

private-sap

Specifies the private SAP ID.

Values 0 to 4094

private-service-name

Specifies the private service name.

create

Keyword used to create the IPsec tunnel instance. The **create** keyword requirement can be enabled or disabled in the **environment>create** context.

Platforms

7705 SAR Gen 2

13.138 ipv4

ipv4

Syntax

ipv4 *max-paths* [**ebgp** *ebgp-max-paths*] [**ibgp** *ibgp-max-paths*] [**restrict** { **same-neighbor-as** | **exact-as-path**}] [**unequal-cost**]

no ipv4

Context

[Tree] (config>service>vprn>bgp>multi-path ipv4)

Full Context

configure service vprn bgp multi-path ipv4

Description

This command sets ECMP multipath parameters that apply only to the (unlabeled) IPv4 unicast address family. These settings override the values set by the **maximum-paths** command.

When multipath is enabled, traffic to the destination is load-shared across a set of paths (BGP routes) that the BGP decision process considers equal to the best path. The actual distribution of traffic over the multiple paths may be equal or unequal (that is, based on weights derived from the Link Bandwidth Extended Community).

To qualify as a multipath, a non-best route must meet the following criteria (some criteria are controlled by this command):

- The multi-path route must be the same type of route as the best path (same AFI/SAFI and, in some cases, same next-hop resolution method).
- The multi-path route must be tied with the best path for all criteria of greater significance than next-hop cost, except for criteria that are configured to be ignored.
- If the best path selection reaches the next-hop cost comparison, the multi-path route must have the same next-hop cost as the best route unless the **unequal-cost** option is configured.
- The multi-path route must not have the same BGP next-hop as the best path or any other multi-path route.
- The multi-path route must not cause the ECMP limit of the routing instance to be exceeded (configured using the **ecmp** command with a value in the range 1 to 64).
- The multi-path route must not cause the applicable *max-paths* limit to be exceeded. If the best path is an EBGP learned route and the **ebgp** option is used, the *ebgp-max-paths* limit overrides the *max-paths* limit. If the best path is an IBGP-learned route and the **ibgp** option is used, the *ibgp-max-paths* limit overrides the *max-paths* limit. All path limits are configurable up to a maximum of 64. Multi-path is effectively disabled if a value is set to 1.
- The multi-path route must have the same neighbor AS in its AS path as the best path if the **restrict same-neighbor-as** option is configured. By default, any path with the same AS path length as the best path (regardless of neighbor AS) is eligible for multi-path.

- The route must have the same AS path as the best path if the **restrict exact-as-path** option is configured. By default, any path with the same AS path length as the best path (regardless of the actual AS numbers) is eligible for multi-path.

The **no** form of this command removes IPv4-specific overrides.

Default

no ipv4

Parameters

max-paths

Specifies the maximum number of multipaths per prefix/NLRI if *ebgp-max-paths* or *ibgp-max-paths* does not apply.

Values 1 to 64

egp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an EBGP learned route.

Values 1 to 64

ibgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an IBGP learned route.

Values 1 to 64

restrict same-neighbor-as

Specifies that the non-best path must have the same neighbor AS in its AS path as the best path.

restrict exact-as-path-as

Specifies that the non-best path must have the same AS path as the best path.

unequal-cost

Instructs BGP to ignore differences in the next-hop cost only when determining eligible multipaths.

no ipv4

Context

[Tree] (config>system>ned>prof>neip ipv4)

Full Context

configure system network-element-discovery profile neip ipv4

Description

This command configures the IPv4 NEIP for this profile. The NEIP can be configured manually or set to be automatically generated using the NEID. If the NEID option is set, the first most significant byte of the IPv4 NEIP is set to 140 and the remaining 3 bytes are set to the NEID value. The NEID can be configured with a vendor ID value, in which case the first most significant byte of the IPv4 NEIP is set to this vendor ID value.

The **no** form of this command removes the IPv4 address association for this profile.

Default

no ipv4

Parameters

ip-address

Specifies the IPv4 address of the NEIP.

auto-generate

Specifies that the NEIP is automatically generated using the NEID.

vendor-id-value

Specifies the vendor ID value.

Values 1 to 255

Platforms

7705 SAR Gen 2

[Tree] (config>router>bgp>add-paths ipv4)

[Tree] (config>router>bgp>group>neighbor>add-paths ipv4)

Full Context

configure router bgp group add-paths ipv4

configure router bgp add-paths ipv4

configure router bgp group neighbor add-paths ipv4

Description

This command configures the add-paths capability for unlabeled IPv4 unicast routes. By default, add-paths is not enabled for unlabeled IPv4 unicast routes.

The maximum number of unlabeled unicast paths per IPv4 prefix to send is the configured send limit, which is a mandatory parameter. The capability to receive multiple unlabeled IPv4 unicast paths per prefix from a peer is configurable using the **receive** keyword, which is optional. If the **receive** keyword is not included in the command the receive capability is enabled by default.

The **no** form of this command disables add-paths support for unlabeled IPv4 unicast routes, causing sessions established using add-paths for unlabeled IPv4 unicast to go down and come back up without the add-paths capability.

Default

no ipv4

Parameters

send-limit

Specifies the maximum number of paths per unlabeled IPv4 unicast prefix that are allowed to be advertised to add-paths peers, the actual number of advertised routes may be less. If the value is **none**, the router does not negotiate the send capability with respect to IPv4 AFI/SAFI. If the value is **multipaths**, then BGP advertises all of the used BGP multipaths for each IPv4 NLRI if the peer has signaled support to receive multiple add-paths.

Values 1 to 16, none, multipaths

receive

Specifies that the router negotiates to receive multiple unlabeled unicast routes per IPv4 prefix.

none

Specifies that the router does not negotiate to receive multiple unlabeled unicast routes per IPv4 prefix.

Platforms

7705 SAR Gen 2

ipv4

Syntax

ipv4 *max-paths* [**ebgp** *ebgp-max-paths*] [**ibgp** *ibgp-max-paths*] [**restrict** { **same-neighbor-as** | **exact-as-path**}] [**unequal-cost**]

no ipv4

Context

[Tree] (config>router>bgp>multi-path ipv4)

Full Context

configure router bgp multi-path ipv4

Description

This command sets ECMP multipath parameters that apply only to the (unlabeled) IPv4 unicast address family. These settings override the values set by the **maximum-paths** command.

When multipath is enabled, traffic to the destination is load-shared across a set of paths (BGP routes) that the BGP decision process considers equal to the best path. The actual distribution of traffic over the multiple paths may be equal or unequal (that is, based on weights derived from the Link Bandwidth Extended Community).

The **no** form of this command removes IPv4-specific overrides.

Default

no ipv4

Parameters

max-paths

Specifies the maximum number of multipaths per prefix/NLRI if *ebgp-max-paths* or *ibgp-max-paths* does not apply.

Values 1 to 64

ebgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an EBGP learned route.

Values 1 to 64

ibgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an IBGP learned route.

Values 1 to 64

restrict same-neighbor-as

Specifies that the non-best path must have the same neighbor AS in its AS path as the best path.

restrict exact-as-path

Specifies that the non-best path must have the same AS path as the best path.

unequal-cost

Instructs BGP to ignore differences in the next-hop cost only when determining eligible multipaths.

configure router isis interface level ipv4-multicast-metric

Description

This command configures the IS-IS interface metric for IPv4 multicast.

The **no** form of this command removes the metric from the configuration.

Parameters

metric

Specifies the IS-IS interface metric for IPv4 multicast.

Values 1 to 16777215

Platforms

7705 SAR Gen 2

13.143 ipv4-multicast-metric-offset

ipv4-multicast-metric-offset

Syntax

ipv4-multicast-metric-offset *offset-value*

no ipv4-multicast-metric-offset

Context

[Tree] (config>service>vprn>isis>link-group>level ipv4-multicast-metric-offset)

Full Context

configure service vprn isis link-group level ipv4-multicast-metric-offset

Description

This command sets the offset value for the IPv4 multicast address family. If the number of operational links drops below the oper-members threshold, the configured offset is applied to the interface metric for the IPv4 multicast topology

The **no** form of this command reverts the offset value to 0.

Default

no ipv4-multicast-metric-offset

Parameters

offset-value

Specifies the amount the interface metric for the associated address family is to be increased if the number of operational members in the associated link-group drops below the oper-members threshold.

Values 0 to 6777215

Platforms

7705 SAR Gen 2

ipv4-multicast-metric-offset

Syntax

13.144 ipv4-multicast-routing

ipv4-multicast-routing

Syntax

ipv4-multicast-routing {**native** | **mt**}

[**no**] **ipv4-multicast-routing**

Context

[Tree] (config>service>vprn>isis ipv4-multicast-routing)

Full Context

configure service vprn isis ipv4-multicast-routing

Description

The multicast RTM is used for Reverse Path Forwarding checks. This command controls which IS-IS topology is used to populate the IPv4 multicast RTM.

The **no** ipv4-multicast-routing form of this command results in none of the IS-IS routes being populated in the IPv4 multicast RTM and would be used if multicast is configured to use the unicast RTM for the RPF check.

Default

ipv4-multicast-routing native

Parameters

native

Causes IPv4 routes from the MT0 topology to be added to the multicast RTM for RPF checks.

mt

Causes IPv4 routes from the MT3 topology to be added to the multicast RTM for RPF checks.

Platforms

7705 SAR Gen 2

13.145 ipv4-node-sid

ipv4-node-sid

Syntax

ipv4-node-sid index *index-value* [**clear-n-flag**]

ipv4-node-sid label *label-value* [**clear-n-flag**]

no ipv4-node-sid

Context

[Tree] (config>router>isis>interface ipv4-node-sid)

Full Context

configure router isis interface ipv4-node-sid

Description

This command assigns a node SID index or label value to the prefix representing the primary address of an IPv4 network interface of **type loopback**. Only a single node SID can be assigned to an interface. The secondary address of an IPv4 interface cannot be assigned a node SID index and does not inherit the SID of the primary IPv4 address.

The command fails if the network interface is not of **type loopback** or if the interface is defined in an IES or a VPRN context. Also, assigning the same SID index or label value to the same interface in two different IGP instances is not allowed within the same node.

The value of the label or index SID is taken from the range configured for this IGP instance. When using the global mode of operation, a new segment routing module checks that the same index or label value cannot be assigned to more than one loopback interface address. When using the per-instance mode of operation, this check is not required since the index and thus label ranges of the various IGP instance are not allowed to overlap.

The **clear-n-flag** option allows the user to clear the N-flag (node-sid flag) in an IS-IS prefix SID sub-TLV originated for the IPv4 prefix of a loopback interface on the system.

By default, the prefix SID sub-TLV for the prefix of a loopback interface is tagged as a node SID, meaning that it belongs to this node only. However, when the user wants to configure and advertise an anycast SID using the same loopback interface prefix on multiple nodes, you must clear the N-flag to assure interoperability with third party implementations, which may perform a strict check on the receiving end and drop duplicate prefix SID sub-TLVs when the N-flag is set.

The SR OS implementation is relaxed on the receiving end and accepts duplicate prefix SIDs with the N-flag set or cleared. SR OS will resolve to the closest owner, or owners if ECMP is configured, of the prefix SID according to its cost.

Default

no ipv4-node-sid

Parameters

index index-value

Specifies the index value.

Values 0 to 4294967295

label label-value

Specifies the label value.

Values 0 to 4294967295

clear-n-flag

Clears the node SID flag.

Default no clear-n-flag

13.148 ipv4-sid

ipv4-sid

Syntax

ipv4-sid index *index-id*

ipv4-sid label *label-id*

no ipv4-sid

Context

[Tree] (config>router>segment-routing>sr-mpls>prefix-sids ipv4-sid)

Full Context

configure router segment-routing sr-mpls prefix-sids ipv4-sid

Description

This command is used to configure the IPv4 segment routing SID associated with the primary IPv4 address of the loopback or system interface.

The **no** form of this command removes the configuration of the IPv4 segment routing SID associated with the primary IPv4 interface address.

Default

no ipv4-sid

Parameters

index *index-id*

Specifies the node SID index for this interface.

Values 0 to 4294967295

label *label-id*

Specifies the label value for the node SID.

Values 32 to 1048575

Platforms

13.149 ipv4-source-address

ipv4-source-address

Syntax

ipv4-source-address *ipv4-address*

no ipv4-source-address

Context

[Tree] (config>service>vprn>dns ipv4-source-address)

Full Context

configure service vprn dns ipv4-source-address

Description

This command configures the IPv4 address of the default secondary DNS server for the subscribers using this interface. Subscribers that cannot obtain an IPv4 DNS server address by other means, can use this for DNS name resolution.

The ipv4-address value can only be set to a nonzero value if the value of VPRN type is set to **subscriber-split-horizon**.

The **no** form of this command reverts to the default.

Parameters

ipv4-address

Specifies the IPv4 address of the default secondary DNS server.

Values ipv4-address - a.b.c.d

Platforms

7705 SAR Gen 2

ipv4-source-address

Syntax

ipv4-source-address *ip-address*

no ipv4-source-address

Context

7705 SAR Gen 2

ipv6

Syntax

ipv6 max-paths [**ebgp** *ebgp-max-paths*] [**ibgp** *ibgp-max-paths*] [**restrict** { **same-neighbor-as** | **exact-as-path**}] [**unequal-cost**]

no ipv6

Context

[Tree] (config>service>vprn>bgp>multi-path ipv6)

Full Context

configure service vprn bgp multi-path ipv6

Description

This command sets ECMP multipath parameters that apply only to the (unlabeled) IPv6 unicast address family. These settings override the values set by the **maximum-paths** command.

When multipath is enabled, traffic to the destination is load-shared across a set of paths (BGP routes) that the BGP decision process considers equal to the best path. The actual distribution of traffic over the multiple paths may be equal or unequal (that is, based on weights derived from the Link Bandwidth Extended Community).

To qualify as a multipath, a non-best route must meet the following criteria (some criteria are controlled by this command):

- The multi-path route must be the same type of route as the best path (same AFI/SAFI and, in some cases, same next-hop resolution method).
- The multi-path route must be tied with the best path for all criteria of greater significance than next-hop cost, except for criteria that are configured to be ignored.
- If the best path selection reaches the next-hop cost comparison, the multi-path route must have the same next-hop cost as the best route unless the **unequal-cost** option is configured.
- The multi-path route must not have the same BGP next-hop as the best path or any other multi-path route.
- The multi-path route must not cause the ECMP limit of the routing instance to be exceeded (configured using the **ecmp** command with a value in the range 1 to 64)

- The multi-path route must not cause the applicable *max-paths* limit to be exceeded. If the best path is an EBGP learned route and the **ebgp** option is used, the *ebgp-max-paths* limit overrides the *max-paths* limit. If the best path is an IBGP-learned route and the **ibgp** option is used, the *ibgp-max-paths* limit overrides the *max-paths* limit. All path limits are configurable up to a maximum of 64. Multi-path is effectively disabled if a value is set to 1.
- The multi-path route must have the same neighbor AS in its AS path as the best path if the **restrict same-neighbor-as** option is configured. By default, any path with the same AS path length as the best path (regardless of neighbor AS) is eligible for multi-path.
- The route must have the same AS path as the best path if the **restrict exact-as-path** option is configured. By default, any path with the same AS path length as the best path (regardless of the actual AS numbers) is eligible for multi-path.

The **no** form of this command removes IPv6-specific overrides.

Default

no ipv6

Parameters

max-paths

Specifies the maximum number of multipaths per prefix/NLRI if *ebgp-max-paths* or *ibgp-max-paths* does not apply.

Values 1 to 64

egp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an EBGP learned route.

Values 1 to 64

ibgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an IBGP learned route.

Values 1 to 64

restrict same-neighbor-as

Specifies that the non-best path must have the same neighbor AS in its AS path as the best path.

restrict exact-as-path-as

Specifies that the non-best path must have the same AS path as the best path.

unequal-cost

Instructs BGP to ignore differences in the next-hop cost only when determining eligible multipaths.

When enabled, the Alc-App-Prof-Str VSA is ignored in a radius Accept that enables portal redirection using this redirect policy. AA functionality will be disabled during portal authentication.

The **no** version of this command allows an Alc-App-Prof-Str to be present and will enable Application Assurance during portal authentication. In this case redirection rules defined in this policy are bypassed and it is assumed the AA function is configured for portal redirection.

Platforms

7705 SAR Gen 2

ipv6

Syntax

ipv6

Context

[Tree] (config>service>vprn>pim>rp ipv6)

Full Context

configure service vprn pim rp ipv6

Description

This command enables access to the context to configure the rendezvous point (RP) of a PIM IPv6 protocol instance.

A Nokia IPv6 PIM router acting as an RP must respond to an IPv6 PIM register message specifying an SSM multicast group address by sending to the first hop router stop register message(s). It does not build an (S, G) shortest path tree toward the first hop router. An SSM multicast group address can be either from the SSM default range or from a multicast group address range that was explicitly configured for SSM.

Default

ipv6 RP enabled when IPv6 PIM is enabled.

[Tree] (config>router>bgp>add-paths ipv6)

Full Context

configure router bgp group neighbor add-paths ipv6

configure router bgp group add-paths ipv6

configure router bgp add-paths ipv6

Description

This command configures the add-paths capability for unlabeled IPv6 unicast routes. By default, add-paths is not enabled for unlabeled IPv6 unicast routes.

The maximum number of unlabeled unicast paths per IPv6 prefix to send is the configured send limit, which is a mandatory parameter. The capability to receive multiple unlabeled IPv6 unicast paths per prefix from a peer is configurable using the **receive** keyword, which is optional. If the **receive** keyword is not included in the command the receive capability is enabled by default.

The **no** form of this command disables add-paths support for unlabeled IPv6 unicast routes, causing sessions established using add-paths for unlabeled IPv6 unicast to go down and come back up without the add-paths capability.

Default

no ipv6

Parameters

send *send-limit*

Specifies the maximum number of paths per unlabeled IPv6 unicast prefix that are allowed to be advertised to add-paths peers. (The actual number of advertised routes may be less.) If the value is **none**, the router does not negotiate the send capability with respect to IPv6 AFI/SAFI. If the value is **multipaths**, then BGP advertises all the used BGP multipaths for each IPv6 NLRI if the peer has signaled support to receive multiple add-paths.

Values 1 to 16, none, multipaths

receive

Specifies the router negotiates to receive multiple unlabeled unicast routes per IPv6 prefix.

none

Specifies the router does not negotiate to receive multiple unlabeled unicast routes per IPv6 prefix.

Platforms

7705 SAR Gen 2

ipv6

Syntax

ipv6 *max-paths* [**ebgp** *ebgp-max-paths*] [**ibgp** *ibgp-max-paths*] [**restrict** { **same-neighbor-as** | **exact-as-path**}] [**unequal-cost**]

[**no**] **ipv6**

Context

[Tree] (config>router>isis>traffic-engineering-options ipv6)

Full Context

configure router isis traffic-engineering-options ipv6

Description

This command enables the advertisement of IPv6 TE in the IS-IS instance. When this command is enabled, traffic engineering behavior with IPv6 TE links is enabled. This IS-IS instance automatically begins advertising the new RFC 6119 IPv6 and TE TLVs and sub-TLVs.

The **no** form of this command disables IPv6 TE in this ISIS instance.

Default

no ipv6

Platforms

7705 SAR Gen 2

ipv6

Syntax

ipv6

Context

[Tree] (config>test-oam>icmp ipv6)

13.152 ipv6-adjacency-sid

ipv6-adjacency-sid

Syntax

ipv6-adjacency-sid label *value*

no ipv6-adjacency-sid

Context

[Tree] (config>router>isis>interface ipv6-adjacency-sid)

Full Context

configure router isis interface ipv6-adjacency-sid

Description

This command allows a static value to be assigned to an IPv6 adjacency SID in IS-IS segment routing.

The **label** option specifies that the value is assigned to an MPLS label.

The **no** form of this command removes the adjacency SID.

Parameters

value

Specifies the adjacency SID label.

Values 18432 to 5248, 1048575 (FP4 or FP5 only)

Platforms

7705 SAR Gen 2

13.153 ipv6-criteria

ipv6-criteria

Syntax

[**no**] **ipv6-criteria**

Context

[Tree] (config>qos>sap-ingress ipv6-criteria)

[Tree] (config>qos>sap-egress ipv6-criteria)

Full Context

configure qos sap-ingress ipv6-criteria

configure qos sap-egress ipv6-criteria

Description

IPv6 criteria-based SAP egress or ingress policies are used to select the appropriate ingress or egress queue or policer and corresponding forwarding class and packet profile for matched traffic.

This command is used to enter the node to create or edit policy entries that specify IPv6 criteria such as IP quintuple lookup or DiffServ code point.

The OS implementation will exit on the first match found and execute the actions in accordance with the accompanying action command. For this reason, entries must be sequenced correctly from most to least explicit.

The **no** form of this command deletes all the entries specified under this node. When ipv6-criteria entries are removed from a SAP ingress policy, the ipv6-criteria is removed from all services where that policy is applied.

Platforms

7705 SAR Gen 2

ipv6-criteria

Syntax

[**no**] **ipv6-criteria**

Context

[Tree] (config>qos>network>ingress ipv6-criteria)

[Tree] (config>qos>network>egress ipv6-criteria)

Full Context

configure qos network ingress ipv6-criteria

configure qos network egress ipv6-criteria

Description

IPv6 criteria-based network ingress and egress policies are used to select the appropriate ingress or egress queue or policer, and the corresponding forwarding class and packet profile for matched traffic. This command is used to enter the context to create or edit policy entries that specify IPv6 criteria such as IP quintuple lookup or DSCP.

The SR OS implementation will exit on the first match found and execute the actions in accordance with the accompanying action command. Entries must be sequenced correctly from most to least explicit.

The ingress classification only applies to the outer IPv6 header of non-tunneled traffic.

Attempting to apply a network QoS policy containing an **ipv6-criteria** statement to any object except a network IP interface will result in an error.

The **no** form of this command deletes all entries specified under this node. When IP criteria entries are removed from a network policy, the IPv6 criteria are removed from all network interfaces to which that policy is applied.

Platforms

7705 SAR Gen 2

13.154 ipv6-eh

ipv6-eh

Syntax

ipv6-eh {**max** | **limited**}

no ipv6-eh

Context

[Tree] (config>system>ip ipv6-eh)

Full Context

configure system ip ipv6-eh

Description

This command defines the maximum number of IPv6 extension headers parsed in the line cards. The system parses up to six extension headers when **ipv6-eh max** is configured.

When the **ipv6-eh limited** command is configured, the system does not parse IPv6 extension headers and provides consistent ipv6-filter matches for the next-header value found in the IPv6 packet header. LAG and ECMP hashing of IPv6 packets with extension headers is limited to Layer 3 IP addresses. Layer 4 ports, TEID, and SPI values are not available for hashing. MLD snooping on Layer 2 services is also not supported in this mode.

The **no** form of this command reverts to the default value.

Default

ipv6-eh max

Parameters

max

Specifies that the maximum number of IPv6 extension headers is parsed in the line cards.

limited

Specifies that the system does not parse IPv6 extension headers and provides consistent ipv6-filter matches for the next-header value found in the IPv6 packet header.

Platforms

7705 SAR Gen 2

13.155 ipv6-error

ipv6-error

Syntax

[**no**] **ipv6-error**

Context

[Tree] (debug>router>ip>event ipv6-error)

7705 SAR Gen 2

13.156 ipv6-exception

ipv6-exception

Syntax

ipv6-exception *exception*

no ipv6-exception

Context

[Tree] (config>service>vprn>if>ipsec ipv6-exception)

[Tree] (config>router>if>ipsec ipv6-exception)

[Tree] (config>service>ies>if>ipsec ipv6-exception)

Full Context

configure service vprn interface ipsec ipv6-exception

configure router interface ipsec ipv6-exception

configure service ies interface ipsec ipv6-exception

Description

This command configures the IPv6 filter exception for an IPsec-secured IPv6 interface. When an IPv6 filter exception is added, clear text packets that match the exception criteria in the IPv6 filter exception policy can ingress the interface, even when IPsec is enabled on that interface.

The **no** form of this command removes the IPv6 filter exception.

Default

no ipv6-exception

Parameters

exception

Specifies the IPv6 filter exception that is used to bypass encryption.

Values *exception-id*: 1 to 65535

exception-name: An existing IPv6 filter exception name up to 64 characters.

Platforms

7705 SAR Gen 2

ipv6-exception

Syntax

ipv6-exception *exception-id* [**name** *exception-name*] [**create**]

no ipv6-exception {*exception-id* | *exception-name*}

Context

[Tree] (config>filter ipv6-exception)

Full Context

configure filter ipv6-exception

Description

Commands in this context configure the specified IPv6 exception filter.

The **no** form of the command deletes the IPv6 exception filter.

Parameters

exception-id

Specifies the IPv6 filter exception ID expressed as a decimal integer.

Values 1 to 65535

name *exception-name*

Specifies the IPv6 filter exception as a name, up to 64 characters.

create

This keyword is required to create the configuration context. Once it is created, the context can be enabled with or without the **create** keyword.

Platforms

7705 SAR Gen 2

13.157 ipv6-filter

ipv6-filter

Syntax

ipv6-filter *ipv6-filter-id* **entry** *entry-id* [*entry-id*]

no ipv6-filter *ipv6-filter-id* [**entry** *entry-id*]

Context

[Tree] (config>mirror>mirror-source ipv6-filter)

Full Context

configure mirror mirror-source ipv6-filter

Description

This command enables mirroring of packets that match specific entries in an existing IPv6 filter.

The **ipv6-filter** command directs packets which match the defined list of entry IDs to be mirrored to the mirror destination referenced by the *mirror-dest-service-id* of the **mirror-source**.

The IPv6 filter must already exist in order for the command to execute. Filters are configured in the **config>filter** context. If the IPv6 filter does not exist, an error will occur. If the filter exists but has not been associated with a SAP or IPv6 interface, an error is not generated but mirroring will not be enabled (there are no packets to mirror). Once the IPv6 filter is defined to a SAP or IPv6 interface, mirroring is enabled.

If the IPv6 filter is defined as ingress, only ingress packets are mirrored. Ingress mirrored packets are mirrored to the mirror destination prior to any ingress packet modifications.

If the IPv6 filter is defined as egress, only egress packets are mirrored. Egress mirrored packets are mirrored to the mirror destination after all egress packet modifications.

An *entry-id* within an IPv6 filter can only be mirrored to a single mirror destination. If the same *entry-id* is defined multiple times, an error occurs and only the first **mirror-source** definition is in effect.

By default, no packets matching any IPv6 filters are mirrored. Mirroring of IPv6 filter entries must be explicitly defined.

The **no ipv6-filter** command, without the **entry** keyword, removes mirroring on all *entry-id*'s within the *ip-filter-id*.

When the **no** form of this command is executed with the **entry** keyword and one or more *entry-id*'s, mirroring that *entry-id* list is terminated within the *ip-filter-id*. If an *entry-id* is listed that does not exist, an error will occur and the command will not execute. If an *entry-id* is listed that is not currently being mirrored, no error will occur for that *entry-id* and the command will execute normally.

Parameters

ipv6-filter-id

Specifies the IPv6 filter ID whose entries are mirrored. If the *ipv6-filter-id* does not exist, an error will occur and the command will not execute. Mirroring of packets will commence once the *ipv6-filter-id* is defined on a SAP or IPv6 interface.

entry-id

Specifies the IP filter entries to use as match criteria for packet mirroring. The **entry** keyword begins a list of *entry-id*'s for mirroring. Multiple *entry-id* entries may be specified with a single command. Each *entry-id* must be separated by a space.

If an *entry-id* does not exist within the IP filter, an error occurs and the command will not execute.

If the filter's *entry-id* is renumbered within the IP filter definition, the old *entry-id* is removed but the new *entry-id* must be manually added to the configuration to include the new (renumbered) entry's criteria.

Platforms

7705 SAR Gen 2

ipv6-filter

Syntax

ipv6-filter *filter-id* [**name** *filter-name*] [**create**]

no ipv6-filter {*filter-id* | *filter-name*}

Context

[Tree] (config>filter ipv6-filter)

Full Context

configure filter ipv6-filter

Description

Commands in this context configure the specified IPv6 filter policy.

The **no** form of the command deletes the IPv6 filter policy. A filter policy cannot be deleted until it is removed from all objects where it is applied.

Parameters

filter-id

Specifies the IPv6 filter policy ID expressed as a decimal integer.

Values 1 to 65535

name

Configures an optional filter name, up to 64 characters in length, to a given filter. This filter name can then be used in configuration references, display, and show commands throughout the system. A defined filter name can help the service provider or administrator to identify and manage filters within the SR OS platforms.

To create a filter, you must assign a filter ID, however, after it is created, either the filter ID or filter name can be used to identify and reference a filter.

If a name is not specified at creation time, then SR OS assigns a string version of the *filter-id* as the name.

Filter names may not begin with an integer (0 to 9).

Values *name*: 64 characters maximum

filter-name

Specifies a string of up to 64 characters uniquely identifying this IPv6 filter policy.

create

This keyword is required to create the configuration context. Once it is created, the context can be enabled with or without the **create** keyword.

Platforms

7705 SAR Gen 2

ipv6-filter

Syntax

[**no**] **ipv6-filter**

Context

[Tree] (config>system>security>mgmt-access-filter ipv6-filter)

ipv6-filter

Syntax

ipv6-filter *src-filter-id* [**src-entry** *src-entry-id*] **to** *dst-filter-id* [**dst-entry** *dst-entry-id*] [**overwrite**]

Context

[Tree] (config>filter>copy ipv6-filter)

Full Context

configure filter copy ipv6-filter

Description

This command copies an existing filter entry for a specific filter ID to another filter ID. The command is a configuration level maintenance tool used to create new entries using an existing filter policy. If **overwrite** is not specified, an error will occur if the destination filter entry exists.

Parameters

src-filter-id

Identifies the source filter policy from which the copy command will attempt to copy. The filter policy must exist within the context of the preceding keyword (**ipv6-filter**).

dst-filter-id

Identifies the destination filter policy to which the copy command will attempt to copy. If the **overwrite** keyword is not specified, the filter entry ID cannot already exist in the destination filter policy. If the **overwrite** keyword is present, the destination entry ID may or may not exist.

overwrite

Specifies that the destination filter entry may exist. If it does, everything in the existing destination filter entry will be completely overwritten with the contents of the source filter entry. If the destination filter entry exists, either **overwrite** must be specified or an error message will be returned. If **overwrite** is specified, the function of copying from source to destination occurs in a "break before make" manner and therefore should be handled with care.

Syntax

[**no**] **ipv6-multicast-disable**

Context

[Tree] (config>router>isis>interface ipv6-multicast-disable)

Full Context

configure router isis interface ipv6-multicast-disable

Description

This command disables IS-IS IPv6 multicast routing for the interface.

The **no** form of this command enables IS-IS IPv6 multicast routing for the interface.

Platforms

7705 SAR Gen 2

13.160 ipv6-multicast-metric

ipv6-multicast-metric

Syntax

ipv6-multicast-metric *metric*

no ipv6-multicast-metric

Context

[Tree] (config>router>isis>if>level ipv6-multicast-metric)

Full Context

configure router isis interface level ipv6-multicast-metric

Description

This command configures the IS-IS interface metric for IPv6 multicast.

The **no** form of this command removes the metric from the configuration.

Default

no ipv6-multicast-metric

Parameters

metric

Specifies the IS-IS interface metric for IPv6 multicast.

Values 1 to 16777215

Platforms

7705 SAR Gen 2

13.161 ipv6-multicast-metric-offset

ipv6-multicast-metric-offset

Syntax

ipv6-multicast-metric-offset *offset-value*

no ipv6-multicast-metric-offset

Context

[Tree] (config>router>isis>link-group>level ipv6-multicast-metric-offset)

Full Context

configure router isis link-group level ipv6-multicast-metric-offset

Description

This command sets the offset value for the IPv6 multicast address family. If the number of operational links drops below the oper-members threshold, the configured offset is applied to the interface metric for the IPv6 multicast topology.

The **no** form of this command reverts the offset value to 0.

Default

no ipv6-multicast-metric-offset

Parameters

offset-value

Specifies the amount the interface metric for the associated address family is to be increased if the number of operational members in the associated link-group drops below the oper-members threshold

Values 0 to 6777215

Platforms

7705 SAR Gen 2

13.162 ipv6-multicast-routing

ipv6-multicast-routing

Syntax

ipv6-multicast-routing {**native** | **mt**}

[**no**] **ipv6-multicast-routing**

Context

[Tree] (config>router>isis ipv6-multicast-routing)

Full Context

configure router isis ipv6-multicast-routing

Description

The multicast RTM is used for Reverse Path Forwarding checks. This command controls which IS-IS topology is used to populate the IPv6 multicast RTM.

The **no** form of this command results in none of the IS-IS routes being populated in the IPv4 multicast RTM and would be used if multicast is configured to use the unicast RTM for the RPF check.

Default

ipv6-multicast-routing native

Parameters

native

Causes IPv6 routes from the MT0 topology to be added to the multicast RTM for RPF checks.

mt

Causes IPv6 routes from the MT3 topology to be added to the multicast RTM for RPF checks.

Platforms

7705 SAR Gen 2

13.163 ipv6-node-sid

ipv6-node-sid

Syntax

ipv6-node-sid index *index-value* [**clear-n-flag**]

ipv6-node-sid label *label-value* [**clear-n-flag**]

no ipv6-node-sid

Context

[Tree] (config>router>isis>interface ipv6-node-sid)

Full Context

configure router isis interface ipv6-node-sid

Description

This command assigns a node SID index or label value to the prefix representing the primary address of an IPv6 network interface of type loopback. Only a single node SID can be assigned to an IPv6 interface. When an IPv6 interface has multiple global addresses, the primary address is always the first one in the list, as displayed by the **interface info** command.

The command fails if the network interface is not of loopback type or if the interface is defined in an IES or a VPRN context. Assigning the same SID index/label value to the same interface in two different IGP instances is not allowed within the same node.

The value of the label or index SID is taken from the range configured for this IGP instance. When using the global mode of operation, a new segment routing module checks that the same index or label value cannot be assigned to more than one loopback interface address. When using the per-instance mode of operation, this check is not required since the index and thus label ranges of the various IGP instance are not allowed to overlap.

The **clear-n-flag** option allows the user to clear the N-flag (node-sid flag) in an IS-IS prefix SID sub-TLV originated for the IPv6 prefix of a loopback interface on the system.

By default, the prefix SID sub-TLV for the prefix of a loopback interface is tagged as a node SID, meaning that it belongs to this node only. However, when the user wants to configure and advertise an anycast SID using the same loopback interface prefix on multiple nodes, you must clear the N-flag to assure interoperability with third-party implementations, which may perform a strict check on the receiving end and drop duplicate prefix SID sub-TLVs when the N-flag is set.

The SR OS implementation is relaxed on the receiving end and accepts duplicate prefix SIDs with the N-flag set or cleared. SR OS will resolve to the closest owner, or owners if ECMP is configured, of the prefix SID according to its cost.

Default

no ipv6-node-sid

Parameters

index-value

Specifies the index value.

Values 0 to 4294967295

label-value

Specifies the label value.

Values 0 to 4294967295

clear-n-flag

Clears the node SID flag.

Default no clear-n-flag

Platforms

7705 SAR Gen 2

13.164 ipv6-prefix

debug router rpki-session packet ipv6-prefix

Description

This command enables debugging for IPv6 prefix RPKI packets.

The **no** form of this command disables debugging for IPv6 prefix RPKI packets.

Platforms

7705 SAR Gen 2

13.165 ipv6-prefix-list

ipv6-prefix-list

Syntax

ipv6-prefix-list *ipv6-prefix-list-name* [**create**]

no ipv6-prefix-list *ipv6-prefix-list-name*

Context

[Tree] (config>qos>match-list ipv6-prefix-list)

Full Context

configure qos match-list ipv6-prefix-list

Description

This command creates a list of IPv6 prefixes for match criteria in QoS policies. An ipv6-prefix-list must contain only IPv6 address prefixes created using the **prefix** command and cannot be deleted if it is referenced by a QoS policy.

The **no** form of this command deletes the specified list.

Parameters

ipv6-prefix-list-name

A string of up to 32 characters of printable ASCII characters. If special characters are used (#, ?, space), the string must be enclosed within double quotes. The name **default** (case insensitive) is reserved by the system.

create

Creates IPv6 prefixes for match criteria in QoS policies.

Platforms

7705 SAR Gen 2

ipv6-prefix-list

Syntax

ipv6-prefix-list *ipv6-prefix-list-name* [**create**]

no ipv6-prefix-list *ipv6-prefix-list-name*

Context

[Tree] (config>filter>match-list ipv6-prefix-list)

Full Context

configure filter match-list ipv6-prefix-list

Description

This command creates a list of IPv6 prefixes for match criteria in ACL and CPM IPv6 filter policies.

The **no** form of this command deletes the specified list.

Operational Notes:

An IPv6 prefix list must contain only IPv6 address prefixes.

An IPv6 prefix list cannot be deleted if it is referenced by a filter policy.

See general description related to match-list usage in filter policies.

Parameters

ipv6-prefix-list-name

Specifies a string of up to 32 printable ASCII characters. If special characters are used, the string must be enclosed within double quotes.

Platforms

7705 SAR Gen 2

13.166 ipv6-routing

ipv6-routing

Syntax

[**no**] **ipv6-routing** {**native** | **mt**}

Context

Full Context

configure router segment-routing sr-mpls prefix-sids ipv6-sid

Description

This command is used to configure the IPv6 segment routing SID associated with the primary IPv6 address of the loopback or system interface.

The **no** form of this command removes the configuration of the IPv6 segment routing SID associated with the primary IPv6 interface address.

Default

no ipv6-sid

Parameters

index *index-id*

Specifies the node SID index for this interface.

Values 0 to 4294967295

label *label-id*

Specifies the label value for the node SID.

Values 32 to 1048575

Platforms

7705 SAR Gen 2

13.168 ipv6-source-address

ipv6-source-address

Syntax

ipv6-source-address *ipv6-address*

no ipv6-source-address

Context

[Tree] (config>aaa>radius-srv-plcy>servers ipv6-source-address)

Full Context

configure aaa radius-server-policy servers ipv6-source-address

Description

This command configures the source address of an IPv6 RADIUS packet.

When no ipv6-source-address is configured, the system IPv6 address (inband RADIUS server connection) or Boot Option File (BOF) IPv6 address (outband RADIUS server connection) must be configured in order for the RADIUS client to work with an IPv6 RADIUS server.

This address is also used in the NAS-IPv6-Address attribute.

The **no** form of this command reverts to the default value.

Parameters

ipv6-address

Specifies the source address of an IPv6 RADIUS packet.

Platforms

7705 SAR Gen 2

ipv6-source-address

Syntax

ipv6-source-address *ipv6-address*

no ipv6-source-address

Context

[Tree] (config>service>vprn>dns ipv6-source-address)

Full Context

configure service vprn dns ipv6-source-address

Description

This command configures the IPv6 address of the default secondary DNS server for the subscribers using this interface. Subscribers that cannot obtain an IPv6 DNS server address by other means, can use this for DNS name resolution.

The ipv6-address value can only be set to a nonzero value if the value of VPRN type is set to **subscriber-split-horizon**.

The **no** form of this command reverts to the default.

Parameters

ipv6-address

Specifies the IPv6 address of the default secondary DNS server.

Values ipv6-address - a.b.c.d

Platforms

7705 SAR Gen 2

ipv6-source-address

Syntax

ipv6-source-address *ipv6-address*

no ipv6-source-address

[Tree] (config>system>file-trans-prof ipv6-source-address)

Full Context

configure system file-transmission-profile ipv6-source-address

Description

This command specifies the IPv6 source address used for transport protocol.

The **no** form of this command uses the default source address which typically is the address of egress interface.

Default

no ipv6-source-address

Parameters

Ipv6-address

Specifies a unicast v6 address. This should be a local interface address.

Platforms

7705 SAR Gen 2

13.169 ipv6-te-router-id

ipv6-te-router-id

Syntax

ipv6-te-router-id interface *interface-name*

no ipv6-te-router-id

Context

[Tree] (config>router ipv6-te-router-id)

Full Context

configure router ipv6-te-router-id

Description

This command configures the IPv6 TE Router ID. The IPv6 TE Router ID, when configured, uniquely identifies the router as being IPv6 TE capable to other routers in an IGP TE domain.

IS-IS advertises this information using the IPv6 TE Router ID TLV.

If this command is not configured, the IPv6 TE Router ID will use the global unicast address of the system interface by default. The user can specify the system interface using this command to achieve the same result. If a different interface is specified, the preferred primary global unicast address of that interface is used instead

The **no** form of this command reverts the IPv6 TE Router ID to the default value.

Parameters

interface interface-name

Specifies the name of the interface to be added or removed. Only system and loopback interfaces are accepted.

Platforms

7705 SAR Gen 2

13.170 ipv6-unicast

ipv6-unicast

Syntax

[**no**] **ipv6-unicast**

Context

[Tree] (config>service>vprn>isis>multi-topology ipv6-unicast)

Full Context

configure service vprn isis multi-topology ipv6-unicast

Description

This command enables multi-topology TLVs.

The **no** form of this command disables multi-topology TLVs.

Platforms

7705 SAR Gen 2

ipv6-unicast

Syntax

[**no**] **ipv6-unicast**

Context

[Tree] (config>router>isis>multi-topology ipv6-unicast)

Full Context

configure router isis multi-topology ipv6-unicast

Description

This command enables multi-topology TLVs.

The **no** form of this command disables multi-topology TLVs.

Default

no ipv6-unicast

Platforms

7705 SAR Gen 2

13.171 ipv6-unicast-disable

ipv6-unicast-disable

Syntax

[**no**] **ipv6-unicast-disable**

Context

[Tree] (config>service>vprn>isis>if ipv6-unicast-disable)

[Tree] (config>router>isis>if ipv6-unicast-disable)

Full Context

configure service vprn isis interface ipv6-unicast-disable

configure router isis interface ipv6-unicast-disable

Description

This command disables IS-IS IPv6 unicast routing for the interface.

By default IPv6 unicast on all interfaces is enabled. However, IPv6 unicast routing on IS-IS is in effect when the **config>router>isis>ipv6-routing mt** command is configured.

The **no** form of this command enables IS-IS IPv6 unicast routing for the interface.

7705 SAR Gen 2

13.172 ipv6-unicast-metric

ipv6-unicast-metric

Syntax

ipv6-unicast-metric *metric*

no ipv6-unicast-metric

Context

[Tree] (config>service>vprn>isis>if>level ipv6-unicast-metric)

Full Context

configure service vprn isis interface level ipv6-unicast-metric

Description

This command configures IS-IS interface metric for IPv6 unicast.

The **no** form of this command removes the metric from the configuration.

Parameters

metric

Specifies the IS-IS interface metric for IPv6 unicast.

Values 1 to 16777215

Platforms

7705 SAR Gen 2

ipv6-unicast-metric

Syntax

ipv6-unicast-metric *metric*

no ipv6-unicast-metric

Context

[Tree] (config>router>isis>if>level ipv6-unicast-metric)

Full Context

configure router isis interface level ipv6-unicast-metric

Description

This command configures the IS-IS interface metric for IPv6 unicast.

The **no** form of this command removes the metric from the configuration.

Default

no ipv6-unicast-metric

Parameters

metric

Specifies the IS-IS interface metric for IPv6 unicast.

Values 1 to 16777215

Platforms

7705 SAR Gen 2

13.173 ipv6-unicast-metric-offset

ipv6-unicast-metric-offset

Syntax

ipv6-unicast-metric-offset *offset-value*

no ipv6-unicast-metric-offset

Context

[Tree] (config>service>vprn>isis>link-group>level ipv6-unicast-metric-offset)

Full Context

configure service vprn isis link-group level ipv6-unicast-metric-offset

Description

This command sets the offset value for the IPv6 unicast address family. If the number of operational links drops below the **oper-members** threshold, the configured offset is applied to the interface metric for the IPv6 topology.

The **no** form of this command reverts the offset value to 0.

Default

no ipv6-unicast-metric-offset

Parameters

offset-value

Specifies the amount the interface metric for the associated address family is to be increased if the number of operational members in the associated link-group drops below the oper-members threshold.

Values 0 to 6777215

Platforms

7705 SAR Gen 2

ipv6-unicast-metric-offset

Syntax

ipv6-unicast-metric-offset *offset-value*

no ipv6-unicast-metric-offset

Context

[Tree] (config>router>isis>link-group>level ipv6-unicast-metric-offset)

Full Context

configure router isis link-group level ipv6-unicast-metric-offset

Description

This command sets the offset value for the IPv6 unicast address family. If the number of operational links drops below the **oper-members** threshold, the configured offset is applied to the interface metric for the IPv6 topology.

The **no** form of this command reverts the offset value to 0.

Default

no ipv6-unicast-metric-offset

Parameters

offset-value

Specifies the amount the interface metric for the associated address family is to be increased if the number of operational members in the associated link-group drops below the oper-members threshold.

Values 0 to 6777215

Platforms

isakmp-lifetime

Syntax
isakmp-lifetime *seconds*

Context
[Tree] (config>ipsec>ike-transform isakmp-lifetime)

Full Context
configure ipsec ike-transform isakmp-lifetime

Description
This command specifies the lifetime of the IKE SA.

Default

isakmp-lifetime 86400

Parameters

seconds

Specifies the Phase 1 life time for this IKE transform.

Values 1200 to 31536000

Platforms

7705 SAR Gen 2

13.177 isis

isis

Syntax

[**no**] **isis** *isis-instance*

Context

[Tree] (config>service>vprn isis)

Full Context

configure service vprn isis

Description

Commands in this context configure the Intermediate-System-to-Intermediate-System (IS-IS) protocol instance in the VPRN.

The IS-IS protocol instance is enabled with the **no shutdown** command in the **config>service>vprn>isis** context. Alternatively, the IS-IS protocol instance is disabled with the **shutdown** command in the **config>service>vprn>isis** context.

IS-IS instances are **shutdown** when created, so that all parameters can be configured prior to the instance being enabled.

The **no** form of this command disables the ISIS protocol instance from the given VPRN service.

Default

0

Parameters

isis-instance

Specifies the instance ID for an IS-IS instance.

Values 0 to 127

Platforms

7705 SAR Gen 2

isis

Syntax

[**no**] **isis** [*isis-instance*]

Context

[Tree] (config>router isis)

Full Context

configure router isis

Description

Commands in this context configure the Intermediate-System-to-Intermediate-System (IS-IS) protocol instance.

The IS-IS protocol instance is enabled with the **no shutdown** command in the **config>router>isis** context. Alternatively, the IS-IS protocol instance is disabled with the **shutdown** command in the **config>router>isis** context.

IS-IS instances are shutdown when created, so that all parameters can be configured prior to the instance being enabled.

The **no** form of this command deletes the IS-IS protocol instance. Deleting the protocol instance removes all configuration parameters for this IS-IS instance.

Parameters

isis-instance

Specifies the instance ID for an IS-IS instance.

Values 0 to 127

Platforms

7705 SAR Gen 2

isis

Syntax

isis [*isis-instance*]

Context

[Tree] (debug>router isis)

Full Context

debug router isis

Description

Commands in this context debug IS-IS protocol entities.

Parameters

isis-instance

Specifies the IS-IS instance.

Values 0 to 127

Platforms

7705 SAR Gen 2

Output

The following output is an example of the debugging information.

14 j Commands

14.1 jitter-event

jitter-event

Syntax

jitter-event rising-threshold *threshold* [**falling-threshold** *threshold*] [*direction*]

no jitter-event

Context

[Tree] (config>saa>test jitter-event)

Full Context

configure saa test jitter-event

Description

This command specifies that at the termination of an SAA test probe, the calculated jitter value is evaluated against the configured rising and falling jitter thresholds. SAA threshold events are generated as required.

Once the threshold (rising/falling) is crossed, it is disabled from generating additional events until the opposite threshold is crossed. If a **falling-threshold** is not supplied, the **rising- threshold** is re-enabled when it falls below the threshold after the initial crossing that generated the event.

The configuration of jitter event thresholds is optional.

The **no** form of the command disables the jitter event.

Parameters

rising-threshold *threshold*

Specifies a rising threshold jitter value, in milliseconds. When the test run is completed, the calculated jitter value is compared to the configured jitter rising threshold. If the test run jitter value is greater than the configured rising threshold value then an SAA threshold event is generated. The SAA threshold event is tmnxOamSaaThreshold, logger application OAM, event #2101.

Values 0 to 2147483

Default 0

falling-threshold *threshold*

Specifies a falling threshold jitter value, in milliseconds. When the test run is completed, the calculated jitter value is compared to the configured jitter falling threshold. If the test

run jitter value is greater than the configured falling threshold value then an SAA threshold event is generated. The SAA threshold event is tmnxOamSaaThreshold, logger application OAM, event #2101.

Values 0 to 2147483

Default 0

direction

Specifies the direction for OAM ping responses received for an OAM ping test run.

Values **inbound** — Monitor the value of jitter calculated for the inbound, one-way, OAM ping responses received for an OAM ping test run.

outbound — Monitor the value of jitter calculated for the outbound, one-way, OAM ping requests sent for an OAM ping test run.

roundtrip — Monitor the value of jitter calculated for the round trip, two-way, OAM ping requests and replies for an OAM ping test run.

Default roundtrip

15 k Commands

15.1 kb-memory-use-alarm

kb-memory-use-alarm

Syntax

kb-memory-use-alarm rising-threshold *threshold* [**falling-threshold** *threshold*] **interval** *seconds* [*rmon-event-type*] [**startup-alarm** *alarm-type*]

no kb-memory-use-warn

Context

[Tree] (config>system>thresholds kb-memory-use-alarm)

Full Context

configure system thresholds kb-memory-use-alarm

Description

This command configures memory use, in kilobytes, alarm thresholds.

The **no** form of the command removes the parameters from the configuration.

Parameters

rising-threshold *threshold*

Specifies a threshold for the sampled statistic. When the current sampled value is greater than or equal to this threshold, and the value at the last sampling interval was less than this threshold, a single threshold crossing event will be generated. A single threshold crossing event will also be generated if the first sample taken is greater than or equal to this threshold and the associated startup-alarm is equal to rising or either.

After a rising threshold crossing event is generated, another such event will not be generated until the sampled value falls below this threshold and reaches less than or equal the falling-threshold value.

The threshold value represents units of kilobytes.

Values -2147483648 to 2147483647

Default 0

falling-threshold *threshold*

Specifies a threshold for the sampled statistic. When the current sampled value is less than or equal to this threshold, and the value at the last sampling interval was greater

than this threshold, a single threshold crossing event will be generated. A single threshold crossing event will also be generated if the first sample taken is less than or equal to this threshold and the associated startup-alarm is equal to falling or either.

After a falling threshold crossing event is generated, another such event will not be generated until the sampled value rises above this threshold and reaches greater than or equal the rising-threshold value.

The threshold value represents units of kilobytes.

Values -2147483648 to 2147483647

Default 0

seconds

Specifies the polling period over which the data is sampled and compared with the rising and falling thresholds.

Values 1 to 2147483647

rmon-event-type

Specifies the type of notification action to be taken when this event occurs.

Values log — In the case of log, an entry is made in the RMON-MIB log table for each event occurrence. This does not create an SR OS logger entry. The RMON-MIB log table entries can be viewed using the **show>system>thresholds** CLI command.

trap — An SR OS logger event is generated. The SR OS logger utility then distributes the notification of this event to its configured log destinations which may be CONSOLE, telnet session, memory log, cflash file, syslog, or SNMP trap destinations logs.

both — Both an entry in the RMON-MIB logTable and an SR OS logger event are generated.

none — No action is taken.

Default both

startup-alarm *alarm-type*

Specifies the alarm that may be sent when this alarm is first created. If the first sample is greater than or equal to the rising threshold value and startup-alarm is equal to rising or either, then a single rising threshold crossing event is generated. If the first sample is less than or equal to the falling threshold value and startup-alarm is equal to falling or either, a single falling threshold crossing event is generated.

Values rising, falling, either

Default either

Platforms

7705 SAR Gen 2

15.2 kb-memory-use-warn

kb-memory-use-warn

Syntax

kb-memory-use-warn rising-threshold *threshold* [**falling-threshold** *threshold*] **interval** *seconds* [*rmon-event-type*] [**startup-alarm** *alarm-type*]

no kb-memory-use-warn

Context

[Tree] (config>system>thresholds kb-memory-use-warn)

Full Context

configure system thresholds kb-memory-use-warn

Description

This command configures memory usage, in kilobytes, for warning thresholds

Parameters

rising-threshold *threshold*

Specifies a threshold for the sampled statistic. When the current sampled value is greater than or equal to this threshold, and the value at the last sampling interval was less than this threshold, a single threshold crossing event will be generated. A single threshold crossing event will also be generated if the first sample taken is greater than or equal to this threshold and the associated startup-alarm is equal to rising or either.

After a rising threshold crossing event is generated, another such event will not be generated until the sampled value falls below this threshold and reaches less than or equal the falling-threshold value.

The threshold value represents units of kilobytes.

Values -2147483648 to 2147483647

Default 0

falling-threshold *threshold*

Specifies a threshold for the sampled statistic. When the current sampled value is less than or equal to this threshold, and the value at the last sampling interval was greater than this threshold, a single threshold crossing event will be generated. A single threshold crossing event will also be generated if the first sample taken is less than or equal to this threshold and the associated startup-alarm is equal to falling or either.

After a falling threshold crossing event is generated, another such event will not be generated until the sampled value rises above this threshold and reaches greater than or equal the rising-threshold value.

The threshold value represents units of kilobytes.

Values -2147483648 to 2147483647

Default 0

seconds

Specifies the polling period over which the data is sampled and compared with the rising and falling thresholds.

Values 1 to 2147483647

rmon-event-type

Specifies the type of notification action to be taken when this event occurs.

Values log — An entry is made in the RMON-MIB log table for each event occurrence. This does not create an SR OS logger entry. The RMON-MIB log table entries can be viewed using the show>system>thresholds CLI command.

trap — An SR OSS logger event is generated. The SR OS logger utility then distributes the notification of this event to its configured log destinations which may be CONSOLE, telnet session, memory log, cflash file, syslog, or SNMP trap destinations logs.

both — Both an entry in the RMON-MIB logTable and an SR OS logger event are generated.

none — No action is taken.

Default both

alarm-type

Specifies the alarm that may be sent when this alarm is first created. If the first sample is greater than or equal to the rising threshold value and startup-alarm is equal to rising or either, then a single rising threshold crossing event is generated. If the first sample is less than or equal to the falling threshold value and startup-alarm is equal to falling or either, a single falling threshold crossing event is generated.

Values rising, falling, either

Default either

15.3 keep-alive

keep-alive

Syntax

keep-alive

Context

[Tree] (config>service>sdp keep-alive)

Full Context

configure service sdp keep-alive

Description

This command enables the context to configure SDP connectivity monitoring keepalive messages for the SDP ID.

SDP ID keepalive messages use SDP Echo Request and Reply messages to monitor SDP connectivity. The operating state of the SDP is affected by the keepalive state on the SDP ID. SDP Echo Request messages are only sent when the SDP ID is completely configured and administratively up. If the SDP ID is administratively down, keepalives for that SDP ID are disabled. SDP Echo Requests (when sent for keepalive messages) are always sent with the *originator-sdp-id*. All SDP ID keepalive SDP Echo Replies are sent using generic IP/GRE OAM encapsulation.

When a keepalive response is received that indicates an error condition, the SDP ID will immediately be brought operationally down. Once a response is received that indicates the error has cleared and the **hold-down-time** interval has expired, the SDP ID will be eligible to be put into the operationally up state. If no other condition prevents the operational change, the SDP ID will enter the operational state.

A set of event counters track the number of keepalive requests sent, the size of the message sent, non-error replies received and error replies received. A keepalive state value is kept indicating the last response event. A keepalive state timestamp value is kept indicating the time of the last event. With each keepalive event change, a log message is generated indicating the event type and the timestamp value.

Table 44: Keepalive Interpretation and Effect of SDP Echo Reply describes the keepalive interpretation of SDP echo reply response conditions and the effect on the SDP ID operational status.

Table 44: Keepalive Interpretation and Effect of SDP Echo Reply

Result of Request	Stored Response State	Operational State
keepalive request timeout without reply	Request Timeout	Down
keepalive request not sent due to non-existent *orig-sdp-id* (This condition should not occur)	Orig-SDP Non-Existent	Down

Result of Request	Stored Response State	Operational State
keepalive request not sent due to administratively down *orig-sdp-id*	Orig-SDP Admin-Down	Down
keepalive reply received, invalid origination-id	Far End: Originator-ID Invalid	Down
keepalive reply received, invalid responder-id	Far End: Responder-ID Error	Down
keepalive reply received, No Error	Success	Up (If no other condition prevents)

keep-multiplier

Syntax

[**no**] **keep-multiplier** *number*

no keep-multiplier

Context

[Tree] (config>router>rsvp keep-multiplier)

Full Context

configure router rsvp keep-multiplier

Description

The **keep-multiplier** *number* is an integer used by RSVP to declare that a reservation is down or the neighbor is down.

The **no** form of this command reverts to the default value.

Default

keep-multiplier 3

Parameters

number

Specifies the **keep-multiplier** value.

Values 1 to 255

Platforms

7705 SAR Gen 2

15.6 keepalive

keepalive

Syntax

keepalive *seconds*

no keepalive

Context

[Tree] (config>service>vprn>bgp>group>neighbor keepalive)

[Tree] (config>service>vprn>bgp>group keepalive)

[Tree] (config>service>vprn>bgp keepalive)

Full Context

configure service vprn bgp group neighbor keepalive

configure service vprn bgp group keepalive

configure service vprn bgp keepalive

Description

This command configures the BGP keepalive timer. A keepalive message is sent every time this timer expires. The **seconds** parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). The most specific value is used.

The **keepalive** value is generally one-third of the **hold-time** interval. Even though the OS implementation allows the **keepalive** value and the **hold-time** interval to be independently set, under the following circumstances, the configured **keepalive** value is overridden by the **hold-time** value:

If the specified **keepalive** value is greater than the configured **hold-time**, then the specified value is ignored, and the **keepalive** is set to one third of the current **hold-time** value.

If the specified **hold-time** interval is less than the configured **hold-time** value, then the **keepalive** value is reset to one third of the specified **hold-time** interval.

If the **hold-time** interval is set to zero, then the configured value of the **keepalive** value is ignored. This means that the connection with the peer is up permanently and no **keepalive** packets are sent to the peer.

The **no** form of this command used at the global level reverts to the default value.

The **no** form of this command used at the group level reverts to the value defined at the global level.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Default

keepalive 30

Parameters

seconds

The keepalive timer in seconds, expressed as a decimal integer.

Values 0 to 21845

Platforms

7705 SAR Gen 2

keepalive

Syntax

keepalive *timeout factor*

no keepalive

configure router ldp interface-parameters ipv6 keepalive

configure router ldp targeted-session ipv6 keepalive

configure router ldp targeted-session ipv4 keepalive

configure router ldp interface-parameters ipv4 keepalive

Description

This command configures the time interval (in s), that LDP waits before tearing down the session. The **factor** parameter derives the keepalive interval.

If no LDP messages are exchanged for the configured time interval, the LDP session is torn down. Keepalive timeout is usually three times the keepalive interval. To maintain the session permanently, regardless of the activity, set the value to zero.

When LDP session is being set up, the keepalive timeout is negotiated to the lower of the two peers. Once an operational value is agreed upon, the keepalive factor is used to derive the value of the keepalive interval.

The **no** form of the command at the interface-parameters and targeted-session levels sets the **keepalive timeout** and the **keepalive factor** to the default value.

The **no** form of this command, at the interface level, sets the **keepalive timeout** and the **keepalive factor** to the value defined under the **interface-parameters** level.

The **no** form of this command, at the peer level, sets the **keepalive timeout** and the **keepalive factor** to the value defined under the **targeted-session** level.

The session must be flapped for the new settings to operate.

Default

Table 45: Timeout Factor Defaults lists the default values.

Table 45: Timeout Factor Defaults

Context	Timeout	Factor
config>router>ldp>if-params	30	3
config>router>ldp>targ-session	40	4
config>router>ldp>if-params>if	Inherits values from interface-parameters context.	
config>router>ldp>targ-session>peer	Inherits values from targeted-session context.	

Parameters

timeout

Configures the time interval, in seconds, that LDP waits before tearing down the session.

Values 1 to 65535

factor

Specifies the number of keepalive messages, expressed as a decimal integer, that should be sent on an idle LDP session in the keepalive timeout interval.

Values 1 to 255

Platforms

7705 SAR Gen 2

keepalive

Syntax

[**no**] **keepalive**

Context

[Tree] (debug>router>ldp>peer>packet keepalive)

Full Context

debug router ldp peer packet keepalive

Description

This command enables debugging for LDP Keepalive packets.

The **no** form of the command disables the debugging output.

Platforms

7705 SAR Gen 2

keepalive

Syntax

keepalive *seconds*

no keepalive

Context

[Tree] (config>router>pcep>pcc keepalive)

Full Context

configure router pcep pcc keepalive

Description

This command configures the PCEP session keep-alive value. A PCEP speaker (PCC or PCE) must send a keep-alive message if no other PCEP message is sent to the peer at the expiry of this timer. This timer is restarted every time a PCEP message or keep-alive message is sent.

The keep-alive mechanism is asymmetric, meaning that each peer can use a different keep-alive timer value at its end.

The **no** form of the command returns the keep-alive timer to the default value.

Default

keepalive 30

Parameters

seconds

the keep-alive value, in seconds

Values 1 to 255

Platforms

7705 SAR Gen 2

keepalive

Syntax

keepalive *seconds*

no keepalive

Context

[Tree] (config>router>bgp>group keepalive)

[Tree] (config>router>bgp>group>neighbor keepalive)

[Tree] (config>router>bgp keepalive)

Full Context

configure router bgp group keepalive

configure router bgp group neighbor keepalive

configure router bgp keepalive

Description

This command configures the BGP keepalive timer. A keepalive message is sent every time this timer expires.

The **keepalive** parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). The most specific value is used.

The **keepalive** value is generally one-third of the **hold-time** interval. Even though the implementation allows the **keepalive** value and the **hold-time** interval to be independently set, under the following circumstances, the configured **keepalive** value is overridden by the **hold-time** value:

- If the specified **keepalive** value is greater than the configured **hold-time**, then the specified value is ignored and the **keepalive** is set to one third of the current **hold-time** value.
- If the specified **hold-time** interval is less than the configured **keepalive** value, then the **keepalive** value is reset to one third of the specified **hold-time** interval.
- If the **hold-time** interval is set to zero, then the configured value of the **keepalive** value is ignored. This means that the connection with the peer is up permanently and no **keepalive** packets are sent to the peer.

The **no** form of this command used at the global level reverts to the default value.

The **no** form of this command used at the group level reverts to the value defined at the global level.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Default

keepalive 30

Parameters

seconds

Specifies the keepalive timer, in seconds, expressed as a decimal integer.

Values 0 to 21845

Platforms

7705 SAR Gen 2

keepalive

Syntax

keepalive [**neighbor** *ip-addr* | **group** *name*]

no keepalive

Context

[Tree] (debug>router>bgp keepalive)

Full Context

debug router bgp keepalive

Description

This command decodes and logs all sent and received keepalive messages in the debug log.

The **no** form of this command disables the debugging.

Parameters

neighbor *ip-address*

Debugs only events affecting the specified BGP neighbor.

Values ipv4-address:

- a.b.c.d (host bits must be 0)

ipv6-address:

- x:x:x:x:x:x:x:x [-interface] (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d [-interface]
- x: [0 to FFFF]H
- d: [0 to 255]D
- interface: up to 32 characters for link local addresses

group *name*

Debugs only events affecting the specified peer group name, up to 64 characters, and associated neighbors.

7705 SAR Gen 2

15.7 kernel

kernel

Syntax

kernel -password *password*

no kernel

Context

[Tree] (environment kernel)

Full Context

environment kernel

Description

This command allows Nokia technical support to access the **kernel** commands. **kernel** commands are used only by Nokia technical support for troubleshooting.

The **no** form of this command disables the **kernel** commands.

Parameters

password

Specifies the password to access the **kernel** commands, up to 256 characters.

Platforms

7705 SAR Gen 2

15.8 kex

kex

Syntax

kex *index* **name** *kex-name*

no kex *index*

Context

[Tree] (config>system>security>ssh>server-kex-list kex)

[Tree] (config>system>security>ssh>client-kex-list kex)

Full Context

configure system security ssh server-kex-list kex

configure system security ssh client-kex-list kex

Description

This command configures phase 1 SSH v2 KEX algorithms for SR OS as an SSH server or an SSH client. By default, the client and server lists are empty. If the user configures this list, SSH uses the hard-coded list with the first-listed algorithm having the highest priority and so on. An empty server or client list is the default list and contains the following algorithms:

ecdh-sha2-nistp512

ecdh-sha2-nistp384

ecdh-sha2-nistp256

diffie-hellman-group16-sha512

diffie-hellman-group14-sha256

diffie-hellman-group14-sha1

diffie-hellman-group-exchange-sha1

diffie-hellman-group1-sha1

The **no** form of this command removes the specified KEX index. If all KEX indexes are removed, the default list is used again.

Parameters

index

Specifies the index of the algorithm in the list. The lowest index in the list is negotiated first on the SSH negotiation list, while the highest index is at the bottom of the SSH negotiation list.

Values 1 to 255

kex-name

Specifies the KEX algorithm for computing the shared secret key.

Values diffie-hellman-group16-sha512, diffie-hellman-group14-sha256, diffie-hellman-group14-sha1, diffie-hellman-group-exchange-sha1, diffie-hellman-group1-sha1

15.9 key

key

Syntax

key *key-file-name*

Context

[Tree] (config>system>security>pki>cert-auto-upd>cert key)

Full Context

configure system security pki certificate-auto-update cert key

Description

This command configures the filename of the key corresponding to the certificate.

Parameters

key-file-name

Specifies the filename of the key.

Platforms

7705 SAR Gen 2

key

Syntax

key *key-filename*

no key

Context

[Tree] (config>ipsec>cert-profile>entry key)

Full Context

configure ipsec cert-profile entry key

Description

This command specifies the filename of an imported key for the **cert-profile entry**.

The **no** form of this command removes the key filename from the entry configuration.

Default

no key

Parameters

key-filename

Specifies the filename of an imported key.

Platforms

7705 SAR Gen 2

key

Syntax

key *password* [**hash** | **hash2** | **custom**] **reference** *reference-number*

no key reference *reference-number*

Context

[Tree] (config>system>security>pki>ca-profile>cmpv2>key-list key)

Full Context

configure system security pki ca-profile cmpv2 key-list key

Description

This command specifies a pre-shared key used for CMPv2 initial registration. Multiples of key commands are allowed to be configured under this context.

The password and reference-number is distributed by the CA via out-of-band means.

The configured password is stored in configuration file in an encrypted form by using SR OS hash2 algorithm.

The **no** form of this command removes the parameters from the configuration.

Parameters

password

Specifies a printable ASCII string, up to 64 characters.

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

custom

Specifies the custom encryption to management interface.

reference *reference-number*

Specifies a printable ASCII string, up to 64 characters in length.

Platforms

7705 SAR Gen 2

key

Syntax

key *key-filename*

no key

Context

[Tree] (config>system>security>tls>cert-profile>entry key)

Full Context

configure system security tls cert-profile entry key

Description

This command specifies the file name of an imported key for the **cert-profile** entry.

The **no** form of the command removes the key.

Default

no key

Parameters

key-filename

Specifies the file name of the key.

Platforms

7705 SAR Gen 2

15.10 key-generation

key-generation

Syntax

key-generation dsa size *bits*

key-generation ecdsa curve *curve*

key-generation rsa size *bits*

key-generation same-as-existing-key

Context

[Tree] (config>system>security>pki>cert-upd-prof key-generation)

Full Context

configure system security pki certificate-update-profile key-generation

Description

This command configures the key generation algorithm and behavior.

Default

key-generation same-as-existing-key

Parameters

bits

Specifies the size in bits..

Values 512 to 8192

Default 2048

curve

Specifies the elliptic curve for key generation.

Values secp256r1, secp384r1, secp521r1

Default secp256r1

same-as-existing-key
Specifies to use the same algorithm and key or size curve as the existing key.

Platforms
7705 SAR Gen 2

configure router ospf3 area key-rollover-interval

Description

This command configures the key rollover interval.

Default

key-rollover-interval 10

Parameters

seconds

Specifies the time, in seconds, after which a key rollover will start.

Values 10 to 300

Platforms

7705 SAR Gen 2

15.14 key-update

key-update

Syntax

key-update ca *ca-profile-name* **newkey** *key-filename* **oldkey** *key-filename* **oldcert** *cert-filename* [**hash-alg** *hash-algorithm*] **save-as** *save-path-of-result-cert*

Context

[Tree] (admin>certificate>cmpv2 key-update)

Full Context

admin certificate cmpv2 key-update

Description

This command requests a new certificate from the CA to update an existing certificate due to reasons such as **key refresh** or **replacing compromised key**.

In some cases, the CA may not return certificate immediately, due to reasons such as request processing need manual intervention. In such cases, the admin certificate cmpv2 poll command can be used to poll the status of the request.

Parameters

ca-profile-name

Specifies a ca-profile name which includes CMP server information, up to 32 characters.

newkey ***key-filename***

Specifies the key file of the requesting certificate, up to 95 characters.

oldkey ***key-filename***

Specifies the key to be replaced, up to 95 characters.

cert-filename

Specifies the file name of an imported certificate to be replaced, up to 95 characters.

hash-algorithm

Specifies the hash algorithm for RSA key.

Values md5,sha1,sha224,sha256,sha384,sha512

save-path-of-result-cert

Specifies the save full path name of saving the result certificate, up to 200 characters.

Platforms

7705 SAR Gen 2

15.15 key-value

key-value

Syntax

key-value *public-key-value*

no key-value

Context

[Tree] (config>system>security>user>public-keys>rsa>rsa-key key-value)

[Tree] (config>system>security>user>public-keys>ecdsa>ecdsa-key key-value)

Full Context

configure system security user public-keys rsa rsa-key key-value

configure system security user public-keys ecdsa ecdsa-key key-value

Description

This command configures a value for the RSA or ECDSA public key. The public key must be enclosed in quotation marks. For RSA, the key is between 768 and 4096 bits. For ECDSA, the key is between 1 and 1024 bits.

Default

no key-value

Parameters

public-key-value

Specifies the public key value, up to 800 characters for RSA and up to 255 characters for ECDSA.

Platforms

7705 SAR Gen 2

15.16 keychain

keychain

Syntax

[**no**] **keychain** *keychain-name*

Context

[Tree] (config>system>security keychain)

Full Context

configure system security keychain

Description

This command enables the context to configure keychain parameters. A keychain must be configured on the system before it can be applied to a session.

The **no** form of this command removes the keychain nodal context and everything under it from the configuration. If the keychain to be removed is in use when the no keychain command is entered, the command will not be accepted and an error indicating that the keychain is in use will be printed.

Parameters

keychain-name

Specifies a keychain name which identifies this particular keychain entry.

Values An ASCII string up to 32 characters.

Platforms
7705 SAR Gen 2

15.17 keygroup-name

keygroup-name

Syntax
keygroup-name *keygroup-name*
no keygroup-name

Context
[Tree] (config>grp-encryp>encryp-keygrp keygroup-name)

Full Context
configure group-encryption encryption-keygroup keygroup-name

Description
This command is used to name the key group. The key group name can be used to reference a key group when configuring services or displaying information.

The **no** form of the command reverts to the default value.

Parameters
keygroup-name
The name of the key group, up to 64 characters.

Platforms
7705 SAR Gen 2

15.18 kill-session

kill-session

Syntax
[**no**] **kill-session**

Context

[Tree] (configure>system>security>profile>netconf>base-op-authorization kill-session)

Full Context

configure system security profile netconf base-op-authorization kill-session

Description

This command authorizes a user associated with the profile to send a NETCONF <kill-session> RPC. This kill session operation allows a NETCONF client to kill another NETCONF session, but not the session in which the operation is requested.

The **no** form of the command denies the user from requesting a kill-session.

Default

no kill-session

Platforms

7705 SAR Gen 2

Full Context

configure service template vpls-sap-template l2pt-termination

configure service vpls spoke-sdp l2pt-termination

configure service vpls sap l2pt-termination

Description

This command enables Layer 2 Protocol Tunneling (L2PT) termination on a specified SAP or spoke-SDP. L2PT termination is supported only for STP BPDUs. PDUs of other protocols are discarded.

This feature can be enabled only if STP is disabled in the context of the specified VPLS service.

The **no** form of this command reverts to the default.

Default

no l2pt-termination

Parameters

cdp

Specifies the Cisco discovery protocol

dtp

Specifies the dynamic trunking protocol

pagp

Specifies the port aggregation protocol

stp

Specifies all spanning tree protocols: stp, rstp, mstp, pvst (default)

udld

Specifies unidirectional link detection

vtp

Specifies the virtual trunk protocol

Platforms

7705 SAR Gen 2

l2pt-termination

Syntax

no l2pt-termination

Context

[Tree] (config>service>pw-template l2pt-termination)

Full Context

configure service pw-template l2pt-termination

Description

This command enables Layer 2 Protocol Tunneling (L2PT) termination on a given SAP or spoke SDP. L2PT termination will be supported only for STP BPDUs. PDUs of other protocols will be discarded.

This feature can be enabled only if STP is disabled in the context of the given VPLS service.

Default

no l2pt-termination

Parameters

cdp

Specifies the Cisco discovery protocol.

dtp

Specifies the dynamic trunking protocol.

pagp

Specifies the port aggregation protocol.

stp

Specifies all spanning tree protocols: stp, rstp, mstp, pvst (default).

udld

Specifies unidirectional link detection.

vtp

Specifies the virtual trunk protocol.

Description

This command configures a Layer 3 multi-chassis ring.

The **no** form of this command reverts to the default.

Platforms

7705 SAR Gen 2

16.4 l4-load-balancing

l4-load-balancing

Syntax

[**no**] **l4-load-balancing**

Context

[Tree] (config>system>load-balancing l4-load-balancing)

Full Context

configure system load-balancing l4-load-balancing

Description

This command configures system-wide Layer 4 load balancing. The configuration at the system level can enable or disable load balancing based on Layer 4 fields. If enabled, the Layer 4 source and destination port fields will be included in hashing calculation for TCP/UDP packets.

The hashing algorithm addresses finer spraying granularity where many hosts are connected to the network.

To address more efficient traffic distribution between network links (forming a LAG group), a hashing algorithm extension takes into account L4 information (that is, src/dst L4-protocol port).

The hashing index can be calculated according to the following algorithm:

Example:

```
– If [(TCP or UDP traffic) & enabled]
    – hash (TCP/UDP ports, IP addresses)
– else if (IP traffic)
    – hash (IP addresses)
– else
    – hash (MAC addresses)
– endif
```

This algorithm will be used in all cases where IP information in per-packet hashing is included (refer to "Traffic Load Balancing Options" in the *7705 SAR Gen 2 Interface Configuration Guide*). However, the Layer 4 information (TCP/UDP ports) will not be used for fragmented packets.

Default

no l4-load-balancing

Platforms

7705 SAR Gen 2

16.5 l4-src-port

l4-src-port

Syntax

l4-src-port *port* [*mask*]

no l4-src-port

Context

[Tree] (config>system>security>mgmt-access-filter>ipv6-filter>entry l4-src-port)

[Tree] (config>system>security>mgmt-access-filter>ip-filter>entry l4-src-port)

Full Context

configure system security management-access-filter ipv6-filter entry l4-src-port

configure system security management-access-filter ip-filter entry l4-src-port

Description

This command configures a destination TCP or UDP port number or port range for a management access filter match criterion.

The **no** form of this command reverts to the default values.

Default

no l4-src-port

Parameters

port

Specifies the destination TCP or UDP port number as a match criterion.

Values 1 to 65535

Default 6 (exact match)

mask

Specifies the mask used to select a range of source port numbers. Table 46: Format Styles to Configure Mask lists the format styles to configure the 16-bit mask.

Table 46: Format Styles to Configure Mask

Format Style	Format Syntax	Example
Decimal	DDDDD	63488
Hexadecimal	0xHHHH	0xF800
Binary	0bBBBBBBBBBBBBBBB	0b1111100000000000

To select a range from 1024 up to 2047, specify 1024 and 0xFC00 for port and mask, respectively.

Values 1 to 65535 (decimal)

Default 65535 (exact match)

7705 SAR Gen 2

16.7 label-allocation

label-allocation

Syntax

label-allocation

Context

[Tree] (config>router>bgp label-allocation)

Full Context

configure router bgp label-allocation

Description

This commands enables the context to configure the allocation of MPLS labels to specific BGP routes.

Platforms

7705 SAR Gen 2

16.8 label-ipv4

label-ipv4

Syntax

label-ipv4 *max-paths* [**ebgp** *ebgp-max-paths*] [**ibgp** *ibgp-max-paths*] [**restrict** {**same-neighbor-as** | **exact-as-path**}] [**unequal-cost**]

no label-ipv4

Context

[Tree] (config>service>vprn>bgp>multi-path label-ipv4)

Full Context

configure service vprn bgp multi-path label-ipv4

Description

This command sets ECMP multipath parameters that apply only to the label unicast IPv4 address family.

When multipath is enabled, traffic to the destination is load-shared across a set of paths (BGP routes) that the BGP decision process considers equal to the best path. The distribution of traffic over the multiple paths may or may not be equal. The distribution is based on weights derived from the Link Bandwidth Extended Community.

For more information about the criteria a non-best route must meet to qualify as a multipath, see "BGP route installation in the route table" in the *7705 SAR Gen 2 Unicast Routing Protocols Guide*.

The **no** form of this command removes label-IPv4-specific overrides.

Default

no label-ipv4

Parameters

max-paths

Specifies the maximum number of multipaths per prefix or NLRI. Setting this value to 1 disables multipath. This limit only applies if neither the *ebgp-max-paths* limit nor the *ibgp-max-paths* limit apply.

Values 1 to 64

ebgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an EBGP learned route. If the **ebgp** option is configured, this value overrides the *max-paths* limit. If the best path is an EBGP learned route and this value is set to 1, multipath is disabled.

Values 1 to 64

ibgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an IBGP learned route. If the **ibgp** option is configured, this value overrides the *max-paths* limit. If the best path is an IBGP learned route and this value is set to 1, multipath is disabled.

Values 1 to 64

restrict same-neighbor-as

Specifies that the non-best path must have the same neighbor AS in its AS path as the best path.

restrict exact-as-path-as

Specifies that the non-best path must have the same AS path as the best path.

unequal-cost

Instructs BGP to ignore differences in the next-hop cost only when determining eligible multipaths.

label-ipv4 send *send-limit*

label-ipv4 send *send-limit* **receive** [**none**]

no label-ipv4

Context

[Tree] (config>router>bgp>add-paths label-ipv4)

[Tree] (config>router>bgp>group>add-paths label-ipv4)

[Tree] (config>router>bgp>group>neighbor>add-paths label-ipv4)

Full Context

configure router bgp add-paths label-ipv4

configure router bgp group add-paths label-ipv4

configure router bgp group neighbor add-paths label-ipv4

Description

This command configures the add-paths capability for labeled-unicast IPv4 routes. By default, add-paths is not enabled for labeled-unicast IPv4 routes.

The maximum number of labeled-unicast paths per IPv4 prefix to send is the configured *send-limit*, which is a mandatory parameter. The capability to receive multiple labeled-unicast paths per prefix from a peer is configurable using the **receive** keyword, which is optional. If the **receive** keyword is not included in the command, receive capability is enabled by default.

The **no** form of this command disables add-paths support for labeled-unicast IPv4 routes, causing sessions established using add-paths for labeled-unicast IPv4 to go down and come back up without the add-paths capability.

Default

no label-ipv4

Parameters

send-limit

Specifies the maximum number of paths per labeled-unicast IPv4 prefix that are allowed to be advertised to add-paths peers. (The actual number of advertised routes may be

less.) If the value is none, the router does not negotiate the send capability with respect to label-IPv4 AFI/SAFI. If the value is **multipaths**, then BGP advertises all the used BGP multipaths for each IPv4 NLRI if the peer has signaled support to receive multiple add paths.

Values 1 to 16, none, multipaths

receive

Specifies the router negotiates to receive multiple labeled-unicast routes per IPv4 prefix.

none

Specifies that the router does not negotiate to receive multiple labeled-unicast routes per IPv4 prefix.

Platforms

7705 SAR Gen 2

label-ipv4

Syntax

label-ipv4 *max-paths* [**ebgp** *ebgp-max-paths*] [**ibgp** *ibgp-max-paths*] [**restrict** {**same-neighbor-as** | **exact-as-path**}] [**unequal-cost**]

no label-ipv4

Context

[Tree] (config>router>bgp>multi-path label-ipv4)

Full Context

configure router bgp multi-path label-ipv4

Description

This command sets ECMP multipath parameters that apply only to the label IPv4 unicast address family. These settings override the values set by the **maximum-paths** command.

When multipath is enabled, traffic to the destination is load-shared across a set of paths (BGP routes) that the BGP decision process considers equal to the best path. The actual distribution of traffic over the multiple paths may be equal or unequal (that is, based on weights derived from the Link Bandwidth Extended Community).

The **no** form of this command removes label-IPv4-specific overrides.

Default

no label-ipv4

Parameters

max-paths

Specifies the maximum number of multipaths per prefix/NLRI if *ebgp-max-paths* or *ibgp-max-paths* does not apply.

Values 1 to 64

ebgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an EBGP learned route.

Values 1 to 64

ibgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an IBGP learned route.

Values 1 to 64

restrict same-neighbor-as

Specifies that the non-best path must have the same neighbor AS in its AS path as the best path.

restrict exact-as-path

Specifies that the non-best path must have the same AS path as the best path.

unequal-cost

Instructs BGP to ignore differences in the next-hop cost only when determining eligible multipaths.

Platforms

7705 SAR Gen 2

16.9 label-ipv6

label-ipv6

Syntax

label-ipv6 *max-paths* [**ebgp** *ebgp-max-paths*] [**ibgp** *ibgp-max-paths*] [**restrict** {**same-neighbor-as** | **exact-as-path**}] [**unequal-cost**]

no label-ipv6

Context

[Tree] (config>service>vprn>bgp>multi-path label-ipv6)

Full Context

configure service vprn bgp multi-path label-ipv6

Description

This command sets ECMP multipath parameters that apply only to the label unicast IPv6 address family.

When multipath is enabled, traffic to the destination is load-shared across a set of paths (BGP routes) that the BGP decision process considers equal to the best path. The distribution of traffic over the multiple paths may or may not be equal. The distribution is based on weights derived from the Link Bandwidth Extended Community.

For more information about the criteria a non-best route must meet to qualify as a multipath, see "BGP route installation in the route table" in the *7705 SAR Gen 2 Unicast Routing Protocols Guide*.

The **no** form of this command removes label-IPv6-specific overrides.

Default

no label-ipv6

Parameters

max-paths

Specifies the maximum number of multipaths per prefix or NLRI. Setting this value to 1 disables multipath. This limit only applies if neither the *ebgp-max-paths* limit nor the *ibgp-max-paths* limit apply.

Values 1 to 64

ebgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an EBGP learned route. If the **ebgp** option is configured, this value overrides the *max-paths* limit. If the best path is an EBGP learned route and this value is set to 1, multipath is disabled.

Values 1 to 64

ibgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an IBGP learned route. If the **ibgp** option is configured, this value overrides the *max-paths* limit. If the best path is an IBGP learned route and this value is set to 1, multipath is disabled.

Values 1 to 64

restrict same-neighbor-as

Specifies that the non-best path must have the same neighbor AS in its AS path as the best path.

restrict exact-as-path-as

Specifies that the non-best path must have the same AS path as the best path.

unequal-cost

Instructs BGP to ignore differences in the next-hop cost only when determining eligible multipaths.

Full Context

configure router bgp group neighbor add-paths label-ipv6

configure router bgp group add-paths label-ipv6

configure router bgp add-paths label-ipv6

Description

This command configures the add-paths capability for labeled-unicast IPv6 routes. By default, add-paths is not enabled for labeled-unicast IPv6 routes.

The maximum number of labeled-unicast paths per IPv6 prefix to send is the configured *send-limit*, which is a mandatory parameter. The capability to receive multiple labeled-unicast paths per prefix from a peer is configurable using the **receive** keyword, which is optional. If the **receive** keyword is not included in the command, receive capability is enabled by default.

The **no** form of this command disables add-paths support for labeled-unicast IPv6 routes, causing sessions established using add-paths for labeled-unicast IPv6 to go down and come back up without the add-paths capability.

Default

no label-ipv6

Parameters

send-limit

Specifies the maximum number of paths per labeled-unicast IPv6 prefix that are allowed to be advertised to add-paths peers. (The actual number of advertised routes may be

less.) If the value is none, the router does not negotiate the send capability with respect to label-IPv6 AFI/SAFI. If the value is **multipaths**, then BGP advertises all the used BGP multipaths for each IPv6 NLRI if the peer has signaled support to receive multiple add paths.

Values 1 to 16, none, multipaths

receive

Specifies that the router negotiates to receive multiple labeled-unicast routes per IPv6 prefix.

none

Specifies that the router does not negotiate to receive multiple labeled-unicast routes per IPv6 prefix.

16.10 label-ipv6-explicit-null

label-ipv6-explicit-null

Syntax

[**no**] **label-ipv6-explicit-null**

Context

[Tree] (config>router>bgp>next-hop-res>lbl-routes>use-bgp-routes label-ipv6-explicit-null)

Full Context

configure router bgp next-hop-resolution labeled-routes use-bgp-routes label-ipv6-explicit-null

Description

This command allows a labelled IPv6 route with the explicit-null label to be resolved by other labelled IPv6 routes with the explicit-null label, and also by unlabeled IPv4 routes and unlabeled IPv6 routes that are resolved by static routes, interface routes, or tunnels. Up to four levels of recursive resolution are supported when the top route is a labelled IPv6 route with an explicit-null label.

Regardless of setting, a labelled IPv6 route with a regular label (other than explicit-null) is never resolved by other labelled IPv6 routes.

The **no** form of this command disables the label-ipv6-explicit-null functionality. When disabled, a labeled IPv6 route cannot be resolved by other labeled IPv6 routes.

Default

no label-ipv6-explicit-null

Platforms

7705 SAR Gen 2

16.11 label-map

label-map

Syntax

[**no**] **label-map** *in-label*

Context

[Tree] (config>router>mpls>interface label-map)

Full Context

configure router mpls interface label-map

Description

This command is used on transit routers when a static LSP is defined. The static LSP on the ingress router is initiated using the **config router mpls static-lsp** *lsp-name* command. An *in-label* can be associated with either a **pop** or a **swap** action, but not both. If both actions are specified, the last action specified takes effect.

The **no** form of this command deletes the static LSP configuration associated with the *in-label*.

Parameters

in-label

Specifies the incoming MPLS label on which to match.

Values 32 to 1023

Platforms

7705 SAR Gen 2

16.12 label-mode

label-mode

Syntax

label-mode {**vrf** | **next-hop**}

no label-mode

Context

[Tree] (config>service>vprn label-mode)

Full Context

configure service vprn label-mode

Description

This command controls the method by which service labels are allocated to routes exported by the VPRN as BGP-VPN routes. The **vrf** option selects service label per VRF mode while the **next-hop** option selects service label per next-hop mode.

The **no** form of this command sets the mode to the default mode of service label per VRF.

Default

no label-mode

Parameters

vrf

Selects service label per VRF mode.

next-hop

Selects service label per next-hop mode.

Full Context

configure service vprn bgp label-preference

configure service vprn bgp group label-preference

configure service vprn bgp group neighbor label-preference

Description

This command configures the route preference for routes learned from labeled-unicast peers.

This command can be configured at three levels:

- Global level — applies to all peers
- Group level — applies to all peers in the peer-group
- Neighbor level — applies only to the specified peer

The most specific value is used.

The lower the preference, the higher the chance of the route being the active route.

The **no** form of this command used at the global level reverts to the default *value* of 170.

The **no** form of this command used at the group level reverts to the *value* defined at the global level.

The **no** form of this command used at the neighbor level reverts to the *value* defined at the group level.

Default

no label-preference

Parameters

value

Specifies the route preference value.

Values 1 to 255

Platforms

7705 SAR Gen 2

7705 SAR Gen 2

16.14 label-route-local

label-route-local

Syntax

label-route-local [{**none** | **all**}]

Context

[Tree] (config>router>ttl-propagate label-route-local)

Full Context

configure router ttl-propagate label-route-local

Description

This command configures the TTL propagation for locally generated packets which are forwarded over a BGP label route in the Global Routing Table (GRT) context.

For IPv4 and IPv6 packets forwarded using an RFC 8277 label route in the global routing instance, including 6PE, the **all** value of the command enables TTL propagation from the IP header into all labels in the transport label stack. The none value reverts to the default mode which disables TTL propagation from the IP header to the labels in the transport label stack. This command does not have a no version.

The TTL of the IP packet is always propagated into the RFC 8277 label itself, and this command only controls the propagation into the transport labels, for example, labels of the RSVP or LDP LSP to which the BGP label route resolves and which are pushed on top of the BGP label.

If the BGP peer advertised the implicit-null label value for the BGP label route, the TTL propagation will not follow the configuration described, but will follow the configuration to which the BGP label route resolves:

RSVP LSP shortcut:

- configure router mpls shortcut-local-ttl-propagate

LDP LSP shortcut:

- configure router ldp shortcut-local-ttl-propagate

This feature does not impact packets forwarded over BGP shortcuts. The ingress LER operates in uniform mode by default and can be changed into pipe mode using the configuration of TTL propagation for RSVP or LDP LSP shortcut listed.

Default

label-route-local none

Parameters

none

Specifies that the TTL of the IP packet is not propagated into the transport label stack.

all

Specifies that the TTL of the IP packet is propagated into all labels of the transport label stack.

Platforms

7705 SAR Gen 2

16.15 label-route-transit

label-route-transit

Syntax

label-route-transit [{**none** | **all**}]

Context

[Tree] (config>router>ttl-propagate label-route-transit)

Full Context

configure router ttl-propagate label-route-transit

Description

This command configures the TTL propagation for transit packets which are forwarded over a BGP label route in the Global Routing Table (GRT) context.

For IPv4 and IPv6 packets forwarded using a RFC 8277 label route in the global routing instance, including 6PE, the **all** value of the command enables TTL propagation from the IP header into all labels in the transport label stack. The none value reverts to the default mode which disables TTL propagation from the IP header to the labels in the transport label stack. This command does not have a no version.

The TTL of the IP packet is always propagated into the RFC 8277 label itself, and this command only controls the propagation into the transport labels, for example, labels of the RSVP or LDP LSP to which the BGP label route resolves and which are pushed on top of the BGP label.

If the BGP peer advertised the implicit-null label value for the BGP label route, the TTL propagation will not follow the configuration described, but will follow the configuration to which the BGP label route resolves.

RSVP LSP shortcut:

- configure router mpls shortcut-transit-ttl-propagate

LDP LSP shortcut:

- configure router ldp shortcut-transit-ttl-propagate

This feature does not impact packets forwarded over BGP shortcuts. The ingress LER operates in uniform mode by default and can be changed into pipe mode using the configuration of TTL propagation for the listed RSVP or LDP LSP shortcut.

Default

label-route-transit none

Parameters

none

Specifies that the TTL of the IP packet is not propagated into the transport label stack.

all

Specifies that the TTL of the IP packet is propagated into all labels of the transport label stack.

7705 SAR Gen 2

16.16 label-stack-reduction

label-stack-reduction

Syntax

[**no**] **label-stack-reduction**

Context

[Tree] (config>router>mpls>lsp-template label-stack-reduction)

[Tree] (config>router>mpls>lsp label-stack-reduction)

Full Context

configure router mpls lsp-template label-stack-reduction

configure router mpls lsp label-stack-reduction

Description

This command enables the label stack size reduction for a SR-TE LSP or SR-TE LSP template.

At a high level, the label stack reduction algorithm attempts to replace a segment of a computed SR-TE LSP path with the farthest node SID on that path that results in using ECMP paths with links which still comply to the TE constraints of the LSP path.

The **no** form of this command returns the command to its default value.

Default

no label-stack-reduction

Platforms

7705 SAR Gen 2

16.17 label-withdrawal-delay

label-withdrawal-delay

Syntax

label-withdrawal-delay *seconds*

no label-withdrawal-delay

Context

[Tree] (config>router>ldp label-withdrawal-delay)

Full Context

configure router ldp label-withdrawal-delay

Description

This command specifies configures the time interval (in s), LDP will delay for the withdrawal of FEC-label binding it distributed to its neighbors when FEC is de-activated. When the timer expires, LDP then sends a label withdrawal for the FEC to all its neighbors. This is applicable only to LDP IPv4 prefix FECs and is not applicable to pseudowires (service FECs).

When there is an upper layer (user of LDP) which depends on LDP control plane for failover detection then label withdrawal delay and tunnel-down-damp-time options must be set to 0.

An example is PW redundancy where the primary PW doesn’t have its own fast failover detection mechanism and the node depends on LDP tunnel down event to activate the standby PW.

Default

no label-withdrawal-delay

Parameters

seconds

Specifies the time that LDP delays the withdrawal of FEC-label binding it distributed to its neighbors when FEC is de-activated.

Values 3 to 120

Platforms

7705 SAR Gen 2

16.18 labeled-routes

labeled-routes

16.19 lacp

lacp

Syntax

lacp [**mode**] [**administrative-key** *admin-key*] [**system-id** *system-id*] [**system-priority** *priority*]

no lacp

Context

[Tree] (config>lag lacp)

Full Context

configure lag lacp

Description

This command enables the LACP protocol. Per the IEEE 802.1ax standard, the Link Aggregation Control Protocol (LACP) provides a standardized means for exchanging information between Partner Systems on a link to allow their Link Aggregation Control instances to reach agreement on the identity of the Link Aggregation Group to which the link belongs, move the link to that Link Aggregation Group, and enable its transmission and reception functions in an orderly manner.

If any of the parameters are omitted, the existing configuration is preserved. The default parameter values are used if a parameter is never explicitly configured.

Default

no lacp

Parameters

mode

Specifies the mode in which LACP will operate.

Values **passive** — Starts transmitting LACP packets only after receiving packets.

active — Initiates the transmission of LACP packets.

admin-key

Specifies an administrative key value to identify the channel group on each port configured to use LACP. A random key is assigned by default if a value is not specified when using classic CLI only.

Values 1 to 65535

system-id

Specifies the 48-bit system ID in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff, where aa, bb, cc, dd, ee and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.

Values 1 to 65535

Default 32768

priority

Specifies the system priority.

Values 0 to 65535

Default 32768

Platforms

7705 SAR Gen 2

16.20 lacp-fallback

lacp-fallback

Syntax

lacp-fallback mode {**static**} [**timeout** *timeout*]

no lacp-fallback

Context

[Tree] (config>lag lacp-fallback)

Full Context

configure lag lacp-fallback

Description

This command configures the LACP fallback mode. LACP fallback allows one or more designated links of an LACP-controlled LAG to go into forwarding mode if LACP is not yet operational after a configured timeout period. Links capable of forwarding traffic assume the Ethernet and IP characteristics configured for the LAG.

Note: In the saved configuration file, the **lacp-xmit-interval** command must precede the **lacp-fallback** command. As well, to change the **lacp-xmit-interval** from **fast** to **slow**, the **lacp-fallback** command must first be changed to a **timeout** value of 90.

The **no** form of this command disables LACP fallback.

Default

no lacp-fallback

Parameters

mode

Keyword to specify the LACP fallback mode.

Values **static** — Keyword to specify that if LACP is not operational after the timeout period, a single designated LAG member goes into forwarding mode.

individual — The individual mode is not supported.

timeout

Specifies the timeout period in seconds. The LACP link becomes active if no LACP PDUs are received within this timeout period.

Note: Timeout range depends on the configuration of the **configure lag lacp-xmit-limit** command.

Values	fast: 4 to 3600 slow: 90 to 3600
Default	fast: 4

Platforms

7705 SAR Gen 2

16.21 lacp-mux-control

lacp-mux-control

Syntax

lacp-mux-control {**coupled** | **independent**}

no lacp-mux-control

[Tree] (config>lag lacp-mux-control)

Full Context

configure lag lacp-mux-control

Description

This command configures the type of multiplexing machine control to be used in a LAG with LACP in active/passive modes.

The **no** form of this command disables multiplexing machine control.

Default

lacp-mux-control coupled

Parameters

coupled

Specifies that TX and RX activate together.

independent

Specifies that RX activates independent of TX.

Platforms

7705 SAR Gen 2

16.22 lacp-system-priority

lacp-system-priority

Syntax

lacp-system-priority *lacp-system-priority*

no lacp-system-priority

Context

[Tree] (config>system lacp-system-priority)

Full Context

configure system lacp-system-priority

Description

This command configures the Link Aggregation Control Protocol (LACP) system priority on aggregated Ethernet interfaces. LACP allows the operator to aggregate multiple physical interfaces to form one logical interface.

Default

lacp-system-priority 32768

Parameters

lacp-system-priority

Specifies the LACP system priority.

Values 1 to 65535

Platforms

7705 SAR Gen 2

16.23 lacp-tunnel

lacp-tunnel

Syntax

[**no**] **lacp-tunnel**

Context

[Tree] (config>port>ethernet lacp-tunnel)

Full Context

configure port ethernet lacp-tunnel

Description

This command enables LACP packet tunneling for the Ethernet port. When tunneling is enabled, the port does not process any LACP packets but tunnels them instead. The port cannot be added as a member to a LAG group.

In this context, the **lacp-tunnel** command is supported for Epipe and VPLS services only.

The **no** form of this command disables LACP packet tunneling for the Ethernet port.

Default

no lacp-tunnel

Platforms

7705 SAR Gen 2

16.24 lacp-xmit-interval

lacp-xmit-interval

Syntax

lacp-xmit-interval {**slow** | **fast**}

no lacp-xmit-interval

Context

[Tree] (config>lag lacp-xmit-interval)

Full Context

configure lag lacp-xmit-interval

Description

This command specifies the interval signaled to the peer and tells the peer at which rate it should transmit.

Default

lacp-xmit-interval fast

Parameters

slow

Transmits packets every 30 seconds.

fast

Transmits packets every second.

Platforms

7705 SAR Gen 2

16.25 lacp-xmit-stdby

lacp-xmit-stdby

Syntax

[**no**] **lacp-xmit-stdby**

Context

[Tree] (config>lag lacp-xmit-stdby)

Full Context

configure lag lacp-xmit-stdby

Description

This command enables LACP message transmission on standby links.

The **no** form of this command disables LACP message transmission. This command should be disabled for compatibility when using active/standby groups. This forces a timeout of the standby links by the peer. Use the **no** form if the peer does not implement the correct behavior regarding the lacp sync bit.

Default

lacp-xmit-stdby

Platforms

7705 SAR Gen 2

no lag *lag-id*

Context

[Tree] (config>redundancy>multi-chassis>peer>mc-lag lag)

Full Context

configure redundancy multi-chassis peer mc-lag lag

Description

This command defines a LAG which is forming a redundant-pair for MC-LAG with a LAG configured on the given peer. The same LAG group can be defined only in the scope of 1 peer. In order MC-LAG to become operational, all parameters (**lacp-key**, **system-id**, **system-priority**) must be configured the same on both nodes of the same redundant pair.

The partner system (the system connected to all links forming MC-LAG) will consider all ports using the same **lacp-key**, **system-id**, **system-priority** as the part of the same LAG. In order to achieve this in MC operation, both redundant-pair nodes have to be configured with the same values. In case of the mismatch, MC-LAG is kept in oper-down status.

Note that the correct CLI command to enable MC LAG for a LAG in **standby-signaling power-off mode** is **lag** *lag-id* [**remote-lag** *remote-lag-id*]. In the CLI help output, the first three forms are used to enable MC LAG for a LAG in LACP mode. MC LAG is disabled (regardless of the mode) for a given LAG with **no lag** *lag-id.*

Parameters

lag-id

The LAG identifier, expressed as an integer. Specifying the *lag-id* allows the mismatch between lag-id on redundant-pair. If no **lag-id** is specified it is assumed that neighbor system uses the same *lag-id* as a part of the specific MC-LAG. If no matching MC-LAG group can be found between neighbor systems, the individual LAGs operates as usual (no MC-LAG operation is established).

Values 1 to 800

admin-key

Specifies a 16 bit key that needs to be configured in the same manner on both sides of the MC-LAG in order for the MC-LAG to come up.

Values 1 to 65535

system-id

Specifies a 6 byte value expressed in the same notation as MAC address.

Values xx:xx:xx:xx:xx:xx - xx [00 to FF]

remote-lag-id

Specifies the LAG ID on the remote system.

Values 1 to 800

system-priority

Specifies the system priority to be used in the context of the MC-LAG. The partner system will consider all ports using the same **lacp-key**, **system-id**, and **system-priority** as part of the same LAG.

Values 1 to 65535

MAC-Lsb

Configures the last 16 bit of the MAC address to be used for all traffic ingressing the MC-LAG link(s) or if use-lacp-key option is used, it will only copy the value of lacp-key (redundancy multi-chassis mc-lag lag lacp-key admin-key). The command will fail if the *value* is the same with any of the following configured attributes:

- Source-bmac-lsb assigned to other MC-LAG ports.
- lsb 16 bits value for the source-bmac configured at chassis or BVPLS level

  The first 32 bits will be copied from the source B-MAC of the BVPLS associated with the IVPLS for a specific IVPLS SAP mapped to the MC-LAG. The BVPLS source B-MAC can be provisioned for each BVPLS or can be inherited from the chassis PBB configuration.

  Values 1 to 65535 or xx-xx or xx:xx

Platforms

7705 SAR Gen 2

lag

Syntax

lag *lag-id* [**name** *lag-name*]

no lag *lag-id*

Context

[Tree] (config lag)

Full Context

configure lag

Description

Commands in this context configure Link Aggregation Group (LAG) attributes.

A LAG is used to group multiple ports into one logical link. The aggregation of multiple physical links allows for load sharing and offers seamless redundancy. If one link fails, traffic is redistributed over the remaining links.

Note:
For all ports in a LAG group, autonegotiation must be set to "limited" or "off".

There are three possible settings for autonegotiation, as follows:

- "on" or enabled with full port capabilities advertised
- "off" or disabled where there is no autonegotiation advertisements
- "limited" where a single speed/duplex is advertised.

When autonegotiation is enabled on a port, the link attempts to automatically negotiate the link speed and duplex parameters; the configured duplex and speed parameters are ignored.

When autonegotiation is disabled on a port, the port does not attempt to autonegotiate and will only operate at the **speed** and **duplex** settings configured for the port.

Note:
Disabling autonegotiation on gigabit ports is not allowed. This is in accordance with the IEEE 802.3 specification for gigabit Ethernet, which requires gigabyte to be enabled for far end fault indication.

If the **config**>**port**>**ethernet autonegotiate limited** keyword option is specified, the port will autonegotiate but only advertise the **speed** and **duplex** settings configured for the port. Use the **limited** mode on multi-speed gigabit ports to force gigabit operation while keeping autonegotiation is enabled for compliance with IEEE 801.3.

The system requires autonegotiation to be disabled or limited for ports in a LAG to guarantee a specific port speed.

The **no** form of this command deletes the LAG from the configuration. A LAG can only be deleted while the LAG is administratively shut down. Any dependencies, such as IP-Interface configurations, must be removed from the configuration before the **no lag** command is issued.

Parameters

lag-id

Specifies the LAG identifier, expressed as an integer.

The LAG ID ranging from 1 to 64 supports up to 64 LAG members and LAG ID above 64 supports 32 LAG members.

Values 1 to 200

lag-name

Specifies an optional LAG name, up to 27 characters.

In model-driven interfaces, the LAG name is used for configuration references and **show** commands. A service provider or administrator can use the defined LAG name to identify and manage LAGs within the SR OS platforms.

In the classic CLI interface, the user must assign a LAG ID to create the LAG. The LAG name is optional and, if specified, must always start with "lag-". If a name is not specified, SR OS automatically assigns a string version of the LAG ID as "lag-<lag-id>".

Values lag-<23 chars max>

debug lag

Description

This command enables debugging for LAG.

Parameters

lag-id

Specifies the link aggregation group ID.

Values 1 to 200

port-id

Specifies the physical port ID.

Values *slot*/*mda*/*port*

all

Specifies to display all LAG information.

sm

Specifies to display trace LACP state machine.

pkt

Specifies to display trace LACP packets.

cfg

Specifies to display trace LAG configuration.

red

Specifies to display trace LAG high availability.

iom-upd

Specifies to display trace LAG IOM updates.

port-state

Specifies to display trace LAG port state transitions.

timers

Specifies to display trace LAG timers.

sel-logic

Specifies to display trace LACP selection logic.

mc

Specifies to display multi-chassis parameters.

mc-packet

Specifies to display the MC-LAG control packets with valid authentication were received on this system.

16.27 lag-port-down

lag-port-down

Syntax

[**no**] **lag-port-down** *lag-id*

Context

[Tree] (config>vrrp>policy>priority-event lag-port-down)

Full Context

configure vrrp policy priority-event lag-port-down

Description

This command creates the context to configure Link Aggregation Group (LAG) priority control events that monitor the operational state of the links in the LAG.

The **lag-port-down** command configures a priority control event. The event monitors the operational state of each port in the specified LAG. When one or more of the ports enter the operational down state, the event is considered to be set. When all the ports enter the operational up state, the event is considered to be clear. As ports enter the operational up state, any previous set threshold that represents more down ports is considered cleared, while the event is considered to be set.

Multiple unique **lag-port-down** event nodes can be configured within the **priority-event** node up to the maximum of 32 events.

The **lag-port-down** command can reference an arbitrary LAG. The *lag-id* does have to already exist within the system. The operational state of the **lag-port-down** event will indicate:

- Set – non-existent
- Set – one port down
- Set – two ports down

- Set – three ports down
- Set – four ports down
- Set – five ports down
- Set – six ports down
- Set – seven ports down
- Set – eight ports down
- Cleared – all ports up

When the *lag-id* is created, or a port in *lag-id* becomes operationally up or down, the event operational state must be updated appropriately.

When one or more of the LAG composite ports enters the operationally down state or the *lag-id* is deleted or does not exist, the event is considered to be set. When an event transitions from clear to set, the set is processed immediately and must be reflected in the associated virtual router instances in-use priority value. As the event transitions from clear to set, a hold-set timer is loaded with the value configured by the events **hold-set** command. This timer prevents the event from clearing until it expires, damping the effect of event flapping. If the event clears and becomes set again before the hold-set timer expires, the timer is reset to the **hold-set** value, extending the time before another clear can take effect.

The **lag-port-down** event is considered to have a tiered event set state. While the priority impact per number of ports down is totally configurable, as more ports go down, the effect on the associated virtual router instances in-use priority is expected to increase (lowering the priority). When each configured threshold is crossed, any higher thresholds are considered further event sets and are processed immediately with the hold-set timer reset to the configured value of the **hold-set** command. As the thresholds are crossed in the opposite direction (fewer ports down then previously), the priority effect of the event is not processed until the hold-set timer expires. If the number of ports down threshold again increases before the hold-set timer expires, the timer is only reset to the **hold-set** value if the number of ports down is equal to or greater than the threshold that set the timer.

The event contains **number-down** nodes that define the priority delta or explicit value to be used based on the number of LAG composite ports that are in the operationally down state. These nodes represent the event set thresholds. Not all port down thresholds must be configured. As the number of down ports increase, the **number-down** *ports-down* node that expresses a value equal to or less than the number of down ports describes the delta or explicit priority value to be applied.

The **no** form of the command deletes the specific LAG monitoring event. The event can be removed at anytime. When the event is removed, the in-use priority of all associated virtual router instances must be reevaluated. The events **hold-set** timer has no effect on the removal procedure.

Default

no lag-port-down — No LAG priority control events are created.

Parameters

lag-id

The LAG ID that the specific event is to monitor expressed as a decimal integer. The *lag-id* can only be monitored by a single event in this policy. The LAG may be monitored by multiple VRRP priority control policies. A port within the LAG and the LAG ID itself are considered to be separate entities. A composite port may be monitored with the **port-down** event while the *lag-id* the port is in is monitored by a **lag-port-down** event in the same policy.

configure service vpls spoke-sdp mld-snooping last-member-query-interval

configure service vpls sap mld-snooping last-member-query-interval

configure service vpls mesh-sdp igmp-snooping last-member-query-interval

Description

This command configures the maximum response time used in group-specific queries sent in response to 'leave' messages, and is also the amount of time between two consecutive group-specific queries. This value may be tuned to modify the leave latency of the network. A reduced value results in reduced time to detect the loss of the last member of a group.

The configured **last-member-query-interval** is ignored when fast leave is enabled on the SAP or SDP.

The **no** form of this command reverts to the default value.

Default

last-member-query-interval 10

Parameters

tenths-of-seconds

Specifies the frequency, in tenths of a second, at which query messages are sent.

Values 1 to 50

Platforms

7705 SAR Gen 2

16.29 latency-event

latency-event

Syntax

latency-event rising-threshold *threshold* [**falling-threshold** *threshold*] [*direction*]

no latency-event

Context

[Tree] (config>saa>test latency-event)

Full Context

configure saa test latency-event

Description

Specifies that at the termination of an SAA test probe, the calculated latency event value is evaluated against the configured rising and falling latency event thresholds. SAA threshold events are generated as required.

Once the threshold (rising/falling) is crossed, it is disabled from generating additional events until the opposite threshold is crossed. If a **falling-threshold** is not supplied, the **rising- threshold** is re-enabled when it falls below the threshold after the initial crossing that generated the event.

The configuration of latency event thresholds is optional.

The **no** form of this command disables the latency event.

Parameters

rising-threshold *threshold*

Specifies a rising threshold latency value, in milliseconds. When the test run is completed, the calculated latency value is compared to the configured latency rising threshold. If the test run latency value is greater than the configured rising threshold value then an SAA threshold event is generated. The SAA threshold event is tmnxOamSaaThreshold, logger application OAM, event #2101.

Values 0 to 2147483

Default 0

falling-threshold *threshold*

Specifies a falling threshold latency value, in milliseconds. When the test run is completed, the calculated latency value is compared to the configured latency falling threshold. If the test run latency value is greater than the configured falling threshold value then an SAA threshold event is generated. The SAA threshold event is tmnxOamSaaThreshold, logger application OAM, event #2101.

Values 0 to 2147483

Default 0

direction

Specifies the direction for OAM ping responses received for an OAM ping test run.

Values **inbound** — Monitor the value of jitter calculated for the inbound, one-way, OAM ping responses received for an OAM ping test run.

outbound — Monitor the value of jitter calculated for the outbound, one-way, OAM ping requests sent for an OAM ping test run.

roundtrip — Monitor the value of jitter calculated for the round trip, two-way, OAM ping requests and replies for an OAM ping test run.

Default roundtrip

Context

[Tree] (config>service>sdp ldp)

Full Context

configure service sdp ldp

Description

This command enables LDP-signaled LSPs on MPLS-encapsulated SDPs.

In MPLS SDP configurations *either* one or more LSP names can be specified *or* LDP can be enabled. The SDP **ldp** and **lsp** commands are mutually exclusive except if the mixed-lsp-mode option is also enabled. If an LSP is specified on an MPLS SDP, then LDP cannot be enabled on the SDP. To enable LDP on the SDP when an LSP is already specified, the LSP must be removed from the configuration using the **no lsp** *lsp-name* command or the mixed-lsp-mode option is also enabled.

Alternatively, if LDP is already enabled on an MPLS SDP, then an LSP cannot be specified on the SDP. To specify an LSP on the SDP, the LDP must be disabled. The LSP must have already been created in the **config>router>mpls** context with a valid far-end IP address. The above rules are relaxed when the **mixed-lsp** option is enabled on the SDP.

Default

no ldp (disabled)

[Tree] (config>router>mpls>lsp-template ldp-over-rsvp)

Full Context

configure router mpls lsp ldp-over-rsvp

configure router mpls lsp-template ldp-over-rsvp

Description

This command configures an LSP so that it can be used by the IGP to calculate its SPF tree.

When the **ldp-over-rsvp** option is also enabled in ISIS or OSPF, the IGP provides LDP with all ECMP IP next-hops and tunnel endpoints that it considers to be the lowest cost path to its destination.

IGP provides only the endpoints which are the closest to the destination in terms of IGP cost for each IP next-hop of a prefix. If this results in more endpoints than the ECMP value configured on the router, it will further prune the endpoints based on the lowest router-id and for the same router-id, it will select lowest interface-index first.

LDP then looks up the tunnel table to select the actual tunnels to the endpoint provided by IGP and further limits the endpoint selection to the ones which are the closest to destination across all the IP next-hops provided by IGP for a prefix. For each remaining endpoint, LDP selects a tunnel in a round-robin fashion until the router ECMP value is reached. For each endpoint, only tunnels with the same lowest metric are candidates. If more than one tunnel qualifies, the selection begins with the lowest tunnel-id.

16.34 ldp-shortcut

ldp-shortcut

Syntax

[**no**] **ldp-shortcut**

Context

[Tree] (config>router ldp-shortcut)

Full Context

configure router ldp-shortcut

Description

This command enables the resolution of IGP routes using LDP LSP across all network interfaces participating in the IS-IS and OSPF routing protocol in the system.

When LDP shortcut is enabled, LDP populates the routing table with next-hop entries corresponding to all prefixes for which it activated an LDP FEC. For a given prefix, two route entries are populated in the system routing table. One corresponds to the LDP shortcut next-hop and has an owner of LDP. The other one is the regular IP next-hop. The LDP shortcut next-hop always has preference over the regular IP next-

hop for forwarding user packets and specified control packets over a given outgoing interface to the route next-hop.

All user and specified control packets for which the longest prefix match in RTM yields the FEC prefix will be forwarded over the LDP LSP.

When an IPv4 packet is received on an ingress network interface, a subscriber IES interface, or a regular IES interface, the lookup of the packet by the ingress forwarding engine will result in the packet being sent labeled with the label stack corresponding to the NHLFE of the LDP LSP when the preferred RTM entry corresponds to an LDP shortcut.

If the preferred RTM entry corresponds to an IP next-hop, the IPv4 packet is forwarded without a label.

When ECMP is enabled and multiple equal-cost next-hops exit for the IGP route, the ingress forwarding engine will spray the packets for this route based on hashing routine currently supported for IPv4 packets. When the preferred RTM entry corresponds to an LDP shortcut route, spraying will be performed across the multiple next-hops for the LDP FEC. The FEC next-hops can either be direct link LDP neighbors or T-LDP neighbors reachable over RSVP LSPs in the case of LDP-over-RSVP but not both.

When the preferred RTM entry corresponds to a regular IP route, spraying will be performed across regular IP next-hops for the prefix.

The **no** form of this command disables the resolution of IGP routes using LDP shortcuts.

Default

no ldp-shortcut

7705 SAR Gen 2

16.35 ldp-sync

ldp-sync

Syntax

[**no**] **ldp-sync**

Context

[Tree] (config>router>static-route-entry>next-hop ldp-sync)

Full Context

configure router static-route-entry next-hop ldp-sync

Description

This command extends the LDP synchronization feature to a static route. When an interface comes back up, it is possible that a preferred static route using the interface as next-hop for a given prefix is enabled before the LDP adjacency to the peer LSR comes up on this interface. In this case, traffic on an SDP that

uses the static route for the far-end address would be black-holed until the LDP session comes up and the FECs exchanged.

This option when enabled delays the activation of the static route until the LDP session comes up over the interface and the ldp-sync-timer configured on that interface has expired

Default

no ldp-sync

Platforms

7705 SAR Gen 2

16.36 ldp-sync-timer

ldp-sync-timer

Syntax

ldp-sync-timer *seconds* [**end-of-lib**]

no ldp-sync-timer

Context

[Tree] (config>router>if ldp-sync-timer)

Full Context

configure router interface ldp-sync-timer

Description

This command enables synchronization of an IGP and LDP. When a link is restored after a failure, the IGP sets the link cost to infinity and advertises it. The actual value advertised in OSPF is 0xFFFF (65535). The actual value advertised in IS-IS regular metric is 0x3F (63) and in IS-IS wide-metric is 0xFFFFFE (16777214). This feature is not supported on RIP interfaces.

If an interface belongs to both IS-IS and OSPF, a physical failure will cause both IGPs to advertise an infinite metric and to follow the IGP-LDP synchronization procedures. If only one IGP bounces on this interface or on the system, then only the affected IGP advertises the infinite metric and follows the IGP-LDP synchronization procedures.

Next, an LDP Hello adjacency is brought up with the neighbor. The LDP synchronization timer is started by the IGP when the LDP session to the neighbor is up over the interface. This is to allow time for the label-FEC bindings to be exchanged.

When the LDP synchronization timer expires, the link cost is restored and is readvertised. The IGP will announce a new best next hop and LDP will use it if the label binding for the neighbor’s FEC is available.

If the user changes the cost of an interface, the new value is advertised at the next flooding of link attributes by the IGP. However, if the LDP synchronization timer is still running, the new cost value will only

be advertised after the timer expires. The new cost value will also be advertised after the user executes any of the following commands:

- **tools>perform>router>isis>ldp-sync-exit**
- **tools>perform>router>ospf>ldp-sync-exit**
- **config>router>if>no ldp-sync-timer**
- **config>router>ospf>disable-ldp-sync**
- **router>isis>disable-ldp-sync**

If the user changes the value of the LDP synchronization timer parameter, the new value will take effect at the next synchronization event. If the timer is still running, it will continue to use the previous value.

If parallel links exist to the same neighbor, then the bindings and services should remain up as long as there is one interface that is up. However, the user-configured LDP synchronization timer still applies on the interface that failed and was restored. In this case, the router will only consider this interface for forwarding after the IGP re-advertises its actual cost value.

The LDP Sync Timer State is not always synchronized across to the standby CPM. Therefore, after an activity switch, the timer state might not be same as it was on the previously active CPM.

If the **end-of-lib** option is configured, then the system will start the LDP synchronization timer as usual. If the LDP End of LIB Typed Wildcard FEC messages are received for every FEC type negotiated for a given session to an LDP peer for that IGP interface, the **ldp-sync-timer** is terminated early and the IGP link cost is restored. If the **ldp-sync-timer** expires before the LDP End of LIB messages are received for every negotiated FEC type, then the system will restore the IGP link cost. The **end-of-lib** option is disabled by default.

The **no** form of this command disables IGP-LDP synchronization and deletes the configuration.

Default

no ldp-sync-timer

Parameters

seconds

Specifies the time interval for the IGP-LDP synchronization timer.

Values 1 to 1800

end-of-lib

Specifies that the system should terminate the **ldp-sync-timer** early if the LDP End of LIB Typed Wildcard FEC messages are received for every FEC type negotiated for a given session to an LDP peer for that IGP interface.

16.40 leak-export

leak-export

Syntax

leak-export *plcy-or-long-expr* [*plcy-or-expr* [*plcy-or-expr*]]

no leak-export

Context

[Tree] (config>router leak-export)

Full Context

configure router leak-export

Description

This command associates up to four policies to control the leaking of GRT routes into the associated VPRN.

If a route is evaluated and the action is accepted, that route is subject leaking into an associated VPRN instance, assuming the route is fully resolved and active.

This process creates the pool of routes that can be leaked. Within each VPRN, a corresponding **import-grt** policy must be configured to import select routes into that specific VPRN instance.

The **no** form of this command removes all route leaking policy associations and effectively disables the leaking of GRT routes into associated VPRNs.

Parameters

plcy-or-long-expr

Specifies the route policy name, up to 64 characters or a policy logical expression, up to 255 characters.

Values *plcy-or-long-expr*: *policy-name* | *long-expr*

policy-name: up to 64 characters

long-expr: up to 255 characters

plcy-or-expr

Specifies the route policy name, up to 64 characters or a policy logical expression, up to 64 characters long. A maximum of four policy names or policy logical expressions can be specified in a single statement.

Values *plcy-or-expr*: *policy-name* | expr

policy-name: up to 64 characters

expr: up to 64 characters

Platforms

[Tree] (config>service>vprn>bgp>rib-management>label-ipv4 leak-import)

[Tree] (config>service>vprn>bgp>rib-management>ipv6 leak-import)

Full Context

configure service vprn bgp rib-management ipv4 leak-import

configure service vprn bgp rib-management label-ipv6 leak-import

configure service vprn bgp rib-management label-ipv4 leak-import

configure service vprn bgp rib-management ipv6 leak-import

Description

This command configures route policies that control the importation of leak-eligible routes from the BGP RIB of another routing instance into the unlabeled-IPv4, unlabeled-IPv6, labeled-IPv4, or labeled-IPv6 RIB of the VPRN instance. To leak a route from one routing instance to another, the origin and destination RIB types must be the same; for example, it is not possible to leak a route from an unlabeled-IPv4 RIB of a VPRN into the labeled-IPv4 RIB of the base router.

The **leak-import** command can reference up to 15 objects, where each object is either a policy logical expression or the name of a single policy. The objects are evaluated in the specified order to determine the final action to accept or reject the route.

Only one of the 15 objects referenced by the **leak-import** command can be a policy logical expression consisting of policy names (enclosed in square brackets) and logical operators (AND, OR, NOT). The first of the 15 objects has a maximum length of 255 characters while the remaining 14 objects have a maximum length of 64 characters each.

When a **leak-import** policy is not specified, no BGP routes from other routing instances are leaked into the VPRN BGP RIB.

The **no** form of this command removes the policy association.

Default

no leak-import

Parameters

plcy-or-long-expr

Specifies the route policy name (up to 64 characters) or a policy logical expression (up to 255 characters). Allowed values are any string of characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

plcy-or-expr

Specifies the route policy name (up to 64 characters) or a policy logical expression (up to 255 characters). Allowed values are any string of characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

16.46 lease-populate

lease-populate

Syntax

lease-populate [*nbr-of-leases*]

lease-populate [*nbr-of-leases*] **l2-header** [**mac** *ieee-address*]

no lease-populate

Context

[Tree] (config>service>vprn>if>dhcp lease-populate)

[Tree] (config>service>vpls>sap>dhcp lease-populate)

[Tree] (config>service>ies>if>dhcp lease-populate)

Full Context

configure service vprn interface dhcp lease-populate

configure service vpls sap dhcp lease-populate

configure service ies interface dhcp lease-populate

Description

Commands in this context configure IPoE host parameters.

For VPLS, DHCP snooping must be explicitly enabled (using the **snoop** command) at all points where DHCP messages requiring snooping enter the VPLS instance (both from the DHCP server and from the subscribers). Lease state information is extracted from snooped DHCP ACK messages to populate lease state table entries for the SAP.

The optional *nbr-of-leases* parameter defines the number lease state table entries allowed.

- for this SAP in case of a VPLS service
- for this interface in case of an IES or VPRN interface
- for each SAP in case of an IES or VPRN group-interface
- for this interface in case of an IES or VPRN retail subscriber-interface

If the *nbr-of-leases* parameter is omitted, only a single entry is allowed. Once the maximum number of entries has been reached, subsequent lease state entries are not allowed and subsequent DHCP ACK messages are discarded.

The retained lease state information representing dynamic hosts may be used to:

- Populate a SAP based anti-spoof filter table to provide dynamic anti-spoof filtering. If the system is unable to populate the dynamic host information in the anti-spoof filter table on the SAP, the DHCP ACK message must be discarded without adding new lease state entry or updating an existing lease state entry.

- Populate the system's ARP cache based on the arp-populate configuration. Applicable to IES and VPRN interfaces or group-interfaces.
- Populate managed entries into a VPLS forwarding database. VPLS forwarding database population is an implicit feature that automatically places the dynamic host's MAC address into the VPLS FDB. When a dynamic host's MAC address is placed in the lease state table, it will automatically be populated into the VPLS forwarding database associated with the SAP on which the host is learned. The dynamic host MAC address will override any static MAC entries using the same MAC and prevent dynamic learning of the MAC on another interface. Existing static MAC entries with the same MAC address as the dynamic host are marked as inactive but not deleted. If all entries in the lease state table associated with the MAC address are removed, the static MAC may be populated. New static MAC definitions for the VPLS instance may be created while a dynamic host exists associated with the static MAC address.
- Generate dynamic ARP replies if **arp-reply-agent** is enabled. Applicable to VPLS service SAPs

The **no** form of this command reverts to the default.

Parameters

nbr-of-leases

Specifies the number of DHCPv4 leases allowed.

l2-header

Indicates a mode of operation where anti-spoof entry associated with the given DHCP state is created based on the *src-mac* address from the Layer 2 header of the DHCP request message. The Layer 2 header flag is not set by default. This parameter is only applicable for group interfaces.

mac

Specifies that the provisioned *ieee-address* is used in the anti-spoofing entries for this SAP. The parameter may be changed mid-session. Existing sessions will not be re-programmed unless a **tools>perform>subscriber-mgmt>remap-lease-state** command is issued for the lease. This parameter is only applicable for group interfaces.

no lease-populate

Context

[Tree] (config>service>ies>if>ipv6>dhcp6-relay lease-populate)

Full Context

configure service ies interface ipv6 dhcp6-relay lease-populate

Description

This command specifies the maximum number of DHCPv6 lease states allocated by the DHCPv6 relay function, allowed on this interface.

Optionally, by specifying **route-populate** parameter, system could:

- Create routes based on the IA_PD/IA_NA/IA_TA prefix option in relay-reply message.
- Create black hole routes based on OPTION_PD_EXCLUDE in IA_PD in relay-reply message.

These routes could be redistributed into IGP/BGP by using route-policy, following protocol types that could be used in "from protocol”:

- dhcpv6-pd
- dhcpv6-na
- dhcpv6-ta
- dhcpv6-pd-excl

Parameters

nbr-of-leases

Defines the number lease state table entries allowed for this interface. If this parameter is omitted, only a single entry is allowed. Once the maximum number of entries has been reached, subsequent lease state entries are not allowed and subsequent DHCPv6 REPLY messages are discarded.

Values 1 to 8000

route-populate

Specifies the route populate parameter.

Values pd/na/ta — Create route based on specified option.

exclude — Create blackhole route based on OPTION_PD_EXCLUDE.

Platforms

7705 SAR Gen 2

16.50 least-fill

least-fill

Syntax

[**no**] **least-fill**

Context

[Tree] (config>router>mpls>lsp-template least-fill)

[Tree] (config>router>mpls>lsp least-fill)

Full Context

configure router mpls lsp-template least-fill

configure router mpls lsp least-fill

Description

This command enables the use of the least-fill path selection method for the computation of the path of this LSP.

When MPLS requests the computation of a path for this LSP, CSPF will find all equal cost shortest paths which satisfy the constraints of this path. Then, CSPF identifies the single link in each of these paths which has the least available bandwidth as a percentage of its maximum reservable bandwidth. It then selects the path which has the largest value of this percentage least available bandwidth figure. CSPF identifies the least available bandwidth link in each equal cost path after it has accounted for the bandwidth of the new requested path of this LSP.

CSPF applies the least-fill path selection method to all requests for a path, primary and secondary, of an LSP for which this option is enabled. The bandwidth of the path can be any value, including zero.

CSPF applies the least-fill criterion separately to each preemption priority in the base TE. A higher setup priority path can preemptively lower holding priority paths.

CSPF also applies the least-fill criterion separately to each Diff-Serv TE class if Diff-Serv TE is enabled on this node. A higher setup priority path can preemptively lower holding priority paths within a Class Type.

MPLS will re-signal and move the LSP to the new path in the following cases:

- Initial LSP path signaling.
- Re-try of an LSP path after failure.
- Make-before-break (MBB) due to pending soft preemption of the LSP path.
- MBB due to LSP path configuration change, that is, a user change to bandwidth parameter of primary or secondary path, or a user enabling of fast-reroute option for the LSP.
- MBB of secondary path due to an update to primary path SRLG.
- MBB due to FRR Global Revertive procedures on the primary path.
- Manual re-signaling of an LSP path or of all LSP paths by the user.

During a manual re-signaling of an LSP path, MPLS will always re-signal the path regardless of whether the new path is exactly the same or different than the current path and regardless of whether the metric of the new path is different or not from that of the current path.

During a timer-based re-signaling of an LSP path which has the least-fill option enabled, MPLS will only re-signal the path if the metric of the new path is different than the one of the current path.

The **no** form of this command deletes a specific node entry in this database.

Default

no least-fill. The path of an LSP is randomly chosen among a set of equal cost paths.

Platforms

7705 SAR Gen 2

16.51 least-fill-min-thd

least-fill-min-thd

Syntax

least-fill-min-thd *percent*

no least-fill-min-thd

Context

[Tree] (config>router>mpls least-fill-min-thd)

Full Context

configure router mpls least-fill-min-thd

Description

This parameter is used in the least-fill path selection process. When comparing the percentage of least available link bandwidth across the sorted paths, whenever two percentages differ by less than the value

configured as the least-fill-min-thresh, CSPF will consider them equal and will apply a random number generator to select the path among these paths

The **no** form of this command resets this parameter to its default value.

Default

least-fill-min-thd 5

Parameters

percentage

Specifies the least fill minimum threshold value as a percentage.

Values 1 to 100%

Platforms

7705 SAR Gen 2

16.52 least-fill-reoptim-thd

least-fill-reoptim-thd

Syntax

least-fill-reoptim-thd *percent*

no least-fill-reoptim-thd

Context

[Tree] (config>router>mpls least-fill-reoptim-thd)

Full Context

configure router mpls least-fill-reoptim-thd

Description

This parameter is used in the least-fill path selection method. During a timer-based re-signaling of an LSP path which has the least-fill option enabled, CSPF will first update the least-available bandwidth figure for the current path of this LSP. It then applies the least-fill path selection method to select a new path for this LSP. If the new computed path has the same cost as the current path, it will compare the least-available bandwidth figures of the two paths and if the difference exceeds the user configured optimization threshold, MPLS will generate a trap to indicate that a better least-fill path is available for this LSP. This trap can be used by an external SNMP based device to trigger a manual re-signaling of the LSP path since the timer-based re-signaling will not re-signal the path in this case. MPLS will generate a path update trap at the first MBB event which results in the re-signaling of the LSP path. This should clear the eligibility status of the path at the SNMP device.

The **no** form of this command resets this parameter to its default value.

Default

least-fill-reoptim-thd 10

Parameters

percentage

Specifies the least fill reoptimization threshold value as a percentage.

Values 1 to 100%

Full Context

configure router ldp legacy-ipv4-lsr-interop

Description

This command provides for a global LDP knob to allow interoperability with legacy IPv4 LSR implementations which do not comply with the processing of Hello TLVs with the U-bit set. Specifically, this feature disables the following Hello TLVs:

- The Nokia proprietary Interface Info TLV (0x3E05) in the Hello message sent to the peer. This also results in the non-generation of the Nokia proprietary Hello Adjacency Status TLV (0x3E06) since the Interface Info TLV is not sent.

  This is performed in SR OS releases 12 and higher.

- The RFC 7552 standard dual-stack capability TLV (0x701) and the Nokia proprietary Adjacency capability TLV (0x3E07) in SR OS releases 13 and higher.

16.58 ler-use-dscp

ler-use-dscp

Syntax

[**no**] **ler-use-dscp**

Context

[Tree] (config>qos>network>ingress ler-use-dscp)

Full Context

configure qos network ingress ler-use-dscp

Description

This command is used to enable tunnel QoS mapping on all ingress network IP interfaces that the network-qos-policy-id is associated with. The command may be defined at any time after the network QoS policy has been created. Any network IP interfaces currently associated with the policy will immediately start to use the internal IP ToS field of any tunnel terminated IP routed packet received on the interface, ignoring any QoS markings in the tunnel portion of the packet.

This attribute provides the ability to ignore the network ingress QoS mapping of a terminated tunnel containing an IP packet that is to be routed to a base router or VPRN destination. This is advantageous when the mapping for the tunnel QoS marking does not accurately or completely reflect the required QoS handling for the IP routed packet. When the mechanism is enabled on an ingress network IP interface, the IP interface will ignore the tunnel's QoS mapping and derive the internal forwarding class and profile based

on the precedence or DiffServ Code Point (DSCP) values within the routed IP header ToS field compared to the Network QoS policy defined on the IP interface.

The default state is not to enforce tunnel termination IP routed QoS override within the network QoS policy.

The **no** form of this command removes tunnel termination IP routed QoS override from the network QoS policy and all ingress network IP interfaces associated with the policy.

Default

no ler-use-dscp

Platforms

16.59 less-specific

less-specific

Syntax

less-specific [**allow-default**]

no less-specific

Context

[Tree] (config>vrrp>policy>priority-event>route-unknown less-specific)

Full Context

configure vrrp policy priority-event route-unknown less-specific

Description

This command allows a CIDR shortest match hit on a route prefix that contains the IP route prefix associated with the route unknown priority event.

The **less-specific** command modifies the search parameters for the IP route prefix specified in the **route-unknown** priority event. Specifying **less-specific** allows a CIDR shortest match hit on a route prefix that contains the IP route prefix.

The **less-specific** command eases the RTM lookup criteria when searching for the *prefix/mask-length*. When the **route-unknown** priority event sends the prefix to the RTM (as if it was a destination lookup), the result route table prefix (if a result is found) is checked to see if it is an exact match or a less specific match. The **less-specific** command enables a less specific route table prefix to match the configured prefix. When **less-specific** is not specified, a less specific route table prefix fails to match the configured prefix. The **allow-default** optional parameter extends the **less-specific** match to include the default route (0.0.0.0).

The **no** form of the command prevents RTM lookup results that are less specific than the route prefix from matching.

Default

no less-specific — The route unknown priority events requires an exact prefix/mask match.

Parameters

allow-default

When the **allow-default** parameter is specified with the **less-specific** command, an RTM return of 0.0.0.0 matches the IP prefix. If **less-specific** is entered without the **allow-default** parameter, a return of 0.0.0.0 will not match the IP prefix. To disable **allow-default**, but continue to allow **less-specific** match operation, only enter the **less-specific** command (without the **allow-default** parameter).

7705 SAR Gen 2

16.60 level

level

Syntax

level *priority-level* **rate** *pir-rate* [**cir** *cir-rate*]

level *priority-level* **percent-rate** *pir-percent* [**percent-cir** *cir-percent*]

no level *priority-level*

Context

[Tree] (config>port>ethernet>egr-scheduler-override level)

Full Context

configure port ethernet egress-scheduler-override level

Description

This command overrides the maximum and CIR rate parameters for a specific priority level on the port or channel's port scheduler instance. When the **level** command is executed for a priority level, the corresponding priority level command in the port-scheduler-policy associated with the port is ignored.

The override level command supports the keyword **max** for the **rate** and **cir** parameter. When executing the level override command, at least the **rate** or **cir** keywords and associated parameters must be specified for the command to succeed.

The **no** form of this command removes the local port priority level rate overrides. Once removed, the port priority level will use the port scheduler policies level command for that priority level.

Parameters

priority-level

Identifies which of the eight port priority levels are being overridden.

Values 1 to 8

pir-rate

Overrides the port scheduler policy's maximum level rate and requires either the **max** keyword or a rate defined in kilobits per second to follow.

Values For Ethernet: 1 to 6400000000, **max**

For SONET-SDH and TDM: 1 to 3200000000, **max**

cir-rate

Overrides the port scheduler policy's within-cir level rate and requires either the max keyword or a rate defined in kilobits per second to follow.

Values For Ethernet: 1 to 6400000000, **max**

For SONET-SDH and TDM: 1 to 3200000000, **max**

pir-percent

Specifies the PIR as a percentage.

Values 0.01 to 100.00

cir-percent

Specifies the CIR as a percentage.

Values 0.00 to 100.00

max

removes any existing rate limit imposed by the port scheduler policy for the priority level allowing it to use as much total bandwidth as possible.

configure service vprn isis interface level

configure service vprn isis link-group level

configure service vprn isis level

Description

This command creates the context to configure IS-IS Level 1 or Level 2 area attributes.

A router can be configured as a Level 1, Level 2, or Level 1/2 system. A Level 1 adjacency can be established if there is at least one area address shared by this router and a neighbor. A Level 2 adjacency cannot be established over this interface.

Level 1/2 adjacency is created if the neighbor is also configured as Level 1/2 router and has at least one area address in common. A Level 2 adjacency is established if there are no common area IDs.

A Level 2 adjacency is established if another router is configured as Level 2 or a Level 1/2 router with interfaces configured as Level 1/2 or Level 2. Level 1 adjacencies are not established over this interface.

To reset global and/or interface level parameters to the default, the following commands must be entered independently:

- **level>no hello-authentication-key**
- **level>no hello-authentication-type**
- **level>no hello-interval**
- **level>no hello-multiplier**
- **level>no metric**
- **level>no passive**
- **level>no priority**

Default

level 1 or level 2

Parameters

level-number

The IS-IS level number.

Values 1, 2

Platforms

no level *priority-level*

Context

[Tree] (config>qos>port-scheduler-policy level)

Full Context

configure qos port-scheduler-policy level

Description

This command configures an explicit within-CIR bandwidth limit and a total bandwidth limit for each port scheduler's priority level. To understand how to set the level rate and CIR parameters, a basic understanding of the port-level scheduler bandwidth allocation mechanism is required. The port scheduler takes all available bandwidth for the port or channel (after the max-rate and any port egress-rate limits have been accounted for) and offers it to each of the eight priority levels twice.

The first pass is called the within-CIR pass and consists of providing the available port bandwidth to each of the 8 priority levels, starting with level 8 and moving down to level 1. Each level takes the offered load and distributes it to all child members that have a port-parent cir-level equal to the current priority level. (Any child with a cir-weight equal to 0 is skipped in this pass.) Each child may consume bandwidth up to the child's frame-based within-CIR offered load. The remaining available port bandwidth is then offered to the next lower priority level until level 1 is reached.

The second pass is called the above-CIR pass and consists of providing the remaining available port bandwidth to each of the eight priority levels a second time. Again, each level takes the offered load and distributes it to all child members that have a port-parent level equal to the current priority level. Each child may consume bandwidth up to the remainder of the child's frame-based offered load (some of the offered load may have been serviced during the within-CIR pass). The remaining available port bandwidth is then offered to the next priority level until level 1 is again reached.

If the port scheduling policy is using the default orphan behavior (orphan-override has not been configured on the policy), the system then takes any remaining port bandwidth and allocates it to the orphan queues and scheduler on priority level 1. In a non-override orphan state, all orphans are attached to priority level 1 using a weight of 0. The zero weight value causes the system to allocate bandwidth equally to all orphans based on each orphan queue or scheduler's ability to use the bandwidth. If the policy has an orphan-override configured, the orphans are handled based on the override commands parameters in a similar fashion to properly parented queues and schedulers.

The port scheduler priority level command rate keyword is used to optionally limit the total amount of bandwidth that is allocated to a priority level (total for the within-CIR and above-CIR passes). The cir keyword optionally limits the first pass bandwidth allocated to the priority level during the within-CIR pass.

When executing the level command, at least one of the optional keywords, **rate** or **cir,** must be specified. If neither keyword is included, the command will fail.

If a previous explicit value for rate or cir exists when the level command is executed, and either rate or cir is omitted, the previous value for the parameter is overwritten by the default value and the previous value is lost.

The configured priority level rate limits may be overridden at the egress port or channel using the egress-scheduler-override level priority-level command. When a scheduler instance has an override defined for a priority level, both the rate and cir values are overridden even when one of them is not explicitly expressed in the override command. For instance, if the cir kilobits per second portion of the override is not expressed, the scheduler instance defaults to not having a CIR rate limit for the priority level even when the port scheduler policy has an explicit CIR limit defined.

The **no** form of this command returns the level to its default value.

Default

no level priority-level

Parameters

priority-level

Specifies to which priority level the level command pertains. Each of the eight levels is represented by an integer value of 1 to 8, with 8 being the highest priority level.

Values 1 to 8 (8 is the highest priority)

pir-rate

Specifies the total bandwidth limits allocated to priority-level, in kilobits per second.

Values 1 to 6400000000, **max**

pir-percent

Specifies the percent bandwidth limits allocated to priority-level.

Values 0.01 to 100.00

cir-rate

The cir specified limits the total bandwidth allocated in the within-CIR distribution pass to priority-level. When cir is not specified, all the available port or channel bandwidth may be allocated to the specified priority level during the within-CIR pass.

Values 0 to 6400000000, **max**

The value given for kilobits per second is expressed in kilobits per second on a base 10 scale as is usual for line rate calculations. If a value of 1 is given, the result is 1000 bits per second (as opposed to a base 2 interpretation that would be 1024 bits per second).

cir-percent

Specifies the percent bandwidth limits allocated to priority-level.

Values 0.00 to 100.00

group ***name***

specifies the existing group that the weighted scheduler group this level maps to, up to 32 characters.

weight

Specifies the weight of the level within this weighted scheduler group.

Values 1 to 100

Default 1

monitor-threshold ***percent***

Specifies the percent of the configured rate. If the offered rate exceeds the configured threshold, a counter monitoring the threshold will be increased.

Values 0 to 100

no lfa-policy-map

Context

[Tree] (config>service>vprn>isis>if lfa-policy-map)

Full Context

configure service vprn isis interface lfa-policy-map

Description

This command applies a route next-hop policy template to the IS-IS interface for the VPRN instance.

When a route next-hop policy template is applied to an interface in IS-IS, it is applied in both level 1 and level 2. When a route next-hop policy template is applied to an interface in OSPF, it is applied in all areas. However, the command in an OSPF interface context can only be executed under the area in which the specified interface is primary and then applied in that area and in all other areas where the interface is secondary. If the user attempts to apply it to an area where the interface is secondary, the command fails.

If the user excluded the interface from LFA using the command **loopfree-alternate-exclude**, the LFA policy, if applied to the interface, has no effect.

Finally, if the user applied a route next-hop policy template to a loopback interface or to the system interface, the command will not be rejected, but it will result in no action being taken.

The **no** form deletes the mapping of a route next-hop policy template to an OSPF or IS-IS interface.

Parameters

template-name

Specifies the name of the template, up to 32 characters.

Platforms

7705 SAR Gen 2

16.65 lifetime

lifetime

Syntax

lifetime {*seconds* | **forever**}

Context

[Tree] (config>system>script-control>script-policy lifetime)

Full Context

configure system script-control script-policy lifetime

Description

This command is used to configure the maximum amount of time that a script may run.

Default

lifetime 3600

Parameters

seconds

Specifies the maximum amount of time that a script may run, in seconds.

Values 0 to 21474836

Default 3600 (1 hour)

forever

Specifies to allow a script to run indefinitely.

Platforms

7705 SAR Gen 2

16.66 limit-init-exchange

limit-init-exchange

Syntax

limit-init-exchange [**reduced-max-exchange-timeout** *seconds*]

no limit-init-exchange

Context

[Tree] (config>ipsec>ike-policy limit-init-exchange)

Full Context

configure ipsec ike-policy limit-init-exchange

Description

This command limits the number of ongoing IKEv2 initial exchanges per tunnel to 1. When the system receives a new IKEv2 IKE_SA_INIT request when there is an ongoing IKEv2 initial exchange from same peer, then system reduces the timeout value of the existing exchange to the specified **reduced-max-exchange-timeout**. If the **reduced-max-exchange-timeout** is **disabled**, then the system does not reduce the timeout value.

The **no** form of this command reverts to the default value.

Default

limit-init-exchange reduced-max-exchange-timeout 2

Parameters

seconds

Specifies the maximum timeout for the in-progress initial IKE exchange.

Values 2 to 60, disabled

Platforms

7705 SAR Gen 2

16.67 limit-mac-move

limit-mac-move

Syntax

limit-mac-move [**blockable** | **non-blockable**]

no limit-mac-move

Context

[Tree] (config>service>vpls>spoke-sdp limit-mac-move)

[Tree] (config>service>vpls>sap limit-mac-move)

Full Context

configure service vpls spoke-sdp limit-mac-move

configure service vpls sap limit-mac-move

Description

This command indicates whether or not the mac-move agent, when enabled using **config>service>vpls>mac-move** or **config>service>epipe>mac-move**, limits the MAC re-learn (move) rate on this SAP.

Default

limit-mac-move blockable

Parameters

blockable

Specifies that the agent monitors the MAC re-learn rate on the SAP, and it blocks it when the re-learn rate is exceeded.

non-blockable

Specifies that this SAP is not blocked, and another blockable SAP is blocked instead.

Platforms

7705 SAR Gen 2

limit-mac-move

Syntax

limit-mac-move [**blockable** | **non-blockable**]

no limit-mac-move

Context

[Tree] (config>service>pw-template limit-mac-move)

Full Context

configure service pw-template limit-mac-move

Description

This command indicates whether or not the mac-move agent will limit the MAC re-learn (move) rate.

Default

limit-mac-move blockable

Parameters

blockable

The agent will monitor the MAC re-learn rate, and it will block it when the re-learn rate is exceeded.

non-blockable

When specified, a SAP will not be blocked, and another blockable SAP will be blocked instead.

7705 SAR Gen 2

16.68 link-address

link-address

Syntax

link-address *ipv6-address*

no link-address

Context

[Tree] (config>service>ies>if>sap>ipsec-gw>dhcp6 link-address)

[Tree] (config>service>vprn>if>sap>ipsec-gw>dhcp6 link-address)

Full Context

configure service ies interface sap ipsec-gw dhcp6 link-address

configure service vprn interface sap ipsec-gw dhcp6 link-address

Description

This command specifies the link address of the relayed DHCPv6 packets sent by the system.

Default

no link-address

Parameters

ipv6-address

Specifies a global unicast IPv6 address.

Platforms

7705 SAR Gen 2

16.69 link-bandwidth

link-bandwidth

Syntax

link-bandwidth

Context

[Tree] (config>service>vprn>bgp>group>neighbor link-bandwidth)

[Tree] (config>service>vprn>bgp>group link-bandwidth)

Full Context

configure service vprn bgp group neighbor link-bandwidth

configure service vprn bgp group link-bandwidth

Description

This command enables the configuration context for handling the link-bandwidth extended community attached to specific BGP routes.

When all used multipaths of an IP prefix correspond to BGP routes with a link-bandwidth extended community, the datapath is programmed to do weighted ECMP across the BGP next-hops in proportion to the bandwidth values.

Platforms

7705 SAR Gen 2

link-bandwidth

Syntax

link-bandwidth

Context

[Tree] (config>router>bgp>group>neighbor link-bandwidth)

16.70 link-group

link-group

Syntax

[**no**] **link-group** *link-group-name*

Context

[Tree] (config>service>vprn>isis link-group)

Full Context

configure service vprn isis link-group

Description

This command configures a link-group for the router or VPRN instance.

The **no** form of this command removes the specified link-group.

Parameters

link-group-name

Name of the link-group to be added or removed from the router or VPRN service.

Platforms

7705 SAR Gen 2

link-group

Syntax

link-group *link-group-name*

no link-group

Context

[Tree] (config>router>isis link-group)

Full Context

configure router isis link-group

Description

This command specifies the IS-IS link group associated with this particular level of the interface.

Default

no link-group

Parameters

link-group-name

Specifies an IS-IS link group name, up to 32 characters in length, on the system.

Platforms

7705 SAR Gen 2

16.71 link-local-address

link-local-address

Syntax

link-local-address *ipv6-address* [**dad-disable**]

no link-local-address

Context

[Tree] (config>service>vprn>if>ipv6 link-local-address)

[Tree] (config>router>if>ipv6 link-local-address)

[Tree] (config>service>ies>if>ipv6 link-local-address)

Full Context

configure service vprn interface ipv6 link-local-address

configure router interface ipv6 link-local-address

configure service ies interface ipv6 link-local-address

Description

This command configures the IPv6 Link Local address that is used as a virtual SRRP IPv6 address by the Master SRRP node. This address is sent in the Router Advertisements initiated by the Master SRRP node. Clients use this address as IPv6 default-gateway. Both SRRP nodes, Master and Backup, must be configured with the same Link Local address.

Only one link-local-address is allowed per interface.

Caution:
Removing a manually configured link local address may impact routing protocols or static routes that have a dependency on that address. It is not recommended to remove a link local address when there are active IPv6 subscriber hosts on an IES or VPRN interface.

The **no** form of this command reverts to the default.

Parameters

ipv6-address

Specifies the IPv6 address in the form:

Values

ipv6-address:	x:x:x:x:x:x:x:x
	x:x:x:x:x:x:d.d.d.d
	x - [0..FFFF]H
	d - [0..255]D

dad-disable

Disables Duplicate Address Detection (DAD) and sets the address to preferred, even if there is a duplicated address.

16.80 load

load

Syntax

load *file-url* [**overwrite** | **insert** | **append**]

Context

[Tree] (candidate load)

Full Context

candidate load

Description

This command loads a previously saved candidate configuration into the current candidate. The edit point will be set to the end of the loaded configuration lines. The candidate configuration cannot be modified while a load is in progress.

Default

If the candidate is empty then a load without any of the optional parameters (such as overwrite, and so on) will load the file-url into the candidate. If the candidate is not empty then one of the options, such as overwrite, insert, and so on, must be specified.

Parameters

file-url

Specifies the directory and filename to load.

overwrite

Discards the contents of the current candidate and replace it with the contents of the file.

insert

Inserts the contents of the file at the current edit point.

append

Inserts the contents of the file at the end of the current candidate.

16.82 load-balancing-algorithm

load-balancing-algorithm

Syntax

load-balancing-algorithm *option*

no load-balancing-algorithm

Context

[Tree] (config>port>ethernet load-balancing-algorithm)

Full Context

configure port ethernet load-balancing-algorithm

Description

This command specifies the load balancing algorithm to be used on this port.

In the default mode, **no load-balancing-algorithm**, the port inherits the global settings. The value is not applicable for ports that do not pass any traffic.

The configuration of load-balancing-algorithm at logical port level has three possible values:

- **include-l4** — Enables inherits system-wide settings including Layer 4 source and destination port value in hashing algorithm.
- **exclude-l4** — Layer 4 source and destination port value will not be included in hashing.
- **no load-balancing-algorithm** — Inherits system-wide settings.

The hashing algorithm addresses finer spraying granularity where many hosts are connected to the network. To address more efficient traffic distribution between network links (forming a LAG group), a hashing algorithm extension takes into account Layer 4 information (src/dst L4-protocol port). The hashing index can be calculated according to the following algorithm:

If [(TCP or UDP traffic) & enabled]

hash (<TCP/UDP ports>, <IP addresses>)

else if (IP traffic)

hash (<IP addresses>)

else

hash (<MAC addresses>)

endif

This algorithm will be used in all cases where IP information in per-packet hashing is included (refer to "Traffic Load Balancing Options” in the *7705 SAR Gen 2 Interface Configuration Guide*). However the Layer 4 information (TCP/UDP ports) will not be used in the following cases:

- fragmented packets

Default

no load-balancing-algorithm

Parameters

option

Specifies the load balancing algorithm to be used on this port.

Values **include-l4** — Specifies that the source and destination ports are used in the hashing algorithm.**exclude-l4** — Specifies that the source and destination ports are not used in the hashing algorithm.

7705 SAR Gen 2

16.83 load-balancing-weight

load-balancing-weight

Syntax

load-balancing-weight *value*

no load-balancing-weight [*value*]

Context

[Tree] (config>service>vprn>static-route-entry>next-hop load-balancing-weight)

Full Context

configure service vprn static-route-entry next-hop load-balancing-weight

Description

This command configures a weighted ECMP load-balancing weight for a static route next-hop.

If all of the ECMP next-hops of a static route have a configured load-balancing-weight then packets matching the route are sprayed according to the relative weights. In other words, the next-hop interface with the largest load-balancing weight should receive the most forwarded traffic if weighted ECMP is applicable.

The **no** form of this command disables weighted ECMP for the interface and effectively disables weighted ECMP for the entire static route.

Parameters

value

Specifies the cost metric value.

Values 0 to 4294967295

Platforms

7705 SAR Gen 2

load-balancing-weight

Syntax

load-balancing-weight [*weight*]

no load-balancing-weight

Context

[Tree] (config>service>vprn>ospf3>area>if load-balancing-weight)

[Tree] (config>service>vprn>ospf>area>if load-balancing-weight)

Full Context

configure service vprn ospf3 area interface load-balancing-weight

configure service vprn ospf area interface load-balancing-weight

Description

This command configures the weighted ECMP load-balancing weight for an IS-IS, OSPF, and OSPF3 interface. If the interface becomes an ECMP next hop for an IPv4 or IPv6 route, and all the other ECMP next hops are interfaces with configured (non-zero) load-balancing weights, then the traffic distribution over the ECMP interfaces is proportional to the weights. This means that the interface with the largest load-balancing weight receives the most forwarded traffic if weighted ECMP is applicable.

The **no** form of this command disables weighted ECMP for the interface which effectively disables weighted ECMP for any IP prefix that has this interface as a next hop.

Default

no load-balancing-weight

Parameters

weight

Specifies the load balancing weight.

Values 1 to 4294967295

Platforms

7705 SAR Gen 2

load-balancing-weight

Syntax

load-balancing-weight *weight*

no load-balancing-weight

Context

[Tree] (config>service>vprn>isis>if load-balancing-weight)

Full Context

configure service vprn isis interface load-balancing-weight

Description

This command configures the weighted ECMP load-balancing weight for an IS-IS interface of the VPRN. If the interface becomes an ECMP next-hop for IPv4 or IPv6 route and all the other ECMP next-hops are interfaces with configured (non-zero) load-balancing weights, then the traffic distribution over the ECMP interfaces is proportional to the weights. In other words, the interface with the largest **load-balancing-weight** should receive the most forwarded traffic if weighted ECMP is applicable.

The **no** form of this command disables weighted ECMP for the interface and, therefore, effectively disables weighted ECMP for any IP prefix that has this interface as a next-hop.

Default

no load-balancing-weight

Parameters

weight

Specifies the load balancing weight.

Values 0 to 4294967295

Platforms

7705 SAR Gen 2

load-balancing-weight

Syntax

load-balancing-weight *weight*

no load-balancing-weight

Context

[Tree] (config>router>ldp>if-params>if load-balancing-weight)

Full Context

configure router ldp interface-parameters interface load-balancing-weight

Description

This command configures the load balancing weight for the LDP interface. The load balancing weight, normalized to 64, is used for weighted ECMP of LDP labeled packets over direct network IP interfaces.

If the interface becomes an ECMP next hop for an LDP FEC, and all the other ECMP next hops are interfaces with configured (non-zero) load-balancing weights, then the traffic distribution over the ECMP interfaces is proportional to the normalized weight with a granularity of 64.

If one or more of the LDP interfaces in the ECMP set does not have a configured load-balancing weight, then the system falls back to ECMP.

The **no** form of this command removes the load balancing weight for the LDP interface.

Parameters

weight

Specifies the load balancing weight value.

Values 0 to 4294967295

Platforms

7705 SAR Gen 2

load-balancing-weight

Syntax

load-balancing-weight *weight*

no load-balancing-weight

Context

[Tree] (config>router>mpls>lsp load-balancing-weight)

Full Context

configure router mpls lsp load-balancing-weight

Description

This command assigns a weight to an MPLS LSP for use in the weighted load-balancing, or weighted ECMP, over MPLS feature.

Parameters

weight

Specifies a 32-bit integer representing the weight of the LSP.

Values 0 to 4294967295

Platforms

7705 SAR Gen 2

load-balancing-weight

Syntax

load-balancing-weight *value*

no load-balancing-weight [*value*]

Context

[Tree] (config>router>static-route-entry>next-hop load-balancing-weight)

Full Context

configure router static-route-entry next-hop load-balancing-weight

Description

This command configures a weighted ECMP load-balancing weight for a static route next-hop.

If all of the ECMP next-hops of a static route have a configured load-balancing-weight then packets matching the route are sprayed according to the relative weights. In other words, the next-hop interface with the largest load-balancing weight should receive the most forwarded traffic if weighted ECMP is applicable.

The **no** form of this command disables weighted ECMP for the interface and effectively disables weighted ECMP for the entire static route.

[Tree] (config>router>ospf>area>if load-balancing-weight)

Full Context

configure router ospf3 area interface load-balancing-weight

configure router ospf area interface load-balancing-weight

Description

This command configures the weighted ECMP load-balancing weight for an OSPF or OSPF3 interface. If the interface becomes an ECMP next hop for an IPv4 or IPv6 route, and all the other ECMP next hops are interfaces with configured (non-zero) load-balancing weights, then the traffic distribution over the ECMP interfaces is proportional to the weights. This means that the interface with the largest load-balancing weight receives the most forwarded traffic if weighted ECMP is applicable.

The **no** form of this command disables weighted ECMP for the interface which effectively disables weighted ECMP for any IP prefix that has this interface as a next hop.

Default

no load-balancing-weight

Parameters

weight

Specifies the load balancing weight.

Values 1 to 4294967295

Platforms

7705 SAR Gen 2

16.84 local

local

Syntax

local [**inherit** | **all** | **vc-only** | **none**]

Context

[Tree] (config>service>vprn>ttl-propagate local)

Full Context

configure service vprn ttl-propagate local

Description

This command overrides the global configuration of the TTL propagation for locally generated packets which are forwarded over a MPLS LSPs in a given VPRN service context.

The global configuration is performed under config>router>ttl-propagate>vprn-local.

The default behavior for a given VPRN instance is to inherit the global configuration for the same command. The user can explicitly set the default behavior by configuring the inherit value

Default

local inherit

Parameters

inherit

Specifies the TTL propagation behavior is inherited from the global configuration under **config**>**router**>**ttl-propagate**>**vprn-local**.

none

Specifies the TTL of the IP packet is not propagated into the VC label or labels in the transport label stack.

vc-only

Specifies the TTL of the IP packet is propagated into the VC label and not into the labels in the transport label stack.

all

Specifies the TTL of the IP packet is propagated into the VC label and all labels in the transport label stack.

16.85 local-address

local-address

Syntax

local-address *ip-address*

no local-address

Context

[Tree] (config>service>vprn>bgp>group local-address)

[Tree] (config>service>vprn>bgp>group>neighbor local-address)

Full Context

configure service vprn bgp group local-address

configure service vprn bgp group neighbor local-address

Description

Configures the local IP address used by the group or neighbor when communicating with BGP peers.

Outgoing connections use the **local-address** as the source of the TCP connection when initiating connections with a peer.

When a local address is not specified, the OS uses the system IP address when communicating with IBGP peers and uses the interface address for directly connected EBGP peers. This command is used at the neighbor level to revert to the value defined under the group level.

The **no** form of this command removes the configured local-address for BGP.

The **no** form of this command used at the group level reverts to the value defined at the global level.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Parameters

no local-address

The router ID is used when communicating with IBGP peers and the interface address is used for directly connected EBGP peers.

ip-address

The local address expressed in dotted decimal notation. Allowed values are a valid routable IP address on the router, either an interface or system IP address.

Platforms

7705 SAR Gen 2

local-address

Syntax

local-address *ip-address*

no local-address

Context

[Tree] (config>router>pcep>pcc local-address)

Full Context

configure router pcep pcc local-address

Description

This command configures the local IPv4 address of the PCEP speaker.

The PCEP protocol operates over TCP using destination TCP port 4189. The PCE client (PCC) always initiates the connection. After the user configures the PCEP local IPv4 address and the peer IPv4 address on the PCC, the latter initiates a TCP connection to the PCE. If both a local IPv4 and a local IPv6 address are configured, the connection uses the local address that is the same family as the peer address. When the connection is established, the PCC and PCE exchange OPEN messages, which initializes the PCEP session and exchanges the session parameters to be negotiated.

By default, the PCC attempts to reach the remote PCE address out of band using the management port. If it cannot, it attempts to reach the remote PCE address in band. The user can change the configuration of the peer to attempt connecting in band only or out of band only. When the session comes up out of band, the management IP address is used as the local address. The local IPv4 address configured by the user is only used for in-band sessions and is otherwise ignored.

The **no** form of the command removes the configured local address of the PCEP speaker.

Parameters

ip-address

Specifies the IP address of the PCEP speaker to be used for in-band sessions.

Platforms

7705 SAR Gen 2

local-address

Syntax

local-address *ip-address*

no local-address

Context

[Tree] (config>router>origin-validation>rpki-session local-address)

Full Context

configure router origin-validation rpki-session local-address

Description

This command configures the local address to use for setting up the TCP connection used by an RPKI-Router session. The default local-address is the outgoing interface IPv4 or IPv6 address. The local-address cannot be changed without first shutting down the session.

Default

no local-address

Parameters

ip-address

Specifies an IPv4 address or an IPv6 address.

Platforms

7705 SAR Gen 2

local-address

Syntax

local-address [*ip-int-name* | *ip-address* | *ipv6-address*]

no local-address

Context

[Tree] (config>router>bgp>group local-address)

[Tree] (config>router>bgp>group>neighbor local-address)

Full Context

configure router bgp group local-address

configure router bgp group neighbor local-address

Description

This command configures the local IP address used by the group or neighbor when communicating with BGP peers.

Outgoing connections use the **local-address** as the source of the TCP connection when initiating connections with a peer.

When a local address is not specified, the router uses the system IP address when communicating with IBGP peers and uses the interface address for directly connected EBGP peers. This command is used at the neighbor level to revert to the value defined under the group level.

When set to a router interface, the **local-address** inherits the primary IPv4 or IPv6 address of the router interface depending on whether BGP is configured for IPv4 or IPv6. If the corresponding IPv4 or IPv6 address is not configured on the router interface, the BGP sessions that have this interface set as the **local-address** are kept down until an interface address is configured on the router interface.

The **no** form of this command removes the configured local-address for BGP.

The **no** form of this command used at the group level returns the configuration to the value defined at the global level.

The **no** form of this command used at the neighbor level returns the configuration to the value defined at the group level.

Default

no local-address

Parameters

ip-address

Specifies the local address expressed in dotted decimal notation. Allowed value is a valid routable IP address on the router, either an interface or system IP address.

Values ipv4-address:

- a.b.c.d (host bits must be 0)

ipv6-address

Specifies the local address expressed in dotted decimal notation. Allowed value is a valid routable IPv6 address on the router, either an interface or system IPv6 address.

Values ipv6-address:

- x:x:x:x:x:x:x:x (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d
- x: [0 to FFFF]H
- d: [0 to 255]D

ip-int-name

Specifies the IP interface name whose address the local address will inherit. The interface can be any network interface configured on the system.

Platforms

7705 SAR Gen 2

16.86 local-address-assignment

local-address-ipv6

Syntax

local-address-ipv6 *ipv6-address*

no local-address-ipv6

Context

[Tree] (config>router>pcep>pcc local-address-ipv6)

Full Context

configure router pcep pcc local-address-ipv6

Description

This command configures the local IPv6 address of the PCEP speaker.

The PCEP protocol operates over TCP using destination TCP port 4189. The PCE client (PCC) always initiates the connection. After the user configures the PCEP local IPv6 address and the peer IPv6 address on the PCC, the latter initiates a TCP connection to the PCE. If both a local IPv4 and a local IPv6 address are configured, the connection uses the local address that is the same family as the peer address. When the connection is established, the PCC and PCE exchange OPEN messages, which initializes the PCEP session and exchanges the session parameters to be negotiated.

By default, the PCC attempts to reach the remote PCE address out of band using the management port. If it cannot, it attempts to reach the remote PCE address in-band. The user can change the configuration of the peer to attempt connecting in band only or out of band only. When the session comes up out of band, the management IP address is used as the local address. The local IPv6 address configured by the user is only used for in-band sessions and is otherwise ignored.

The **no** form of the command removes the configured local address of the PCEP speaker.

Parameters

ipv6-address

Specifies the IP address of the PCEP speaker to be used for in-band sessions.

16.88 local-age

local-age

Syntax

local-age *aging-timer*

no local-age [*aging-timer*]

Context

[Tree] (config>service>vpls local-age)

[Tree] (config>service>template>vpls-template local-age)

Full Context

configure service vpls local-age

configure service template vpls-template local-age

Description

Specifies the aging time for locally learned MAC addresses in the forwarding database (FDB) for the Virtual Private LAN Service (VPLS) instance. In a VPLS service, MAC addresses are associated with a Service Access Point (SAP) or with a service destination point (SDP). MACs associated with a SAP are classified as local MACs, and MACs associated with an SDP are remote MACs.

Like in a Layer 2 switch, learned MACs can be aged out if no packets are sourced from the MAC address for a period of time (the aging time). In each VPLS service instance, there are independent aging timers for local learned MAC and remote learned MAC entries in the FDB. The **local-age** timer specifies the aging time for local learned MAC addresses.

The **no** form of this command returns the local aging timer to the default value.

Default

local age 300 — Local MACs aged after 300 seconds.

Parameters

aging-timer

Specifies the aging time for local MACs expressed in seconds

Values 60 to 86400

Platforms

7705 SAR Gen 2

16.89 local-as

local-as

Syntax

local-as *as-number* [**private**] [**no-prepend-global-as**]

no local-as

Context

[Tree] (config>service>vprn>bgp>group>neighbor local-as)

[Tree] (config>service>vprn>bgp local-as)

[Tree] (config>service>vprn>bgp>group local-as)

Full Context

configure service vprn bgp group neighbor local-as

configure service vprn bgp local-as

configure service vprn bgp group local-as

Description

This command configures a BGP virtual autonomous system (AS) number.

In addition to the global AS number configured for BGP in the config>router>autonomous-system context, a virtual (local) AS number can be configured to support various AS number migration scenarios. The local AS number is added to the to the beginning the as-path attribute ahead of the router's AS number.

This configuration parameter can be set at three levels: global level (applies to all EBGP peers), group level (applies to all EBGP peers in peer-group) or neighbor level (only applies to EBGP specified peer). Thus, by specifying this at each neighbor level, it is possible to have a separate local-as per EBGP session. The local-as command is not supported for IBGP sessions. When the optional **private** keyword is specified in the command the local-as number is not added to inbound routes from the EBGP peer that has **local-as** in effect.

When a command is entered multiple times for the same AS, the last command entered is used in the configuration. The **private** attribute can be added or removed dynamically by reissuing the command.

Changing the local AS at the global level in an active BGP instance causes the BGP instance to restart with the new local AS number. Changing the local AS at the global level in an active BGP instance causes BGP to re-establish the peer relationships with all peers in the group with the new local AS number. Changing the local AS at the neighbor level in an active BGP instance causes BGP to re-establish the peer relationship with the new local AS number.

This is an optional command and can be used in the following circumstance:

Provider router P is moved from AS1 to AS2. The customer router that is connected to P, however, is configured to belong to AS1. To avoid reconfiguring the customer router, the **local-as** value on router P can be set to AS1. Thus, router P adds AS1 to the as-path message for routes it advertises to the customer router.

The **no** form of this command used at the global level removes any virtual AS number configured.

The **no** form of this command used at the group level reverts to the value defined at the global level.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Default

no local-as

Parameters

as-number

The virtual autonomous system number, expressed as a decimal integer.

Values 1 to 65535

private

Specifies the local-as is hidden in paths learned from the peering.

no-prepend-global-as

Specifies that the global-as is hidden in paths announced to the EBGP peer.

Platforms

7705 SAR Gen 2

local-as

Syntax

local-as *as-number* [**private**] [no-prepend-global-as]

no local-as

Context

[Tree] (config>router>bgp local-as)

[Tree] (config>router>bgp>group local-as)

Full Context

configure router bgp local-as

configure router bgp group neighbor local-as

configure router bgp group local-as

Description

This command configures a BGP local autonomous system (AS) number. In addition to the global AS number configured for BGP using the autonomous-system command, a local AS number can be configured to support various AS number migration scenarios.

When the **local-as** command is applied to a BGP neighbor and the local-as is different from the peer-as, the session comes up as EBGP and by default the global-AS number and then (in that order) the local-as number are prepended to the AS_PATH attribute in outbound routes sent to the peer. In received routes from the EBGP peer, the local AS is prepended to the AS path by default, but this can be disabled with the **private** option.

When the **local-as** command is applied to a BGP neighbor and the local-as is the same as the peer-as, the session comes up as IBGP, and by default, the global-AS number is prepended to the AS_PATH attribute in outbound routes sent to the peer.

This configuration parameter can be set at three levels: global level (applies to all BGP peers), group level (applies to all BGP peers in group) or neighbor level (only applies to one specific BGP neighbor). By specifying this at the neighbor level, it is possible to have a separate **local-as** for each BGP session.

When the optional **no-prepend-global-as** command is configured, the global-as number is not added in outbound routes sent to an IBGP or EBGP peer.

When a command is entered multiple times for the same AS, the last command entered is used in the configuration. The private option can be added or removed dynamically by reissuing the command. Changing the local AS at the global level in an active BGP instance causes the BGP instance to restart with the new local AS number. Changing the local AS at the global level in an active BGP instance causes BGP to re-establish the peer relationships with all peers in the group with the new local AS number. Changing the local AS at the neighbor level in an active BGP instance causes BGP to re-establish the peer relationship with the new local AS number.

The **no** form of this command used at the group level reverts to the value defined at the global level.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Default

no local-as

Parameters

as-number

Specifies the virtual autonomous system number expressed as a decimal integer.

Values 1 to 4294967295

private

Specifies the local-as is hidden in paths learned from the peering.

no-prepend-global-as

Specifies that the global-as is hidden in paths announced to the BGP peer.

Context

[Tree] (debug>router local-dhcp-server)

Full Context

debug router local-dhcp-server

Description

This command enables, disables or configures debugging for a local DHCP server.

Parameters

server-name

Specifies an existing local DHCP server name.

ip-prefix[/prefix-length]

Specifies the IP prefix and prefix length of the subnet.

Values ip-prefix — a.b.c.d (host bits must be 0)
length — 0 to 32

ieee-address
Specifies that the provisioned MAC address for the local DHCP server.

ipv6z-address
Specifies the IPv6z address.

ipv6-address:	x:x:x:x:x:x:x:x [-interface]
	x:x:x:x:x:x:d.d.d.d [-interface]
	x: [0 to FFFF]H
	d: [0 to 255]D
interface	up to 32 characters, mandatory for link local addresses

16.92 local-end

local-end

Syntax

local-end {*ip-address* | *ipv6-address*}

no local-end

Context

[Tree] (config>service>sdp local-end)

Full Context

configure service sdp local-end

Description

This command configures the local-end address of the following SDP encapsulation types:

- IPv6 address of the termination point of a SDP of encapsulation **l2tpv3** (L2TP v3 tunnel).
- IPv4/IPv6 source address of a SDP of encapsulation **eth-gre-bridged** (L2oGRE SDP).
- IPv4 source address of a SDP of encapsulation **gre** (GRE SDP).

A change to the value of the local-end parameter requires that the SDP be shut down.

When used as the source address of a SDP of encapsulation **gre** (GRE SDP), the primary IPv4 address of any local network IP interface, loopback or otherwise, may be used.

The address of the following interfaces are not supported:

- unnumbered network IP interface

- IES interface
- VPRN interface
- CSC VPRN interface

The **local-end** parameter value adheres to the following rules:

- A maximum of 15 distinct address values can be configured for all GRE SDPs under the **config**>**service**>**sdp**>**local-end** context, and all L2oGRE SDPs under the **config**>**service**>**system**>**gre-eth-bridged**>**tunnel-termination** context.
- The same source address cannot be used in both contexts since an address configured for a L2oGRE SDP matches an internally created interface that is not available to other applications.
- The **local-end** address of a GRE SDP, when different from system, need not match the primary address of an interface that has the MPLS-over-GRE termination subnet configured, unless a GRE SDP or tunnel from the far-end router terminates on this address.

The **no** form of the command removes the address from the local-end configuration.

Parameters

ip-address* | *ipv6-address

Specifies a IPv4 or IPv6 address for local-end of an SDP in dotted decimal notation.

Values

ip-address	a.b.c.d
ipv6-address	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x - [0..FFFF]H
	d - [0..255]D

configure service ies interface ipsec ipsec-tunnel dynamic-keying local-id

configure ipsec ipsec-transport-mode-profile dynamic-keying local-id

Description

This command specifies the local ID used for IDi or IDr for IKEv2 negotiation.

The default behavior depends on the local-auth-method as follows:

- Psk: local tunnel IP address
- Cert-auth: subject of the local certificate

The **no** form of this command removes the parameters from the configuration.

Default

no local-id

Parameters

type

Specifies the type of local ID payload, which could be IPv4 or IPv6 address or FQDN domain name or distinguish the name of the subject in the X.509 certificate.

Values ipv4 — Specifies to use IPv4 as the local ID type; the default value is the local tunnel end-point address.

ipv6 — Specifies to use IPv6 as the local ID type; the default value is the local tunnel end-point address.

fq1dn — Specifies to use FQDN as the local ID type. The value must be configured.

value

Specifies the data type as an enumerated integer that describes the local identifier type used for IDi or IDr for IKEv2, up to 255 characters.

Platforms

local-ip

Syntax

local-ip {*ip-prefix/prefix-length* | *ip-prefix netmask* | **any**}

Context

[Tree] (config>service>vprn>ipsec>sec-plcy>entry local-ip)

[Tree] (config>router>ipsec>sec-plcy>entry local-ip)

Full Context

configure service vprn ipsec security-policy entry local-ip

configure router ipsec security-policy entry local-ip

Description

This command configures the local (from the VPN) IP prefix/mask for the policy parameter entry.

Only one entry is necessary to describe a potential flow. The **local-ip** and **remote-ip** commands can be defined only once. The system evaluates:

- the local IP as the source IP when traffic is examined in the direction of the flows from private to public and as the destination IP when traffic flows from public to private
- the remote IP as the source IP when traffic flows public to private and as the destination IP when traffic flows from private to public

Parameters

ip-prefix

The destination address of the aggregate route in dotted decimal notation

Values a.b.c.d (host bits must be 0)

prefix-length 1 to 32

netmask

The subnet mask in dotted decimal notation

any

keyword to specify that it can be any address

Full Context

configure router ldp interface-parameters interface ipv4 local-lsr-id

configure router ldp interface-parameters interface ipv6 local-lsr-id

Description

This command enables the use of the address of the local LDP interface, or any other network interface configured on the system, as the LSR-ID to establish link LDP Hello adjacency and LDP session with directly connected LDP peers. The network interface can be a loopback or not.

Link LDP sessions to all peers discovered over a given LDP interface share the same local LSR-ID. However, LDP sessions on different LDP interfaces can use different network interface addresses as their local LSR-ID.

By default, the LDP session to a peer uses the system interface address as the LSR-ID unless explicitly configured using this command. The system interface must always be configured on the router, or the LDP protocol will not come up on the node. There is no requirement to include the system interface in any routing protocol.

At initial configuration, the LDP session to a peer will remain down while the network interface used as LSR-ID is down. LDP will not try to bring it up using the system interface.

If the network IP interface used as LSR-ID goes down, the LDP sessions to all discovered peers using this LSR-ID go down.

When an interface other than the system is used as the LSR-ID, the transport connection (TCP) for the link LDP session will also use the address of that interface as the transport address. If the system or interface value is configured in the **config**>**router**>**ldp**>**if-params**>**if**>**ipv4** or **config**>**router**>**ldp**>**if-**

params>if>ipv6> transport-address context, it will be overridden with the address of the LSR-ID interface.

When the **local-lsr-id** command is enabled with the **32bit-format** option, an SR OS LSR will be able to establish an LDP IPv6 Hello adjacency and an LDP IPv6 session with an RFC 7552 compliant peer LSR. The LSR uses a 32-bit LSR-ID set to the value of the IPv4 address of the specified local LSR-ID interface and a 128-bit transport address set to the value of the IPv6 address of the specified local LSR-ID interface.

Note:
The system interface cannot be used as a local LSR-ID with the **32bit-format** option enabled because the system interface is the default LSR-ID and transport address for all LDP sessions to peers on this LSR. This configuration is blocked in the CLI.

If the user enables the **32bit-format** option in the IPv6 context of a running LDP interface, the already established LDP IPv6 Hello adjacency and LDP IPv6 session will be brought down and re-established with the new 32-bit LSR-ID value.

If the user changes the LSR-ID value between **system**, **interface**, and *interface-name*, or enables the **32bit-format** option while the LDP session is up, LDP will immediately tear down all sessions using this LSR-ID and will attempt to re-establish them using the new LSR-ID.

The **no** form of this command returns to the default behavior, in which case the system interface address is used as the LSR-ID.

Default

no local-lsr-id

Parameters

system

Specifies the use of the address of the system interface as the value of the LSR-ID of this LDP LSR.

interface

Specifies the use of the address of the local LDP interface as the value of the LSR-ID of this LDP LSR.

interface-name interface-name

Specifies the name, up to 32 character, of the network IP interface (which address is used as the LSR-ID of this LDP LSP). An interface name cannot be in the form of an IP address. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

32bit-format

Specifies the use of the IPv4 address of the local LSR-ID interface as the LSR-ID of this LDP LSR.

Platforms

7705 SAR Gen 2

local-lsr-id

Syntax

local-lsr-id *interface-name* [**32bit-format**]

no local-lsr-id

Context

[Tree] (config>router>ldp>targ-session>peer-template local-lsr-id)

[Tree] (config>router>ldp>targ-session>peer local-lsr-id)

Full Context

configure router ldp targeted-session peer-template local-lsr-id

configure router ldp targeted-session peer local-lsr-id

Description

This command enables the use of the address of any network interface configured on the system, as the LSR-ID to establish a targeted LDP Hello adjacency and a targeted LDP session with an LDP peer. The network interface can be a loopback or not.

By default, the targeted LDP session to a peer uses the system interface address as the LSR-ID and as the transport address, unless explicitly configured using this command. The system interface must always be configured on the router, or the LDP protocol will not come up on the node. There is no requirement to include the system interface in any routing protocol.

When the **local-lsr-id** command is enabled with the **32bit-format** option, an SR OS LSR will be able to establish a targeted LDP IPv6 Hello adjacency and a targeted LDP IPv6 session with an RFC 7552 compliant peer LSR. The LSR uses a 32-bit LSR-ID set to the value of the IPv4 address of the specified local LSR-ID interface and a 128-bit transport address set to the value of the IPv6 address of the specified local LSR-ID interface.

Note:
The system interface cannot be used as a local LSR-ID with the 3**2bit-format** option enabled because the system interface is the default LSR-ID and transport address for all targeted LDP sessions to peers on this LSR. This configuration is blocked in the CLI.

If the user enables the **32bit-format** option in the IPv6 context of a running targeted LDP peer, the already established targeted LDP IPv6 Hello adjacency and targeted LDP IPv6 session will be brought down and re-established with the new 32-bit LSR-ID value.

If the user changes the local LSR-ID value or enables/disables the **32bit-format** option, while the targeted LDP session is up, LDP will immediately tear down the targeted session using this LSR-ID and will attempt to re-establish it using the new LSR-ID.

The **no** form of this command returns to the default behavior, in which case the system interface address is used as the LSR-ID.

Default

no local-lsr-id

Parameters

interface-name

Specifies the name, up to 32 characters, of the network IP interface (which address is used as the LSR-ID of this LDP LSP). An interface name cannot be in the form of an IP address. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

32bit-format

Specifies the use of the IPv4 address of the local LSR-ID interface as the LSR-ID of this LDP LSR.

16.98 local-monitoring-policer

local-monitoring-policer

Syntax

[**no**] **local-monitoring-policer** *policer-name* [**create**]

Context

[Tree] (config>sys>security>dist-cpu-protection>policy local-monitoring-policer)

Full Context

configure system security dist-cpu-protection policy local-monitoring-policer

Description

This command configures a monitoring policer that is used to monitor the aggregate rate of several protocols arriving on an object (for example, SAP). When the **local-monitoring-policer** is determined to be in a nonconforming state (at the end of a minimum monitoring time of 60 seconds) then the system will attempt to allocate dynamic policers for the particular object for any protocols associated with the local monitor (for example, using the **protocol** *name* **enforcement dynamic** *policer-name* CLI command).

If the system cannot allocate all the dynamic policers within 150 seconds, it will stop attempting to allocate dynamic policers, raise a LocMonExcdAllDynAlloc log event, and go back to using the local monitor. The local monitor may then detect exceeded packets again and make another attempt at allocating dynamic policers.

Once this *policer-name* is referenced by a protocol then this policer will be instantiated for each "object" that is created and references this DDoS policy. If there is no policer free then the object will be blocked from being created.

Parameters

policy-name

Specifies name of the policy, up to 32 characters.

Platforms

7705 SAR Gen 2

16.99 local-preference

local-preference

Syntax

local-preference *local-preference*

no local-preference

Context

[Tree] (config>service>vprn>bgp local-preference)

Full Context

configure service vprn bgp group local-preference

configure service vprn bgp group neighbor local-preference

configure service vprn bgp local-preference

Description

This command enables setting the BGP local-preference attribute in incoming routes if not specified and configures the default value for the attribute. This value is used if the BGP route arrives from a BGP peer without the **local-preference** integer set.

The specified value can be overridden by any value set via a route policy. This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). The most specific value is used.

The **no** form of this command at the global level specifies that incoming routes with local-preference set are not overridden and routes arriving without local-preference set are interpreted as if the route had local-preference value of 100.

The **no** form of this command used at the group level reverts to the value defined at the global level.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Default

no local-preference - Does not override the local-preference value set in arriving routes and analyze routes without local preference with value of 100.

Parameters

local-preference

The local preference value to be used as the override value, expressed as a decimal integer.

Values 0 to 4294967295

Platforms

7705 SAR Gen 2

local-preference

Syntax

configure router bgp group neighbor local-preference

configure router bgp local-preference

configure router bgp group local-preference

Description

This command enables setting the BGP local-preference attribute in incoming routes if not specified and configures the default value for the attribute.

This value is used if the BGP route arrives from a BGP peer without the **local-preference** integer set.

The specified value can be overridden by any value set via a route policy. This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to the specified peer). The most specific value is used.

The **no** form of this command at the global level specifies that incoming routes with local-preference set are not overridden and routes arriving without local-preference set are interpreted as if the route had local-preference value of 100.

The **no** form of this command used at the group level reverts to the value defined at the global level.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Default

no local-preference

Parameters

local-preference

Specifies the local preference value to be used as the override value expressed as a decimal integer.

Values 0 to 4294967295

Platforms

7705 SAR Gen 2

local-preference

Syntax

local-preference *preference* [**equal** | **or-higher** | **or-lower**]

no local-preference

Context

[Tree] (config>router>policy-options>policy-statement>entry>from local-preference)

Full Context

configure router policy-options policy-statement entry from local-preference

Description

This command matches BGP routes based on local preference (the value in the LOCAL_PREF attribute).

If no comparison qualifiers are present (**equal**, **or-higher**, **or-lower**), then **equal** is the implied default.

A non-BGP route does not match a policy entry if it contains the **local-preference** command.

Default

no local-preference

Parameters

preference

Specifies the local preference value.

Values 0 to 4294967295, or a parameter name delimited by starting and ending at-sign (@) characters

equal

Specifies that matched routes should have the same local preference as the value specified.

or-higher

Specifies that matched routes should have the same or a greater local preference as the value specified.

or-lower

Specifies that matched routes should have the same or a lower local preference as the value specified.

Platforms

7705 SAR Gen 2

local-preference

Syntax

local-preference *preference*

no local-preference

Context

[Tree] (config>router>policy-options>policy-statement>default-action local-preference)

Full Context

configure router policy-options policy-statement default-action local-preference

Description

This command assigns a BGP local preference to routes matching a route policy statement entry.

If no local preference is specified, the BGP configured local preference is used.

The **no** form of this command disables assigning a local preference in the route policy entry.

Default

no local-preference

Parameters

preference

Specifies the local preference expressed as a decimal integer.

Values 0 to 4294967295 name — Specifies the local preference parameter variable name. Allowed values are any string up to 32 characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes. Policy parameters must start and end with at-signs (@); for example, "@variable@”.

Platforms

7705 SAR Gen 2

16.100 local-prefix

local-prefix

Syntax

local-prefix *local-prefix* [**create**]

no local-prefix *local-prefix*

Context

[Tree] (config>service>pw-routing local-prefix)

Full Context

configure service pw-routing local-prefix

Description

This command configures one or more node prefix values to be used for MS-PW routing. At least one prefix must be configured on each node that is an S-PE or a T-PE.

The **no** form of this command removes a previously configured prefix, and will cause the corresponding route to be withdrawn if it has been advertised in BGP.

Default

no local-prefix

Parameters

local-prefix

Specifies a 32 bit prefix for the AII. One or more prefix values, up to a maximum of 16, may be assigned to the 7705 SAR Gen 2 node. The global ID can contain the 2-octet or 4-octet value of the provider's Autonomous System Number (ASN). The presence of a global ID based on the provider's ASN ensures that the AII for spoke-SDPs configured on the node will be globally unique.

Values <global-id>:<ip-addr>| <raw-prefix>

ip-addr	a.b.c.d
raw-prefix	1 to 4294967295
global-id	1 to 4294967295

16.103 local-routes-domain-id

local-routes-domain-id

Syntax

local-routes-domain-id [*global-field*:*local-field*]

no local-routes-domain-id

Context

[Tree] (config>service>vprn local-routes-domain-id)

Full Context

configure service vprn local-routes-domain-id

Description

This command specifies the domain ID that is used in the D-PATH attribute for local routes before those routes are exported to a BGP neighbor using BGP-IPVPN, EVPN-IFF, EVPN-IFL or PE-CE BGP. A local route is a non-BGP route installed in the VPRN route table and learned using static route or an IGP.

The domain IDs are used in the D-PATH attribute, in accordance with *draft-ietf-bess-evpn-ipvpn-interworking*. The D-PATH attribute is modified by gateway routers, where a gateway is defined as a PE where a VPRN is instantiated, and that VPRN advertises or receives routes from multiple BGP owners (for example, EVPN-IFL and BGP-IPVPN).

The D-PATH attribute is used on gateways to detect loops (for received routes where the D-PATH contains a local domain ID) and to make BGP best path selection decisions based on the D-PATH length (shorter D-PATH is preferred).

The **no** form of this command removes the domain ID for local routes.

Default

no local-routes-domain-id

Parameters

global-field:local-field

Specifies the domain ID for local routes.

Values *4byte-GlobalAdminValue:2byte-LocalAdminValue*

4byte-GlobalAdminValue:	0 to 4294967295
2byte-LocalAdminValue	0 to 65535

[Tree] (config>router>mpls>lsp-template local-sr-protection)

Full Context

configure router mpls lsp local-sr-protection

configure router mpls lsp-template local-sr-protection

Description

This command configures the SR LFA protection needed for the adjacencies used in the path computation of an SR-TE LSP by the local CSPF.

The default value of the command is **preferred**. The local CSPF will prefer a protected adjacency over an unprotected adjacency whenever both exist for a TE link. However, the entire computed path can combine both types of adjacencies.

When the user enables the **mandatory** value, CSPF uses it as an additional path constraint and selects protected adjacencies exclusively in computing the path of the SR-TE LSP. CSPF will return no path if all candidate paths that otherwise satisfy all other LSP path constraints do not have an unprotected SID for each of their TE links.

Similarly, if the user enables the value **none**, CSPF uses it as an additional path constraint and selects unprotected adjacencies exclusively in computing the path of the SR-TE LSP. CSPF will return no path if all candidate paths that otherwise satisfy all other LSP path constraints do not have a protected SID for each of their TE links.

The **no** form of this command returns the command to its default value.

Default

no local-sr-protection

Parameters

local-sr-protection

Specifies the local-sr-protection for LSPs.

Values none — Selects unprotected adjacencies only in the SR-TE LSP path computation.

preferred — Prefers protected adjacencies in the SR-TE LSP path computation.

mandatory — Selects protected adjacencies only in the SR-TE LSP path computation.

[Tree] (config>system>persistence>ancp location)

Full Context

configure system persistence nat-port-forwarding location

configure system persistence dhcp-server location

configure system persistence ancp location

Description

This command instructs the system where to write the persistency files for the corresponding application. Each application creates two files on the flash card, one with suffix .i<version>, referencing an index file, and the other with suffix .0<version>, where <version> is a 2-digit number reflecting the file version. These versions are not related to the SR OS release running on the node. The <version> can remain the same over two major releases, for example, when no format change is made to the persistency file. On boot, the system scans the file systems looking for the corresponding persistency files, and the load begins.

For example, in the subscriber management context, the location specifies the flash device on a CPM card where the data for handling subscriber management persistency is stored.

The **no** form of this command returns the system to the default. If there is a change in file location while persistence is running, a new file will be written on the new flash, and then the old file will be removed.

Default

no location

Parameters

cflash-id

Specifies the compact flash device name.

Values cf1:, cf2:, cf3:

location

Syntax

location *cflash-id* [*backup-cflash-id*]

no location

Context

[Tree] (config>log>file-id location)

Full Context

configure log file-id location

Description

This command specifies the primary and optional backup location where the log or billing file will be created.

The **location** command is optional. If the location command not explicitly configured, log files will be created on cf1: and accounting files will be created on cf2: without overflow onto other devices. Generally, cf3: is reserved for system files (configurations, images, and so on).

When multiple location commands are entered in a single file ID context, the last command overwrites the previous command.

When the location of a file ID that is associated with an active log ID is changed, the log events are not immediately written to the new location. The new location does not take effect until the log is rolled over either because the rollover period has expired or a **clear log log-id** command is entered to manually rollover the log file.

When creating files, the primary location is used as long as there is available space. If no space is available, an attempt is made to delete unnecessary files that are past their retention date.

If sufficient space is not available an attempt is made to remove the oldest to newest closed log or accounting files. After each file is deleted, the system attempts to create the new file.

A medium severity trap is issued to indicate that a compact flash is either not available or that no space is available on the specified flash and that the backup location is being used.

A high priority alarm condition is raised if none of the configured compact flash devices for this file ID are present or if there is insufficient space available. If space does become available, then the alarm condition will be cleared.

Log files are created on cf1: and accounting files are created on cf2.

Use the **no** form of this command to revert to default settings.

Default

no location

Parameters

cflash-id

Specify the primary location.

Values cflash-id: cf1:, cf2:, cf3:

backup-cflash-id

Specify the secondary location.

Values cflash-id: cf1:, cf2:, cf3:

Platforms

7705 SAR Gen 2

location

Syntax

location *location-id* [**primary-ip-address** *ipv4-address*] [**secondary-ip-address** *ipv4-address*] [**tertiary-ip-address** *ipv4-address*]

Context

[Tree] (config>router>bgp>optimal-route-reflection location)

Full Context

configure router bgp optimal-route-reflection location

Description

This command configures the location ID for the for the route reflector. A BGP neighbor can be associated with a location if it is a route-reflector client.

Parameters

location-id

Specifies an optimal-route-reflection location.

Values 1 to 255

ipv4-address

Specifies the primary, secondary, or tertiary IP address.

Values primary ipv4-address, secondary ipv4-address, tertiary ipv4-address

Platforms

7705 SAR Gen 2

16.109 lock

lock

Syntax

[**no**] **lock**

Context

[Tree] (configure>system>security>profile>netconf>base-op-authorization lock)

Full Context

configure system security profile netconf base-op-authorization lock

Description

This command authorizes a user associated with the profile to send a NETCONF <lock> RPC. This lock RPC allows a NETCONF client to lock a configuration datastore.

The **no** form of the command denies the user from requesting a lock.

Default

no lock

Platforms

7705 SAR Gen 2

16.110 lock-override

lock-override

Syntax

[**no**] **lock-override**

Context

[Tree] (config>system>script-control>script-policy lock-override)

Full Context

configure system script-control script-policy lock-override

Description

This command allows a triggered EHS/CRON script to execute while there is a datastore lock, started by an MD interface, in place.

A triggered EHS/CRON script queues until an **ongoing commit** (or **confirmed-commit**) is done. When an EHS/CRON script is triggered while the **lock-override** CLI knob is on, SR OS behaves as follows.

When an exclusive session is in place:

- Keep if it is an MD-CLI session. Disconnect if it is a NETCONF session
- Lose the exclusive lock
- Lose any uncommitted configuration changes

When a global session is in place:

- Keep the MD-CLI or NETCONF session
- Keep the uncommitted configuration changes
- An update may be required after committing the EHS/CRON script configuration changes

The **no** form of this command does not allow the script to execute while there is a datastore lock in place.

Default

lock-override

Platforms

7705 SAR Gen 2

16.111 lockout

lockout

Syntax

lockout failed-attempts *count* **duration** *duration-minutes* **block** *block-minutes* [**max-port-per-ip** *number-of-ports*]

no lockout

Context

[Tree] (config>ipsec>ike-policy lockout)

Full Context

configure ipsec ike-policy lockout

Description

This command enables the lockout mechanism for the IPsec tunnel. The system will lock out an IPsec client for the configured time interval if the number of failed authentications exceeds the configured value within the specified duration. This command only applies when the system acts as a tunnel responder.

A client is defined as the tunnel IP address plus the port.

Optionally, the **max-port-per-ip** parameter can be configured as the maximum number of ports allowed behind the same IP address. If this threshold is exceeded, then all ports behind the IP address are blocked.

The **no** form of this command disables the lockout mechanism.

Default

no lockout

Parameters

count

Specifies the maximum number of failed authentications allowed during the *duration-minutes* interval.

Values 1 to 64

Default 3

duration-minutes

Specifies the interval of time, in minutes, during which the configured failed authentication count must be exceeded in order to trigger a lockout.

Values 1 to 60

Default 5

block-minutes

Specifies the number of minutes that the client is blocked if the configured failed authentication count is exceeded.

Values 1 to 1440, infinite

Default 10

number-of-ports

Specifies the maximum number of ports allowed behind the same IP address.

Values 1 to 32000

Default 16

Platforms

7705 SAR Gen 2

lockout

Syntax

clear lockout {**user** *user-name* | **all**}

Context

[Tree] (admin>clear lockout)

Full Context

admin clear lockout

Description

This command is used to clear any lockouts for a specific user, or for all users.

Parameters

user-name

Clears the locked username.

all

Clears all locked usernames.

Platforms

7705 SAR Gen 2

16.112 log

log

Syntax

log

Context

[Tree] (config log)

Full Context

configure log

Description

Commands in this context are used to configure both event logs and accounting logs. Event logs control the generation, dissemination and recording of system events for monitoring status and troubleshooting faults within the system. Event logging configuration includes syslog, snmp notifications (traps), NETCONF notifications and other types of event log outputs. Accounting logs collect comprehensive accounting statistics and write them to XML files on the compact flash in order to support a variety of billing models.

Platforms

7705 SAR Gen 2

log

Syntax

[**no**] **log**

Context

[Tree] (config>service>vprn>static-route-entry>indirect>cpe-check log)

[Tree] (config>service>vprn>static-route-entry>next-hop>cpe-check log)

Full Context

configure service vprn static-route-entry indirect cpe-check log

configure service vprn static-route-entry next-hop cpe-check log

Description

This optional parameter enables the ability to log transitions between active and in-active based on the CPE connectivity check. Events will be sent to the system log, syslog and SNMP traps.

Default

no log

Platforms

7705 SAR Gen 2

log

Syntax

log

Context

[Tree] (config>service>vprn log)

Full Context

configure service vprn log

Description

Commands in this context configure event logging within a specific VPRN.

By default, the log events in a VPRN log are a subset of the complete set of possible log events in SR OS. See the **config**>**log**>**services-all-events** command for more details.

Platforms

7705 SAR Gen 2

log

Syntax

log *log-id*

no log

Context

[Tree] (config>filter>ipv6-filter>entry log)

[Tree] (config>filter>ip-filter>entry log)

Full Context

configure filter ipv6-filter entry log

configure filter ip-filter entry log

Description

This command associates a filter log to the current filter policy entry and therefore enables logging for that filter entry.

The filter log must exist before a filter entry can be enabled to use the filter log.

The **no** form of the command disables logging for the filter entry.

Default

no log

Parameters

log-id

Specifies the filter log ID expressed as a decimal integer.

Values 101 to 199

Platforms

7705 SAR Gen 2

log

Syntax

log *log-id* [**create**]

no log *log-id*

Context

[Tree] (config>filter log)

Full Context

configure filter log

Description

This command, creates a configuration context for the specified filter log if it does not exist, and enables the context to configure the specified filter log.

The **no** form of the command deletes the filter log. The log cannot be deleted if there are filter entries configured to write to the log. All filter entry logging associations need to be removed before the log can be deleted.

Default

log 101

Parameters

log-id

Specifies the filter log ID expressed as a decimal integer.

Values 101 to 199

create

This keyword is required to create the configuration context. After it is created, the context can be enabled with or without the **create** keyword.

Platforms

7705 SAR Gen 2

log

Syntax

[**no**] **log**

Context

[Tree] (config>router>static-route-entry>indirect>cpe-check log)

[Tree] (config>router>static-route-entry>next-hop>cpe-check log)

Full Context

configure router static-route-entry indirect cpe-check log

configure router static-route-entry next-hop cpe-check log

Description

This optional parameter enables the ability to log transitions between active and in-active based on the CPE connectivity check. Events will be sent to the system log, syslog and SNMP traps.

Default

no log

Platforms

7705 SAR Gen 2

log

Syntax

[**no**] log

Context

[Tree] (config>system>security>mgmt-access-filter>mac-filter>entry log)

[Tree] (config>system>security>mgmt-access-filter>ip-filter>entry log)

[Tree] (config>system>security>mgmt-access-filter>ipv6-filter>entry log)

Full Context

configure system security management-access-filter mac-filter entry log

configure system security management-access-filter ip-filter entry log

configure system security management-access-filter ipv6-filter entry log

Description

This command enables match logging. When enabled, matches on this entry will cause the Security event mafEntryMatch to be raised.

Default

no log

Platforms

7705 SAR Gen 2

16.113 log-events

log-events

Syntax

log-events [**verbose**]

no log-events

Context

[Tree] (config>sys>security>dist-cpu-protection>policy>local-monitoring-policer log-events)

Full Context

configure system security dist-cpu-protection policy local-monitoring-policer log-events

Description

This command controls the creation of log events related to **local-monitoring-policer** status and activity.

Default

log-events

Parameters

verbose

Sends the same events as just "log-events” plus DcpLocMonExcd, DcpLocMonExcdAllDynAlloc, and DcpLocMonExcdAllDynFreed. The optional "verbose” includes some events that are more likely used during debug/tuning/investigations

Platforms

7705 SAR Gen 2

log-events

Syntax

[**no**] **log-events** [**verbose**]

no log-events

Context

[Tree] (config>sys>security>dist-cpu-protection>policy>protocol>dyn-para log-events)

Full Context

configure system security dist-cpu-protection policy protocol dynamic-parameters log-events

Description

This command controls the creation of log events related to dynamic enforcement policer status and activity.

Default

log-events

Parameters

verbose

This parameter sends the same events as just "log-events" plus Hold Down Start, Hold Down End, DcpDynamicEnforceAlloc and DcpDynamicEnforceFreed events. This includes the allocation/de-allocation events (typically used for debug/tuning only – could be very noisy even when there is nothing much of concern).

Platforms

7705 SAR Gen 2

log-events

Syntax

log-events [**verbose**]

no log-events

Context

[Tree] (config>sys>security>dist-cpu-protection>policy>static-policer log-events)

Full Context

configure system security dist-cpu-protection policy static-policer log-events

Description

This command controls the creation of log events related to static-policer status and activity.

Default

log-events

Parameters

verbose

Sends the same events as just "log-events" plus Hold Down Start and Down End events. The optional "verbose" includes some events that are more likely used during debug/tuning/investigations.

Platforms

7705 SAR Gen 2

16.114 log-files-total-size

log-files-total-size

Syntax

log-files-total-size *megabytes*

no log-files-total-size

Context

[Tree] (config>log>storage log-files-total-size)

Full Context

configure log file-storage-control log-files-total-size

Description

This command configures the limit for the total space that all log files can occupy on each storage device on the active CPM.

When this threshold is reached, log events are no longer written to the files in the `\log` directory until SR OS removes older log files and the occupancy is below the limit.

When unconfigured, there is no specific limit for the total size of all log files.

Only log files in the `\log` directory with system generated names (including no file extension) are applicable toward the total size limit.

If a user manually adds or deletes log files from the `\log` directory, the size of the files is not taken into account for up to 1 hour.

The configured total size limit is not validated against the actual size of the installed storage devices. If the configured limit is larger than the installed CF device, the limit is never reached.

Default

no log-files-total-size

Parameters

megabytes

Specifies the total size limit for log files, in MB.

Values 50 to 4,194,304 MB (4 TBytes, 2^{22} MB)

Default 0

Platforms

7705 SAR Gen 2

16.115 log-filter

log-filter

Syntax

log-filter *filter-id*

no log-filter

Context

[Tree] (config>log>event-trigger>event>trigger-entry log-filter)

Full Context

configure log event-trigger event trigger-entry log-filter

Description

This command configures the log filter to be used for this trigger entry. The log filter defines the matching criteria that must be met in order for the log event to trigger the handler execution. The log filter is applied to the log event and, if the filtering decision results in a forward action, then the handler is triggered.

It is typically unnecessary to configure match criteria for the application or number in the log filter used for EHS since the particular filter is only applied for a specific log event application and number, as configured under the **config**>**log**>**event-trigger** context.

The **no** form of this command removes the log filter configuration.

Parameters

filter-id

Specifies the identifier of the filter.

Values 1 to 1500

Platforms

7705 SAR Gen 2

16.116 log-id

log-id

Syntax

log-id *log-id* [**name** *log-name*]

no log-id *log-id*

Context

[Tree] (config>service>vprn>log log-id)

Full Context

configure service vprn log log-id

Description

This command creates a context to configure destinations for event streams.

The **log-id** context is used to direct events, alarms or traps, and debug information to respective destinations.

A maximum of 30 logs can be configured.

Before an event can be associated with this log-id, the **from** command identifying the source of the event must be configured.

Only one destination can be specified for a *log-id*. The destination of an event stream can be an in-memory buffer, console, session, snmp-trap-group, Syslog, or file.

Use the **event-control** command to suppress the generation of events, alarms, and traps for all log destinations.

An event filter policy can be applied in the log-id context to limit which events, alarms, and traps are sent to the specified log-id.

By default, the log events in a VPRN log are a subset of the complete set of possible log events in SR OS. See the **config**>**log**>**services-all-events** command for more details.

The **no** form of this command deletes the log destination ID from the configuration.

Default

No log destinations are defined.

Parameters

log-id

Specifies the log ID number, expressed as a decimal integer.

Values 1 to 100

name log-name

Configures an optional log name, up to 64 characters, that can be used to refer to the log destination after it is created.

Platforms

7705 SAR Gen 2

log-id

Syntax

log-id *log-id* [**name** *log-name*]

no log-id *log-id*

Context

[Tree] (config>log log-id)

Full Context

configure log log-id

Description

This command creates a context to configure destinations for event streams.

The **log-id** context is used to direct events, alarms or traps, and debug information for specific destinations.

A maximum of 30 logs can be configured.

Before an event can be associated with this log ID, the **from** command identifying the source of the event must be configured.

Only one destination can be specified for a *log-id*. The destination of an event stream can be an in-memory buffer, console, session, snmp-trap-group, syslog, or file.

Use the **event-control** command to suppress the generation of events, alarms, and traps for all log destinations.

An event filter policy can be applied in the log-id context to limit which events, alarms, and traps are sent to the specified log-id.

Log-IDs 99 and 100 are created by the agent. Log-ID 99 captures all log messages. Log-ID 100 captures log messages with a severity level of major and above.

Note:
Log-ID 99 provides valuable information for the admin-tech file. Removing or changing the log configuration may hinder debugging capabilities. It is strongly recommended not to alter the configuration for Log-ID 99.

The **no** form of this command deletes the log destination ID from the configuration.

Parameters

log-id

Specifies the log ID, expressed as a decimal integer.

Values 1 to 101

name log-name

Configures an optional log name, up to 64 characters, that can be used to refer to the log destination after it is created.

Platforms

7705 SAR Gen 2

16.117 log-prefix

log-prefix

Syntax

log-prefix *log-prefix-string*

no log-prefix

Context

[Tree] (config>service>vprn>log>syslog log-prefix)

Full Context

configure service vprn log syslog log-prefix

Description

This command adds the string prepended to every syslog message sent to the syslog host.

RFC 3164, *The BSD syslog Protocol,* allows an alphanumeric string (tag) to be prepended to the content of every log message sent to the syslog host. This alphanumeric string can, for example, be used to identify the node that generates the log entry. The software appends a colon (:) and a space to the string and it is inserted in the syslog message after the date stamp and before the syslog message content.

Only one string can be entered. If multiple strings are entered, the last string overwrites the previous string. The alphanumeric string can contain lowercase (a-z), uppercase (A-Z) and numeric (0-9) characters.

The **no** form of this command removes the log prefix string.

Default

log-prefix "TMNX".

Parameters

log-prefix-string

Specifies the alphanumeric string of up to 32 characters. Spaces and colons (:) cannot be used in the string.

Platforms

7705 SAR Gen 2

log-prefix

Syntax

log-prefix *log-prefix-string*

no log-prefix

Context

[Tree] (config>log>syslog log-prefix)

Full Context

configure log syslog log-prefix

Description

This command adds the string prepended to every syslog message sent to the syslog host.

RFC 3164, allows an alphanumeric string (tag) to be prepended to the content of every log message sent to the syslog host. This alphanumeric string can, for example, be used to identify the node that generates the log entry. The software appends a colon (:) and a space to the string and it is inserted in the syslog message after the date stamp and before the syslog message content.

Only one string can be entered. If multiple strings are entered, the last string overwrites the previous string. The alphanumeric string can contain lowercase (a-z), uppercase (A-Z) and numeric (0 to 9) characters.

The **no** form of this command removes the log prefix string.

16.118 logger-event-bundling

logger-event-bundling

Syntax

[**no**] **logger-event-bundling**

Context

[Tree] (config>router>mpls logger-event-bundling)

Full Context

configure router mpls logger-event-bundling

Description

This feature merges two of the most commonly generated MPLS traps, vRtrMplsXCCreate and vRtrMplsXCDelete, which can be generated at both LER and LSR into a new specific trap vRtrMplsSessionsModified. In addition, this feature perform bundling of traps of multiple RSVP sessions, that is LSPs, into this new specific trap.

The intent is to provide a tool for the user to minimize trap generation in an MPLS network. Note that the MPLS trap throttling will not be applied to this new trap.

The **no** version of this command disables the merging and bundling of the above MPLS traps.

Platforms

7705 SAR Gen 2

16.119 login-banner

login-banner

Syntax

[**no**] **login-banner**

Context

[Tree] (config>system>login-control login-banner)

Full Context

configure system login-control login-banner

Description

This command enables or disables the display of a login banner. The login banner contains the SR OS copyright and build date information for a console login attempt.

The **no** form of this command causes only the configured pre-login-message and a generic login prompt to display.

Platforms

7705 SAR Gen 2

configure system login-control

Description

This command creates the context to configure the session control for console, Telnet, SSH, and FTP sessions.

Platforms

7705 SAR Gen 2

16.121 login-exec

login-exec

Syntax

login-exec *url-prefix*: *source-url*

no login-exec

Context

[Tree] (config>system>security>user>console login-exec)

[Tree] (config>system>security>user-template>console login-exec)

Full Context

configure system security user console login-exec

configure system security user-template console login-exec

Description

This command configures a user's login exec file which executes whenever the user successfully logs in to a console session.

Only one exec file can be configured. If multiple **login-exec** commands are entered for the same user, each subsequent entry overwrites the previous entry.

The **no** form of this command disables the login exec file for the user.

Default

no login-exec

Parameters

url-prefix: source-url

Specifies either a local or remote URL, up to 200 characters, that identifies the exec file that is executed after the user successfully logs in.

Platforms

7705 SAR Gen 2

16.122 login-scripts

login-scripts

Syntax

login-scripts

Context

[Tree] (config>system>login-control login-scripts)

Full Context

configure system login-control login-scripts

Description

Commands in this context configure CLI scripts that execute when a user (authenticated via any method including local user database, TACACS+, or RADIUS) first logs into a CLI session.

Platforms

7705 SAR Gen 2

16.123 logout

logout

Syntax

logout

Context

[Tree] (logout)

Full Context

logout

Description

This command logs out of the router session.

When the **logout** command is issued from the console, the login prompt is displayed, and any log IDs directed to the console are discarded. When the console session resumes (regardless of the user), the log output to the console resumes.

When a Telnet session is terminated from a **logout** command, all log IDs directed to the session are removed. When a user logs back in, the log IDs must be re-created.

16.125 loop-detect

loop-detect

Syntax

loop-detect {**drop-peer** | **discard-route** | **ignore-loop** | **off**}

no loop-detect

Context

[Tree] (config>service>vprn>bgp loop-detect)

[Tree] (config>service>vprn>bgp>group>neighbor loop-detect)

[Tree] (config>service>vprn>bgp>group loop-detect)

Full Context

configure service vprn bgp loop-detect

configure service vprn bgp group neighbor loop-detect

configure service vprn bgp group loop-detect

Description

This command configures how the BGP peer session handles loop detection in the AS path.

This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). The most specific value is used.

Dynamic configuration changes of **loop-detect** are not recognized.

The **no** form of this command used at the global level reverts to default, which is **loop-detect ignore-loop**.

The **no** form of this command used at the group level reverts to the value defined at the global level.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Default

loop-detect ignore-loop

Parameters

drop-peer

Sends a notification to the remote peer and drops the session.

discard-route

Discards routes received with loops in the AS path.

ignore-loop

ignores routes with loops in the AS path but maintains peering.

off

Disables loop detection.

Platforms

7705 SAR Gen 2

Full Context

configure router bgp group loop-detect

configure router bgp group neighbor loop-detect

configure router bgp loop-detect

Description

This command configures how the BGP peer session handles loop detection in the AS path.

This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). The most specific value is used.

Note:
Dynamic configuration changes of **loop-detect** are not recognized.

The **no** form of this command used at the global level reverts to default, which is **loop-detect ignore-loop**.

The **no** form of this command used at the group level reverts to the value defined at the global level.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Default

loop-detect ignore-loop

Parameters

drop-peer

Sends a notification to the remote peer and drops the session.

discard-route

Discards routes received from a peer with the same AS number as the router itself. This option prevents routes looped back to the router from being added to the routing information base and consuming memory. When this option is changed, the change will not be active for an established peer until the connection is re-established for the peer.

ignore-loop

Ignores routes with loops in the AS path but maintains peering.

off

Disables loop detection.

Full Context

configure service vprn bgp group neighbor loop-detect-threshold

configure service vprn bgp loop-detect-threshold

configure service vprn bgp group loop-detect-threshold

Description

This command provides additional control over the behavior enabled by the **loop-detect** command. If this command specifies a threshold value of *n,* then a route received by the local BGP speaker with an AS path

that contains up to *n* occurrences of the local speaker's AS number is considered valid and not treated as an AS path loop. An AS loop is considered to occur only when the received AS path has more than *n* occurrences of the local speaker's AS number.

The **no** form of this command removes the configuration and sets the value to 0. One or more occurrence of the local speaker's AS number in the received AS path triggers the **loop-detect** behavior.

Default

no loop-detect-threshold

Parameters

loop-detect-threshold

The maximum number of occurrences of the local speaker's AS number in the received AS path before the AS path is considered to be a loop.

Values 0 to 15

Default 0

[**no**] **loopfree-alternates**

Context

[Tree] (config>router>isis loopfree-alternates)

Full Context

configure router isis loopfree-alternates

Description

This command enables Loop-Free Alternate (LFA) computation by SPF for the IS-IS routing protocol.

When this command is enabled, it instructs the IGP SPF to attempt to pre-compute both a primary nexthop and an LFA next-hop for every learned prefix. When found, the LFA next-hop is populated into the routing table along with the primary next-hop for the prefix.

The user enables the remote LFA next-hop calculation by the IGP LFA SPF by appending the remote-lfa option. When this option is enabled in an IGP instance, SPF performs the remote LFA additional computation following the regular LFA next-hop calculation when the latter resulted in no protection for one or more prefixes which are resolved to a given interface.

Remote LFA extends the protection coverage of LFA-FRR to any topology by automatically computing and establishing/tearing-down shortcut tunnels, also referred to as repair tunnels, to a remote LFA node which puts the packets back into the shortest without looping them back to the node which forwarded them over the repair tunnel. The remote LFA node is referred to as PQ node. A repair tunnel can in theory be an RSVP LSP, a LDP-in-LDP tunnel, or a SR tunnel. In this feature, it is restricted to use SR repair tunnel to the remote LFA node.

The remote LFA algorithm is a per-link LFA SPF calculation and not a per-prefix like the regular LFA one. So, it provides protection for all destination prefixes which share the protected link by using the neighbor on the other side of the protected link as a proxy for all these destinations.

The Topology-Independent LFA (TI-LFA) further improves the protection coverage of a network topology by computing and automatically instantiating a repair tunnel to a Q node which is not in shortest path from the computing node. The repair tunnel uses shortest path to the P node and a source routed path from the P node to the Q node.

In addition, the TI-LFA algorithm selects the backup path which matches the post-convergence path. This helps the capacity planning in the network since traffic will always flow on the same path when transitioning to the FRR next-hop and then onto the new primary next-hop.

At a high level, the TI-LFA protection algorithm is searching for a candidate P-Q set separated with a number of hops such that the label stack size does not exceed the value of **ti-lfa max-sr-frr-labels**, on each of the post-convergence paths to each destination node or prefix D.

When the **ti-lfa** option is enabled in IS-IS, it provides TI-LFA node-protect or link-protect backup path in IS-IS MT=0 for an SR-ISIS IPV4/IPv6 tunnel (node SID and adjacency SID), for an IPv4 SR-TE LSP, and for LDP IPv4 FEC when the LDP **fast-reroute backup-sr-tunnel** option is enabled.

The **max-sr-frr-labels** parameter is used to limit the search for the TI-LFA backup next-hop:

1. 0 — The IGP LFA SPF restricts the search to TI-LFA backup next-hop which does not require a repair tunnel, meaning that P node and Q node are the same and match a neighbor. This is also the case when both P and Q node match the advertising router for a prefix.
2. 1 to 3 — The IGP LFA SPF will widen the search to include a repair tunnel to a P node which itself is connected to the Q nodes with a 0-to-2 hops for a total of maximum of three labels: one node SID to P node and two adjacency SIDs from P node to the Q node. If the P node is a neighbor of the computing node, its node SID is compressed and meaning that up to three adjacency SIDs can separate the P and Q nodes.
3. 2 (default) — Corresponds to a repair tunnel to a non-adjacent P which is adjacent to the Q node. If the P node is a neighbor of the computing node, then the node SID of the P node is compressed and the default value of two labels corresponds to two adjacency SIDs between the P and Q nodes.

When the **node-protect** command is enabled, the router will prefer a node-protect over a link-protect repair tunnel for a given prefix if both are found in the Remote LFA or TI-LFA SPF computations. The SPF computations may only find a link-protect repair tunnel for prefixes owned by the protected node. This

node-protect backup protects against the failure of a downstream node in the path of the prefix of a node SID except for the node owner of the node SID.

The parameter **max-pq-nodes** in Remote LFA controls the maximum number of PQ nodes found in the LFA SPFs for which the node protection check is performed. The node-protect condition means the router must run the original Remote LFA algorithm plus one extra forward SPF on behalf of each PQ node found, potentially after applying the **max-pq-cost** parameter, to check if the path from the PQ node to the destination does not traverse the protected node. Setting this parameter to a lower value means the LFA SPFs will use less computation time and resources but may result in not finding a node-protect repair tunnel.

The **no** form of this command disables the LFA computation by IGP SPF.

[Tree] (config>router>ospf3 loopfree-alternates)

Full Context

configure router ospf loopfree-alternates

configure router ospf3 loopfree-alternates

Description

This command enables Loop-Free Alternate (LFA) computation by SPF under the OSPF or OSPFv3 routing protocol instance.

When this command is enabled, it instructs the IGP SPF to attempt to precalculate both a primary next hop and an LFA next hop for every learned prefix. When found, the LFA next hop is populated into the routing table along with the primary next hop for the prefix.

The user enables the remote LFA next hop calculation by the IGP LFA SPF by appending the **remote-lfa** option. When this option is enabled in an IGP instance, SPF performs the remote LFA additional computation following the regular LFA next hop calculation when the latter resulted in no protection for one or more prefixes which are resolved to a particular interface.

Remote LFA extends the protection coverage of LFA-FRR to any topology by automatically computing and establishing or tearing down shortcut tunnels, also referred to as repair tunnels, to a remote LFA node that puts the packets back into the shortest path without looping them back to the node that forwarded them over the repair tunnel. The remote LFA node is referred to as a PQ node. A repair tunnel can, in theory, be

an RSVP-TE LSP, an LDP-in-LDP tunnel, or a segment routing (SR) tunnel. In this command, **remote-lfa** is restricted to using an SR repair tunnel to the remote LFA node.

The remote LFA algorithm is a per-link LFA SPF calculation and not a per-prefix calculation like the regular LFA algorithm. The remote LFA algorithm provides protection for all destination prefixes that share the protected link by using the neighbor on the other side of the protected link as a proxy for all the destinations.

The Topology-Independent LFA (TI-LFA) further improves the protection coverage of a network topology by computing and automatically instantiating a repair tunnel to a Q node which is not in shortest path from the computing node. The repair tunnel uses shortest path to the P node and a source routed path from the P node to the Q node.

In addition, the TI-LFA algorithm selects the backup path which matches the post-convergence path. This helps the capacity planning in the network since traffic will always flow on the same path when transitioning to the FRR next hop and then onto the new primary next hop.

At a high level, the TI-LFA protection algorithm is searching for a candidate P-Q set separated with a number of hops such that the label stack size does not exceed the value of **ti-lfa max-sr-frr-labels**, on each of the post-convergence paths to each destination node or prefix D.

When the **ti-lfa** option is enabled in OSPF, it provides TI-LFA node-protect or link-protect backup path for a SR-OSPF IPV4 tunnel (node SID and adjacency SID), and for a IPv4 SR-TE LSP.

The **max-sr-frr-labels** parameter is used to limit the search for the TI-LFA backup next hop:

1. 0 — The IGP LFA SPF restricts the search to TI-LFA backup next hop which does not require a repair tunnel, meaning that P node and Q node are the same and match a neighbor. This is also the case when both P and Q node match the advertising router for a prefix.
2. 1 to 3 — The IGP LFA SPF will widen the search to include a repair tunnel to a P node which itself is connected to the Q nodes with a 0-to-2 hops for a total of maximum of three labels: one node SID to P node and two adjacency SIDs from P node to the Q node. If the P node is a neighbor of the computing node, its node SID is compressed and meaning that up to three adjacency SIDs can separate the P and Q nodes.
3. 2 (default) — Corresponds to a repair tunnel to a non-adjacent P which is adjacent to the Q node. If the P node is a neighbor of the computing node, then the node SID of the P node is compressed and the default value of two labels corresponds to two adjacency SIDs between the P and Q nodes.

The TI-LFA repair tunnel can have a maximum of three labels pushed in addition to the label of the destination node or prefix. The user can set a lower maximum value for the additional FRR labels by configuring the CLI option **max-sr-frr-labels** *labels*. The default value is 2.

When the **node-protect** command is enabled, the router will prefer a node-protect over a link-protect repair tunnel for a given prefix if both are found in the Remote LFA or TI-LFA SPF computations. The SPF computations may only find a link-protect repair tunnel for prefixes owned by the protected node. This node-protect backup protects against the failure of a downstream node in the path of the prefix of a node SID except for the node owner of the node SID.

The parameter **max-pq-nodes** in Remote LFA controls the maximum number of PQ nodes found in the LFA SPFs for which the node protection check is performed. The node-protect condition means the router must run the original Remote LFA algorithm plus one extra forward SPF on behalf of each PQ node found, potentially after applying the **max-pq-cost** parameter, to check if the path from the PQ node to the destination does not traverse the protected node. Setting this parameter to a lower value means the LFA SPFs will use less computation time and resources but may result in not finding a node-protect repair tunnel.

The **no** form of this command disables the LFA computation by the IGP SPF.

configure saa test loss-event

Description

Specifies that at the termination of an SAA test run, the calculated loss event value is evaluated against the configured rising and falling loss event thresholds. SAA threshold events are generated as required.

The configuration of loss event thresholds is optional.

The **no** form of this command disables the loss-event test run.

Parameters

rising-threshold *threshold*

Specifies a rising threshold loss event value, in packets. When the test run is completed, the calculated loss event value is compared to the configured loss event rising threshold. If the test run loss event value is greater than the configured rising threshold value then an SAA threshold event is generated. The SAA threshold event is tmnxOamSaaThreshold, logger application OAM, event #2101.

Values 0 to 2147483647

Default 0

falling-threshold *threshold*

Specifies a falling threshold loss event value, in packets. When the test run is completed, the calculated loss event value is compared to the configured loss event falling threshold. If the test run loss event value is greater than the configured falling threshold value then an SAA threshold event is generated. The SAA threshold event is tmnxOamSaaThreshold, logger application OAM, event #2101.

Values 0 to 2147483647

Default 0

direction

Specifies the direction for OAM ping responses received for an OAM ping test run.

Values **inbound** — Monitor the value of jitter calculated for the inbound, one-way, OAM ping responses received for an OAM ping test run.

outbound — Monitor the value of jitter calculated for the outbound, one-way, OAM ping requests sent for an OAM ping test run.

roundtrip — Monitor the value of jitter calculated for the round trip, two-way, OAM ping requests and replies for an OAM ping test run.

Default roundtrip

16.138 lower-bound

lower-bound

Syntax

lower-bound *microseconds*

no lower-bound

Context

[Tree] (config>oam-pm>bin-group>bin-type>bin lower-bound)

Full Context

configure oam-pm bin-group bin-type bin lower-bound

Description

This command allows the operator to specify the individual floors thresholds for the bins. The operator does not have to specific a lower threshold for every bin that was previously defined by the bin-count for the specific type. By default, each bin is the bin-number times 5000 microseconds. Lower thresholds in the previous adjacent bin must be lower than the threshold of the next higher bin threshold. A separate line per bin is required to configure an operator-specific threshold. An error prevents the bin from entering the active state if this is not maintained, at the time the **no shutdown** is issued. Bin 0 is the result of the difference between 0 and the configured lower-threshold of bin 1. The highest bin in the bin-count captures every result above the threshold. Any negative delay metric result is treated as zero and placed in bin 0.

The **no** form of this command removes the user configured threshold value and applies the default for the bin.

Parameters

microseconds

Specifies the threshold that defines the floor of the bin. The bin range is the difference between its configured threshold and the threshold of the next higher bin in microsecond threshold value.

Values 1 to 4294967295

Default bin-number * 5000

16.139 lsa-accumulate

lsa-accumulate

Syntax

lsa-accumulate *lsa-accumulate*

no lsa-accumulate

Context

[Tree] (config>router>ospf3>timers lsa-accumulate)

[Tree] (config>router>ospf>timers lsa-accumulate)

Full Context

configure router ospf3 timers lsa-accumulate

configure router ospf timers lsa-accumulate

Description

This command sets the internal OSPF delay to allow for the accumulation of multiple LSA so OSPF messages can be sent as efficiently as possible. The **lsa-accumulate** timer applies to all LSAs except Type 1 and Type 2 LSAs, which are sent immediately. LSAs are accumulated and then sent when:

- its size reaches the MTU size of the interface
- a new LSA is received on the interface
- the **lsa-accumulate** timer expires

Shorting this delay can speed up the advertisement of LSAs to OSPF neighbors but may increase the number of OSPF messages sent.

The **no** form of this command reverts to the default value.

Note:
The timer granularity is 10 ms if the value is less than 500 ms, and 100 ms if the value is greater than or equal to 500 ms. Timer values are rounded down to the nearest granularity, for example a configured value of 550 ms is internally rounded down to 500 ms.

Default

lsa-accumulate 1000

Parameters

lsa-accumulate

Specifies the LSA accumulation delay in milliseconds.

Values 0 to 1000

Platforms

7705 SAR Gen 2

16.140 lsa-arrival

lsa-arrival

Syntax

lsa-arrival *lsa-arrival-time*

no lsa-arrival

Context

[Tree] (config>service>vprn>ospf3>timers lsa-arrival)

[Tree] (config>service>vprn>ospf>timers lsa-arrival)

Full Context

configure service vprn ospf3 timers lsa-arrival

configure service vprn ospf timers lsa-arrival

Description

This parameter defines the minimum delay that must pass between receipt of the same Link State Advertisements (LSAs) arriving from neighbors.

It is recommended that the neighbor's configured **lsa-generate** *lsa-second-wait* interval is equal to or greater than the **lsa-arrival** timer configured here.

Use the **no** form of this command to return to the default.

Note:
The timer granularity is 10 ms if the value is less than 500 ms, and 100 ms if the value is ≥ 500 ms. Timer values are rounded down to the nearest granularity, for example a configured value of 550 ms is internally rounded down to 500 ms.

Default

lsa-arrival 1000

Parameters

lsa-arrival-time

Specifies the timer in milliseconds.

Values 0 to 600000

Platforms

7705 SAR Gen 2

lsa-arrival

Syntax

lsa-arrival *lsa-arrival-time*

configure service vprn ospf area interface lsa-filter-out

configure router ospf area interface lsa-filter-out

configure service vprn ospf3 area interface lsa-filter-out

configure router ospf3 area interface lsa-filter-out

Description

This command enables filtering of outgoing OSPF LSAs on the selected OSPFv2 or OSPFv3 interface. Three filtering options are provided:

- Do not flood any LSAs out the interface. This option is suitable if the neighbor is simply-connected and has a statically configured default route with the address of this interface as next-hop.
- Flood the router's own router-LSA out the interface and suppress all other flooded LSAs. This option is suitable if the neighbor is simply-connected and has a statically configured default route with a loopback or system interface address (contained in the router-LSA) as next-hop.

- Flood the router's own router-LSA and all self-generated type-3, type-5 and type-7 LSAs advertising a default route (0/0) out the interface; suppress all other flooded LSAs. This option is suitable if the neighbor is simply-connected and does not have a statically configured default route.

The **no** form of this command disables OSPF LSA filtering (normal operation).

Default

no lsa-filter-out

Platforms

7705 SAR Gen 2

16.142 lsa-generate

lsa-generate

Syntax

lsa-generate *max-lsa-wait* [lsa-initial-wait *lsa-initial-wait* [*lsa-second-wait lsa-second-wait*]]

no lsa-generate-interval

Context

[Tree] (config>service>vprn>ospf3>timers lsa-generate)

[Tree] (config>service>vprn>ospf>timers lsa-generate)

Full Context

configure service vprn ospf3 timers lsa-generate

configure service vprn ospf timers lsa-generate

Description

This parameter customizes the throttling of OSPF LSA-generation. Timers that determine when to generate the first, second, and subsequent LSAs can be controlled with this command. Subsequent LSAs are generated at increasing intervals of the *lsa-second-wait* timer until a maximum value is reached.

Configuring the **lsa-arrival** interval to equal or less than the *lsa-second-wait* interval configured in the **lsa-generate** command is recommended.

The **no** form of this command reverts to the default.

Note:
The timer granularity is 10 ms if the value is less than 500 ms, and 100 ms if the value is ≥ 500 ms. Timer values are rounded down to the nearest granularity, for example a configured value of 550 ms is internally rounded down to 500 ms.

Parameters

max-lsa-wait

Specifies the maximum interval, in milliseconds, between two consecutive occurrences of an LSA being generated.

Values 10 to 600000

Default 5000

lsa-initial-wait

Specifies the first waiting period between link-state advertisements (LSA) originate(s), in milliseconds. When the LSA exceeds the **lsa-initial-wait** timer value and the topology changes, there is no wait period and the LSA is immediately generated.

When an LSA is generated, the initial wait period commences. If, within the specified **lsa-initial-wait** period and another topology change occurs, then the **lsa-initial-wait** timer applies.

Values 10 to 600000

Default 5000

lsa-second-wait

Specifies the hold time in milliseconds between the first and second LSA generation. The next topology change is subject to this second wait period. With each subsequent topology change, the wait time doubles (this is 2x the previous wait time). This assumes that each failure occurs within the relevant wait period.

Values 10 to 600000

Default 5000

Platforms

7705 SAR Gen 2

[Tree] (debug>router>ospf lsdb)

Full Context

debug router ospf3 lsdb

debug router ospf lsdb

Description

This command enables debugging for an OSPF link-state database (LSDB).

Parameters

type

Specifies the OSPF link-state database (LSDB) type.

Values in the **ospf** context — router, network, summary, asbr, extern, nssa, area-opaque, as-opaque, link-opaque

in the **ospf3** context — router, network, inter-area-pfx, inter-area-rtr, external, nssa, intra-area-pfx, rtr-info-link, rtr-info-area, rtr-info-as

ls-id

Specifies an LSA type specific field containing either a router ID or an IP address. It identifies the piece of the routing domain being described by the advertisement.

adv-rtr-id

Specifies the router identifier of the router advertising the LSA.

area area-id

Specifies a 32-bit integer uniquely identifying an area.

Values ip-address — a.b.c.d

area — 0 to 4294967295

Platforms

7705 SAR Gen 2

lsn

Syntax

lsn router *router-instance* [**b4** *ipv6-address*] [**aftr** *ipv6-address*] **ip** *ip-address* **protocol** {**tcp** | **udp**} [**port** *port*] [**outside-ip** *ipv4-address*] [**outside-port** *port*] [**nat-policy** *nat-policy-name*] [*force*]

no lsn router *router-instance* [**b4** *ipv6-address*] **ip** *ip-address* **protocol** {**tcp** | **udp**} **port** *port* [**nat-policy** *nat-policy-name*]

Context

[Tree] (config>service>nat>fwd lsn)

Full Context

configure service nat port-forwarding lsn

Description

This command creates NAT static port forwards for LSN44, Ds-Lite and NAT64. Static port forwards (SPF) are static mappings created so that certain applications on the inside (private side) can be reached from host that are on the outside of the NAT. SPF statically map the subscriber (inside IP address in LSN44, CPE IPv6 address/prefix in DS-Lite and IPv6 prefix in NAT64), inside port and protocol to an outside IPv4 address, port and the same protocol.

If only the inside router, the inside IPv4/v6 address/prefix and the protocol are configured as parameters in the SPF request, the remaining fields in the mapping (outside port and outside IPv4 address) will be selected automatically by the node and reported in CLI once the command execution is completed.

Specifying the outside IPv4 address in the SPF request, mandates that all other, otherwise optional, parameters be also specified in the request (inside port and outside port). This creates a fully specified SPF request. Fully specified SPF request can be used in multi-chassis NAT redundancy deployments where the SPF is manually replicated between the SR OS nodes. In single chassis NAT deployments, fully specified SPF request is guaranteed to work only in the system with a single MS-ISA in it. Otherwise (multiple MS-ISAs in the system) a conflict may arise where two distinct inside IP addresses that may reside on separate MS-ISAs are requested to be mapped to the same outside IPv4 address. This will not be possible since the outside IPv4 address cannot be split across the MS-ISAs (each IP address, inside or outside, is tied to a single MS-ISA).

In non-fully specified SPF requests (missing the inside port and/or outside port and the outside IPv4 address within the SPF request), the outside IPv4 address selection will depend on the configuration of the outside port in the SPF request:

- If the outside port is not specified or is specified from the configured **port-forwarding-range** [1024..port-forwarding-range], then the outside IPv4 address will be the same as the outside IPv4 address in an existing dynamic mapping for the same subscriber. If the subscriber does not exist (no dynamic mappings exist at the time of SPF creation request), then the subscriber will be automatically created and an outside IPv4 address will be assigned. In case that the outside ports are not available from the outside IPv4 address of the corresponding dynamic mapping, then the SPF request will fail. In other words, the dynamic and static mappings (created in this manner) for the same subscriber must use the same outside IPv4 address.
- If the outside port from the well-known port range [0 to 1023] is requested, then the outside IPv4 address does not have to match the outside IPv4 address of an existing dynamic mapping for the same subscriber, but can instead be any outside IPv4 address.

If multiple NAT policies per inside routing context are used, then the NAT policy must be specified in the SPF creation request. This is needed so the SPF be created in the correct pool.

SPFs are disabled by default and they must be explicitly enabled by the **port-limits forwarding** command within the NAT policy.

Configured SPFs, unlike SPFs created with the **tools** commands, are preserved across reboots without having to configure persistency (**config>system>persistence>nat-port-forwarding**) since they are part of the configuration. When the pool is shutdown the SPFs are deactivated. When the pool is enabled (no shutdown), the SPFs (as created by the **tools** command or by configuration) are activated.

To avoid possible persistency related conflicts, SPFs can only be created using one method on a given node: either as configuration (the CLI **configure** branch) or using the **tools** command. For example: if a first SPF entry is created via CLI **tools** commands, the node prevents SPF creation via configuration (the CLI **configure** branch) and vice versa.

The **no** form of the command deletes NAT static port forwards for LSN44, Ds-Lite and NAT64.

Parameters

router *router-instance*

This mandatory parameter specifies the inside routing instance; router name or service-id.

Values router-name, service-id

b4 *ipv6-address*

This optional parameter specifies the IPv6 address of the B4 element in DS-Lite.

Values <ipv6-address> : ipv6-address - x:x:x:x:x:x:x:x (eight 16-bit pieces)
x:x:x:x:x:x:d.d.d.d
x - [0..FFFF]H
d - [0..255]D

aftr *ipv6-address*

This optional parameter specifies IPv6 address of the AFTR element in DS-Lite.

Values <ip-address> : ipv4-address - a.b.c.d
ipv6-address - x:x:x:x:x:x:x:x (eight 16-bit pieces)
x:x:x:x:x:x:d.d.d.d
x - [0..FFFF]H
d - [0..255]D

protocol {tcp | udp}

This mandatory parameter specifies the protocol to use, either TCP or UDP.

port *port*

This optional parameter specifies a source port.

Values 1 to 65535

outside-ip *ipv4-address*

This mandatory parameter specifies the outside IPv4 address. If the outside IPv4 address is specified, then all other optional parameters become mandatory.

outside-port *port*

This optional parameter specifies the outside port.

nat-policy *policy-name*

If multiple NAT policies are used inside the routing context, then the NAT policy should be specified in the SPF request so the SPF is created in the correct NAT pool. Otherwise, the default NAT policy from the inside routing context will be used.

force

Force allocation of static port forwards.

This command is only applicable to a LSN44 pool with flexible port allocations. Such pools allow interleaving of static port forwards with other dynamically allocated ports triggered by traffic flow.

If the requested outside port in the static port forward command is already occupied by a dynamically allocated port, using the force keyword preempts the dynamically allocated port and reassigns it as a port forwarding port.

During preemption, all the flows associated with the dynamically allocated port are terminated.

When the requested port forward is occupied by another static port and not a dynamic port, the command fails even if the force keyword is configured.

When a static port forwarding command requests an arbitrary outside port that is not specified in the command, the force keyword has an effect if the entire port space is already occupied. In this case, one of the dynamic ports is preempted.

Values Keyword

16.145 lsp

lsp

Syntax

[**no**] **lsp** *lsp-name*

Context

[Tree] (config>router>ldp>targ-session>peer>tunneling lsp)

Full Context

configure router ldp targeted-session peer tunneling lsp

Description

This command configures a specific LSP destined to this peer and to be used for tunneling of LDP FEC over RSVP. A maximum of 4 RSVP LSPs can be explicitly used for tunneling LDP FECs to the T-LDP peer.

It is not necessary to specify any RSVP LSP in this context unless there is a need to restrict the tunneling to selected LSPs. All RSVP LSPs with a to address matching that of the T-LDP peer are eligible by default. The user can also exclude specific LSP names by using the ldp-over-rsvp exclude command in the **config>router>mpls>lsp** context.

Platforms

7705 SAR Gen 2

lsp

Syntax

[**no**] **lsp** *lsp-name* [**bypass-only** | **p2mp-lsp** | **mpls-tp** *src-tunnel-num* | **sr-te**]

Context

[Tree] (config>router>mpls lsp)

Full Context

configure router mpls lsp

Description

This command creates an LSP that is either signaled dynamically by the router, or a statically provisioned MPLS-TP LSP.

When the LSP is created, the egress router must be specified using the **to** command and at least one **primary** or **secondary** path must be specified for signaled LSPs, or at least one working path for MPLS-TP LSPs. All other statements under the LSP hierarchy are optional.

LSPs are created in the administratively down (**shutdown**) state.

The **no** form of this command deletes the LSP. All configuration information associated with this LSP is lost. The LSP must be administratively shutdown before it can be deleted. The LSP must also be unbound from all SDPs before it can be deleted.

Parameters

lsp-name

Specifies the name that identifies the LSP. The LSP name can be up to 64 characters long and must be unique.

bypass-only

Defines an LSP as a manual bypass LSP exclusively. When a path message for a new LSP requests bypass protection, the PLR first checks if a manual bypass tunnel satisfying the path constraints exists. If one if found, the router selects it. If no manual bypass tunnel is found, the router dynamically signals a bypass LSP in the default behavior. The CLI for this feature includes a knob that provides the user with the option to disable dynamic bypass creation on a per node basis.

p2mp-lsp

Defines an LSP as a point-to-multipoint LSP. The following parameters can be used with a P2MP LSP: adaptive, adspec, cspf, exclude, fast-reroute, from, hop-limit, include, metric, retry-limit, retry-timer, resignal-timer. The following parameters cannot be used with a P2MP LSP: primary, secondary, to, dest-global-id, dest-tunnel-number, working-tp-path, protect-tp-path.

mpls-tp ***src-tunnel-num***

Defines an LSP as an MPLS-TP LSP. The *src-tunnel-num* is a mandatory create time parameter for mpls-tp LSPs, and has to be assigned by the user based on the configured range of tunnel IDs. The following parameters can only be used with an MPLS-TP LSP: to, dest-global-id, dest-tunnel-number, working-tp-path, protect-tp-path. Other parameters defined for the above LSP types cannot be used.

sr-te

Defines an LSP of type Segment Routing Traffic Engineering (SR-TE) LSP. The user can associate an empty path or a path with strict or loose explicit hops with the primary path of the SR-TE LSP. A hop which corresponds to an adjacency SID must be identified with its far-end host IP address (next-hop) on the subnet. If the local end host IP address is provided, this hop is ignored since this router can have multiple adjacencies (next-hops) on the same subnet. A hop which corresponds to a node SID is identified by the prefix address. The user is only allowed to configure a primary path for the SR-TE LSP.

configure service sdp lsp

Description

This command creates associations between one or more label switched paths (LSPs) and an Multi-Protocol Label Switching (MPLS) service destination point (SDP). This command is implemented *only* on MPLS-type encapsulated SDPs.

In MPLS SDP configurations *either* one or more LSP names can be specified *or* LDP can be enabled. The SDP **ldp** and **lsp** commands are mutually exclusive except if the mixed-lsp-mode option is also enabled. If an LSP is specified on an MPLS SDP, then LDP cannot be enabled on the SDP. To enable LDP on the SDP when an LSP is already specified, the LSP must be removed from the configuration using the **no lsp lsp-name** command.

Alternatively, if LDP is already enabled on an MPLS SDP, then an LSP cannot be specified on the SDP. To specify an LSP on the SDP, the LDP must be disabled or the mixed-lsp-mode option is also enabled. The LSP must have already been created in the **config>router>mpls** context. with a valid far-end IP address. RSVP must be enabled.

If no LSP is associated with an MPLS SDP, the SDP cannot enter the operationally up state. The SDP can be administratively enabled (**no shutdown)** with no LSP associations. The *lsp-name* may be shutdown, causing the association with the SDP to be operationally down (the LSP will not be used by the SDP).

Up to 16 LSP names can be entered on a single command line.

The **no** form of this command deletes one or more LSP associations from an SDP. If the *lsp-name* does not exist as an association or as a configured LSP, no error is returned. An *lsp-name* must be removed from all SDP associations before the *lsp-name* can be deleted from the system. The SDP must be administratively disabled (**shutdown)** before the last *lsp-name* association with the SDP is deleted.

Parameters

lsp-name

Specifies the name of the LSP to associate with the SDP. An LSP name is case sensitive and is limited to 32 ASCII 7-bit printable characters with no spaces. If an exact match of *lsp-name* does not already exist as a defined LSP, an error message is generated. If the *lsp-name* does exist and the LSP **to** IP address matches the SDP **far-end** IP address, the association is created.

Syntax

lsp *lsp-name*

[**no**] **lsp**

Context

[Tree] (config>oam-pm>session>ip>tunnel>mpls>rsvp-te lsp)

Full Context

configure oam-pm session ip tunnel mpls rsvp-te lsp

Description

This command configures the name of the RSVP-TE LSP to transport the test packets.

The **no** form of this command removes the *lsp-name* from the configuration.

Parameters

lsp-name

Specifies the LSP name, up to 64 characters.

Platforms

7705 SAR Gen 2

lsp

Syntax

lsp *lsp-name*

no lsp

Context

[Tree] (config>oam-pm>session>ip>tunnel>mpls>sr-te lsp)

Full Context

configure oam-pm session ip tunnel mpls sr-te lsp

Description

This command configures specification of SR-TE specific tunnel information that is used to transport the test packets. Entering this context removes all other tunnel type options configured under the **configure oam-pm session ip tunnel mpls** context. Only a single **mpls** type can be configured for an OAM-PM session.

The **no** form of this command removes the SR-TE LSP name from the configuration.

Default

no lsp

Parameters

lsp-name

Specifies the SR-TE LSP name, up to 64 characters.

Platforms

7705 SAR Gen 2

16.146 lsp-bsid-block

lsp-bsid-block

Syntax

lsp-bsid-block *name*

no lsp-bsid-block

Context

[Tree] (config>router>mpls lsp-bsid-block)

Full Context

configure router mpls lsp-bsid-block

Description

This command configures a reference to a pre-existing reserved label block for statically configured binding SIDs.

The **no** form of this command removes the use of the label block as a pool of binding SIDs.

Parameters

name

Specifies an existing reserved label block name, up to 64 characters.

Platforms

7705 SAR Gen 2

16.147 lsp-exp

lsp-exp

Syntax

lsp-exp *lsp-exp-value* **fc** *fc-name* **profile** {**in** | **out**}

no lsp-exp

Context

[Tree] (config>qos>network>ingress lsp-exp)

Full Context

configure qos network ingress lsp-exp

Description

This command creates a mapping between the LSP EXP bits of the network ingress traffic and the forwarding class.

Ingress traffic that matches the specified LSP EXP bits will be assigned to the corresponding forwarding class. Multiple commands can be entered to define the association of some or all eight LSP EXP bit values to the forwarding class. For undefined values, packets are assigned to the forwarding class specified under the **default-action** command.

The **no** form of this command removes the association of the LSP EXP bit value to the forwarding class. The **default-action** then applies to that LSP EXP bit pattern.

Default

no lsp-exp

Parameters

lsp-exp-value

Specify the LSP EXP values to be associated with the forwarding class.

Values 0 to 8 (Decimal representation of three EXP bit field)

fc *fc-name*

Enter this required parameter to specify the fc-name that the EXP bit pattern will be associated with.

Values be, l2, af, l1, h2, ef, h1, nc

profile {in | out}

Enter this required parameter to indicate whether the LSP EXP value is the in-profile or out-of-profile value.

Values in, out

Platforms

7705 SAR Gen 2

16.148 lsp-exp-in-profile

lsp-exp-in-profile

Syntax

lsp-exp-in-profile *lsp-exp-value*

no lsp-exp-in-profile

Context

[Tree] (config>qos>network>egress>fc lsp-exp-in-profile)

Full Context

configure qos network egress fc lsp-exp-in-profile

Description

This command specifies the in-profile LSP EXP value for the forwarding class. The EXP value will be used for all LSP labeled packets requiring marking that require marking at egress on this forwarding class queue, and that are in-profile. The inplus-profile traffic is marked with the same value as in-profile traffic.

When multiple EXP values are associated with the forwarding class at network egress, the last name entered will overwrite the previous value.

The **no** form of this command resets the configuration to the factory default in-profile EXP setting.

Default

Policy-id 1:	Factory setting
Policy-id 2 to 65535:	Policy-id setting

Parameters

lsp-exp-value

Specifies the 3-bit LSP EXP bit value, expressed as a decimal integer.

Values 0 to 7

Platforms

7705 SAR Gen 2

16.149 lsp-exp-out-profile

lsp-exp-out-profile

Syntax

lsp-exp-out-profile *lsp-exp-value*

no lsp-exp-out-profile

Context

[Tree] (config>qos>network>egress>fc lsp-exp-out-profile)

Full Context

configure qos network egress fc lsp-exp-out-profile

Description

This command specifies the out-of-profile LSP EXP value for the forwarding class. The EXP value will be used for all LSP labeled packets that require marking at egress on this forwarding class queue, and that are out-of-profile. The exceed-profile traffic is marked with the same value as out-of-profile traffic.

When multiple EXP values are associated with the forwarding class at network egress, the last name entered will overwrite the previous value.

The **no** form of this command resets the configuration to the factory default out-of-profile EXP setting.

Default

Policy-id 1:	Factory setting
Policy-id 2 to 65535:	Policy-id setting

Parameters

mpls-exp-value

Specifies the 3-bit MPLS EXP bit value, expressed as a decimal integer.

Values 0 to 7

Platforms

7705 SAR Gen 2

16.150 lsp-history

lsp-history

Syntax

[no] lsp-history

Context

[Tree] (config>router>mpls lsp-history)

Full Context

configure router mpls lsp-history

Description

This command allocates memory, which may be used to store up to the last 100 significant events for each RSVP-TE and SR-TE LSP.

The **no** form of this command deallocates memory for storing LSP history events and deletes any event history .

Default

no lsp-history

16.151 lsp-init-retry-timeout

lsp-init-retry-timeout

Syntax

lsp-init-retry-timeout *seconds*

no lsp-init-retry-timeout

Context

[Tree] (config>router>mpls lsp-init-retry-timeout)

Full Context

configure router mpls lsp-init-retry-timeout

Description

This command configures the initial LSP path retry-timer.

The new LSP path initial retry-timer is used instead of the retry-timer to abort the retry cycle when no RESV is received. The retry-timer exclusively governs the time between two retry cycles and to handle retrying of an LSP path in a failure case with PATH errors or RESVTear.

The intent is that the user can now control how many refreshes of the pending PATH state can be performed before starting a new retry-cycle with a new LSP ID. This is all done without affecting the ability to react faster to failures of the LSP path, which will continue to be governed by the retry-timer.

The **no** form of this command returns the timer to the default value.

Default

lsp-init-retry-timeout 30

Parameters

seconds

Specifies the value (in s), used as the fast retry timer for a secondary path.

Values 10 to 600

Default 30

Platforms

7705 SAR Gen 2

16.152 lsp-lifetime

lsp-lifetime

Syntax

lsp-lifetime *seconds*

no lsp-lifetime

Context

[Tree] (config>service>vprn>isis lsp-lifetime)

Full Context

configure service vprn isis lsp-lifetime

Description

This command sets the time, in seconds, the router wants the LSPs it originates to be considered valid by other routers in the domain.

Each LSP received is maintained in an LSP database until the **lsp-lifetime** expires unless the originating router refreshes the LSP. By default, each router refreshes its LSPs every 20 minutes (1200 seconds) so other routers will not age out the LSP.

The LSP refresh timer is derived from this formula: lsp-lifetime/2

LSPs originated by the router should be valid for 1200 seconds (20 minutes).

The **no** form of this command reverts to the default value.

Default

lsp-lifetime 1200

Parameters

seconds

Specifies the time, in seconds, that the router wants the LSPs it originates to be considered valid by other routers in the domain.

Values 350 to 65535

Platforms

7705 SAR Gen 2

lsp-lifetime

Syntax

16.153 lsp-minimum-remaining-lifetime

lsp-minimum-remaining-lifetime

Syntax

lsp-minimum-remaining-lifetime *seconds*

no lsp-minimum-remaining-lifetime

Context

[Tree] (config>service>vprn>isis lsp-minimum-remaining-lifetime)

Full Context

configure service vprn isis lsp-minimum-remaining-lifetime

Description

This command configures the minimum value to which the remaining lifetime of the LSP is set. The value is a counter that decrements, in seconds, starting from the value in the received LSP (if not self-originated) or from **lsp-lifetime** *seconds* (if self-originated). When the remaining lifetime becomes zero, the contents of the LSP is purged. The remaining lifetime of an LSP is not changed when there is no **lsp-minimum-remaining-lifetime** value configured.

The configured value must be greater than or equal to the **lsp-lifetime** value.

The **no** form of this command removes the *seconds* value from the configuration.

Default

no lsp-minimum-remaining-lifetime

Parameters

seconds

Specifies the decrementing counter, in seconds. The configured value must be greater than or equal to the locally configured value of lsp-lifetime (MaxAge).

Values 350 to 65535

Platforms

7705 SAR Gen 2

16.155 lsp-pacing-interval

lsp-pacing-interval

Syntax

lsp-pacing-interval *milliseconds*

no lsp-pacing-interval

Context

[Tree] (config>service>vprn>isis>if lsp-pacing-interval)

Full Context

configure service vprn isis interface lsp-pacing-interval

Description

This command configures the interval at which LSPs are sent from the interface.

To avoid overwhelming neighbors that have less CPU processing power with LSPs, the pacing interval can be configured to limit how many LSPs are sent at the interval. LSPs are sent in bursts at the interval up to the configured limit. If a value of 0 is configured, no LSPs are sent from the interface.

If configured to the default LSP pacing interval of 100, LSPs are sent in 100 millisecond intervals.

The **no** form of this command reverts to the default value.

Note:
The IS-IS LSP pacing interval is 100 milliseconds for values < 100 milliseconds, and 1 second for values ≥ 100 milliseconds. For example, a pacing interval of 2 milliseconds means that a maximum of 50 LSPs are sent in a burst at 100 millisecond intervals. The default pacing interval of 100 milliseconds means that a maximum of 10 LSPs are sent in a burst at 1 second intervals.

Default

lsp-pacing-interval 100

Parameters

milliseconds

Specifies the pacing interval in milliseconds at which IS-IS LSPs are sent from the interface at each interval expressed as a decimal integer.

Values 0 to 65535

Platforms

7705 SAR Gen 2

lsp-pacing-interval

Syntax

lsp-pacing-interval *milliseconds*

no lsp-pacing-interval

[Tree] (config>router>isis>interface lsp-pacing-interval)

Full Context

configure router isis interface lsp-pacing-interval

Description

This command configures the interval at which LSPs are sent from the interface.

To avoid overwhelming neighbors that have less CPU processing power with LSPs, the pacing interval can be configured to limit how many LSPs are sent at the interval. LSPs are sent in bursts at the interval up to the configured limit. If a value of 0 is configured, no LSPs are sent from the interface. The interval applies to all LSPs: LSPs generated by the router, and LSPs received from other routers.

If configured to the default LSP pacing interval of 100, LSPs are sent in 100 millisecond intervals.

The **no** form of this command reverts to the default value.

Note:
The IS-IS LSP pacing interval is 100 milliseconds for values < 100 milliseconds, and 1 second for values ≥ 100 milliseconds. For example, a pacing interval of 2 milliseconds means that a maximum of 50 LSPs are sent in a burst at 100 millisecond intervals. The default pacing interval of 100 milliseconds means that a maximum of 10 LSPs are sent in a burst at 1 second intervals.

Default

lsp-pacing-interval 100

Parameters

milli-seconds

Specifies the interval in milliseconds during which IS-IS LSPs are sent from the interface expressed as a decimal integer.

Values 0 to 65535

Platforms

7705 SAR Gen 2

Context

[Tree] (oam lsp-ping)

[Tree] (config>saa>test>type lsp-ping)

Full Context

oam lsp-ping

configure saa test type lsp-ping

Description

This command performs in-band LSP connectivity tests.

This command performs an LSP ping using the protocol and data structures defined in the RFC 8029, *Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures*.

The LSP ping operation is modeled after the IP ping utility which uses ICMP echo request and reply packets to determine IP connectivity.

In an LSP ping, the originating device creates an MPLS echo request packet for the LSP and path to be tested. The MPLS echo request packet is sent through the data plane and awaits an MPLS echo reply packet from the device terminating the LSP. The status of the LSP is displayed when the MPLS echo reply packet is received.

This command, when used with the **static** option, performs in-band on-demand LSP connectivity verification tests for static MPLS-TP LSPs. For other LSP types, the **static** option should be excluded and these are described elsewhere in this user guide.

The **lsp-ping static** command performs an LSP ping using the protocol and data structures defined in the RFC 8029, *Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures*, as extended by RFC 6426, *MPLS On-Demand Connectivity Verification and Route Tracing*.

In MPLS-TP, the echo request and echo reply messages are always sent in-band over the LSP, either in a G-ACh channel or encapsulated as an IP packet below the LSP label.

The timestamp format to be sent, and to be expected when received in a PDU, is as configured by the **config>test-oam>mpls-time-stamp-format** command. If RFC 4379 (obsoleted by RFC 8029) is selected, then the timestamp is in seconds and microseconds since 1900, otherwise it is in seconds and microseconds since 1970.

Default

The active LSP path

Values: Any path name associated with the LSP

Parameters

lsp-name

Specifies the name of the target RSVP-TE LSP, up to 64 characters.

rsvp-te lsp-name

Specifies the name of the target RSVP-TE LSP, up to 64 characters.

Note:
The **rsvp-te** explicit target FEC type is not supported under the SAA context.

path-name

Specifies the LSP path name, up to 32 characters, to which to send the LSP ping request.

Values Any path name associated with the LSP.

Default The active LSP path.

bgp-label prefix *ip-prefix/prefix-length*

Specifies the address prefix and subnet mask of the target BGP IPv4 /32 label route or the target BGP IPv6 /128 label route.

Values <ipv4-prefix>/32 | <ipv6-prefix>/128

ipv4-prefix a.b.c.d

ipv6-prefix x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x: [0 to FFFF]H

d: [0 to 255]D

path-destination *ip-address*

Specifies the IP address of the path destination from the range 127/8. When the LDP FEC prefix is IPv6, the user must enter a 127/8 IPv4 mapped IPv6 address, that is, in the range ::ffff:127/104.

ipv4-address: a.b.c.d

ipv6-address: x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x: [0 to FFFF]H

d: [0 to 255]D

flex-algo *flex-algo-num*

Specifies the Segment Routing Flexible Algorithm for the test.

Values 128 to 255

interface if-name

Specifies the name of an IP interface, up to 32 characters, to send the MPLS echo request message to. The name must already exist in the **config>router>interface** context.

next-hop *ip-address*

Specifies the next-hop address to send the MPLS echo request message to.

Values

ipv4-address: a.b.c.d

ipv6-address: x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x: [0 to FFFF]H

d: [0 to 255]D

prefix *ip-prefix/prefix-length*

Specifies the address prefix and subnet mask of the target LDP FEC.

Values <ipv4-prefix>/32 | <ipv6-prefix>/128

ipv4-prefix a.b.c.d

ipv6-prefix x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x: [0 to FFFF]H

d: [0 to 255]D

ldp prefix *ip-prefix/prefix-length*

Specifies the address prefix and subnet mask of the target LDP FEC.

Values <ipv4-prefix>/32 | <ipv6-prefix>/128

ipv4-prefix a.b.c.d

ipv6-prefix x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x: [0 to FFFF]H

d: [0 to 255]D

sr-isis prefix *ip-prefix/prefix-length*

Specifies the address prefix and subnet mask of the target node SID of the SR-IS-IS tunnel.

Values <ipv4-prefix>/32 | <ipv6-prefix>/128

ipv4-prefix a.b.c.d

ipv6-prefix x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x: [0 to FFFF]H

d: [0 to 255]D

igp-instance

Specifies the IGP instance of the node SID prefix.

Values isis-inst: 0 to 127

ospf3-inst: 0 to 31, 64 to 95

ospf-inst: 0 to 31

sr-ospf prefix *ip-prefix/prefix-length*

Specifies the address prefix and subnet mask of the target node SID of the SR-OSPF tunnel.

Values <ipv4-prefix>/32 | <ipv6-prefix>/128

ipv4-prefix - a.b.c.d

ipv6-prefix - x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x - [0 to FFFF]H

d - [0 to 255]D

sr-ospf3 prefix *ip-prefix/prefix-length*

Specifies the address prefix and subnet mask of the target node SID of the SR-OSPF3 tunnel. Note that only IPv6 prefixes in OSPFv3 instance ID 0-31 are supported.

Values

ipv6-prefix - x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x - [0 to FFFF]H

d - [0 to 255]D

sr-policy color *color-id* endpoint *ip-address* segment-list *segment-list-id*

Specifies the name of the target IPv4 or IPv6 SR policy.

Note:
The **sr-policy** target FEC type is supported under the OAM context and under **type-multi-line node** in the SAA context.

color *color-id* — Specifies the color ID.

Values 0 to 4294967295

endpoint *ip-address* — Specifies the endpoint address.

Values

ipv4-address: a.b.c.d

ipv6-address: x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x: [0 to FFFF]H

d: [0 to 255]D

segment-list *segment-list-id* — Specifies the segment list ID.

Values 1 to 32

detail

Displays detailed information.

sr-te *lsp-name*

Specifies the name of the target SR-TE LSP, up to 64 characters.

static

Specifies the target FEC stack sub-type "Static LSP”.

assoc-channel {ipv4 | non-ip | none}

Specifies the launched echo request’s usage of the Associated Channel (ACH) mechanism, when testing an MPLS-TP LSP.

Values **ipv4** — Use an Associated Channel with IP encapsulation, as described in RFC 6426, Section 3.2.

non-ip — Do not use an Associated Channel, as described in RFC 6426, Section 3.1.

none — Use the Associated Channel mechanism described in RFC 6426, Section 3.3.

Default non-ip

global-id

Specifies the MPLS-TP global ID for the far end node of the LSP under test. If this is not entered, then the dest-global-id is taken from the LSP context.

Values 0 to 4294967295

Default 0

node-id

Specifies the MPLS-TP global ID for the far end node of the LSP under test. If this is not entered, then the dest-global-id is taken from the LSP context.

Values a.b.c.d, 1 to 4294967295

Default 0

force

Allows LSP ping to test a path that is operationally down, including cases where MPLS-TP BFD CC/V is enabled and has taken a path down. This parameter is only allowed in the OAM context; it is not allowed for a test configured as a part of an SAA.

Default disabled

path-type {active | working | protect}

The LSP path to test.

Values **active** — The currently active path. If MPLS-TP linear protection is configured on the LSP, then this is the path that is selected by the

MPLS-TP PSC protocol for sending user plane traffic. If MPLS-TP linear protection is not configured, then this is the working path.

working — The working path of the MPLS-TP LSP.

protect — The protect path of the MPLS-TP LSP.

Default active

fc-name

Specifies the FC and profile parameters that are used to indicate the forwarding class and profile of the MPLS echo request packet.

When an MPLS echo request packet is generated in CPM and is forwarded to the outgoing interface, the packet is queued in the egress network queue corresponding to the specified fc and profile parameter values. The marking of the packet's EXP is dictated by the LSP-EXP mappings on the outgoing interface.

When the MPLS echo request packet is received on the responding node, The FC and profile parameter values are dictated by the LSP-EXP mappings of the incoming interface.

When an MPLS echo reply packet is generated in CPM and is forwarded to the outgoing interface, the packet is queued in the egress network queue corresponding to the FC and profile parameter values determined by the classification of the echo request packet, which is being replied to, at the incoming interface. The marking of the packet's EXP is dictated by the LSP-EXP mappings on the outgoing interface. The ToS byte is not modified. Table 50: lsp-ping Request Packet and Behavior summarizes this behavior.

Table 50: lsp-ping Request Packet and Behavior

CPM (sender node)	Echo request packet: • packet {tos=1, fc1, profile1} • fc1 and profile1 are as entered by user in OAM command or default values • tos1 as per mapping of {fc1, profile1} to IP precedence in network egress QoS policy of outgoing interface
Outgoing interface (sender node)	Echo request packet: • packet queued as {fc1, profile1} • ToS field=tos1 not remarked • EXP=exp1, as per mapping of {fc1, profile1} to EXP in network egress QoS policy of outgoing interface
Incoming interface (responder node)	Echo request packet: • packet {tos1, exp1} • exp1 mapped to {fc2, profile2} as per classification in network QoS policy of incoming interface
CPM (responder node)	Echo reply packet:

	• packet{tos=1, fc2, profile2}
Outgoing interface (responder node)	Echo reply packet: • packet queued as {fc2, profile2} • ToS filed= tos1 not remarked (reply inband or out-of-band) • EXP=exp2, if reply is inband, remarked as per mapping of {fc2, profile2} to EXP in network egress QoS policy of outgoing interface
Incoming interface (sender node)	Echo reply packet: • packet {tos1, exp2} • exp2 mapped to {fc1, profile1} as per classification in network QoS policy of incoming interface

The LSP-EXP mappings on the receive network interface controls the mapping of the message reply at the originating router**.**

Values be, l2, af, l1, h2, ef, h1, nc

Default be

profile {in | out}

Specifies the profile state of the MPLS echo request packet.

Default out

flex-algo *flex-algo-num*

Specifies the Segment Routing Flexible Algorithm for the test. This option is only supported for **oam lsp-ping sr-isis** and **oam lsp-ping sr-ospf**. This option is not supported for SAA. If this option is not set, then the system looks up the prefix without flex-algo awareness.

Values 128 to 255

Default **none**

interval

Specifies the time, in seconds, used to override the default request message send interval and defines the minimum amount of time that must expire before the next message request is sent.

Values 1 to 10

Default 1

send-count

Specifies the number of messages to send, expressed as a decimal integer. The **send-count** parameter is used to override the default number of message requests sent. Each message request must either time out or receive a reply before the next message request

is sent. The message **interval** value must be expired before the next message request is sent.

Values 1 to 100

Default 1

octets

Specifies the MPLS echo request packet size in octets, expressed as a decimal integer. The request payload is padded with zeros to the specified size.

Values 1 to 9786

Default 1

src-ip-address *ip-address*

Specifies the source IP address. This option is used when an OAM packet must be generated from a different address than the node's system interface address. An example is when the OAM packet is sent over an LDP LSP and the LDP LSR-ID of the corresponding LDP session to the next-hop is set to an address other than the system interface address.

Values

ipv4-address:	a.b.c.d
ipv6-address:	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x: [0 to FFFF]H
	d: [0 to 255]D

timeout

Specifies number, in seconds, used to override the default *timeout* value and is the amount of time that the router waits for a message reply after sending the last probe for a specific test. Upon the expiration of the time out, the test is marked complete and no more packets are processed for any of those request probes.

Values 1 to 10

Default 5

label-ttl

Specifies the TTL value for the MPLS label, expressed as a decimal integer.

Values 1 to 255

Default 255

Platforms

7705 SAR Gen 2

Output

Output Example

The following output is an example of LDP IPv4 and IPv6 prefix FECs.

7705 SAR Gen 2

16.158 lsp-refresh-interval

lsp-refresh-interval

Syntax

lsp-refresh-interval [*seconds*] [**half-lifetime** {**enable** | **disable**}]

no lsp-refresh-interval

Context

[Tree] (config>service>vprn>isis lsp-refresh-interval)

Full Context

configure service vprn isis lsp-refresh-interval

Description

This command configures the IS-IS LSP refresh timer interval for the VPRN instance. When configuring the LSP refresh interval, the value that is specified for **lsp-lifetime** must also be considered. The LSP refresh interval cannot be greater than 90% of the LSP lifetime.

The **no** form of this command reverts to the default (600 seconds), unless this value is greater than 90% of the LSP lifetime. For example, if the LSP lifetime is 400, then the no lsp-refresh-interval command will be rejected.

Default

lsp-refresh-interval 600 half-lifetime enable

Parameters

seconds

Specifies the refresh interval.

Values 150 to 65535

half-lifetime

Sets the refresh interval to always be half the **lsp-lifetime** value. When this parameter is set to **enable**, the configured refresh interval is ignored.

Values enable, disable

Platforms

7705 SAR Gen 2

lsp-refresh-interval

Syntax

16.159 lsp-self-ping

lsp-self-ping

Syntax

lsp-self-ping {**enable** | **disable** | **inherit**}

no lsp-self-ping

Context

[Tree] (config>router>mpls>lsp-template lsp-self-ping)

Full Context

configure router mpls lsp-template lsp-self-ping

Description

This command enables LSP Self-ping on a given RSVP-TE LSP or LSP template. If set to **disable**, then LSP Self-ping is disabled irrespective of the setting of **lsp-self-ping**>**rsvp-te** under the **mpls** context. By default, each LSP and LSP template inherits this value.

The **no** form of this command reverts to the default.

Default

lsp-self-ping inherit

Parameters

enable

Enables LSP Self-ping on this RSVP LSP or RSVP LSPs (one-hop-p2p or mesh-p2p) using this LSP template.

disable

Disables LSP Self-ping on this RSVP LSP or RSVP LSPs using this LSP template.

inherit

Inherits the value configured under **config**>**router**>**mpls**>**lsp-self-ping**>**rsvp-te**.

16.161 lsp-template

lsp-template

Syntax

lsp-template *template-name* [**mesh-p2p** | **mesh-p2p-srte** | **one-hop-p2p** | **on-demand-p2p-srte** | **one-hop-p2p-srte** | **p2mp** | **pce-init-p2p-srte template-id** {**default** | *template-id*}]

no lsp-template *template-name*

Context

[Tree] (config>router>mpls lsp-template)

Full Context

configure router mpls lsp-template

Description

This command creates a template that can be referenced by a client application where dynamic LSP creation is required. The LSP template type (**p2mp**, **one-hop-p2p**, **mesh-p2p**, **one-hop-p2p-srte**, **mesh-p2p-srte**, **pce-init-p2p-srte**, or **on-demand-p2p-srte**) is mandatory.

The **no** form of this command deletes the LSP template. An LSP template cannot be deleted if a client application is using it.

Parameters

template-name

Specifies the name of the LSP template, up to 32 characters. An LSP template name and LSP name must not be the same.

mesh-p2p | mesh-p2p-srte | one-hop-p2p | one-hop-p2p-srte | p2mp | pce-init-p2p-srte | on-demand-p2p-srte

Identifies the type of LSP this template will signal.

default

Sets the template to be the default LSP template for PCE-initiated SR-TE LSPs.

template-id

Specifies the value that is signaled in the PCE to identify the LSP template.

Platforms

7705 SAR Gen 2

lsp-template

Syntax

lsp-template *template-name*

no lsp-template

Context

[Tree] (config>oam-pm>session>ip>tunnel>mpls>rsvp-te-auto lsp-template)

Full Context

configure oam-pm session ip tunnel mpls rsvp-te-auto lsp-template

Description

This command configures the name of the LSP template used to identify the unique LSP. Configure the following three commands to identify an RSVP-TE Auto LSP: **from**, **to**, and **lsp-template**. When all three of these values are configured, the specific RSVP LSP can be identified and the test packets can be carried across the tunnel

The **no** form of this command removes the LSP template name from the configuration.

Parameters

template-name

Specifies the LSP template name, up to 32 characters.

Platforms

7705 SAR Gen 2

16.162 lsp-trace

lsp-trace

Syntax

lsp-trace *lsp-name* [**path** *path-name*] [**detail**]

Context

[Tree] (oam lsp-trace)

Full Context

oam lsp-trace

Description

This command performs an LSP traceroute using the protocol and data structures defined in IETF RFC 8029.

The LSP trace operation is modeled after the IP traceroute utility, which uses ICMP echo request and reply packets with increasing TTL values to determine the hop-by-hop route to a destination IP.

In an LSP trace, the originating device creates an MPLS echo request packet for the LSP to be tested with increasing values of the TTL in the outermost label. The MPLS echo request packet is sent through the data plane and awaits a TTL exceeded response or the MPLS echo reply packet from the device terminating the LSP. The devices that reply to the MPLS echo request packets with the TTL exceeded and the MPLS echo reply are displayed.

The downstream mapping TLV is used in **lsp-trace** to provide a mechanism for the sender and responder nodes to exchange and validate interface and label stack information for each downstream hop in the path of the LDP FEC an RSVP LSP, or a BGP IPv4 label route.

Two downstream mapping TLVs are supported. The original Downstream Mapping (DSMAP) TLV defined in RFC 4379 (obsoleted by RFC 8029) and the new Downstream Detailed Mapping (DDMAP) TLV defined in RFC 6424 AND RFC 8029. More details are provided in the DDMAP TLV sub-section below.

In addition, when the responder node has multiple equal cost next hops for an LDP FEC, a BGP label IPv4 prefix, an SR-ISIS node SID, an SR-OSPF node SID, or an SR-TE LSP, it replies in the Downstream Mapping TLV with the downstream information for each outgoing interface which is part of the ECMP next-hop set for the prefix. The downstream mapping TLV can further be used to exercise a specific path of the ECMP set using the **path-destination** option.

This command, when used with the **static** option, performs in-band on-demand LSP traceroute tests for static MPLS-TP LSPs. For other LSP types, the **static** option should be excluded and these are described elsewhere in this user guide.

The **lsp-trace static** command performs an LSP trace using the protocol and data structures defined in the RFC 8029, Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures, as extended by RFC 6426, MPLS On-Demand Connectivity Verification and Route Tracing.

In MPLS-TP, the echo request and echo reply messages are always sent in-band over the LSP, either in a G-ACh channel or encapsulated as an IP packet below the LSP label.

The timestamp format to be sent, and to be expected when received in a PDU, is as configured by the **configure test-oam mpls-time-stamp-format** command. If RFC 4379 (obsoleted by RFC 8029) is selected, the timestamp is in seconds and microseconds since 1900, otherwise it is in seconds and microseconds since 1970.

Parameters

lsp-name

Specifies the name of the target RSVP-TE LSP, up to 64 characters.

rsvp-te lsp-name

Specifies the name of the target RSVP-TE LSP, up to 64 characters.

Note:
The **rsvp-te** explicit target FEC type is not supported under the SAA context.

path-name

Specifies the LSP path name along which to send the LSP trace request.

Values Any path name associated with the LSP.

Default The active LSP path.

bgp-label prefix *ip-prefix/prefix-length*

Specifies the address prefix and subnet mask of the target BGP IPv4 /32 label route or the target IPv6 /128 label route.

Values <ipv4-prefix>/32 | <ipv6-prefix>/128

ipv4-prefix a.b.c.d

ipv6-prefix x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x: [0 to FFFF]H

d: [0 to 255]D

path-destination *ip-address*

Specifies the IP address of the path destination from the range 127/8. When the LDP FEC prefix is IPv6, the user must enter a 127/8 IPv4 mapped IPv6 address, that is, in the range ::ffff:127/104.

if-name

Specifies the name of an IP interface, up 32 characters, to send the MPLS echo request to. The name must already exist in the **config>router>interface** context.

next-hop *ip-address*

Specifies the next hop to send the MPLS echo request message to.

Values ipv4-address: a.b.c.d

ipv6-address: x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x: [0 to FFFF]H

d: [0 to 255]D

prefix *ip-prefix/prefix-length*

Specifies the address prefix and subnet mask of the target LDP FEC.

Values <ipv4-prefix>/32 | <ipv6-prefix>/128

ipv4-prefix - a.b.c.d

ipv6-prefix - x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x - [0 to FFFF]H

d - [0 to 255]D

ldp prefix *ip-prefix/prefix-length*

Specifies the address prefix and subnet mask of the target LDP FEC.

Values <ipv4-prefix>/32 | <ipv6-prefix>/128

ipv4-prefix a.b.c.d

ipv6-prefix x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x: [0 to FFFF]H

d: [0 to 255]D

sr-isis prefix *ip-prefix/prefix-length*

Specifies the address prefix and subnet mask of the target node SID of the SR-ISIS tunnel.

Values <ipv4-prefix>/32 | <ipv6-prefix>/128

ipv4-prefix a.b.c.d

ipv6-prefix x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x: [0 to FFFF]H

d: [0 to 255]D

igp-instance

Specifies the IGP instance of the node SID prefix.

Values isis-inst: 0 to 127

ospf3-inst: 0 to 31, 64 to 95

ospf-inst: 0 to 31

sr-ospf prefix *ip-prefix/prefix-length*

Specifies the address prefix and subnet mask of the target node SID of the SR-OSPF tunnel.

Values <ipv4-prefix>/32 | <ipv6-prefix>/128

ipv4-prefix - a.b.c.d

ipv6-prefix - x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x - [0 to FFFF]H

d - [0 to 255]D

sr-ospf3 prefix *ip-prefix/prefix-length*

Specifies the address prefix and subnet mask of the target node SID of the SR-OSPF3 tunnel. Only IPv6 prefixes in OSPFv3 instance ID 0-31 are supported.

Values

ipv6-prefix - x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x - [0 to FFFF]H

d - [0 to 255]D

sr-policy color *color-id* endpoint *ip-address* segment-list *segment-list-id*

Specifies the name of the target IPv4 or IPv6 SR policy.

Note:
The **sr-policy** target FEC type is supported under the OAM context and under **type-multi-line node** in the SAA context.

color *color-id* — Specifies the color ID.

Values 0 to 4294967295

endpoint *ip-address* — Specifies the endpoint address.

Values

ipv4-address: a.b.c.d

ipv6-address: x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x: [0 to FFFF]H

d: [0 to 255]D

segment-list *segment-list-id* — Specifies the segment list ID.

Values 1 to 32

detail

Displays detailed information and allows the user to display hop 0 (that is, ingress) information. When this parameter is applied to static LSPs, the next hop 0 information is not displayed. This information is also not displayed if the **min-ttl** *min-label-ttl* value is greater than 1.

sr-te *lsp-name*

Specifies the name of the target SR-TE LSP, up to 64 characters.

static

Specifies the selection of the target FEC Stack sub-type "Static LSP”.

assoc-channel {ipv4 | non-ip | none}

Specifies the launched echo request’s usage of the Associated Channel (ACH) mechanism, when testing an MPLS-TP LSP.

Values **ipv4** — Use the Associated Channel mechanism with IP encapsulation, as described in RFC 6426, Section 3.2.

non-ip — Do not use an Associated Channel, as described in RFC 6426, Section 3.1.

none — Use the Associated Channel mechanism described in RFC 6426, Section 3.3.

path-type {active | working | protect}

Specifies the LSP path to test.

Values **active** — Specifies the currently active path. If MPLS-TP linear protection is configured on the LSP, then this is the path that is selected by the MPLS-TP PSC protocol for sending user plane traffic. If MPLS-TP linear protection is not configured, then this is the working path.

working — Specifies the working path of the MPLS-TP LSP.

protect — Specifies the protect path of the MPLS-TP LSP.

Default active

downstream-map-tlv

Specifies which format of the downstream mapping TLV to use in the LSP trace packet. The DSMAP TLV is the original format in RFC 4379 (obsoleted by RFC 8029). The DDMAP is the new enhanced format specified in RFC 6424 and RFC 8029. The user can also choose not to include the downstream mapping TLV by entering the value none. When lsp-trace is used on a MPLS-TP LSP (static option), it can only be executed if the control-channel is set to none. In addition, the DSMAP/DDMAP TLV is only included in the echo request message if the egress interface is either a numbered IP interface, or an unnumbered IP interface. The TLV is not included if the egress interface is of type **unnumbered-mpls-tp**.

Values ddmap: Sends a detailed downstream mapping TLV.

dsmap: Sends a downstream mapping TLV.

none: No mapping TLV is sent.

Default Inherited from global configuration of downstream mapping TLV in option **mpls-echo-request-downstream-map {dsmap | ddmap}**.

fc-name

Specifies the FC and profile parameters are used to indicate the forwarding class and profile of the MPLS echo request packet.

When an MPLS echo request packet is generated in CPM and is forwarded to the outgoing interface, the packet is queued in the egress network queue corresponding to the specified FC and profile parameter values. The marking of the packet EXP is dictated by the LSP-EXP mappings on the outgoing interface.

When the MPLS echo request packet is received on the responding node, The FC and profile parameter values are dictated by the LSP-EXP mappings of the incoming interface.

When an MPLS echo reply packet is generated in CPM and is forwarded to the outgoing interface, the packet is queued in the egress network queue corresponding to the fc and profile parameter values determined by the classification of the echo request packet, which is being replied to, at the incoming interface. The marking of the packet's EXP is dictated by the LSP-EXP mappings on the outgoing interface. The ToS byte is not modified. Table 51: lsp-trace Request Packet and Behavior summarizes this behavior.

Table 51: lsp-trace Request Packet and Behavior

CPM (sender node)	Echo request packet: • packet {tos=1, fc1, profile1} • fc1 and profile1 are as entered by user in OAM command or default values • tos1 as per mapping of {fc1, profile1} to IP precedence in network egress QoS policy of outgoing interface
Outgoing interface (sender node)	Echo request packet: • pkt queued as {fc1, profile1} • ToS field=tos1 not remarked • EXP=exp1, as per mapping of {fc1, profile1} to EXP in network egress QoS policy of outgoing interface
Incoming interface (responder node)	Echo request packet: • packet {tos1, exp1} • exp1 mapped to {fc2, profile2} as per classification in network QoS policy of incoming interface
CPM (responder node)	Echo reply packet: • packet {tos=1, fc2, profile2}
Outgoing interface (responder node)	Echo reply packet: • pkt queued as {fc2, profile2} • ToS filed= tos1 not remarked (reply inband or out-of-band) • EXP=exp2, if reply is inband, remarked as per mapping of {fc2, profile2} to EXP in network egress QoS policy of outgoing interface

Incoming interface (sender node)	Echo reply packet: • packet {tos1, exp2} • exp2 mapped to {fc1, profile1} as per classification in network QoS policy of incoming interface

Values be, l2, af, l1, h2, ef, h1, nc

Default be

profile {in | out}

Specifies the profile state of the MPLS echo request packet.

Default out

interval

Specifies the number of seconds to override the default request message send interval and defines the minimum amount of time that must expire before the next message request is sent.

If the **interval** is set to 1 second, and the *timeout* value is set to 10 seconds, then the maximum time between message requests is 10 seconds and the minimum is 1 second. This depends upon the receipt of a message reply corresponding to the outstanding message request.

Values 1 to 10

Default **1**

no-response-count

Specifies the maximum number of consecutive MPLS echo requests, expressed as a decimal integer that do not receive a reply before the trace operation fails for a given TTL.

Values 1 to 255

Default 5

max-label-ttl

Specifies the maximum TTL value in the MPLS label for the LDP treetrace test, expressed as a decimal integer.

Values 1 to 255

Default 30

min-label-ttl

Specifies the minimum TTL value in the MPLS label for the LSP trace test, expressed as a decimal integer.

Values 1 to 255

Default 1

probes-per-hop

Specifies the probes per hop.

Values 1 to 10

Default 1

octets

Specifies the size in octets, expressed as a decimal integer, of the MPLS echo request packet, including the IP header but not the label stack. The request payload is padded with zeros to the specified size. Note that an OAM command is not failed if the user entered a size lower than the minimum required to build the packet for the echo request message. The payload is automatically padded to meet the minimum size.

Values 1 to 9786

Default 1

src-ip-address *ip-address*

Specifies the source IP address. This option is used when an OAM packet must be generated from a different address than the node's system interface address. An example is when the OAM packet is sent over an LDP LSP and the LDP LSR-ID of the corresponding LDP session to the next-hop is set to an address other than the system interface address.

Values

ipv4-address: a.b.c.d

ipv6-address: x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x - [0 to FFFF]H

d - [0 to 255]D

timeout

Specifies the time, in seconds, used to override the default *timeout* value and is the amount of time that the router waits for a message reply after sending the message request. Upon the expiration of the message time out, the requesting router assumes that the message response is not received. A **request timeout** message is displayed by the CLI for each message request sent that expires. Any response received after the request times out is silently discarded.

Values 1 to 60

Default 3

Platforms

7705 SAR Gen 2

16.163 lsp-wait

lsp-wait

Syntax

lsp-wait *lsp-wait* **lsp-initial-wait** [*initial-wait*] [**lsp-second-wait** *second-wait*]

Context

[Tree] (config>service>vprn>isis>timers lsp-wait)

Full Context

configure service vprn isis timers lsp-wait

Description

This command configures the throttling of IS-IS LSP-generation. Timers that determine when to generate the first, second, and subsequent LSPs are controlled with this command. Subsequent LSPs are generated at increasing intervals of the second **lsp-wait** timer until a maximum value is reached.

Note: The timer granularity is 10 ms if the value is less than 500 ms, and 100 ms if the value is greater than or equal to 500 ms. Timer values are rounded down to the nearest granularity; for example, a configured value of 550 ms is internally rounded down to 500 ms.

The **no** form of this command reverts to the default value.

Default

lsp-wait 5000 lsp-initial-wait 10 lsp-second-wait 1000

Parameters

lsp-wait

Specifies the maximum interval, in milliseconds, between two consecutive occurrences of an LSP being generated.

Values 10 to 120000

initial-wait

Specifies the initial LSP generation delay, in milliseconds. Values less than 100 ms are internally rounded down to 0, so that there is no added initial LSP generation delay.

Values 10 to 100000

second-wait

Specifies the hold time, in milliseconds, between the first and second LSP generation.

Values 10 to 100000

Platforms

7705 SAR Gen 2

16.164 lsr-label-route

lsr-label-route

Syntax

lsr-label-route [{**none** | **all**}]

Context

[Tree] (config>router>ttl-propagate lsr-label-route)

Full Context

configure router ttl-propagate lsr-label-route

Description

This command configures the TTL propagation for transit packets at a router acting as an LSR for a BGP label route.

When an LSR swaps the BGP label for a ipv4 prefix packet, therefore acting as a ABR, ASBR, or data-path Route-Reflector (RR) in the base routing instance, or swaps the BGP label for a vpn-ipv4 or vpn-ipv6 prefix packet, therefore acting as an inter-AS Option B VPRN ASBR or VPRN data path Route-Reflector (RR), the **all** value of this command enables TTL propagation of the decremented TTL of the swapped BGP label into all outgoing LDP or RSVP transport labels.

When an LSR swaps a label or stitches a label, it always writes the decremented TTL value into the outgoing swapped or stitched label. What this feature controls is whether this decremented TTL value is also propagated to the transport label stack pushed on top of the swapped or stitched label.

The none value reverts to the default mode which disables TTL propagation. This changes the existing default behavior which propagates the TTL to the transport label stack. When a customer upgrades, the new default becomes in effect. This command does not have a no version.

This feature also controls the TTL propagation at an LDP-BGP stitching LSR in the LDP to BGP stitching direction. It also controls the TTL propagation in Carrier Supporting Carrier (CsC) VPRN at both the CsC CE and CsC PE.

SR OS does not support ASBR or data path RR functionality for labeled IPv6 routes in the global routing instance (6PE). As such the CLI command of this feature has no impact on prefix packets forwarded in this context.

Default

lsr-label-route none

Parameters

none

Specifies that the TTL of the swapped label is not propagated into the transport label stack.

all

Specifies that the TTL of the swapped label is propagated into all labels of the transport label stack.

Platforms

7705 SAR Gen 2

16.165 lsr-load-balancing

lsr-load-balancing

Syntax

lsr-load-balancing *hashing-algorithm*

no lsr-load-balancing

Context

[Tree] (config>service>vprn>nw-if>load-balancing lsr-load-balancing)

Full Context

configure service vprn network-interface load-balancing lsr-load-balancing

Description

This command specifies whether the IP header is used in the LAG and ECMP LSR hashing algorithm. This is the per interface setting.

Default

no lsr-load-balancing

Parameters

lbl-only

Only the label is used in the hashing algorithm.

lbl-ip

The IP header is included in the hashing algorithm.

ip-only

The IP header is used exclusively in the hashing algorithm.

eth-encap-ip

The hash algorithm parses down the label stack and once it hits the bottom, the stack assumes Ethernet II non-tagged/dot1q or qinq header follows. At the expected Ethertype offset location, algorithm checks whether the value present is IPv4/v6 (0x0800 or 0x86DD). If the check passes, the hash algorithm checks the first nibble at the expected IP header location for IPv4/IPv6 (0x0100/0x0110). If the secondary check passes, the hash is performed using IP SA/DA fields in the expected IP header; otherwise (if any of the checks failed) label-stack hash is performed.

Platforms

7705 SAR Gen 2

lsr-load-balancing

Syntax

lsr-load-balancing {**lbl-only** | **lbl-ip** | **ip-only** | **eth-encap-ip** | **lbl-ip-l4-teid**}

no lsr-load-balancing

Context

[Tree] (config>router>if>load-balancing lsr-load-balancing)

Full Context

configure router interface load-balancing lsr-load-balancing

Description

This command specifies whether the IP header is used in the LAG and ECMP LSR hashing algorithm. This is the per interface setting.

Default

no lsr-load-balancing

Parameters

lbl-only

Specifies that only the label is used in the hashing algorithm

lbl-ip

Specifies that only the IP header is included in the hashing algorithm.

ip-only

Specifies that only the IP header is used exclusively in the hashing algorithm

eth-encap-ip

Specifies that the hash algorithm parses down the label stack and once it hits the bottom, the stack assumes Ethernet II non-tagged/dot1q or qinq header follows. At the expected

Ethertype offset location, algorithm checks whether the value present is IPv4/v6 (0x0800 or0x86DD). If the check passes, the hash algorithm checks the first nibble at the expected IP header location for IPv4/IPv6 (0x0100/0x0110). If the secondary check passes, the hash is performed using IP SA/DA fields in the expected IP header; otherwise (any of the check failed) label-stack hash is performed.

lbl-ip-l4-teid

Specifies that this hashing algorithm hashes based on label, IP header, Layer 4 header and GTP header (TEID) in order. The algorithm uses all the supported headers that are found in the header fragment of incoming traffic.

Platforms

7705 SAR Gen 2

lsr-load-balancing

Syntax

lsr-load-balancing *hashing-algorithm*

no lsr-load-balancing

Context

[Tree] (config>system>load-balancing lsr-load-balancing)

Full Context

configure system load-balancing lsr-load-balancing

Description

This command configures system-wide LSR load balancing. Hashing can be enabled on the label stack, IP header, or both. The hashing can be at an LSR for spraying labeled IP packets over multiple equal-cost paths, or over multiple links of a LAG group.

For IPv4 packets, the LSR hash routine operates on the label stack and the IP header. An LSR considers a packet to be IPv4 if the first nibble following the bottom of the label stack is 4. You can enable or disable hashing on the label stack and IPv4 and IPv6 headers at the system level or incoming network IP interface level.

Default

no lsr-load-balancing

Parameters

lbl-only

Specifies that only the label is used in the hashing algorithm.

lbl-ip

Specifies that the IP header is included in the hashing algorithm.

ip-only

Specifies that the IP header is used exclusively in the hashing algorithm.

eth-encap-ip

Specifies that the hash algorithm parses down the label stack and after it reaches the bottom, the stack assumes the Ethernet II non-tagged, dot1q, or QinQ header follows. At the expected Ethertype offset location, the algorithm checks whether the value present is IPv4/IPv6 (0x0800/0x86DD). If the check passes, the hash algorithm checks the first nibble at the expected IP header location for IPv4/IPv6 (0x0100/0x0110). If the secondary check passes, the algorithm performs the hash using the IP SA/DA fields in the expected IP header. If any of the checks fail, the label-stack hash is performed.

lbl-ip-l4-teid

Specifies that the hashing applies as follows for Layer 2 and Layer 3 encapsulated traffic:

- If an IPv4 or IPv6 header is found immediately after the MPLS label stack, the hashing includes label stack, source and destination IP addresses, TCP/UDP port numbers, and, if present, TEID values.
- If an IPv4 or IPv6 header is not found immediately after the MPLS label stack, the data plane searches for a valid Ethertype value for the IPv4 and IPv6 payload. If a valid Ethertype value is found and an IP header follows the Ethernet header, hashing includes the source and destination IP addresses, TCP/UDP port numbers, and, if present, TEID values.

17.1 mac

mac

Syntax

mac *ieee-address*

no mac

Context

[Tree] (config>subscr-mgmt>loc-user-db>ipoe>host>host-ident mac)

Full Context

configure subscriber-mgmt local-user-db ipoe host host-identification mac

Description

This command specifies the MAC address to match for a host lookup.

Note:
This command is only used when **mac** is configured as one of the **match-list** parameters.

The **no** form of this command removes the MAC address from the configuration.

Parameters

ieee-address

Specifies the 48-bit MAC address in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee, and ff are hexadecimal numbers.

Platforms

7705 SAR Gen 2

configure service vprn interface vrrp mac

configure service vprn network-interface mac

Description

This command assigns a specific MAC address to a VPRN IP interface.

The **no** form of this command returns the MAC address of the IP interface to the default value.

Default

The physical MAC address associated with the Ethernet interface on which the SAP is configured.

Parameters

ieee-mac-address

Specifies the 48-bit MAC address for the static ARP in the form *aa*:*bb*:*cc*:*dd*:*ee*:*ff* or *aa-bb-cc-dd-ee-ff* where *aa*, *bb*, *cc*, *dd*, *ee* and *ff* are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.

Platforms

7705 SAR Gen 2

mac

Syntax

[**no**] **mac** *ieee-address*

Context

[Tree] (config>service>vpls>mac-protect mac)

Full Context

configure service vpls mac-protect mac

Description

This command specifies the 48-bit IEEE 802.3 MAC address.

The **no** form of the command reverts to the default.

Parameters

ieee-address

Specifies the 48-bit MAC address in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee, and ff are hexadecimal numbers.

Platforms

7705 SAR Gen 2

mac

Syntax

mac *ieee-address*

no mac [*ieee-address*]

Context

[Tree] (config>service>ies>if mac)

Full Context

configure service ies interface mac

Description

This command assigns a specific MAC address to an IES IP interface.

For Routed Central Office (CO), a group interface has no IP address explicitly configured but inherits an address from the parent subscriber interface when needed. For example, a MAC will respond to an ARP request when an ARP is requested for one of the IPs associated with the subscriber interface through the group interface.

The **no** form of this command returns the MAC address of the IP interface to the default value.

Default

The physical MAC address associated with the Ethernet interface that the SAP is configured on (the default MAC address assigned to the interface, assigned by the system).

Parameters

ieee-address

Specifies the 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff, where aa, bb, cc, dd, ee, and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.

Platforms

7705 SAR Gen 2

mac

Syntax

mac *ieee-address*

no mac

Context

[Tree] (config>service>vpls>mcr-default-gtw mac)

Full Context

configure service vpls mcr-default-gtw mac

Description

This command relates to a system configured for Dual Homing in L2-TPSDA. It defines the MAC address used when the system sends out a gratuitous ARP on an active SAP after a ring heals or fails in order to attract traffic from subscribers on the ring with connectivity to that SAP.

The **no** form of this command reverts to the default.

Default

no mac

Parameters

ieee-address

Specifies the address in xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx format (cannot be all zeros).

Platforms

7705 SAR Gen 2

mac

Syntax

mac *ieee-address*

no mac

Context

[Tree] (config>port>ethernet mac)

[Tree] (config>lag mac)

Full Context

configure port ethernet mac

configure lag mac

Description

This command assigns a specific MAC address to an Ethernet port, Link Aggregation Group (LAG), Ethernet tunnel, or BCP-enabled port or sub-port.

Only one MAC address can be assigned to a port. When multiple **mac** commands are entered, the last command overwrites the previous command. When the command is issued while the port is operational, IP will issue an ARP, if appropriate, and BPDUs are sent with the new MAC address.

The **no** form of this command returns the MAC address to the default value.

By default, a MAC address is assigned by the system from the chassis MAC address pool. The use of an all-zeroes MAC address indicates that an operational MAC address should be assigned from the chassis MAC address pool.

Default

mac 00:00:00:00:00:00

Parameters

ieee-address

Specifies the 48-bit MAC address in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.

mac

Syntax

[no] mac *ieee-address*

Context

[Tree] (config>service>proxy-arp-nd>mac-list mac)

Full Context

configure service proxy-arp-nd mac-list mac

Description

This command configures the proxy ARP or ND MAC address information.

The **no** form of the command deletes the MAC address.

Parameters

ieee-address

Specifies the MAC address added to the list. The MAC list can be empty or contain up to 10 addresses.

Values xx:xx:xx:xx:xx:xx
xx-xx-xx-xx-xx-xx

Platforms

7705 SAR Gen 2

mac

Syntax

mac *ieee-address* [**create**] **black-holemac** *ieee-address* [**create**] **sap** *sap-id* **monitor** {**fwd-status**}

mac *ieee-address* [**create**] **spoke-sdp** *sdp-id:vc-id* **monitor** {**fwd-status**}

no mac ieee-address

Context

[Tree] (config>service>vpls>static-mac mac)

Full Context

configure service vpls static-mac mac

Description

This command assigns a conditional static MAC address entry to an SPBM B-VPLS SAP/spoke-SDP allowing external MACs for single and multi-homed operation.

For the 7705 SAR Gen 2, this command also assigns a conditional static MAC address entry to an EVPN VPLS SAP/spoke-SDP.

Static MACs are used for PBB Epipe and I-VPLS services that may terminate external to SPBM. If this is configured under a Control B-VPLS the interface referenced will not use IS-IS for this neighbor. This may also be configured under a User B-VPLS where the corresponding interface is not supported under the Control B-VPLS.

Parameters

ieee-address

Specifies the static MAC address to an SPBM/sdp-binding interface.

Values 6-byte mac-address (xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx) Cannot be all zeros.

sap-id

Specifies the SAP identifier.

sdp-id

Specifies the SDP identifier.

Values 1 to 17407

vc-id

Specifies the virtual circuit identifier.

Values 1 to 4294967295

create

Mandatory keyword used to create a static MAC.

fwd-status

Specifies that this static mac is based on the forwarding status of the SAP or spoke-SDP for multi-homed operation.

black-hole

Specifies for TLS FDB entries defined on a local SAP the value 'sap', remote entries defined on an SDP have the value 'sdp'.

Platforms

7705 SAR Gen 2

mac

Syntax

mac *ieee-address* [**mask** *six-byte-mask*]

no mac *ieee-address*

Context

[Tree] (config>service>mac-list mac)

Full Context

configure service mac-list mac

Description

This command adds a protected MAC address entry.

The **no** form of this command removes the protected MAC address entry.

Parameters

ieee-address

Specifies the address in xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx format (cannot be all zeros), up to 30 characters.

six-byte-mask

Specifies the mask address in xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx format (cannot be all zeros), up to 30 characters.

Context

[Tree] (config>router>if>ipv6>vrrp mac)

[Tree] (config>router>if>vrrp mac)

Full Context

configure router interface ipv6 vrrp mac

configure router interface vrrp mac

Description

This command sets an explicit MAC address used by the virtual router instance overriding the VRRP default derived from the VRID.

Changing the default MAC address is useful when an existing HSRP or other non-VRRP default MAC is in use by the IP hosts using the virtual router IP address. Many hosts do not monitor unessential ARPs and continue to use the cached non-VRRP MAC address after the virtual router becomes master of the host's gateway address.

The **mac** command sets the MAC address used in ARP responses when the virtual router instance is master. Routing of IP packets with *mac-address* as the destination MAC is also enabled. The **mac** setting must be the same for all virtual routers participating as a virtual router or indeterminate connectivity by the

attached IP hosts will result. All VRRP advertisement messages are transmitted with *mac-address* as the source MAC.

The command can be configured in both non-owner and owner **vrrp** nodal contexts.

The **mac** command can be executed at any time and takes effect immediately. When the virtual router MAC on a master virtual router instance changes, a gratuitous ARP is immediately sent with a VRRP advertisement message. If the virtual router instance is disabled or operating as backup, the gratuitous ARP and VRRP advertisement message is not sent.

The **no** form of the command restores the default VRRP MAC address to the virtual router instance.

Default

no mac

Parameters

mac-address

The 48-bit MAC address for the virtual router instance in the form *aa*:*bb*:*cc*:*dd*:*ee*:*ff* or *aa-bb-cc-dd-ee-ff* where *aa*, *bb*, *cc*, *dd*, *ee* and *ff* are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC, and non-IEEE reserved MAC addresses.

configure service vpls bgp-evpn mac-advertisement

Description

This command enables the advertisement in BGP of the learned macs on SAPs and SDP bindings. When the mac-advertisement is disabled, the local macs will be withdrawn in BGP.

Default

mac-advertisement

Platforms

7705 SAR Gen 2

17.4 mac-criteria

mac-criteria

Syntax

[**no**] **mac-criteria**

Context

[Tree] (config>qos>sap-ingress mac-criteria)

Full Context

configure qos sap-ingress mac-criteria

Description

This command is used to enter the node to create or edit policy entries that specify MAC criteria.

The **mac-criteria** based SAP ingress policies are used to select the appropriate ingress queue and corresponding forwarding class for matched traffic.

Router implementation will exit on the first match found and execute the actions in accordance with the accompanying action command. For this reason, entries must be sequenced correctly from most to least explicit.

The **no** form of this command deletes all the entries specified under this node. When mac-criteria entries are removed from a SAP ingress policy, the mac-criteria is removed from all services where that policy is applied.

17.7 mac-list

mac-list

Syntax
mac-list *name* [**create**]

no mac-list *name*

Context
[Tree] (config>service>proxy-arp-nd mac-list)

Full Context
configure service proxy-arp-nd mac-list

Description

This command creates a list of MAC addresses that can be pointed at from the service for a specified IP. The list may contain up to 10 MAC addresses; an empty list is also allowed.

The MAC list allows on-the-fly changes, but a change in the list deletes the proxy entries for all the IPs using that list.

The **no** form of the command deletes the entire MAC-list. Deleting a MAC list is only possible if it is not referenced in the configuration.

Parameters

name

Specifies the name of the MAC address list, which can be up to 32 characters.

create

Mandatory keyword to create a MAC list.

Platforms

7705 SAR Gen 2

mac-list

Syntax

mac-list *name*

no mac-list

configure service vpls proxy-nd dynamic mac-list

configure service vpls proxy-arp dynamic mac-list

Description

This command associates a previously created MAC list to a dynamic IP. The MAC list is created using the **configure service proxy-arp-nd mac-list** command.

The **no** form of the command deletes the association of the MAC list and the dynamic IP.

Parameters

name

Specifies the name of the MAC list previously created using the **configure service proxy-arp-nd mac-list** command.

Platforms

7705 SAR Gen 2

mac-list

Syntax

mac-list *name* [**create**]

no mac-list *name*

Context

[Tree] (config>service mac-list)

Full Context

configure service mac-list

Description

This command configures a MAC list name. The MAC list is composed of a list of MAC addresses and masks, which along with Auto-Learn Mac Protect (ALMP) can be used to exclude certain MACs from being protected in a given object. This is typically used on SAPs and spoke SDPs configured with ALMP where certain MACs must be able to move to other objects (for example, VRRP virtual MACs).

The **no** form of this command removes the MAC list name.

Parameters

name

Specifies the MAC list name, up to 32 characters.

create

Keyword used to create the MAC list.

Platforms

7705 SAR Gen 2

17.8 mac-move

mac-move

Syntax

[**no**] **mac-move**

Context

[Tree] (config>service>vpls mac-move)

[Tree] (config>service>template>vpls-template mac-move)

Full Context

configure service vpls mac-move

configure service template vpls-template mac-move

Description

Commands in this context configure MAC move attributes. A sustained high re-learn rate can be a sign of a loop somewhere in the VPLS topology. Typically, STP detects loops in the topology, but for those networks that do not run STP, the mac-move feature is an alternative way to protect your network against loops.

When enabled in a VPLS, **mac-move** monitors the re-learn rate of each MAC. If the rate exceeds the configured maximum allowed limit, it disables the SAP where the source MAC was last seen. The SAP can be disabled permanently (until a **shutdown**/**no shutdown** command is executed) or for a length of time that grows linearly with the number of times the specified SAP was disabled. You have the option of marking a SAP as non-blockable in the **config>service>vpls>sap>limit-mac-move** or **config>service>vpls>spoke-sdp>limit-mac-move** contexts. This means that when the re-learn rate has exceeded the limit, another (blockable) SAP will be disabled instead.

The **mac-move** command enables the feature at the service level for SAPs and spoke-SDPs, as only those objects can be blocked by this feature. Mesh SDPs are never blocked, but their re-learn rates (sap-to-mesh/spoke-to-mesh or vice versa) are still measured.

The operation of this feature is the same on the SAP and spoke-SDP. For example, if a MAC address moves from SAP to SAP, from SAP to spoke-SDP, or between spoke-SDPs, one will be blocked to prevent thrashing. If the MAC address moves between a SAP and mesh SDP or spoke-SDP and mesh SDP combinations, the respective SAP or spoke-SDP will be blocked.

mac-move will disable a VPLS port when the number of relearns detected has reached the number of relearns needed to reach the move-frequency in the 5-second interval. For example, when the move-frequency is configured to 1 (relearn per second) mac-move will disable one of the VPLS ports when 5 relearns were detected during the 5-second interval because then the average move-frequency of 1 relearn per second has been reached. This can already occur in the first second if the real relearn rate is 5 relearns per second or higher.

The **no** form of this command disables MAC move.

Platforms

7705 SAR Gen 2

17.9 mac-move-level

mac-move-level

Syntax

mac-move-level {**primary** | **secondary**| **tertiary**}

Context

[Tree] (config>service>template>vpls-sap-template mac-move-level)

Full Context

configure service template vpls-sap-template mac-move-level

Description

When a SAP is instantiated using vpls-sap-template, if the MAC move feature is enabled at VPLS level, the command mac-move-level indicates whether the sap should be populated as primary-port, secondary-port, or tertiary-port in the instantiated VPLS.

If configured to the default, SAP is populated as a tertiary-port.

Default

no mac-move-level

Platforms

Full Context

configure service vpls spoke-sdp mac-pinning

configure service vpls mesh-sdp mac-pinning

configure service vpls sap mac-pinning

configure service vpls endpoint mac-pinning

Description

This command disables re-learning of MAC addresses on other SAPs within the VPLS. The MAC address will remain attached to a given SAP for duration of its age-timer.

The age of the MAC address entry in the FDB is set by the age timer. If **mac-aging** is disabled on a given VPLS service, any MAC address learned on a SAP or SDP with **mac-pinning** enabled will remain in the FDB on this SAP or SDP forever.

Every event that would otherwise result in re-learning is logged (MAC address; original-SAP; new-SAP).

When a SAP or spoke SDP is part of a Residential Split Horizon Group (RSHG), MAC pinning is activated at creation of the SAP. Otherwise MAC pinning is not enabled by default.

The **no** form of the command enables re-learning of MAC addresses.

Note:
MAC addresses learned during DHCP address assignment (DHCP snooping enabled) are not impacted by this command. MAC-pinning for such addresses is implicit.

Default

no mac-pinning

Platforms

7705 SAR Gen 2

mac-pinning

17.13 mac-subnet-length

mac-subnet-length

Syntax

mac-subnet-length *subnet-length*

no mac-subnet-length

Context

[Tree] (config>service>vpls mac-subnet-length)

Full Context

configure service vpls mac-subnet-length

Description

This command specifies the number of bits to be considered when performing MAC learning (MAC source) and MAC switching (MAC destination). Specifically, this value identifies how many bits, starting from the beginning of the MAC address are used. For example, if the mask-value of 28 is used, MAC learning only performs a lookup for the first 28 bits of the source MAC address when comparing with existing FDB entries. Then, it installs the first 28 bits in the FDB while zeroing out the last 20 bits of the MAC address. When performing switching in the reverse direction, only the first 28 bits of the destination MAC address are used to perform a FDB lookup to determine the next hop.

The **no** form of this command switches back to full MAC lookup.

Default

mac-subnet-length 48

Parameters

subnet-length

Specifies the number of bits to be considered when performing MAC learning or MAC switching.

Values 24 to 48

[Tree] (config>macsec>connectivity-association macsec-encrypt)

Full Context

configure macsec connectivity-association macsec-encrypt

Description

This command specifies that all PDUs are encrypted and authenticated (ICV payload).

The **no** form of this command specifies that all PDUs are transmitted with cleartext, but still authenticated and have the trailing ICV.

Default

macsec-encrypt

Platforms

7705 SAR Gen 2

17.16 main-ct-retry-limit

main-ct-retry-limit

Syntax

main-ct-retry-limit *number*

no main-ct-retry-limit

Context

[Tree] (config>router>mpls>lsp main-ct-retry-limit)

[Tree] (config>router>mpls>lsp-template main-ct-retry-limit)

Full Context

configure router mpls lsp main-ct-retry-limit

configure router mpls lsp-template main-ct-retry-limit

Description

This command configures the maximum number of retries the LSP primary path should be retried with the LSP Diff-Serv main Class Type (CT).

When an unmapped LSP primary path goes into retry, it uses the main CT until the number of retries reaches the value of the new main-ct-retry-limit parameter. If the path did not come up, it must start using the backup CT at that point in time. By default, this parameter is set to infinite value. The new main-ct-retry-limit parameter has no effect on an LSP primary path which retries due to a failure event.

An unmapped LSP primary path is a path which has never received a Resv in response to the first Path message sent. This can occur when performing a "shut/no-shut" on the LSP or LSP primary path or when the node reboots. An unmapped LSP primary path goes into retry if the retry timer expired or the head-end node received a PathErr message before the retry timer expired.

If the user entered a value of the main-ct-retry-limit parameter that is greater than the value of the LSP retry-limit, the number of retries will still stop when the LSP primary path reaches the value of the LSP retry-limit. In other words, the meaning of the LSP retry-limit parameter is not changed and always represents the upper bound on the number of retries. The unmapped LSP primary path behavior applies to both CSPF and non-CSPF LSPs.

The **no** form of this command sets the parameter to the default value of zero (0) which means the LSP primary path will retry forever.

Default

no main-ct-retry-limit

Parameters

number

Specifies the number of times MPLS will attempt to re-establish the LSP primary path using the Diff-Serv main CT. Allowed values are integers in the range of zero (0) to 10,000, where zero indicates to retry infinitely.

Values 0 to 1000, integer

Platforms

7705 SAR Gen 2

17.17 maintenance-policy

maintenance-policy

Syntax

[**no**] **maintenance-policy** *maintenance-policy-name*

Context

[Tree] (config>router>segment-routing maintenance-policy)

Full Context

configure router segment-routing maintenance-policy

Description

This command configures a named maintenance policy that can be applied to SR Policy candidate paths that are either statically configured or imported via BGP. A maintenance policy is used to configure seamless BFD and protection for an SR Policy candidate path.

A maintenance policy must be administratively disabled in order to change any of the parameters.

A maintenance policy cannot be enabled unless a **mode**, **bfd-enable**, and **bfd-template** are configured.

If a maintenance-template is administratively disabled, then all candidate paths to which it is applied are deprogrammed from the data path.

The **no** form of this command removes the specified maintenance policy.

Parameters

maintenance-policy-name

Specifies the name of the maintenance policy, up to 32 characters and cannot start with a space or underscore.

Platforms

7705 SAR Gen 2

maintenance-policy

Syntax

[**no**] **maintenance-policy** *maintenance-policy-name*

Context

[Tree] (conf>router>segment-routing>sr-policies>policy maintenance-policy)

Full Context

configure router segment-routing sr-policies static-policy maintenance-policy

Description

This command applies a named maintenance policy to the static SR policy path. The maintenance policy must exist under the **configure router segment-routing** context.

The **no** form of this command removes the specified maintenance policy.

Parameters

maintenance-policy-name

Specifies the name of the maintenance policy, up to 32 characters and cannot start with a space or underscore.

Platforms

7705 SAR Gen 2

17.18 managed-configuration

managed-configuration

Syntax

[**no**] **managed-configuration**

Context

[Tree] (config>router>router-advert>if managed-configuration)

[Tree] (config>service>vprn>router-advert>if managed-configuration)

Full Context

configure router router-advertisement interface managed-configuration

configure service vprn router-advertisement interface managed-configuration

Description

This command sets or resets managed address configuration flag for this group-interface. This flag indicates that DHCPv6 is available for address configuration in addition to any address auto-configured using stateless address auto-configuration. See RFC 3315 for additional details.

The **no** form of this command reverts to the default.

Default

no managed-configuration

Platforms

7705 SAR Gen 2

17.19 managed-vlan-list

managed-vlan-list

Syntax

managed-vlan-list

Context

[Tree] (config>service>vpls>sap managed-vlan-list)

Full Context

configure service vpls sap managed-vlan-list

Description

Commands in this context configure VLAN ranges to be managed by a management VPLS. The list indicates, for each SAP, the ranges of associated VLANs that will be affected when the SAP changes state. This managed-vlan-list is not used when STP mode is MSTP in which case the vlan-range is taken from the **config>service>vpls>stp>msti** configuration.

This command is only valid when the VPLS in which it is entered was created as a management VPLS.

Platforms

7705 SAR Gen 2

17.20 management

management

Syntax

management [**create**]

no management

Context

[Tree] (config>service>vprn management)

Full Context

configure service vprn management

Description

Commands in this context configure node management within the VPRN.

Parameters

create

Keyword used to create a management server entry.

Platforms

7705 SAR Gen 2

management

Syntax

management

Context

[Tree] (config>system>security management)

Full Context

configure system security management

Description

Commands in this context allow access to management servers.

Platforms

7705 SAR Gen 2

17.21 management-access-filter

management-access-filter

Syntax

[**no**] **management-access-filter**

Context

[Tree] (config>system>security management-access-filter)

Full Context

configure system security management-access-filter

Description

This command creates the context to edit management access filters and to reset match criteria.

Management access filters control all traffic in and out of the CPM. They can be used to restrict management of the router by other nodes outside either specific (sub)networks or through designated ports.

Management filters, as opposed to other traffic filters, are enforced by system software.

The **no** form of this command removes management access filters from the configuration.

Platforms

7705 SAR Gen 2

17.22 management-interface

management-interface

Syntax

management-interface

Context

[Tree] (config>system management-interface)

Full Context

configure system management-interface

Description

Commands in this context configure the capabilities of router management interfaces such as CLI and NETCONF.

Platforms

7705 SAR Gen 2

management-interface

Syntax

management-interface

Context

[Tree] (config>system>security management-interface)

Full Context

configure system security management-interface

Description

Commands in this context configure the selection of a management interface for hash configuration. The management interfaces are **classic-cli**, **md-cli**, **netconf**, or **grpc**.

Platforms

7705 SAR Gen 2

17.23 manager

manager

Syntax

manager *manager-name* [**create**]

no manager *manager-name*

Context

[Tree] (config>system>management-interface>remote-management manager)

Full Context

configure system management-interface remote-management manager

Description

Commands configured in this context take precedence over command values specified directly in the **configure management-interface remote-management** context.

If a command is not configured in this context, the command setting is inherited from the higher level context.

The **no** form of this command removes the remote manager configuration.

Default

system-name

Parameters

manager-name

Specifies the name of the remote manager, up to 32 characters.

Platforms

7705 SAR Gen 2

17.24 manager-address

manager-address

Syntax

manager-address *ip-address* | *fqdn*

no manager-address

Context

[Tree] (config>system>management-interface>remote-management>manager manager-address)

Full Context

configure system management-interface remote-management manager manager-address

Description

This command configures the destination IP address or FQDN of the manager.

The no form of this command removes the configured IP address or FQDN of the configured manager.

Parameters

ip-address

Specifies the IP address, up to 255 characters.

fqdn

Specifies the FQDN, up to 255 characters.

Platforms

7705 SAR Gen 2

17.25 manager-port

manager-port

Syntax

manager-port *port*

no manager-port

Context

[Tree] (config>system>management-interface>remote-management>manager manager-port)

Full Context

configure system management-interface remote-management manager manager-port

Description

This command assigns a destination TCP port to be used for opening gRPC connections to the specified remote manager.

The **no** form of this command reverts the destination TCP port for the remote manager to the default gRPC port (57400).

Parameters

port

Specifies the TCP destination port.

Values 1 to 65535

Default 57400

Platforms

7705 SAR Gen 2

17.26 manual-keying

manual-keying

Syntax

[**no**] **manual-keying**

Context

[Tree] (config>service>vprn>if>sap>ipsec-tunnel manual-keying)

[Tree] (config>service>vprn>if>ipsec>ipsec-tunnel manual-keying)

[Tree] (config>service>ies>if>ipsec>ipsec-tunnel manual-keying)

[Tree] (config>router>if>ipsec>ipsec-tunnel manual-keying)

Full Context

configure service vprn interface sap ipsec-tunnel manual-keying

configure service vprn interface ipsec ipsec-tunnel manual-keying

configure service ies interface ipsec ipsec-tunnel manual-keying

configure router interface ipsec ipsec-tunnel manual-keying

Description

This command configures Security Association (SA) for manual keying. When enabled, the command specifies whether this SA entry is created manually, by the user, or dynamically by the IPsec sub-system.

Platforms

7705 SAR Gen 2

17.27 mapping-server

mapping-server

Syntax

[**no**] **mapping-server**

Context

[Tree] (config>router>isis>segment-routing mapping-server)

Full Context

configure router isis segment-routing mapping-server

Description

Commands in this context configures the Segment Routing mapping server feature in an IS-IS instance.

SR mapping server enables the configuration and advertisement, via IS-IS, of the node SID index for IS-IS prefixes of routers which are in the LDP domain. This is performed in the router acting as a mapping server, which uses a prefix-SID sub-TLV within the SID/Label binding TLV in IS-IS.

The **no** form of this command deletes all node SID entries in the IS-IS instance.

Platforms

7705 SAR Gen 2

mapping-server

Syntax

[**no**] **mapping-server**

Context

[Tree] (config>router>ospf>segm-rtng mapping-server)

Full Context

configure router ospf segment-routing mapping-server

Description

Commands in this context configure the Segment Routing mapping server feature in an OSPF instance.

The mapping server feature allows the configuration and advertisement in OSPF of the node SID index for OSPF prefixes of routers which are in the LDP domain. This is performed in the router acting as a mapping server and using a prefix-SID sub-TLV within the Extended Prefix Range TLV in OSPF.

The **no** form of this command deletes all node SID entries in the OSPF instance.

Platforms

7705 SAR Gen 2

17.28 mask

mask

Syntax

mask type *ppp-match-type* {[**prefix-string** *prefix-string* | **prefix-length** *prefix-length*] [**suffix-string** *suffix-string* | **suffix-length** *suffix-length*]}

no mask type *ppp-match-type*

mask type *ipoe-match-type* {[**prefix-string** *prefix-string* | **prefix-length** *prefix-length*] [**suffix-string** *suffix-string* | **suffix-length** *suffix-length*]}

no mask type *ipoe-match-type*

Context

[Tree] (config>subscr-mgmt>loc-user-db>ipoe mask)

Full Context

configure subscriber-mgmt local-user-db ipoe mask

Description

This command configures a mask for the specified match type. The masking is applied on the parameter when performing an LUDB lookup to identify a host.

The **no** form of this command removes the mask from the configuration.

Parameters

ppp-match-type

Specifies the parameter on which the mask should be applied for an LUDB lookup to identify a PPP host.

Values circuit-id, mac, remote-id, sap-id, service-name, username

ipoe-match-type

Specifies the parameter on which the mask should be applied for an LUDB lookup to identify an IPoE host.

The *prefix-string* and *suffix-string* command options are not supported when the *ipoe-match-type* value is set to **duid-en** or **duid-ll-llt**.

Values circuit-id, duid-en, duid-ll-llt, option60, remote-id, sap-id, string, system-id

prefix-string

Specifies a substring that is stripped of the start of the incoming parameter value before it is matched against the value configured in the LUDB host identification.

This string can only contain printable ASCII characters. The "*” character is a wildcard that matches any substring. If a "\" character is masked, use the escape key so it becomes "\\".

This command option is unsupported when the *ppp-match-type* equals mac.

Values up to 127 characters, "*”

prefix-length

Specifies the number of characters to remove from the start of the incoming parameter value before it is matched against the value configured in the LUDB host identification.

When used with the **mac** or **duid-ll-llt** parameter, it specifies the number of bits to remove from the start of the MAC address. For example, if the MAC address is 0a:0b:0c:0d:0e:0f, to obtain the last bit for matching purposes (match an odd or even MAC address), the prefix length is 47. The result in this example would be a binary number of 1 (0xf = 1111).

Values 1 to 127

suffix-string

Specifies a substring that is stripped of the end of the incoming parameter value before it is matched against the value configured in the LUDB host identification.

This string can only contain printable ASCII characters. The "*" character is a wildcard that matches any substring. If a "\" character is masked, use the escape key so it becomes "\\".

This command option is unsupported when the *ppp-match-type* equals **mac**.

Values up to 127 characters

suffix-length

Specifies the number of characters to remove from the end of the incoming parameter value before it is matched against the value configured in the LUDB host identification.

When used with the **mac** or **duid-ll-llt** command option, the number of bits to remove from the end of the MAC address is specified.

Values 1 to 127

Platforms

7705 SAR Gen 2

mask

Syntax

mask *mask-value* [**type** {**included** | **excluded**}]

no mask

Context

[Tree] (config>system>security>snmp>view mask)

Full Context

configure system security snmp view mask

Description

The mask value and the mask type, along with the *oid-value* configured in the **view** command, determines the access of each sub-identifier of an object identifier (MIB subtree) in the view.

Each bit in the mask corresponds to a sub-identifier position. For example, the most significant bit for the first sub-identifier, the next most significant bit for the second sub-identifier, and so on. If the bit position on the sub-identifier is available, it can be included or excluded.

For example, the MIB subtree that represents MIB-II is 1.3.6.1.2.1. The mask that catches all MIB-II would be 0xfc or 0b11111100.

Only a single mask may be configured per view and OID value combination. If more than one entry is configured, each subsequent entry overwrites the previous entry.

The **no** form of this command removes the mask from the configuration.

Parameters

mask-value

The mask value associated with the OID value determines whether the sub-identifiers are included or excluded from the view. (Default: all 1s)

The mask can be entered either:

- In hex. For example, 0xfc.
- In binary. For example, 0b11111100.

Note:
If the number of bits in the bit mask is less than the number of sub-identifiers in the MIB subtree, then the mask is extended with ones until the mask length matches the number of sub-identifiers in the MIB subtree.

type

Specifies to include or exclude MIB subtree objects.

Values **included** - All MIB subtree objects that are identified with a 1 in the mask are available in the view.

excluded - All MIB subtree objects that are identified with a 1 in the mask are denied access in the view.

Default **included**

Platforms

7705 SAR Gen 2

17.29 mask-reply

mask-reply

Syntax

[**no**] **mask-reply**

Context

[Tree] (config>service>ies>if>icmp mask-reply)

[Tree] (config>service>vprn>nw-if>icmp mask-reply)

[Tree] (config>service>vprn>if>icmp mask-reply)

Full Context

configure service ies interface icmp mask-reply

configure service vprn network-interface icmp mask-reply

configure service vprn interface icmp mask-reply

Description

This command enables responses to Internet Control Message Protocol (ICMP) mask requests on the router interface.

If a local node sends an ICMP mask request to the router interface, the **mask-reply** command configures the router interface to reply to the request.

By default, the router instance replies to mask requests.

The **no** form of this command disables replies to ICMP mask requests on the router interface.

Default

mask-reply — Specifies to reply to ICMP mask requests.

Platforms

7705 SAR Gen 2

mask-reply

Syntax

[**no**] **mask-reply**

Context

[Tree] (config>router>if>icmp mask-reply)

Full Context

configure router interface icmp mask-reply

Description

This command enables responses to ICMP mask requests on the router interface.

If a local node sends an ICMP mask request to the router interface, the **mask-reply** command configures the router interface to reply to the request.

The **no** form of this command disables replies to ICMP mask requests on the router interface.

Default

mask-reply — Replies to ICMP mask requests.

configure service vprn interface ipv6 vrrp master-int-inherit

configure service vprn interface vrrp master-int-inherit

Description

This command allows the master instance to dictate the master down timer (non-owner context only).

Default

no master-int-inherit

Platforms

7705 SAR Gen 2

master-int-inherit

Syntax

[**no**] **master-int-inherit**

Context

[Tree] (config>router>if>vrrp master-int-inherit)

[Tree] (config>router>if>ipv6>vrrp master-int-inherit)

Full Context

configure router interface vrrp master-int-inherit

configure router interface ipv6 vrrp master-int-inherit

Description

This command enables the virtual router instance to inherit the master VRRP router's advertisement interval timer which is used by backup routers to calculate the master down timer.

The **master-int-inherit** command is only available in the non-owner nodal context and is used to allow the current virtual router instance master to dictate the master down timer for all backup virtual routers. The **master-int-inherit** command has no effect when the virtual router instance is operating as master.

If **master-int-inherit** is not enabled, the locally configured **message-interval** must match the master's VRRP advertisement message advertisement interval field value or the message is discarded.

The **no** form of the command restores the default operating condition which requires the locally configured **message-interval** to match the received VRRP advertisement message advertisement interval field value. The virtual router instance does not inherit the master VRRP router's advertisement interval timer and uses the locally configured message interval.

Default

no master-int-inherit

Platforms

7705 SAR Gen 2

17.31 match

match

Syntax

match

Context

[Tree] (config>service>vprn>bgp>group>dynamic-neighbor match)

Full Context

configure service vprn bgp group dynamic-neighbor match

Description

This command configures match conditions for the dynamic neighbors.

Platforms

7705 SAR Gen 2

match

Syntax

[**no**] **match**

Context

[Tree] (config>service>vprn>log>filter>entry match)

Full Context

configure service vprn log filter entry match

Description

This command creates context to enter/edit match criteria for a filter entry. When the match criteria is satisfied, the action associated with the entry is executed.

If more than one match parameter (within one match statement) is specified, then all the criteria must be satisfied (AND functional) before the action associated with the match is executed.

Use the **match** command to display a list of the valid applications.

Match context can consist of multiple match parameters (application, event-number, severity, subject), but multiple **match** statements cannot be entered per entry.

The **no** form of this command removes the match criteria for the *entry-id*.

Default

no match

Platforms

7705 SAR Gen 2

match

Syntax

match [**protocol** *protocol-id*]

no match

Context

[Tree] (config>qos>sap-egress>ip-criteria>entry match)

[Tree] (config>qos>sap-ingress>ip-criteria>entry match)

Full Context

configure qos sap-egress ip-criteria entry match

configure qos sap-ingress ip-criteria entry match

Description

This command creates a context to configure match criteria for SAP QoS policy match criteria. When the match criteria have been satisfied, the action associated with the match criteria is executed.

If more than one match criteria (within one match statement) are configured, all criteria must be satisfied (AND function) before the action associated with the match is executed.

A **match** context can consist of multiple match criteria, but multiple **match** statements cannot be entered per entry.

It is possible that a SAP policy includes the **dscp** map command, the **dot1p** map command, and an IP match criteria. When multiple matches occur for the traffic, the order of precedence is used to arrive at the final action. The order of precedence is as follows:

1. 802.1p bits
2. DSCP
3. IP quintuple or MAC headers

The **no** form of this command removes the match criteria for the *entry-id*.

Parameters

protocol *protocol-id*

Specifies an IP protocol to be used as a SAP QoS policy match criterion.

The protocol type such as TCP / UDP / OSPF is identified by its respective protocol number. Well-known protocol numbers include ICMP(1), TCP(6), UDP(17)

Table 53: IP Protocol Names lists the IP protocols and their respective IDs and descriptions.

Values protocol-id: 0 to 255 protocol numbers accepted in decimal, hexadecimal, or binary

keywords: none, crtp, crudp, egp, eigrp, encap, ether-ip, gre, icmp, idrp, igmp, igp, ip, ipv6, ipv6-frag, ipv6-icmp, ipv6-no-nxt, ipv6-opts, ipv6-route, isis, iso-ip, l2tp, ospf-igp, pim, pnni, ptp, rdp, rsvp, stp, tcp, udp, vrrp

Table 53: IP Protocol Names

Protocol	Protocol ID	Description
icmp	1	Internet Control Message
igmp	2	Internet Group Management
ip	4	IP in IP (encapsulation)
tcp	6	Transmission Control
egp	8	Exterior Gateway Protocol
igp	9	Any private interior gateway (used by Cisco for their IGRP)
udp	17	User Datagram
rdp	27	Reliable Data Protocol
ipv6	41	IPv6
ipv6-route	43	Routing Header for IPv6

Protocol	Protocol ID	Description
ipv6-frag	44	Fragment Header for IPv6
idrp	45	Inter-Domain Routing Protocol
rsvp	46	Reservation Protocol
gre	47	General Routing Encapsulation
ipv6-icmp	58	ICMP for IPv6
ipv6-no-nxt	59	No Next Header for IPv6
ipv6-opts	60	Destination Options for IPv6
iso-ip	80	ISO Internet Protocol
eigrp	88	EIGRP
ospf-igp	89	OSPFIGP
ether-ip	97	Ethernet-within-IP Encapsulation
encap	98	Encapsulation Header
pnni	102	PNNI over IP
pim	103	Protocol Independent Multicast
vrrp	112	Virtual Router Redundancy Protocol
l2tp	115	Layer Two Tunneling Protocol
stp	118	Schedule Transfer Protocol
ptp	123	Performance Transparency Protocol
isis	124	ISIS over IPv4
crtp	126	Combat Radio Transport Protocol
crudp	127	Combat Radio User Datagram

Platforms

7705 SAR Gen 2

match

Syntax

match [**next-header** *next-header*]

no match

Context

[Tree] (config>qos>sap-ingress>ipv6-criteria>entry match)

[Tree] (config>qos>sap-egress>ipv6-criteria>entry match)

Full Context

configure qos sap-ingress ipv6-criteria entry match

configure qos sap-egress ipv6-criteria entry match

Description

This command creates a context to configure match criteria for ingress SAP QoS policy match IPv6 criteria. When the match criteria have been satisfied, the action associated with the match criteria is executed.

If more than one match criteria (within one match statement) are configured, all criteria must be satisfied (logical AND) before the action associated with the match is executed.

A **match** context can consist of multiple match criteria, but multiple **match** statements cannot be created per entry.

A SAP ingress policy may include the **dscp** map command, the **dot1p** map command, and an IPv6 match criteria. When multiple matches occur for the traffic, the following order of precedence is used to arrive at the final action.

1. 802.1p bits
2. DSCP
3. IP quintuple or MAC headers

The **no** form of this command removes the match criteria for the *entry-id*.

Parameters

next-header

protocol-number, *protocol-name*

Specifies the IPv6 next header to match.

On the 7705 SAR Gen 2, the protocol type such as TCP, UDP, or OSPF is identified by its respective protocol number. Well-known protocol numbers include ICMP(1), TCP(6) and UDP(17).

protocol-number

Specifies the protocol number value to be configured as a match criterion.

Values [0 to 255]D

[0x0 to 0xFF]H

[0b0 to 0b11111111]B

protocol-name

Specifies the protocol name to be configured as a match criterion.

Values none, icmp, igmp, ip, tcp, egp, igp, udp, rdp, ipv6, ipv6-route, ipv6-frag, idrp, rsvp, gre, ipv6-icmp, ipv6-no-nxt, ipv6-opts, iso-ip, eigrp, ospf-igp, ether-ip, encap, pnni, pim, vrrp, l2tp, stp, ptp, isis, crtp, crudp, sctp

* - udp/tcp wildcard

7705 SAR Gen 2

match

Syntax

match [**frame-type** {**802dot3** | **802dot2-llc** | **802dot2-snap** | **ethernet-II** | **atm**}]

no match

Context

[Tree] (config>qos>sap-ingress>mac-criteria>entry match)

Full Context

configure qos sap-ingress mac-criteria entry match

Description

This command creates a context for entering/editing match MAC criteria for ingress SAP QoS policy match criteria. When the match criteria have been satisfied, the action associated with the match criteria is executed.

If more than one match criteria (within one match statement) are configured, all criteria must be satisfied (AND function) before the action associated with the match will be executed.

A **match** context can consist of multiple match criteria, but multiple **match** statements cannot be entered per entry.

The **no** form of this command removes the match criteria for the *entry-id*.

Parameters

frame-type

The **frame-type** keyword configures an Ethernet frame type or an ATM frame type to be used for the MAC filter match criteria.

Values 802dot3, 802dot2-llc, 802dot2-snap, ethernet_II, atm

Default 802dot3

802dot3

Specifies the frame type is Ethernet IEEE 802.3.

802dot2-llc

Specifies the frame type is Ethernet IEEE 802.2 LLC.

802dot2-snap

Specifies the frame type is Ethernet IEEE 802.2 SNAP.

ethernet-II

Specifies the frame type is Ethernet Type II.

atm

Specifies the frame type as ATM cell. The user is not allowed to configure entries with frame type of atm and a frame type of other supported values in the same QoS policy.

match

Syntax

match [**protocol** *protocol-id*]

no match

Context

[Tree] (config>qos>network>ingress>ip-criteria>entry match)

[Tree] (config>qos>network>egress>ip-criteria>entry match)

Full Context

configure qos network ingress ip-criteria entry match

configure qos network egress ip-criteria entry match

Description

This command creates a context to configure match criteria for a network QoS policy. When the match criteria have been satisfied, the action associated with it is executed.

If more than one match criteria (within one match statement) are configured, then all criteria must be satisfied before the associated action with the match is executed.

A match context can consist of multiple match criteria, but multiple match statements cannot be entered per entry.

A network QoS policy can include the DSCP map command, the dot1p map command (ingress only), the prec map command (egress only), and an IP match criteria. When multiple matches occur for the traffic, the order of precedence is used to arrive at the final action. The order of precedence is as follows:

- 802.1p bits (ingress only)
- DSCP
- prec (egress only)
- IP quintuple

The **no** form of this command removes the match criteria for the entry identifier.

Parameters

protocol *protocol-id*

Specifies an IP protocol to be used as an ingress or egress network QoS policy match criterion.

The protocol type is identified by its respective protocol number. Well-known protocol numbers include ICMP(1), TCP(6), and UDP(17).

Values *protocol-id*: 0 to 255 protocol numbers accepted in decimal, hexadecimal, or binary

keywords: none, crtp, crudp, egp, eigrp, encap, ether-ip, gre, icmp, idrp, igmp, igp, ip, ipv6, ipv6-frag, ipv6-icmp, ipv6-no-nxt, ipv6-opts, ipv6-route, isis, iso-ip, l2tp, ospf-igp, pim, pnni, ptp, rdp, rsvp, stp, tcp, udp, vrrp

* — udp/tcp wildcard

[Tree] (config>qos>network>ingress>ipv6-criteria>entry match)

[Tree] (config>qos>network>egress>ipv6-criteria>entry match)

Full Context

configure qos network ingress ipv6-criteria entry match

configure qos network egress ipv6-criteria entry match

Description

This command creates a context to configure match criteria for a network QoS policy match IPv6 criteria. When the match criteria have been satisfied, the action associated with the match criteria is executed.

If more than one match criteria (within one match statement) are configured, all criteria must be satisfied (logical AND) before the action associated with the match is executed.

A match context can consist of multiple match criteria, but multiple match statements cannot be created per entry.

A network policy can include the DSCP map command, the dot1p map command (ingress only), the prec map command (egress only), and an IPv6 match criteria. When multiple matches occur for the traffic, the following order of precedence is used to arrive at the final action.

- 802.1p bits (ingress only)
- DSCP
- prec (egress only)
- IP quintuple

The **no** form of this command removes the match criteria for the entry identifier.

Parameters

next-header

protocol-number, *protocol-name*

Specifies the next header to match.

The protocol type is identified by its respective protocol number. Well-known protocol numbers include ICMP(1), TCP(6), and UDP(17).

protocol-number

Specifies the protocol number value to be configured as a match criterion.

Values [0 to 255]D

[0x0 to 0xFF]H

[0b0 to 0b11111111]B

protocol-name

Specifies the protocol name to be configured as a match criterion.

Values none, icmp, igmp, ip, tcp, egp, igp, udp, rdp, ipv6, ipv6-route, ipv6-frag, idrp, rsvp, gre, ipv6-icmp, ipv6-no-nxt, ipv6-opts, iso-ip, eigrp, ospf-igp, ether-ip, encap, pnni, pim, vrrp, l2tp, stp, ptp, isis, crtp, crudp, sctp

match

Syntax

match [**protocol** *protocol-id*]

match protocol none

no match

Context

[Tree] (config>filter>ip-exception>entry match)

Full Context

configure filter ip-exception entry match

Description

Commands in this context enter match criteria for the filter entry. When the match criteria have been satisfied the action associated with the match criteria is executed.

A **match** context may consist of multiple match criteria, but multiple **match** statements cannot be entered per entry. More precisely, the command can be entered multiple times but this only results in modifying the *protocol-id*. and does not affect the underlying match criteria configuration.

The **no** form of the command removes all the match criteria from the filter entry and sets the *protocol-id* of the match command to **none** (keyword). As per above, **match protocol none** is however not equivalent to **no match**.

Default

match protocol none

Parameters

protocol-id

Sets an IP protocol to be used as an IP filter match criterion. The protocol type, such as TCP or UDP, is identified by its respective protocol number.

Values protocol-number: [0..255]D

[0x0..0xFF]H

[0b0..0b11111111]B

protocol-name:0 to 255 in decimal format. Values can also be specified in hexadecimal format, in binary format, or using the following keywords:

IPv4 filter keywords: none (default), icmp, igmp, ip, tcp, egp, igp, udp, rdp, ipv6, ipv6-route, ipv6-frag, idrp, rsvp, gre, ipv6-icmp, ipv6-no-nxt, ipv6-opts, iso-ip, eigrp, ospf-igp, ether-ip, encap, pnni, pim, vrrp, l2tp, stp, ptp, isis, crtp, crudp, sctp

IP exception filter keywords: none, icmp, igmp, ospf-igp, pim, rsvp, tcp, udp, vrrp

* — udp/tcp wildcard

match

Syntax

match [{**protocol** *protocol-id* | **protocol-list** *protocol-list-name*}]

match protocol none

no match

Context

[Tree] (config>filter>ip-filter>entry match)

Full Context

configure filter ip-filter entry match

Description

Commands in this context enter match criteria for the filter entry. When the match criteria have been satisfied, the action associated with the match criteria is executed.

A match context may consist of multiple match criteria, but multiple match statements cannot be created per entry. More precisely, the **protocol** command can be entered multiple times but this only results in modifying the *protocol-id*. Matching on more than one protocol can be achieved using the protocol-list match criteria in an IP filter policy.

The **no** form of the command removes all the match criteria from the filter entry and sets the *protocol-id* of the match command to **none**. However, **match protocol none** is not equivalent to **no match**.

Default

match protocol none

Parameters

protocol-id

protocol-number | *protocol-name*

protocol-number

Specifies the protocol number value to be configured as a match criterion. The value can be expressed as a decimal integer, or in hexadecimal or binary format.

Values [0..255]D, [0x0..0xFF]H, [0b0..0b11111111]B

protocol-name

Specifies the protocol name to be configured as a match criterion.

Values IPv4 filter keywords: none (default), icmp, igmp, ip, tcp, egp, igp, udp, rdp, ipv6, ipv6-route, ipv6-frag, idrp, rsvp, gre, ipv6-icmp, ipv6-no-nxt, ipv6-opts, iso-ip, eigrp, ospf-igp, ether-ip, encap, pnni, pim, vrrp, l2tp, stp, ptp, isis, crtp, crudp, sctp

Syntax

match [**next-header** *next-header*]

no match

Context

[Tree] (config>filter>ipv6-exception>entry match)

Full Context

configure filter ipv6-exception entry match

Description

Commands in this context enter match criteria for the IPv6 filter exception. When the match criteria have been satisfied, the action associated with the match criteria is executed.

The **no** form of the command removes all the match criteria from the IPv6 filter exception.

Parameters

next-header

protocol-number, *protocol-name*

Specifies the next header to match.

protocol-number

Specifies the protocol number value to be configured as a match criterion.

Values [0 to 255]D

[0x0 to 0xFF]H

[0b0 to 0b11111111]B

protocol-name

Specifies the protocol name to be configured as a match criterion.

Values none, icmp, igmp, ip, tcp, egp, igp, udp, rdp, ipv6, ipv6-route, ipv6-frag, idrp, rsvp, gre, ipv6-icmp, ipv6-no-nxt, ipv6-opts, iso-ip, eigrp, ospf-igp, ether-ip, encap, pnni, pim, vrrp, l2tp, stp, ptp, isis, crtp, crudp, sctp

Syntax

match [{**next-header** *protocol-id* | **next-header-list** *protocol-list-name*}]

match next-header none

no match

Context

[Tree] (config>filter>ipv6-filter>entry match)

Full Context

configure filter ipv6-filter entry match

Description

Commands in this context enter match criteria for the filter entry. When the match criteria have been satisfied, the action associated with the match criteria is executed.

A match context may consist of multiple match criteria, but multiple match statements cannot be created per entry. More precisely, the **next-header** command can be entered multiple times, but this only results in modifying the *protocol-id*. Matching on more than one protocol can be achieved using the **next-header-list** match criteria.

The **no** form of the command removes all the match criteria from the filter entry and sets the *protocol-id* of the match command to **none**. However, **match next-header none** is not equivalent to **no match**.

Default

match next-header none

Parameters

next-header

protocol-number, *protocol-name*

Specifies the IPv6 next header to match. This parameter is analogous to the protocol parameter used in IPv4 filter match command.

protocol-number

Specifies the protocol number value to be configured as a match criterion.

Values [0 to 255]D

[0x0 to 0xFF]H

[0b0 to 0b11111111]B

protocol-name

Specifies the protocol name to be configured as a match criterion.

Values none, icmp, igmp, ip, tcp, egp, igp, udp, rdp, ipv6, ipv6-route, ipv6-frag, idrp, rsvp, gre, ipv6-icmp, ipv6-no-nxt, ipv6-opts, iso-ip, eigrp, ospf-igp, ether-ip, encap, pnni, pim, vrrp, l2tp, stp, ptp, isis, crtp, crudp, sctp

* - udp/tcp wildcard

protocol-list-name

Specifies the name of the protocol list, up to 32 characters.

Platforms

7705 SAR Gen 2

match

Syntax

[**no**] **match**

Context

[Tree] (config>log>filter>entry match)

Full Context

configure log filter entry match

Description

This command creates the context to enter and edit match criteria for a filter entry. When the match criteria is satisfied, the action associated with the entry is executed.

If more than one match parameter (within one match statement) is specified, then all the criteria must be satisfied (AND functional) before the action associated with the match is executed.

Use the **application** command to display a list of the valid applications.

Match context can consist of multiple match parameters (application, event-number, severity, subject), but multiple **match** statements cannot be entered per entry.

The **no** form of this command removes the match criteria for the *entry-id*.

no match-list

Context

[Tree] (config>subscr-mgmt>loc-user-db>ipoe match-list)

Full Context

configure subscriber-mgmt local-user-db ipoe match-list

Description

This command specifies the type of matching done to identify a host. There are different match-types for IPoE hosts of which a maximum of four can be specified.

The **no** form of this command removes all match criteria.

Parameters

match-type-x

Specifies up to four matching types to identify a host.

Values For IPoE: circuit-id, derived-id, dual-stack-remote-id, duid-en, duid-ll-llt, encap-tag-range, encap-tag-separate-range, ip, mac, option60, remote-id, sap-id, service-id, string, system-id

Note:
The format of **remote-id** in IPv6 is different than the format of **remote-id** in IPv4; IPv6 **remote-id** contains *enterprise-id* field that is also honored in matching.

circuit-id — Specifies to use the circuit ID to match against.

derived-id — Specifies the value extracted by Python script during processing of DHCP Discover/Solicit/Request/Renew/Rebind Messages (client to server bound messages). The value is stored in the DHCP Transaction Cache (DTC) in a variable named alc.dtc.derivedId. This value has a lifespan of a DHCP transaction (a single pair of messages exchanged between the client and the server, for example DHCP Discover and DHCP Offer).

dual-stack-remote-id — Specifies the enterprise-id in IPv6 remote-id is stripped off before LUDB matching is performed. Processing of IPv4 remote ID remains unchanged. This will allow a single host entry in LUDB for dual-stack host where host identification is performed based on the remote ID field.

duid-en — Specifies to match against the concatenation of the enterprise number and identifier fields of DHCPv6 option CLIENTID (1) with DUID type = 2 (assigned by vendor based on the enterprise number) in the DHCPv6 client message.

duid-ll-llt — Specifies to match against the link-layer address field of DHCPv6 option CLIENTID (1) with DUID type = 3 (based on link-layer address) or DUID type = 1 (based on link-layer address plus time) and hardware type = 1 (Ethernet) in the DHCPv6 client message. For DUID type = 1, the time field is ignored.

encap-tag-separate-range — Specifies the match encapsulation inner and outer tag in two separate ranges.

encap-tag-range — Specifies to match tag ranges for inner and outer tags.

ip — Specifies the source IPv4/IPv6 address of a data-trigger packet.

mac — Specifies to use the MAC address to match against.

option-60 — Specifies to use Option60 to match against.

remote-id — Specifies to use the remote ID to match against.

sap-id — Specifies the SAP ID on which DHCPv4 packet are received. The SAP ID is inserted as ALU VSO (82,9,4) by the DHCPv4 relay in router. This is enabled via configuration under the vendor-specific-option CLI hierarchy of the DHCPv4 relay. Since the **dhcp-relay** configuration is enabled under the group interface CLI hierarchy, the group interface and the service ID must be known before the SAP ID can be used for LUDB match.

service-id — Specifies the service ID of the ingress SAP for DHCPv4 packets. The service ID is inserted as ALU VSO (82,9,3) by the DHCPv4 relay in router. This is enabled via configuration under the vendor-specific-option CLI hierarchy of the DHCPv4 relay.

string — Specifies the custom string configured under the vendor-specific-option CLI hierarchy of the DHCPv4 relay. The string is inserted as ALU VSO (82,9,5) by the DHCPv4 relay in router. Since the **dhcp-relay** configuration is enabled under the group-interface CLI hierarchy, the group-interface and the service ID must be known before the string can be used for LUDB match.

system-id — Specifies the system ID of the node name configured under the **system>name** CLI hierarchy. The system ID is inserted as ALU VSO (82,9,1) by the

DHCPv4 relay in router. This is enabled via configuration under the vendor-specific-option CLI hierarchy of the DHCPv4 relay. Since the **dhcp-relay** configuration is enabled under the group interface CLI hierarchy, the group interface and the service ID must be known before the system ID can be used for LUDB match.

[Tree] (config>service>vpls>sap>ingress match-qinq-dot1p)

Full Context

configure service ies interface sap ingress match-qinq-dot1p

configure service vpls sap ingress match-qinq-dot1p

Description

This command specifies which dot1Q tag position dot1P bits in a QinQ encapsulated packet should be used to evaluate dot1P QoS classification.

The **match-qinq-dot1p** command allows the top or bottom PBits to be used when evaluating the applied sap-ingress QoS policy's dot1P entries. The **top** and **bottom** keywords specify which position should be evaluated for QinQ encapsulated packets.

By default, the bottom-most service delineating dot1Q tag's dot1P bits are used. Table 57: Default QinQ and TopQ SAP Dot1P Evaluation defines the default behavior for dot1P evaluation when the **match-qinq-dot1p** command is not executed.

Table 57: Default QinQ and TopQ SAP Dot1P Evaluation

Port/SAP Type	Existing Packet Tags	PBits Used for Match
Null	None	None
Null	Dot1P (VLAN-ID 0)	Dot1P PBits
Null	Dot1Q	Dot1Q PBits
Null	TopQ BottomQ	TopQ PBits
Null	TopQ (No BottomQ)	TopQ PBits
Dot1Q	None (Default SAP)	None
Dot1Q	Dot1P (Default SAP VLAN-ID 0)	Dot1P PBits
Dot1Q	Dot1Q	Dot1Q PBits

Port/SAP Type	Existing Packet Tags	PBits Used for Match
QinQ/TopQ	TopQ	TopQ PBits
QinQ/TopQ	TopQ BottomQ	TopQ PBits
QinQ/TopQ	TopQ BottomQ	BottomQ PBits

The **no** form of this command restores the default dot1p evaluation behavior for the SAP.

Default

no match-qinq-dot1p (no filtering based on p-bits)

(top or bottom must be specified to override the default QinQ dot1p behavior)

Parameters

top

The top parameter is mutually exclusive to the bottom parameter. When the **top** parameter is specified, the topmost PBits are used (if existing) to match any dot1p dot1p-value entries. Table 58: Top Position QinQ and TopQ SAP Dot1P Evaluation defines the dot1p evaluation behavior when the **top** parameter is specified.

Table 58: Top Position QinQ and TopQ SAP Dot1P Evaluation

Port/SAP Type	Existing Packet Tags	PBits Used for Match
Null	None	None
Null	Dot1P (VLAN-ID 0)	Dot1P PBits
Null	Dot1Q	Dot1Q PBits
Null	TopQ BottomQ	TopQ PBits
Null	TopQ (No BottomQ)	TopQ PBits
Dot1Q	None (Default SAP)	None
Dot1Q	Dot1P (Default SAP VLAN-ID 0)	Dot1P PBits
Dot1Q	Dot1Q	Dot1Q PBits
QinQ/TopQ	TopQ	TopQ PBits
QinQ/TopQ	TopQ BottomQ	TopQ PBits
QinQ/QinQ	TopQ BottomQ	TopQ PBits

bottom

The **bottom** parameter is mutually exclusive to the **top** parameter. When the bottom parameter is specified, the bottom most PBits are used (if existing) to match any dot1p

dot1p-value entries. Table 59: Bottom Position QinQ and TopQ SAP Dot1P Evaluation defines the dot1p evaluation behavior when the bottom parameter is specified.

Table 59: Bottom Position QinQ and TopQ SAP Dot1P Evaluation

Port/SAP Type	Existing Packet Tags	PBits Used for Match
Null	None	None
Null	Dot1P (VLAN-ID 0)	Dot1P PBits
Null	Dot1Q	Dot1Q PBits
Null	TopQ BottomQ	BottomQ PBits
Null	TopQ (No BottomQ)	TopQ PBits
Dot1Q	None (Default SAP)	None

Syntax

match-qinq-dot1p {**top** | **bottom**}

no match-qinq-dot1p de

Context

[Tree] (config>service>epipe>sap>ingress match-qinq-dot1p)

Full Context

configure service epipe sap ingress match-qinq-dot1p

Description

This command specifies which Dot1Q tag position Dot1P bits in a QinQ encapsulated packet should be used to evaluate Dot1P QoS classification.

The **match-qinq-dot1p** command allows the top or bottom PBits to be used when evaluating the applied sap-ingress QoS policy's Dot1P entries. The **top** and **bottom** keywords specify which position should be evaluated for QinQ encapsulated packets.

The setting also applies to classification based on the DE indicator bit.

The **no** form of this command reverts the dot1p and de bits matching to the default tag.

By default, the bottom most service delineating Dot1Q tags Dot1P bits are used. Table 60: Default QinQ and TopQ SAP Dot1P Evaluation defines the default behavior for Dot1P evaluation. Top or bottom must be specified to override the default QinQ dot1p behavior.

Table 60: Default QinQ and TopQ SAP Dot1P Evaluation

Port/SAP Type	Existing Packet Tags	PBits Used for Match
Null	None	None
Null	Dot1P (VLAN ID 0)	Dot1P PBits
Null	Dot1Q	Dot1Q PBits
Null	TopQ BottomQ	TopQ PBits
Null	TopQ (No BottomQ)	TopQ PBits
Dot1Q	None (Default SAP)	None
Dot1Q	Dot1P (Default SAP VLAN ID 0)	Dot1P PBits
Dot1Q	Dot1Q	Dot1Q PBits
QinQ / TopQ	TopQ	TopQ PBits
QinQ / TopQ	TopQ BottomQ	TopQ PBits
QinQ / QinQ	TopQ BottomQ	BottomQ PBits

Default

no match-qinq-dot1p (no filtering based on p-bits)

Parameters

top

The top parameter is mutually exclusive to the bottom parameter. When the top parameter is specified, the top most PBits are used (if existing) to match any dot1p dot1p-value entries. Table 61: Top Position QinQ dpt1p Evaluation Behavior defines the dot1p evaluation behavior when the top parameter is specified.

Table 61: Top Position QinQ dpt1p Evaluation Behavior

Port/SAP Type	Existing Packet Tags	PBits Used for Match
Null	None	None

Port/SAP Type	Existing Packet Tags	PBits Used for Match
Null	Dot1P (VLAN ID 0)	Dot1P PBits
Null	Dot1Q	Dot1Q PBits
Null	TopQ BottomQ	TopQ PBits
Null	TopQ (No BottomQ)	TopQ PBits
Dot1Q	None (Default SAP)	None
Dot1Q	Dot1P (Default SAP VLAN ID 0)	Dot1P PBits
Dot1Q	Dot1Q	Dot1Q PBits
QinQ / TopQ	TopQ	TopQ PBits
QinQ / TopQ	TopQ BottomQ	TopQ PBits
QinQ / QinQ	TopQ BottomQ	TopQ PBits

bottom

The bottom parameter and the top parameter are mutually exclusive. When the bottom parameter is specified, the bottom most PBits are used (if existing) to match any dot1p dot1p-value entries. Table 62: Bottom Position QinQ and TopQ SAP Dot1P Evaluation defines the dot1p evaluation behavior when the bottom parameter is specified.

Table 62: Bottom Position QinQ and TopQ SAP Dot1P Evaluation

Port/SAP Type	Existing Packet Tags	PBits Used for Match
Null	None	None
Null	Dot1P (VLAN ID 0)	Dot1P PBits
Null	Dot1Q	Dot1Q PBits
Null	TopQ BottomQ	TopQ PBits
Null	TopQ (No BottomQ)	TopQ PBits
Dot1Q	None (Default SAP)	None
Dot1Q	Dot1P (Default SAP VLAN ID 0)	Dot1P PBits
Dot1Q	Dot1Q	Dot1Q PBits
QinQ / TopQ	TopQ	TopQ PBits
QinQ / TopQ	TopQ BottomQ	BottomQ PBits
QinQ / QinQ	TopQ BottomQ	BottomQ PBits

Table 63: Egress SAP Types

Egress SAP Type	Ingress Packet Preserved Dot1P State	Marked (or Remarked) PBits
Null	No preserved Dot1P bits	None
Null	Preserved Dot1P bits	Preserved tag PBits remarked using dot1p-value
Dot1Q	No preserved Dot1P bits	New PBits marked using dot1p-value
Dot1Q	Preserved Dot1P bits	Preserved tag PBits remarked using dot1p-value
TopQ	No preserved Dot1P bits	TopQ PBits marked using dot1p-value
TopQ	Preserved Dot1P bits (used as TopQ and BottomQ PBits)	TopQ PBits marked using dot1p-value, BottomQ PBits preserved
QinQ	No preserved Dot1P bits	TopQ PBits and BottomQ PBits marked using dot1p-value
QinQ	Preserved Dot1P bits (used as TopQ and BottomQ PBits)	TopQ PBits and BottomQ PBits marked using dot1p-value

The QinQ and TopQ SAP PBit/DEI bit marking follows the default behavior defined in the preceding table when **qinq-mark-top-only** is not specified.

The dot1p *dot1p-value* command must be configured without the qinq-mark-top-only parameter to remove the TopQ PBits only marking restriction.

A QinQ-encapsulated Ethernet port can have two different sap types:

For a TopQ SAP type, only the outer (top) tag is explicitly specified. For example, **sap 1/1/1:10.***

For QinQ SAP type, both inner (bottom) and outer (top) tags are explicitly specified. For example, **sap 1/1/1:10.100**.

Platforms

7705 SAR Gen 2

match-qinq-dot1p

Syntax

match-qinq-dot1p {**top** | **bottom**}

no match-qinq-dot1p

Context

[Tree] (config>service>vprn>if>sap>ingress match-qinq-dot1p)

Full Context

configure service vprn interface sap ingress match-qinq-dot1p

Description

This command specifies which Dot1Q tag position Dot1P bits in a QinQ encapsulated packet should be used to evaluate Dot1P QoS classification.

The **match-qinq-dot1p** command allows the top or bottom PBits to be used when evaluating the applied sap-ingress QoS policy's Dot1P entries. The **top** and **bottom** keywords specify which position should be evaluated for QinQ encapsulated packets.

The **no** form of this command restores the default dot1p evaluation behavior for the SAP.

By default, the bottom most service delineating Dot1Q tags Dot1P bits are used. Table 64: Dot1P Default Behavior defines the default behavior for Dot1P evaluation when the **match-qinq-dot1p** command is not executed.

Table 64: Dot1P Default Behavior

Port / SAP Type	Existing Packet Tags	PBits Used for Match
null	none	none
null	Dot1P (VLAN-ID 0)	Dot1P PBits
null	—	Dot1Q PBits
null	TopQ BottomQ	TopQ PBits
null	TopQ (No BottomQ)	TopQ PBits
Dot1Q	none (Default SAP)	none
Dot1Q	Dot1P (Default SAP VLAN-ID 0)	Dot1P PBits
Dot1Q	Dot1Q	Dot1Q PBits
QinQ / TopQ	TopQ	TopQ PBits
QinQ / TopQ	TopQ BottomQ	TopQ PBits
QinQ / QinQ	TopQ BottomQ	BottomQ PBits

Default

no match-qinq-dot1p - No filtering based on p-bits.

top or **bottom** must be specified to override the default QinQ dot1p behavior.

Parameters

top

The top parameter is mutually exclusive to the bottom parameter. When the top parameter is specified, the top most PBits are used (if existing) to match any dot1p dot1p-value entries. Table 65: Dot1P Evaluation Behavior defines the dot1p evaluation behavior when the top parameter is specified.

Table 65: Dot1P Evaluation Behavior

Port / SAP Type	Existing Packet Tags	PBits Used for Match
null	none	none
null	Dot1P (VLAN-ID 0)	Dot1P PBits
null	Dot1Q	Dot1Q PBits
null	TopQ BottomQ	TopQ PBits
null	TopQ (No BottomQ)	TopQ PBits
Dot1Q	none (Default SAP)	none
Dot1Q	Dot1P (Default SAP VLAN-ID 0)	Dot1P PBits
Dot1Q	Dot1Q	Dot1Q PBits
QinQ / TopQ	TopQ	TopQ PBits
QinQ / TopQ	TopQ BottomQ	TopQ PBits
QinQ / TopQ	TopQ BottomQ	TopQ PBits

bottom

The bottom parameter is mutually exclusive to the top parameter. When the bottom parameter is specified, the bottom most PBits are used (if existing) to match any **dot1p** *dot1p-value* entries. The following tables define the bottom position QinQ and TopQ SAP dot1p evaluation and the default dot1p explicit marking actions.

Table 66: Bottom Position QinQ and TopQ SAP Dot1P Evaluation

Port / SAP Type	Existing Packet Tags	PBits Used for Match
null	none	none
null	Dot1P (VLAN-ID 0)	Dot1P PBits
null	Dot1Q	Dot1Q PBits
null	TopQ BottomQ	BottomQ PBits
null	TopQ (No BottomQ)	TopQ PBits

Port / SAP Type	Existing Packet Tags	PBits Used for Match
Dot1Q	none (default SAP)	none
Dot1Q	Dot1P (default SAP VLAN-ID 0)	Dot1P PBits
Dot1Q	Dot1Q	Dot1Q PBits
QinQ / TopQ	TopQ	TopQ PBits
QinQ / TopQ	TopQ BottomQ	BottomQ PBits
QinQ / QinQ	TopQ BottomQ	BottomQ PBits

Table 67: Default Dot1P Explicit Marking Actions

Egress SAP Type	Ingress Packet Preserved Dot1P State	Marked (or Remarked) PBits
null	no preserved Dot1P bits	none
null	preserved Dot1P bits	preserved tag PBits remarked using dot1p-value
Dot1Q	no preserved Dot1P bits	new PBits marked using dot1p-value
Dot1Q	preserved Dot1P bits	preserved tag PBits remarked using dot1p-value
TopQ	no preserved Dot1P bits	TopQ PBits marked using dot1p-value
TopQ	preserved Dot1P bits (used as TopQ and BottomQ PBits)	TopQ PBits marked using dot1p-value, BottomQ PBits preserved
QinQ	no preserved Dot1P bits	TopQ PBits and BottomQ PBits marked using dot1p-value
QinQ	preserved Dot1P bits (used as TopQ and BottomQ PBits)	TopQ PBits and BottomQ PBits marked using dot1p-value

The **dot1p** *dot1p-value* command must be configured without the **qinq-mark-top-only** parameter to remove the TopQ PBits only marking restriction.

[Tree] (config>router>router-advert>if max-advertisement-interval)

Full Context

configure service vprn router-advertisement interface max-advertisement-interval

configure router router-advertisement interface max-advertisement-interval

Description

This command configures the maximum interval between sending router advertisement messages.

Default

max-advertisement-interval 600

Parameters

seconds

Specifies the maximum interval in seconds between sending router advertisement messages.

Values 4 to 1800

Platforms

7705 SAR Gen 2

17.37 max-age

max-age

Syntax

max-age *max-age*

no max-age [*max-age*]

Context

[Tree] (config>service>vpls>stp max-age)

[Tree] (config>service>template>vpls-template>stp max-age)

Full Context

configure service vpls stp max-age

configure service template vpls-template stp max-age

Description

This command indicates how many hops a BPDU can traverse the network starting from the root bridge. The message age field in a BPDU transmitted by the root bridge is initialized to 0. Each other bridge will

take the message_age value from BPDUs received on their root port and increment this value by 1. The message_age therefore reflects the distance from the root bridge. BPDUs with a message age exceeding max-age are ignored.

STP uses the max-age value configured in the root bridge. This value is propagated to the other bridges via the BPDUs.

The **no** form of this command returns the max age to the default value.

Default

max-age 20

Parameters

max-age

The max info age for the STP instance in seconds. Allowed values are integers in the range 6 to 40.

Platforms

7705 SAR Gen 2

17.38 max-auth-req

max-auth-req

Syntax

max-auth-req *max-auth-request*

Context

[Tree] (config>port>ethernet>dot1x max-auth-req)

Full Context

configure port ethernet dot1x max-auth-req

Description

This command configures the maximum number of times that the router will send an access request RADIUS message to the RADIUS server. If a reply is not received from the RADIUS server after the specified number attempts, the 802.1x authentication procedure is considered to have failed.

The **no** form of this command returns the value to the default.

Default

max-auth-req 2

Parameters

max-auth-request

The maximum number of RADIUS retries.

Values 1 to 10

Platforms

7705 SAR Gen 2

17.39 max-bulk-duration

max-bulk-duration

Syntax

max-bulk-duration *milliseconds*

no max-bulk-duration

Context

[Tree] (config>system>snmp max-bulk-duration)

Full Context

configure system snmp max-bulk-duration

Description

This command sets the maximum duration to process an SNMP request before bulk responses are returned to avoid a timeout on the management system when a lot of information is returned in the response.

Default

no max-bulk-duration

Parameters

milliseconds

Specifies the maximum duration to process requests before bulk responses are returned.

Values 100 to 5000

Platforms

7705 SAR Gen 2

17.40 max-burst

max-burst

Syntax

max-burst *number*

no max-burst

Context

[Tree] (config>router>rsvp>msg-pacing max-burst)

Full Context

configure router rsvp msg-pacing max-burst

Description

This command specifies the maximum number of RSVP messages that are sent in the specified period under normal operating conditions.

Default

max-burst 650

Parameters

number

Specifies the maximum number of RSVP messages to be sent in increments of 10.

Values 100 to 1000

Platforms

7705 SAR Gen 2

17.41 max-bypass-associations

max-bypass-associations

Syntax

max-bypass-associations *integer*

no max-bypass-associations

Context

[Tree] (config>router>mpls max-bypass-associations)

Full Context

configure router mpls max-bypass-associations

Description

This command allows the user to set a maximum number of LSP primary path associations with each manual or dynamic bypass LSP that is created in the system.

By default, a Point of Local Repair (PLR) node will associate a maximum of 1000 primary LSP paths with a given bypass before using the next available manual bypass or signaling a new dynamic bypass.

Note that a new bypass LSP may need to be signaled if the constraint of a given primary LSP path is not met by an existing bypass LSP even if the max-bypass-associations for this bypass LSP has not been reached.

The **no** form of this command reinstates the default value of this parameter.

Default

max-bypass-associations 1000

Parameters

integer

Configures the number of LSP primary path associations

Values 100 to 131072

Platforms

7705 SAR Gen 2

17.42 max-bypass-plr-associations

max-bypass-plr-associations

Syntax

max-bypass-plr-associations *plr-value*

no max-bypass-plr-associations

Context

[Tree] (config>router>mpls max-bypass-plr-associations)

Full Context

configure router mpls max-bypass-plr-associations

Description

This command enables the configuration of the maximum number of Points of Local Repair (PLRs) per RSVP-TE bypass LSP.

A PLR summarizes the constraints applied to the computation of the path of the bypass LSP. It consists of the avoid link/node constraint, and potentially other TE constraints such as exclude SRLG, that are needed to protect against the failure of the primary path of the RSVP-TE LSP that is associated with this bypass LSP.

Additional PLRs with the same avoid link/node constraint are associated with the same bypass to minimize the number of bypass LSPs created. This command controls the maximum number of such PLRs.

Because MPLS saves only the PLR constraints of the first LSP that triggered the dynamic bypass creation, subsequent LSPs for the same avoid link/node and with the non-strict bypass SRLG disjointness enabled may be associated with the same bypass. This is even in cases where there exists a bypass LSP path that strictly satisfies the SRLG constraint.

When the maximum PLRs per bypass is configured with a value of 1, MPLS triggers the signaling of a new dynamic bypass LSP for each new PLR and saves each PLR constraint separately with its own bypass. As a result, when MPLS re-optimizes a bypass LSP it guarantees that SRLG disjointness of that PLR are checked and enforced.

The **no** form of this command returns the command to its default value.

Default

max-bypass-plr-associations 16

Parameters

plr-value

Configures the number of LSP primary path associations

Values 1 to 16

Default 16

Platforms

7705 SAR Gen 2

max-channels-per-connection

Syntax

max-channels-per-connection *number-of-channels*

no max-channels-per-connection

Context

[Tree] (config>system>login-control>ssh max-channels-per-connection)

Full Context

configure system login-control ssh max-channels-per-connection

Description

This command configures the maximum number of channels supported on an SSH connection.

The **no** form of this command configures this value to 5, which is the default.

Default

max-channels-per-connection 5

Parameters

number-of-channels

Specifies the number of channels.

Values 1 to 50

Platforms

7705 SAR Gen 2

17.44 max-cleared

max-cleared

Syntax

max-cleared *maximum*

Context

[Tree] (config>system>alarms max-cleared)

Full Context

configure system alarms max-cleared

Description

This command configures the maximum number of cleared alarms that the system will store and display.

Default

max-cleared 500

Parameters

maximum

Specifies the maximum number of cleared alarms, up to 500.

Platforms

7705 SAR Gen 2

17.45 max-completed

max-completed

Syntax

max-completed *unsigned*

Context

[Tree] (config>system>script-control>script-policy max-completed)

Description

This command is used to configure the maximum number of script run history status entries to keep.

Default

max-completed 1

Parameters

unsigned

Specifies the maximum number of script run history status entries to keep.

Values 1 to 1500

Default 1

Platforms

7705 SAR Gen 2

17.46 max-conn-prefix

max-conn-prefix

Syntax

max-conn-prefix *count*

no max-conn-prefix

Context

[Tree] (config>test-oam>twamp>server>prefix max-conn-prefix)

Full Context

configure test-oam twamp server prefix max-conn-prefix

Description

This command configures the maximum number of control connections by clients with an IP address in a specific prefix. A new control connection is rejected if accepting it would cause either the prefix limit defined by this command or the server limit (max-conn-server) to be exceeded.

The **no** form of this command returns the value to the default.

Default

max-conn-prefix 32

Parameters

count

Specifies the maximum number of control connections.

Values 0 to 64

Default 32

Platforms

7705 SAR Gen 2

17.47 max-conn-server

max-conn-server

Syntax

max-conn-server *count*

[Tree] (config>test-oam>twamp>server max-conn-server)

Full Context

configure test-oam twamp server max-conn-server

Description

This command configures the maximum number of TWAMP control connections from all TWAMP clients. A new control connection is rejected if accepting it would cause either this limit or a prefix limit (max-conn-prefix) to be exceeded.

The **no** form of this command returns the value to the default.

Default

max-conn-server 32

Parameters

count

Specifies the maximum number of control connections.

Values 0 to 64

Default 32

Platforms

7705 SAR Gen 2

17.48 max-drop-count

max-drop-count

Syntax

max-drop-count *count*

no max-drop-count

Context

[Tree] (config>service>sdp>keep-alive max-drop-count)

Full Context

configure service sdp keep-alive max-drop-count

Description

This command configures the number of consecutive SDP keepalive failed request attempts or remote replies that can be missed after which the SDP is operationally downed. If the **max-drop-count** consecutive keepalive request messages cannot be sent or no replies are received, the SDP-ID will be brought operationally down by the keepalive SDP monitoring.

The **no** form of this command reverts the **max-drop-count** *count* value to the default settings.

Default

max-drop-count 3

Parameters

count

Specifies the number of consecutive SDP keepalive requests that are failed to be sent or replies missed, expressed as a decimal integer.

Values 1 to 5

Platforms

7705 SAR Gen 2

17.49 max-ecmp-routes

max-ecmp-routes

Syntax

max-ecmp-routes *max-routes*

no max-ecmp-routes

Context

[Tree] (config>router>ldp max-ecmp-routes)

Full Context

configure router ldp max-ecmp-routes

Description

This command sets the maximum number of ECMP routes that LDP may use to resolve the next hop for a FEC.

Note:
The system-wide maximum number of ECMP routes is limited by the **config>router>ecmp** command. This command, under the LDP context, simply allows LDP to use more than 32 routes, if they are available in RTM or TTM. When configured, the actual number of ECMP routes used by LDP is therefore min[**config>router>ecmp**, **config>router>ldp>max-ecmp-routes**].

The **no** form of this command reverts to the default value.

Default

max-ecmp-routes 32

Parameters

max-routes

Specifies the maximum number of routes.

Values 1 to 64

Platforms

7705 SAR Gen 2

17.50 max-groups

max-groups

Syntax

max-groups *max-groups*

no max-groups

Context

[Tree] (config>service>vprn>igmp>if max-groups)

Full Context

configure service vprn igmp interface max-groups

Description

This command configures the maximum number of groups for which IGMP can have local receiver information based on received IGMP reports on this interface. When this configuration is changed dynamically to a value lower than currently accepted number of groups, the groups that are already accepted are not deleted. Only new groups will not be allowed.

The **no** form of this command removes the value.

Parameters

max-groups

Specifies the maximum number of groups for this interface.

Values 1 to 16000

Platforms

7705 SAR Gen 2

max-groups

Syntax

max-groups *value*

no max-groups

Context

configure service ies interface sap ipsec-gw max-history-esp-key-records

configure service ies interface ipsec ipsec-tunnel max-history-esp-key-records

configure service vprn interface sap ipsec-tunnel max-history-esp-key-records

Description

This command enables the system to keep records of CHILD-SA keys. There is a system wide limit of maximum number of IPsec tunnels that save keys. If the number of tunnel exceeds that limit, the system does not save keys for the new tunnels. Contact Nokia support for details of the limitation.

This command is ignored if the **config>ipsec>no show-ipsec-keys** command is configured.

The **no** form of this command prevents the system from keeping records.

Default

no max-history-esp-key-records

Parameters

max-records

Specifies the maximum number of recent records.

Values 1 to 48

Platforms

7705 SAR Gen 2

17.53 max-history-ike-key-records

max-history-ike-key-records

Syntax

Full Context

configure service template vpls-sap-template max-nbr-mac-addr

configure service vpls spoke-sdp max-nbr-mac-addr

configure service vpls sap max-nbr-mac-addr

Description

This command specifies the maximum number of FDB entries for both learned and static MAC addresses for this instance.

When the configured limit is reached, no new addresses are learned from the SAP or spoke SDP until at least one FDB entry is aged out or cleared.

When the configured limit is reached and the **discard-unknown-source** command is enabled for this instance, packets with unknown source MAC addresses are discarded. If **discard-unknown-source** is disabled, the packets are forwarded if their destination MAC addresses are known, or flooded if their destination MAC addresses are unknown.

However, if the **configure service vpls discard-unknown** command is enabled, packets with unknown destination MAC addresses are discarded, even if the limit of FDB entries on the specific VPLS instance is not reached.

The **no** form of this command restores the global MAC learning limitations for this instance.

Default

no max-nbr-mac-addr

Parameters

table-size

Specifies the maximum number of learned and static entries allowed in the FDB of this service.

Values 1 to 32767

Platforms

7705 SAR Gen 2

max-nbr-mac-addr

Syntax

max-nbr-mac-addr *table-size*

no max-nbr-mac-addr

Context

Full Context

configure card fp ingress access queue-group policer-control-override max-rate

configure card fp ingress network queue-group policer-control-override max-rate

Description

This command defines the parent policer's PIR leaky bucket's decrement rate. A parent policer is created for each time the policer-control-policy is applied to either a SAP or subscriber instance. Packets that are not discarded by the child policers associated with the SAP or subscriber instance are evaluated against the parent policer's PIR leaky bucket.

For each packet, the bucket is first decremented by the correct amount based on the decrement rate to derive the current bucket depth. The current depth is then compared to one of two discard thresholds associated with the packet. The first discard threshold (discard-unfair) is applied if the FIR (Fair Information Rate) leaky bucket in the packet's child policer is in the confirming state. The second discard threshold (discard-all) is applied if the child policer's FIR leaky bucket is in the exceed state. Only one of the two thresholds is applied per packet. If the current depth of the parent policer PIR bucket is less than the threshold value, the parent PIR bucket is in the conform state for that particular packet. If the depth is equal to or greater than the applied threshold, the bucket is in the violate state for the packet.

If the result is "conform," the bucket depth is increased by the size of the packet (plus or minus the per-packet-offset setting in the child policer) and the packet is not discarded by the parent policer. If the result is "violate," the bucket depth is not increased and the packet is discarded by the parent policer. When the parent policer discards a packet, any bucket depth increases (PIR, CIR and FIR) in the parent policer caused by the packet are canceled. This prevents packets that are discarded by the parent policer from consuming the child policers PIR, CIR and FIR bandwidth.

The **policer-control-policy root max-rate** setting may be overridden on each SAP or sub-profile where the policy is applied.

The **no** form of this command returns the policer-control-policy's parent policer maximum rate to **max**.

Default

max-rate max

Parameters

rate

Specifies that a kilobits-per-second value is mutually exclusive with the **max** keyword. The kilobits-per-second value must be defined as an integer that represents the number of kilobytes that the parent policer will be decremented per second. The actual decrement is performed per packet based on the time that has elapsed since the last packet associated with the parent policer.

Values 0 to 2000000000

max

The **max** keyword is mutually exclusive with defining a kilobits-per-second value. When max is specified, the parent policer does not enforce a maximum rate on the aggregate throughput of the child policers. This is the default setting when the **policer-control-policy** is first created and is the value that the parent policer returns to when no max-rate is executed. In order for the parent policer to be effective, a kilobits-per-second value should be specified.

Platforms

7705 SAR Gen 2

max-rate

Syntax

max-rate *pir-rate*

max-rate percent *percent-rate*

no max-rate

Context

[Tree] (config>port>ethernet>egr-scheduler-override max-rate)

Full Context

configure port ethernet egress-scheduler-override max-rate

Description

This command overrides the **max-rate** parameter found in the port-scheduler-policy associated with the port. When a max-rate is defined at the port or channel level, the port scheduler policies max-rate parameter is ignored.

The egress-scheduler-override **max-rate** command supports a parameter that allows the override command to restore the default of not having a rate limit on the port scheduler. This is helpful when the port scheduler policy has an explicit maximum rate defined and it is desirable to remove this limit at the port instance.

The **no** form of this command removes the maximum rate override from the egress port or channels port scheduler context. Once removed, the max-rate parameter from the port scheduler policy associated with the port or channel will be used by the local scheduler context.

Parameters

pir-rate

Specifies the explicit maximum frame based bandwidth limit, in kilobits per second. This value overrides the QoS scheduler policy rate.

Values **For Ethernet:** 1 to 6400000000, **max**

For SONET-SDH and TDM: 1 to 3200000000, **max**

percent-rate

Specifies the percent rate.

Values 0.01 to 100.00

Platforms

7705 SAR Gen 2

max-rate

Syntax

max-rate {*rate* | **max**}

Specifies the rate override in kilobits per second or use the maximum override value.

Values 1 to 6400000000, max

Platforms

7705 SAR Gen 2

max-rate

Syntax

max-rate *rate*

no max-rate

Context

[Tree] (config>qos>plcr-ctrl-plcy>root max-rate)

Full Context

configure qos policer-control-policy root max-rate

Description

The **max-rate** command defines the parent policer's PIR leaky bucket's decrement rate. A parent policer is created for each time the policer-control-policy is applied to either a SAP or subscriber instance. Packets that are not discarded by the child policers associated with the SAP or subscriber or multiservice site instances are evaluated against the parent policer's PIR leaky bucket.

For each packet, the bucket is first decremented by the correct amount based on the decrement rate to derive the current bucket depth. The current depth is then compared to one of two discard thresholds associated with the packet. The first discard threshold (discard-unfair) is applied if the FIR (Fair Information Rate) leaky bucket in the packet's child policer is in the confirming state. The second discard threshold (discard-all) is applied if the child policer's FIR leaky bucket is in the exceed state. Only one of the two thresholds is applied per packet. If the current depth of the parent policer PIR bucket is less than the threshold value, the parent PIR bucket is in the conform state for that particular packet. If the depth is equal to or greater than the applied threshold, the bucket is in the violate state for the packet.

If the result is "conform," the bucket depth is increased by the size of the packet (plus or minus the per-packet-offset setting in the child policer) and the packet is not discarded by the parent policer. If the result is "violate," the bucket depth is not increased and the packet is discarded by the parent policer. When the parent policer discards a packet, any bucket depth increases (PIR, CIR and FIR) in the parent policer caused by the packet are canceled. This prevents packets that are discarded by the parent policer from consuming the child policers PIR, CIR, and FIR bandwidth.

The **policer-control-policy root max-rate** setting may be overridden on each SAP or sub-profile where the policy is applied.

The **no** form of this command returns the policer-control-policy's parent policer maximum rate to **max**.

Parameters

rate

The kilobits-per-second value must be defined as an integer that represents the number of kilobytes that the parent policer will be decremented per second. The actual decrement is performed per packet, based on the time that has elapsed since the last packet associated with the parent policer.

Values 1 to 6400000000, **max**

max

When **max** is specified, the parent policer does not enforce a maximum rate on the aggregate throughput of the child policers. This is the default setting when the **policer-control-policy** is first created and is the value that the parent policer returns to when no max-rate is executed. In order for the parent policer to be effective, a kilobits-per-second value should be specified.

Platforms

7705 SAR Gen 2

max-rate

Syntax

max-rate *pir-rate*

max-rate percent *percent-rate*

no max-rate

Context

[Tree] (config>qos>port-scheduler-policy max-rate)

Full Context

configure qos port-scheduler-policy max-rate

Description

This command defines an explicit maximum frame-based bandwidth limit for the port scheduler policies scheduler context. By default, when a scheduler policy is associated with a port or channel, the instance of the scheduler on the port automatically limits the bandwidth to the lesser of port or channel line rate and a possible egress-rate value (for Ethernet ports). If a max-rate is defined that is smaller than the port or channel rate, the expressed kilobits per second value is used instead. The max-rate command is another way to sub-rate the port or channel.

The **max-rate** command may be executed at any time for an existing port-scheduler-policy. When a new max-rate is given for a policy, the system evaluates all instances of the policy to see if the configured rate is smaller than the available port or channel bandwidth. If the rate is smaller and the maximum rate is not currently overridden on the scheduler instance, the scheduler instance is updated with the new maximum rate value.

The max-rate value defined in the policy may be overridden on each scheduler instance. If the maximum rate is explicitly defined as an override on a port or channel, the policies max-rate value has no effect.

The **no** form of this command removes an explicit rate value from the port scheduler policy. When removed, all instances of the scheduler policy on egress ports or channel are allowed to run at the available line rate unless the instance has a max-rate override in place.

Parameters

pir-rate

Specifies the PIR rate, in kilobits per second.

Values 1 to 6400000000, **max**

percent *percent-rate*

Specifies the percent rate.

Values 0.01 to 100.00

Description

This command configures the maximum number of concurrent TWAMP-Test sessions by clients with an IP address in a specific prefix. A new test session (described by a Request-TW-Session message) is rejected if accepting it would cause either the limit defined by this command or the server limit (max-sess-server) to be exceeded.

The **no** form of this command returns the value to the default.

Default

max-sess-prefix 32

Parameters

count

Specifies the maximum number of concurrent test sessions.

Values 0 to 128

Default 32

Platforms

7705 SAR Gen 2

17.65 max-sess-server

max-sess-server

Syntax

max-sess-server *count*

no max-sess-server

Context

[Tree] (config>test-oam>twamp>server max-sess-server)

Full Context

configure test-oam twamp server max-sess-server

Description

This command configures the maximum number of concurrent TWAMP-Test sessions across all allowed clients. A new test session (described by a Request-TW-Session message) is rejected if accepting it would cause either the limit defined by this command or a prefix limit (max-sess-prefix) to be exceeded.

The **no** form of this command returns the value to the default.

Default

max-sess-server 32

Parameters

count

Specifies the maximum number of concurrent test sessions.

Values 0 to 128

Default 32

Platforms

7705 SAR Gen 2

17.66 max-sessions

max-sessions

Syntax

max-sessions *number*

Context

[Tree] (config>service>vprn>bgp>group>dynamic-neighbor>interface max-sessions)

[Tree] (config>router>bgp>group>dynamic-neighbor>interface max-sessions)

Full Context

configure service vprn bgp group dynamic-neighbor interface max-sessions

configure router bgp group dynamic-neighbor interface max-sessions

Description

This command configures the maximum number of dynamic sessions that are allowed to be set up on the interface as a result of accepting sessions from link-local addresses or initiating sessions by receiving IPv6 router advertisements.

Default

max-sessions 1

Parameters

number

Specifies the maximum number of sessions.

Values 1 to 255

Platforms

7705 SAR Gen 2

17.67 max-sources

max-sources

Syntax

max-sources *max-sources*

no max-sources

Context

[Tree] (config>service>vprn>mld>interface max-sources)

[Tree] (config>service>vprn>igmp>if max-sources)

Full Context

configure service vprn mld interface max-sources

configure service vprn igmp interface max-sources

Description

This command specifies the maximum number of sources for which IGMP can have local receiver information based on received IGMP reports on this interface. When this configuration is changed dynamically to a value lower than currently accepted number of sources, the sources that are already accepted are not deleted. Only new sources will not be allowed.

Parameters

sources

Specifies the maximum number of sources for this interface.

Values 1 to 1000

Platforms

7705 SAR Gen 2

max-sources

Syntax

max-sources *value*

no max-sources

Context

[Tree] (config>router>igmp>if max-sources)

Full Context

configure router igmp interface max-sources

Description

This command configures the maximum number of group sources for this group-interface.

Parameters

value

Specifies the maximum number of group sources.

Values 1 to 1000

Platforms

7705 SAR Gen 2

max-sources

Syntax

max-sources [*grp-source*]

no max-sources

Context

[Tree] (config>router>mld>if max-sources)

Full Context

configure router mld interface max-sources

Description

This command configures the maximum number of group sources for this interface.

The **no** form of this command reverts to the default.

Default

no max-sources

Parameters

grp-source

Specifies the maximum number of group sources for this interface.

Platforms

7705 SAR Gen 2

17.68 max-sr-labels

max-sr-labels

Syntax

max-sr-labels *label-stack-size* [**additional-frr-labels** *labels*]

no max-sr-labels

Context

[Tree] (config>router>mpls>lsp-template max-sr-labels)

[Tree] (config>router>mpls>lsp max-sr-labels)

Full Context

configure router mpls lsp-template max-sr-labels

configure router mpls lsp max-sr-labels

Description

This command configures the maximum number of labels which the ingress LER can push for a given SR-TE LSP.

This command is used to allow room to insert additional transport, service, and other labels when packets are forwarded in a given context.

The **max-sr-labels** *label-stack-size* value should reflect the desired maximum label stack of the primary path of the SR-TE LSP.

The value in **additional-frr-labels** *labels* should reflect additional labels inserted by remote LFA for the backup next-hop of the SR-TE LSP.

The sum of both label values represents the worst case transport of SR label stack size for this SR-TE LSP and is populated by MPLS in the TTM such that services and shortcut applications can check it to decide if a service can be bound or a route can be resolved to this SR-TE LSP.

The maximum label stack supported by the router is always signaled by PCC in the PCEP Open object as part of the as SR-PCE-CAPABILITY TLV. It is referred to as the Maximum Stack Depth (MSD).

In addition, the per-LSP value for the max-sr-labels option, if configured, is signaled by PCC to PCE in the Segment-ID (SID) Depth value in a METRIC object for both a PCE computed LSP and a PCE controlled LSP. PCE will compute and provide the full explicit path with TE-links specified. If there is no path with the number of hops lower than the MSD value, or the Segment-ID (SID) Depth value if signaled, a reply with no path will be returned to PCC.

For a PCC controlled LSP, if the label stack returned by the TE-DB's hop-to-label translation exceeds the per LSP maximum SR label stack size, the LSP is brought down.

The **no** form of this command reverts to the default value.

Default

max-sr-labels 6 additional-frr-labels 1

Parameters

label-stack-size

Specifies the label stack size.

Values 1 to 11

additional-frr-labels ***labels***

Specifies the addition FRR labels.

Values 0 to 3

Platforms

7705 SAR Gen 2

17.69 max-srte-pce-init-lsps

max-srte-pce-init-lsps

Syntax

max-srte-pce-init-lsps *max-number*

no max-srte-pce-init-lsps

Context

[Tree] (config>router>pcep>pcc max-srte-pce-init-lsps)

Full Context

configure router pcep pcc max-srte-pce-init-lsps

Description

This command configures the maximum number of PCE-initiated SR-TE LSPs that can be created by the router.

The **no** form of the command sets this value to the default.

Default

max-srte-pce-init-lsps 8191

Parameters

max-number

Specifies the maximum number of SR-TE PCE-initiated LSPs.

Values 0 to 8191

Platforms

7705 SAR Gen 2

17.70 max-suppress

max-suppress

Syntax

max-suppress *minutes*

no max-suppress

Context

[Tree] (config>router>policy-options>damping max-suppress)

Full Context

configure router policy-options damping max-suppress

Description

This command configures the maximum suppression parameter for the route damping profile.

This value indicates the maximum time, expressed in minutes, that a route can remain suppressed.

The **no** form of this command removes the maximum suppression parameter from the damping profile.

Default

no max-suppress

Parameters

minutes

Specifies the maximum suppression time, in minutes, expressed as a decimal integer.

Values 1 to 720

Platforms

7705 SAR Gen 2

17.71 max-time-granularity

max-time-granularity

Syntax

[no] max-time-granularity *time*

Context

[Tree] (config>system>telemetry>notification-bundling max-time-granularity)

Full Context

configure system telemetry notification-bundling max-time-granularity

Description

This command sets the maximum time interval during which telemetry notifications are bundled. All bundled notifications will have the same timestamp, which is the timestamp of the bundle.

The **no** form of this command returns the time granularity to the default value.

Default

max-time-granularity 100

Parameters

time

Specifies the maximum time interval during which telemetry notifications are bundled, in milliseconds.

Values 1 to 1000

Platforms

7705 SAR Gen 2

17.72 max-ve-id

max-ve-id

Syntax

max-ve-id *value*

no max-ve-id

Context

[Tree] (config>service>vpls>bgp-vpls max-ve-id)

Full Context

configure service vpls bgp-vpls max-ve-id

Description

This command configures the allowed range for the VE-id value: locally configured and received in a NLRI. Configuration of a VE-id higher than the value specified in this command is not allowed.

Also upon reception of a higher VE-id in an NLRI imported in this VPLS instance (RT is the configured import RT) the following action must be taken:

- a trap must be generated informing the operator of the mismatch.
- NLRI must be dropped
- no service labels are to be installed for this VE-id
- no new NLRI must be generated if a new offset is required for VE-id.

The **no** form of this command sets the max-ve-id to un-configured. The BGP VPLS status should be administratively down for "no max-ve-id" to be used.

The max-ve-id value can be changed without shutting down bgp-vpls if the newly provisioned value does not conflict with the already configured local VE-ID. If the value of the local-VE-ID is higher than the new

max-ve-id value the command is rejected. The operator needs to decrease first the VE-ID before running the command.

The actions taken for other max-ve-id values are as follows:

- max-ve-id value higher than all VE-IDs (local and received) is allowed and there are no effects.
- max-ve-id higher than the local VE-ID but smaller than the remote VE-IDs:
  - Provisioning is allowed
  - A warning message will be generated stating that "Higher VE-ID values were received in the BGP VPLS context. Related pseudowires will be removed."
  - The pseudowires associated with the higher VE-IDs will be removed locally.
  - This is a situation that should be corrected by the operator as the pseudowire may be down just at the local PE, consuming unnecessarily core bandwidth. The higher VE-IDs should be removed or lowered.

If the max-ve-id has increased a BGP route refresh is sent to the VPLS community to get the routes which might have been rejected earlier due to max-ve-id check. A max-ve-id value needs to be provisioned for BGP VPLS to be in "no shutdown" state.

Default

no max-ve-id

Parameters

value

Specifies the allowed range of [1-value] for the VE-id. The configured value must be bigger than the existing VE-ids

Values 1 to 65535

Platforms

7705 SAR Gen 2

17.73 max-wait-to-advertise

max-wait-to-advertise

Syntax

max-wait-to-advertise *seconds*

no max-wait-to-advertise

Context

[Tree] (config>service>vprn>bgp>convergence>family max-wait-to-advertise)

Full Context

configure service vprn bgp convergence family max-wait-to-advertise

Description

This command configures the maximum amount of time that BGP waits until it starts advertising IPv4-unicast or IPv6-unicast routes to its BGP peers. For IPv4-unicast routes, *seconds* is measured from the time when the first peer that supports the IPv4-unicast address family comes up. For IPv6-unicast routes *seconds* is measured from the time when the first peer that negotiates the IPv6-unicast address family comes up.

The time limit configured by this command should allow sufficient time for all important peers to re-establish their sessions with the restarting router and advertise their complete set of IPv4-unicast or IPv6-unicast routes (followed by the applicable End of RIB marker).

The **no** form of this command implements the default value, which is three times the value of the **min-wait-to-advertise** time limit.

Default

no max-wait-to-advertise

Parameters

seconds

Specifies the maximum amount of time, in seconds, that BGP waits until IPv4-unicast or IPv6-unicast routes are advertised to peers.

Values 0 to 3600

Platforms

7705 SAR Gen 2

max-wait-to-advertise

Syntax

max-wait-to-advertise *seconds*

no max-wait-to-advertise

Context

[Tree] (config>router>bgp>convergence>family max-wait-to-advertise)

Full Context

configure router bgp convergence family max-wait-to-advertise

Description

This command configures the maximum amount of time that BGP waits until it starts advertising IPv4-unicast or IPv6-unicast routes to its BGP peers. For IPv4-unicast routes, the time limit value is measured from the time when the first peer that supports the IPv4-unicast address family comes up. For IPv6-unicast

routes the time limit value is measured from the time when the first peer that negotiates the IPv6-unicast address family comes up.

The time limit configured by this command should allow sufficient time for all important peers to re-establish their sessions with the restarting router and advertise their complete set of IPv4-unicast or IPv6-unicast routes (followed by the applicable End of RIB marker).

The **no** form of this command implements the default value, which is three times the value of the **min-wait-to-advertise** time-limit.

Default

no max-wait-to-advertise

Parameters

seconds

Specifies the maximum amount of time, in seconds, that BGP waits until IPv4-unicast or IPv6-unicast routes are advertised to peers.

Values 0 to 3600

Platforms

7705 SAR Gen 2

17.74 maximum-cert-chain-depth

maximum-cert-chain-depth

Syntax

maximum-cert-chain-depth *level*

no maximum-cert-chain-depth

Context

[Tree] (config>system>security>pki maximum-cert-chain-depth)

Full Context

configure system security pki maximum-cert-chain-depth

Description

This command defines the maximum depth of certificate chain verification. This number is applied system wide.

The **no** form of this command reverts to the default.

Default

maximum-cert-chain-depth 7

Parameters

level

Specifies the maximum depth level of certificate chain verification, range from 1 to 7. the certificate under verification is not counted in. for example, if this parameter is set to 1, then the certificate under verification must be directly signed by trust anchor CA.

Values 1 to 7

Platforms

7705 SAR Gen 2

configure service vprn dhcp6 local-dhcp-server pool failover maximum-client-lead-time

configure service vprn dhcp6 local-dhcp-server failover maximum-client-lead-time

Description

The command configures the maximum time that a DHCP server can extend client's lease time beyond the lease time currently known by the DHCP partner node. In dual-homed environment, the initial lease time for all DHCP clients is by default restricted to MCLT. Consecutive DHCP renews can extend the lease time beyond the MCLT.

The maximum client lead time (MCLT) is a safeguard against IP address/prefix duplication in cases of a lease synchronization failure when local-remote failover model is deployed.

Once the intercommunication link failure between the redundant DHCP servers is detected, the DHCP IP address range configured as remote will not be allowed to start delegating new leases until the MCLT + partner-down-delay intervals expire. This is to ensure that the new lease that was delegated from the local IP address-range/prefix on one node but was never synchronized due to the intercommunication link failure, will expire before the same IP address/prefix is allocated from the remote IP address-range/prefix on the other node.

However, the already existing (and synchronized) lease times can be renewed from the remote IP address range at any time, regardless of the state of the intercommunication link (operational or failed).

Lease synchronization failure can be caused either by a node failure, or a failure of the link over which the DHCP leases are synchronized (intercommunication link). Synchronization failure detection can take up to 3 seconds.

During the failure, the DHCP lease time for the new clients is restricted to MCLT while for the existing clients the lease time will over time (by consecutive DHCP renews) be gradually reduced to the MCLT.

The **no** form of this command reverts to the default.

Default

maximum-client-lead-time min 10

Parameters

maximum-client-lead-time

Specifies the maximum client lead time.

Values	**hrs** *hours*	1 to 23
	min *minutes*	1 to 59
	sec *seconds*	1 to 59

Platforms

7705 SAR Gen 2

Full Context

configure router dhcp local-dhcp-server pool subnet maximum-declined

configure service vprn dhcp local-dhcp-server pool subnet maximum-declined

Description

This command configures the maximum number of declined addresses allowed.

The **no** form of the reverts to the default.

Default

maximum-declined 64

Parameters

maximum-declined

Specifies the maximum number of declined addresses allowed.

Values 0 to 4294967295

Platforms

7705 SAR Gen 2

17.77 maximum-ipv6-routes

maximum-ipv6-routes

Syntax

maximum-ipv6-routes *number* [**log-only**] [**threshold** *percentage*]

no maximum-ipv6-routes

Context

[Tree] (config>service>vprn maximum-ipv6-routes)

Full Context

configure service vprn maximum-ipv6-routes

Description

This command specifies the maximum number of remote IPv6 routes that can be held within a VPN routing/ forwarding (VRF) context. The **local**, **host**, **static** and **aggregate** routes are not counted.

The VPRN service ID must be in a shutdown state in order to modify maximum-routes command parameters.

If the **log-only** parameter is not specified and the maximum-routes value is set below the existing number of routes in a VRF, then the offending RIP peer (if applicable) is brought down (but the VPRN instance remains up). BGP peering will remain up but the exceeding BGP routes will not be added to the VRF.

The maximum route threshold can dynamically change to increase the number of supported routes even when the maximum has already been reached. Protocols will resubmit their routes which were initially rejected.

The **no** form of this command disables any limit on the number of routes within a VRF context. The threshold will not be raised. Issue the **no** form of this command only when the VPRN instance is shutdown.

Default

0 or disabled

Parameters

number

Specifies an integer that specifies the maximum number of routes to be held in a VRF context.

Values 1 to 2147483647

log-only

Specifies that if the maximum limit is reached, only log the event. **log-only** does not disable the learning of new routes.

threshold percentage

Specifies the percentage at which a warning log message and SNMP trap should be set. There are two warnings, the first is a mid-level warning at the threshold value set and the second is a high-level warning at level between the maximum number of routes and the mid-level rate ([mid+max] / 2).

Values 0 to 100

Platforms

Full Context

configure test-oam icmp ipv6 maximum-original-datagram

Description

This command enables the original datagram field of the ICMPv6 error message to be a maximum of 1232 bytes.

The **no** form of this command may result in an original datagram field of the ICMPv6 error message smaller than 1232 bytes be built smaller.

Default

no maximum-original-datagram

Platforms

7705 SAR Gen 2

17.80 maximum-paths

maximum-paths

Syntax

maximum-paths *max-paths* [**ebgp** *ebgp-max-paths*] [**ibgp** *ibgp-max-paths*] [**restrict** {**same-neighbor-as** | **exact-as-path**}] [**unequal-cost**]

no maximum-paths

Context

[Tree] (config>service>vprn>bgp>multi-path maximum-paths)

Full Context

configure service vprn bgp multi-path maximum-paths

Description

This command sets ECMP multi-path parameters that apply to all address families for that BGP multi-path. For some address families it is possible to override these settings on a per address family basis.

When multi-path is enabled, traffic to the destination is load-shared across a set of paths (BGP routes) that the BGP decision process considers equal to the best path. The actual distribution of traffic over the multiple paths may be equal or unequal (that is, based on weights derived from the Link Bandwidth Extended Community).

To qualify as a multi-path, a non-best route must meet the following criteria (some criteria are controlled by this command):

- The multi-path route must be the same type of route as the best path (same AFI/SAFI and, in some cases, same next-hop resolution method).
- The multi-path route must be tied with the best path for all criteria of greater significance than next-hop cost, except for criteria that are configured to be ignored.
- If the best path selection reaches the next-hop cost comparison, the multi-path route must have the same next-hop cost as the best route unless the **unequal-cost** option is configured.
- The multi-path route must not have the same BGP next-hop as the best path or any other multi-path route.
- The multi-path route must not cause the ECMP limit of the routing instance to be exceeded (configured using the **ecmp** command with a value in the range 1 to 64).
- The multi-path route must not cause the applicable *max-paths* limit to be exceeded. If the best path is an EBGP learned route and the **ebgp** option is used, the *ebgp-max-paths* limit overrides the *max-paths* limit. If the best path is an IBGP-learned route and the **ibgp** option is used, the *ibgp-max-paths* limit overrides the *max-paths* limit. All path limits are configurable up to a maximum of 64. Multi-path is effectively disabled if a value is set to 1.
- The multi-path route must have the same neighbor AS in its AS path as the best path if the **restrict same-neighbor-as** option is configured. By default, any path with the same AS path length as the best path (regardless of neighbor AS) is eligible for multi-path.
- The route must have the same AS path as the best path if the **restrict exact-as-path** option is configured. By default, any path with the same AS path length as the best path (regardless of the actual AS numbers) is eligible for multi-path.

The **no** form of this command disables BGP multi-path.

Default

no maximum-paths

Parameters

max-paths

Specifies the maximum number of multipaths per prefix/NLRI if *ebgp-max-paths* or *ibgp-max-paths* does not apply.

Values 1 to 64

egp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an EBGP learned route.

Values 1 to 64

ibgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an IBGP learned route.

Values 1 to 64

restrict same-neighbor-as

Specifies that the non-best path must have the same neighbor AS in its AS path as the best path.

restrict exact-as-path-as

Specifies that the non-best path must have the same AS path as the best path.

unequal-cost

Instructs BGP to ignore differences in the next-hop cost only when determining eligible multipaths.

Platforms

7705 SAR Gen 2

maximum-paths

Syntax

maximum-paths *max-paths* [**ebgp** *ebgp-max-paths*] [**ibgp** *ibgp-max-paths*] [**restrict** {**same-neighbor-as** | **exact-as-path**}] [**unequal-cost**]

no maximum-paths

Context

Description

This command specifies the maximum number of remote routes that can be held within a VPN routing/forwarding (VRF) context. The **local**, **host**, **static** and **aggregate** routes are not counted.

The VPRN service ID must be in a shutdown state in order to modify maximum-routes command parameters.

If the **log-only** parameter is not specified and the maximum-routes value is set below the existing number of routes in a VRF, then the offending RIP peer (if applicable) is brought down (but the VPRN instance remains up). BGP peering will remain up but the exceeding BGP routes will not be added to the VRF.

The maximum route threshold can dynamically change to increase the number of supported routes even when the maximum has already been reached. Protocols will resubmit their routes which were initially rejected.

The **no** form of this command disables any limit on the number of routes within a VRF context. Issue the **no** form of this command only when the VPRN instance is shutdown.

Default

0 or disabled — The threshold will not be raised.

Parameters

number

An integer that specifies the maximum number of routes to be held in a VRF context.

Values 1 to 2147483647

log-only

Specifies that if the maximum limit is reached, only log the event. **log-only** does not disable the learning of new routes.

threshold percentage

The percentage at which a warning log message and SNMP trap should be set. There are two warnings, the first is a mid-level warning at the threshold value set and the second is a high-level warning at level between the maximum number of routes and the mid-level rate ([mid+max] / 2).

Syntax

[**no**] **mbb-prefer-current-hops**

Context

[Tree] (config>router>mpls mbb-prefer-current-hops)

Full Context

configure router mpls mbb-prefer-current-hops

Description

This command implements a new option in the CSPF path computation during a Make-Before-Break (MBB) procedure of an RSVP LSP.

When MPLS performs an MBB for the primary or secondary path of a P2P LSP, or the S2L path of a P2MP LSP, and the new **mbb-prefer-current-hops** option is enabled in MPLS context, CSPF will select a path, among equal-cost candidate paths, with the most overlapping links with the current path. Normally, CSPF selects the path randomly.

The procedures of the new MBB CSPF path selection apply to LSP without the least-fill option enabled. If the least-fill rule results in a different path, the LSP path will be moved though. Users can still favor stability over least-fill condition by applying a larger value to the parameter **least-fill-min-thd** under the MPLS context such that a path will only be moved when the difference of the least-available bandwidth becomes significant enough between the most used links in the equal cost paths. If that difference is not significant enough, CSPF will select the path with the most overlapping links instead of selecting a path randomly.

The procedures when the new **mbb-prefer-current-hops** option is enabled apply to all MBB types. Thus, it applies to the auto-bandwidth MBB, the configuration change MBB, the soft preemption MBB, the TE graceful shutdown MBB, the delayed retry MBB (for SRLG secondary LSP path), the path change MBB, the timer resignal MBB, and the manual resignal MBB.

During the FRR global revertive MBB, CSPF selects a random link among the ones available between the PLR node and the Merge Point node, including the failed link if it has restored in the meantime. These links cannot be checked for overlap with the current path.

The TE graceful shutdown MBB will still avoid the link or node that is in maintenance and the soft preemption MBB will still avoid the link that is overbooked.

For an inter-area LSP, this feature applies to the subset of the path from the ingress LER to the exit ABR.

The procedures of this feature are not applied to a zero bandwidth CSPP LSP, including an auto-bandwidth CSPF LSP while its operational bandwidth is zero, and to a non-CSPF LSP.

configure service ies interface sap ingress queue-override queue mbs

configure service vprn interface sap ingress queue-override queue mbs

configure service vprn interface sap egress queue-override queue mbs

configure service ies interface sap egress queue-override queue mbs

Description

This command overrides specific attributes of the specified queue's MBS parameters. The MBS is a mechanism to override the default maximum size for the queue.

The sum of the MBS for all queues on an egress access port can oversubscribe the total amount of buffering available. When congestion occurs and buffers become scarce, access to buffers is controlled by the RED slope a packet is associated with. A queue that has not exceeded its MBS size is not guaranteed that a buffer is available when needed or that the packets RED slope is not forced the discard of the packet. Setting proper CBS parameters and controlling CBS oversubscription is one major safeguard to queue starvation (when a queue does not receive its fair share of buffers). Another is properly setting the RED slope parameters for the needs of services on this port or channel.

If the CBS value is larger than the MBS value, an error will occur, preventing the MBS change.

The **no** form of this command returns the MBS size assigned to the queue.

Default

mbs default

Parameters

size

This required parameter specifies that the MBS is expressed as an integer representing the required size in either bytes or kilobytes. The default is **kilobytes**. The optional **byte** and **kilobyte** keywords are mutually exclusive and are used to explicitly to define the size. By specifying the keyword **default** sets the MBS to its default value.

Values 0 to 1073741824, default

bytes

Specifies that the value given for *size* is interpreted as the queue's MBS value in bytes.

kilobytes

Specifies that the value given for *size* is interpreted as the queue's MBS value in kb/s.

Full Context

configure card fp ingress network queue-group policer-override policer mbs

configure card fp ingress access queue-group policer-override policer mbs

Description

This command configures the policer’s PIR leaky bucket’s violate threshold. The **high-prio-only** command is applied to the MBS value to derive the bucket’s low priority violate threshold. For ingress, trusted in-profile packets and untrusted high priority packets use the policer’s high priority violate threshold while trusted out-of-profile and untrusted low priority packets use the policer’s low priority violate threshold.

The PIR bucket’s violate threshold represent the maximum burst tolerance allowed by the policer. If the policer’s offered rate is equal to or less than the policer’s defined rate, the PIR bucket depth hovers around the 0 depth with spikes up to the maximum packet size in the offered load. If the offered rate increases beyond the metering rate, the amount of data allowed above the rate is capped by the threshold. The low priority violate threshold provides a smaller burst size for the lower priority traffic associated with the

policer. Since all lower priority traffic is discarded at the lower burst tolerance size, the remaining burst tolerance defined by **high-prio-only** is available for the higher priority traffic.

The policer's mbs size defined in the QoS policy may be overridden on an sla-profile or SAP where the policy is applied.

The **no** form of this command reverts the policer to its default MBS size. By default, the MBS is 16 Mbytes when PIR equals max or is greater than or equal to the FP capacity (this overrides an explicit configured MBS value); otherwise, 10 ms volume of traffic for a configured non-zero/non-max PIR capped to 3968 kbytes, with a minimum of 256 bytes.

Parameters

size

The *size* parameter is required when specifying **mbs** and is expressed as an integer representing the required size in either bytes or kilobytes. The default is kilobytes. The optional **bytes** and **kilobytes** keywords are mutually exclusive and are used to explicitly define whether size represents bytes or kilobytes.

Values 0 to 2683435456, **default**

bytes

When **bytes** is defined, the value given for size is interpreted as the policer's MBS value given in bytes.

kilobytes

When **kilobytes** is defined, the value is interpreted as the policer's MBS value given in kilobytes.

default

configure port ethernet network egress queue-group queue-overrides queue mbs

configure port ethernet access egress queue-group queue-overrides queue mbs

configure port ethernet access ingress queue-group queue-overrides queue mbs

Description

The Maximum Burst Size (MBS) command specifies the default maximum buffer size for the template queue. The value is given in kilobytes.

The MBS value is used by a queue to determine whether it has exhausted all of its buffers while enqueuing packets. Once the queue has exceeded the amount of buffers allowed by MBS, all packets are discarded until packets have been drained from the queue.

The **queue-group** or network egress QoS context for mbs provides a mechanism for overriding the default maximum size for the queue.

The sum of the MBS for all queues on an ingress access port can oversubscribe the total amount of buffering available. When congestion occurs and buffers become scarce, access to buffers is controlled by the RED slope a packet is associated with. A queue that has not exceeded its MBS size is not guaranteed that a buffer will be available when needed or that the packets RED slope will not force the discard of the packet. Setting proper CBS parameters and controlling CBS oversubscription is one major safeguard to queue starvation (when a queue does not receive its fair share of buffers). Another is properly setting the RED slope parameters for the needs of services on this port or channel.

This command applies to egress queue group queues as the queue-delay is only supported on egress queues. This command **the queue-delay** command are mutually exclusive.

The **no** form of this command returns the MBS size assigned to the queue to the value.

Default

mbs default

Parameters

Full Context

configure qos sap-egress policer mbs

configure qos sap-ingress policer mbs

Description

This command is used to configure the policer's PIR leaky bucket's high-priority violate threshold. The **high-prio-only** command is applied to the MBS value to derive the bucket's low-priority violate threshold. For ingress, trusted in-profile packets and untrusted high-priority packets use the policer's high-priority violate threshold while trusted out-of-profile and untrusted low-priority packets use the policer's low-priority violate threshold. At egress, inplus-profile, and in-profile packets use the policer's high-priority violate threshold and out-of-profile packets use the policer's low-priority violate threshold. Exceed-profile packets are discarded unless **enable-exceed-pir** is configured, in which case they are forwarded.

The PIR bucket's violate threshold represents the maximum burst tolerance allowed by the policer. If the policer's offered rate is equal to or less than the policer's defined rate, the PIR bucket depth hovers around the 0 depth with spikes up to the maximum packet size in the offered load. If the offered rate increases beyond the metering rate, the amount of data allowed above the rate is capped by the threshold. The low-priority violate threshold provides a smaller burst size for the lower priority traffic associated with the policer. Since all lower priority traffic is discarded at the lower burst tolerance size, the remaining burst tolerance defined by **high-prio-only** is available for the higher priority traffic.

The policer's MBS size defined in the QoS policy may be overridden on an SLA profile or SAP where the policy is applied.

The **no** form of this command returns the queue to its default MBS size. By default, the MBS is 16 Mbytes when PIR equals max or is greater than or equal to the FP capacity (this overrides an explicit configured MBS value); otherwise, 10 ms volume of traffic for a configured non-zero/non-max PIR capped to 3968 kbytes, with a minimum of 256 bytes.

Full Context

configure qos network-queue queue mbs

Description

This command specifies the relative amount of buffer pool space for the maximum buffers for a specific ingress network FP forwarding class queue or egress network port forwarding class queue. The value is entered as a percentage.

The MBS value is used by a queue to determine whether it has exhausted its total allowed buffers while enqueuing packets. When the queue has exceeded its maximum amount of buffers, all packets are discarded until the queue transmits a packet. A queue that has not exceeded its MBS is not guaranteed to have a buffer available when needed or that the packet's RED slope will not force the discard of the packet. In order to safeguard against queue starvation (when a queue does not receive its fair share of buffers), set proper CBS parameters and control CBS oversubscription. Another safeguard is to properly set the RED slope parameters for the needs of the network queues.

The MBS can sometimes be smaller than the CBS. This will result in a portion of the CBS for the queue to be unused and should be avoided.

The **no** form of this command returns the MBS for the queue to the default for the forwarding class.

Parameters

percent

The percent of buffers from the total buffer pool space for the maximum number of buffers, expressed as a decimal integer. If 10 Mbytes is the total buffer space in the buffer pool, a value of 10 would limit the maximum queue size to 1 Mbyte (10%) of buffer space for the forwarding class queue. If the total size is increased to 20 Mbytes, the existing value of 10 would automatically increase the maximum size of the queue to 2 Mbytes.

configure qos queue-group-templates egress queue-group policer mbs

configure qos queue-group-templates ingress queue-group policer mbs

Description

This command specifies the default maximum buffer size for the template queue in bytes or kilobytes.

The MBS value is used by a queue to determine whether it has exhausted all of its buffers while enqueuing packets. When the queue has exceeded the amount of buffers allowed by MBS, all packets are discarded until packets have been drained from the queue.

The **port>ethernet>access>ingress>queue-group** and **port>ethernet>access>egress>queue-group** contexts for **mbs** provides a mechanism for overriding the default maximum size for the queue.

The sum of the MBS for all queues on an ingress access port can oversubscribe the total amount of buffering available. When congestion occurs and buffers become scarce, access to buffers is controlled by the RED slope that a packet is associated with. A queue that has not exceeded its MBS size is not guaranteed that a buffer will be available when needed or that the packet's RED slope will not force the discard of the packet. Setting proper CBS parameters and controlling CBS oversubscription is one major safeguard against queue starvation (when a queue does not receive its fair share of buffers). Another is properly setting the RED slope parameters for the needs of services on this port or channel.

When configured on an egress queue group queue, this command and the **queue-delay** command are mutually exclusive. In order to change between the **mbs** and **queue-delay** parameters, the current parameter must be removed before adding the new parameter; that is, changing from **mbs** to **queue-delay** requires a **no mbs** before the **queue-delay** is configured and changing from **queue-delay** to **mbs** requires a **no queue-delay** before the **mbs** is configured. If **queue-delay** is configured for an egress queue group queue, it is not possible to override the MBS for that queue.

For policers, this command is used to configure the policer's PIR leaky bucket's high-priority violate threshold. The **high-prio-only** command is applied to the MBS value to derive the bucket's low-priority violate threshold.

At ingress, trusted in-profile packets and untrusted high-priority packets use the policer's high-priority violate threshold while trusted out-of-profile and untrusted low-priority packets use the policer's low-priority violate threshold.

At egress, inplus-profile and in-profile packets use the policer's high-priority violate threshold and out-of-profile packets use the policer's low-priority violate threshold. Exceed-profile packets are discarded unless **enable-exceed-pir** is configured, in which case they are forwarded.

The PIR bucket's violate threshold represents the maximum burst tolerance allowed by the policer. If the policer's offered rate is equal to or less than the policer's defined rate, the PIR bucket depth hovers around the 0 depth with spikes up to the maximum packet size in the offered load. If the offered rate increases beyond the metering rate, the amount of data allowed above the rate is capped by the threshold. The low-priority violate threshold provides a smaller burst size for the lower priority traffic associated with the policer. Since all lower priority traffic is discarded at the lower burst tolerance size, the remaining burst tolerance defined by high-prio-only is available for the higher priority traffic.

The policer's mbs size defined in the QoS policy may be overridden on an SLA profile or SAP where the policy is applied.

The **no** form of this command returns the MBS size to its default value. By default, the MBS is 16 Mbytes when PIR equals max or is greater than or equal to the FP capacity (this overrides an explicit configured MBS value); otherwise, 10 ms volume of traffic for a configured non-zero/non-max PIR capped to 3968 kbytes, with a minimum of 256 bytes.

Default

default

Parameters

size

For queues, the size parameter is an integer expression of the maximum number of bytes or kilobytes of buffering allowed for the queue. For a value of 100 kbytes, enter the value 100. A value of 0 causes the queue to discard all packets. For policers, the size parameter is an integer expression of the maximum number of bytes for the policer's MBS. The queue MBS maximum value used is constrained by the pool size in which the queue exists and by the shared pool space in the corresponding megapool.

Values 0 to 2683435456

Default value: 16 Mbytes when PIR equals max or is greater than or equal to the FP capacity (this overrides an explicitly configured MBS value); otherwise, 10 ms volume of traffic for a configured non-zero/non-max PIR capped to 3968 kbytes, with a minimum of 256 bytes.

[bytes | kilobytes]

[Tree] (config>qos>qgrps>egr>qgrp>queue mbs)

Full Context

configure qos queue-group-templates ingress queue-group queue mbs

configure qos queue-group-templates egress queue-group queue mbs

Description

This command specifies the default maximum buffer size for the template queue in bytes or kilobytes.

The MBS value is used by a queue to determine whether it has exhausted all of its buffers while enqueuing packets. When the queue has exceeded the amount of buffers allowed by MBS, all packets are discarded until packets have been drained from the queue.

The **port>ethernet>access>ingress>queue-group** and **port>ethernet>access>egress>queue-group** contexts for **mbs** provides a mechanism for overriding the default maximum size for the queue.

The sum of the MBS for all queues on an ingress access port can oversubscribe the total amount of buffering available. When congestion occurs and buffers become scarce, access to buffers is controlled by the RED slope that a packet is associated with. A queue that has not exceeded its MBS size is not guaranteed that a buffer will be available when needed or that the packet's RED slope will not force the discard of the packet. Setting proper CBS parameters and controlling CBS oversubscription is one major safeguard against queue starvation (when a queue does not receive its fair share of buffers). Another is properly setting the RED slope parameters for the needs of services on this port or channel.

When configured on an egress queue group queue, this command and the **queue-delay** command are mutually exclusive. In order to change between the **mbs** and **queue-delay** parameters, the current parameter must be removed before adding the new parameter; that is, changing from **mbs** to **queue-delay** requires a **no mbs** before the **queue-delay** is configured and changing from **queue-delay** to **mbs** requires

a **no queue-delay** before the **mbs** is configured. If **queue-delay** is configured for an egress queue group queue, it is not possible to override the MBS for that queue.

For policers, this command is used to configure the policer's PIR leaky bucket's high-priority violate threshold. The **high-prio-only** command is applied to the MBS value to derive the bucket's low-priority violate threshold.

At ingress, trusted in-profile packets and untrusted high-priority packets use the policer's high-priority violate threshold while trusted out-of-profile and untrusted low-priority packets use the policer's low-priority violate threshold.

At egress, inplus-profile and in-profile packets use the policer's high-priority violate threshold and out-of-profile packets use the policer's low-priority violate threshold. Exceed-profile packets are discarded unless **enable-exceed-pir** is configured, in which case they are forwarded.

The PIR bucket's violate threshold represents the maximum burst tolerance allowed by the policer. If the policer's offered rate is equal to or less than the policer's defined rate, the PIR bucket depth hovers around the 0 depth with spikes up to the maximum packet size in the offered load. If the offered rate increases beyond the metering rate, the amount of data allowed above the rate is capped by the threshold. The low-priority violate threshold provides a smaller burst size for the lower priority traffic associated with the policer. Since all lower priority traffic is discarded at the lower burst tolerance size, the remaining burst tolerance defined by high-prio-only is available for the higher priority traffic.

The policer's mbs size defined in the QoS policy may be overridden on an SLA profile or SAP where the policy is applied.

The **no** form of this command returns the MBS size assigned by the queue.

Default

default

Parameters

size

For queues, the size parameter is an integer expression of the maximum number of bytes or kilobytes of buffering allowed for the queue. For a value of 100 kbytes, enter the value 100. A value of 0 causes the queue to discard all packets. For policers, the size parameter is an integer expression of the maximum number of bytes for the policer's MBS. The queue MBS maximum value used is constrained by the pool size in which the queue exists and by the shared pool space in the corresponding megapool.

Values 0 to 1048576 or **default**

Minimum configurable non-zero value: 6 kbytes on an FP2, 7680 bytes on an FP3, and 16 kbytes on an FP4

Minimum non-zero default value: maximum of 10 ms of CIR, or 6 kbytes on an FP2, 7680 bytes on an FP3, and 16 kbytes on an FP4

[bytes | kilobytes]

configure card fp ingress network queue-group policer-control-override priority-mbs-thresholds priority mbs-contribution

configure card fp ingress access queue-group policer-control-override priority-mbs-thresholds priority mbs-contribution

Description

This command configures the policy-based burst tolerance for a parent policer instance created when the policy is applied to a SAP or subscriber context. The system uses the parent policer's **min-thresh-separation** value, the priority level's **mbs-contribution** value and the number of child policers currently attached to the priority level to derive the priority level's shared-portion and fair-portion of burst tolerance within the local priority level. The shared-portion and fair-portions for each priority level are then used by the system to calculate each priority level's discard-unfair threshold and discard-all threshold.

The value for a priority level's **mbs-contribution** within the policer-control-policy may be overridden on the SAP or subscriber sub-profile where the policy is applied in order to allow fine tuning of the discard-unfair and discard-all thresholds relevant to the needs of the local child policers on the object.

Accumulative Nature of Burst Tolerance for a Parent Policer Priority Level

When defining **mbs-contribution**, the specified size may only be a portion of the burst tolerance associated with the priority level. The packets associated with the priority level share the burst tolerance of lower within the parent policer. As the parent policer PIR bucket depth increases during congestion, the lower priority packets eventually experience discard based on each priority's discard-unfair and discard-all thresholds. Assuming congestion continues once all the lower priority packets have been prevented from consuming bucket depth, the burst tolerance for the priority level will be consumed by its own packets and any packets associated with higher priorities.

The Effect of Fair and Unfair Child Policer Traffic at a Parent Policer Priority Level

The system continually monitors the offered rate of each child policer on each parent policer priority level and detects when the policer is in a congested state (the aggregate offered load is greater than

the decrement rate defined on the parent policer). As previously stated, the result of congestion is that the parent policer's bucket depth will increase until it eventually hovers around either a discard-unfair or discard-all threshold belonging to one of the priority levels. This threshold is the point where enough packets are being discarded that the increment rate and decrement rate begin to even out. If only a single child policer is associated to the priority level, the discard-unfair threshold is not used since fairness is only applicable when multiple child policers are competing at the same priority level.

When multiple child policers are sharing the congested priority level, the system uses the offered rates and the parenting parameters of each child to determine the fair rate per child when the parent policer is unable to meet the bandwidth needs of each child. The fair rate represents the amount of bandwidth that each child at the priority level should receive relative to the other children at the same level according to the policer control policy instance managing the child policers. This fair rate is applied as the decrement rate for each child's FIR bucket. Changing a child's FIR rate does not modify the amount of packets forwarded by the parent policer for the child's priority level. It simply modifies the forwarded ratio between the children on that priority level. Since each child FIR bucket has some level of burst tolerance before marking its packets as unfair, the current parent policer bucket depth may at times rise above the discard-unfair threshold. The mbs-contribution value provides a means to define how much separation is provided between the priority level's discard-unfair and discard-all threshold to allow the parent policer to absorb some amount of FIR burst before reaching the priority's discard-all threshold.

This level of fair aggregate burst tolerance is based on the decrement rate of the parent policer's PIR bucket while the individual fair bursts making up the aggregate are based on each child's FIR decrement rate. The aggregate fair rate of the priority level is managed by the system with consideration of the current rate of traffic in higher priority levels. In essence, the system ensures that for each iteration of the child FIR rate calculation, the sum of the child FIR decrement rates plus the sum of the higher priority traffic increment rates equals the parent policers decrement rate. This means that dynamic amounts of higher priority traffic can be ignored when sizing a lower priority's fair aggregate burst tolerance. Consider the following:

- The parent policer decrement rate is set to 20 Mb/s (max-rate 20,000).
- A priority level's fair burst size is set to 30 kbytes (mbs-contribution 30 kilobytes).
- Higher priority traffic is currently taking 12 Mb/s.
- The priority level has three child policers attached.
- Each child's PIR MBS is set to 10 kbytes, which makes each child's FIR MBS 10 kbytes.
- The children want 10 Mb/s, but only 8 Mb/s is available.
- The following table describes the FIR rates of the children based on weights.

Table 68: FIR Rates of the Children Based on Weights

	FIR Rate	FIR MBS
Child 1	4 Mb/s	10 kbytes
Child 2	3 Mb/s	10 kbytes
Child 3	1 Mb/s	10 kbytes

The 12 Mb/s of the higher priority traffic and the 8 Mb/s of fair traffic equal the 20 Mb/s decrement rate of the parent policer.

It is clear that the higher priority traffic is consuming 12 Mb/s of the parent policer's decrement rate, leaving 8 Mb/s of decrement rate for the lower priority's fair traffic.

- The burst tolerance of child 1 is based on 10 kbytes above 4 Mb/s,
- The burst tolerance of child 2 is based on 10 kbytes above 3 Mb/s,
- The burst tolerance of child 3 is based on 10 kbytes above 1 Mb/s.

If all three children burst simultaneously (unlikely), they will consume 30 kbytes above 8 Mb/s. This is the same as the remaining decrement rate after the higher priority traffic.

Parent Policer Total Burst Tolerance and Downstream Buffering

The highest in-use priority level's discard-all threshold is the total burst tolerance of the parent policer. In some cases the parent policer represents downstream bandwidth capacity and the max-rate of the parent policer is set to prevent overrunning the downstream bandwidth. The burst tolerance of the parent policer defines how much more traffic may be sent beyond the downstream scheduling capacity. In the worst case scenario, when the downstream buffering is insufficient to handle the total possible burst from the parent policer, downstream discards based on lack of buffering may occur. However, in all likelihood, this is not the case.

In most cases, lower priority traffic in the policer will be responsible for the greater part of congestion above the parent policer rate. Since this traffic is discarded with a lower threshold, this lowers the effective burst tolerance even while the highest priority traffic is present.

Configuring a Priority Level's MBS Contribution Value

In the most conservative case, a priority level's **mbs-contribution** value may be set to be greater than the sum of child policer's MBS and one max-size-frame per child policer. This ensures that even in the absolute worst case where all the lower priority levels are simultaneously bursting to the maximum capacity of each child, enough burst tolerance for the priority's children will exist if they also burst to their maximum capacity.

Since simply adding up all the child policer's PIR MBS values may result in large overall burst tolerances that are not ever likely to be needed, you should consider some level of burst oversubscription when configuring the **mbs-contribution** value for each priority level. The amount of oversubscription should be determined based on the needs of each priority level.

Using the Fixed Keyword to Create Deterministic Parent Policer Discard Thresholds

In the default behavior, the system ignores the **mbs-contribution** values for a priority level on a subscriber or SAP parent policer when a child policer is not currently associated with the level. This prevents additional burst tolerance from being added to higher priority traffic within the parent policer.

This does cause fluctuations in the defined threshold values when child policers are added or removed from a parent policer instance. If this behavior is undesirable, the fixed keyword may be used which causes the **mbs-contribution** value to always be included in the calculation of parent policer's discard thresholds. The defined **mbs-contribution** value may be overridden on a subscriber SLA profile or on a SAP instance, but the fixed nature of the contribution cannot be overridden.

If the defined **mbs-contribution** value for the priority level is zero, the priority level will have no effect on the parent policer's defined discard thresholds. A packet associated with the priority level will use the next lower priority level's discard-unfair and discard-all thresholds.

The **no** form of this command reverts to the policy's priority level's MBS contribution to the default value. When changed, the thresholds for the priority level and all higher priority levels for all instances of the parent policer are recalculated.

Default

no mbs-contribution

Parameters

size

Specifies that the size parameter is required when executing the **mbs-contribution** command. It is expressed as an integer and specifies the priority's specific portion amount of accumulative MBS for the priority level in bytes or kilobytes which is selected by the trailing **bytes** or **kilobytes** keywords. If both **bytes** and **kilobytes** are missing, **kilobytes** is assumed. Setting this value has no effect on parent policer instances where the priority level's **mbs-contribution** value has been overridden. Clearing an override on parent policer instance causes this value to be enforced.

Values 0 to 16777216

bytes, kilobytes

Specifies that the **bytes** keyword is optional and is mutually exclusive with the **kilobytes** keyword. When specified, size is interpreted as specifying the size of **min-thresh-separation** in bytes.

The **kilobytes** keyword is optional and is mutually exclusive with the **bytes** keyword. When specified, size is interpreted as specifying the size of min-thresh-separation in kilobytes.

configure service epipe sap ingress policer-control-override priority-mbs-thresholds priority mbs-contribution

configure service epipe sap egress policer-control-override priority-mbs-thresholds priority mbs-contribution

Description

The mbs-contribution override command within the SAP ingress and egress contexts is used to override a parent policer's priority level's mbs-contribution parameter that is defined within the policer-control-policy applied to the SAP. This override allow the priority level's burst tolerance to be tuned based on the needs of the SAP's child policers attached to the priority level.

When the override is defined, modifications to the policer-control-policy priority level's mbs-contribution parameter have no effect on the SAP's parent policer priority level until the override is removed using the no mbs-contribution command within the SAP.

The **no** form of this command removes the override and allows the mbs-contribution setting from the policer-control-policy to control the parent policer's priority level's burst tolerance.

Default

no mbs-contribution

Parameters

size

Specifies the mbs-contribution override value.

Values 1 to 16777216 | default

bytes

Specifies that *size* is expressed in bytes. The bytes and kilobytes keywords are mutually exclusive and optional. The default is kilobytes.

kilobytes

Specifies that *size* is expressed in kilobytes. The bytes and kilobytes keywords are mutually exclusive and optional. The default is kilobytes.

configure qos policer-control-policy root priority-mbs-thresholds priority mbs-contribution

Description

The **mbs-contribution** command is used to configure the policy-based burst tolerance for a parent policer instance created when the policy is applied to a SAP or a subscriber context. The system uses the parent policer's **min-thresh-separation** value, the priority level's **mbs-contribution** value, and the number of child policers currently attached to the priority level to derive the priority level's shared-portion and fair-portion of burst tolerance within the local priority level. The shared-portion and fair-portions for each priority level are then used by the system to calculate each priority level's discard-unfair threshold and discard-all threshold. The mbs-contribution is the minimum separation between two adjacent active discard-all thresholds.

The value for a priority level's **mbs-contribution** within the policer-control-policy may be overridden on the SAP or subscriber sub-profile where the policy is applied in order to allow fine tuning of the discard-unfair and discard-all thresholds relevant to the needs of the local child policers on the object.

Accumulative Nature of Burst Tolerance for a Parent Policer Priority Level

When defining **mbs-contribution**, the specified size may only be a portion of the burst tolerance associated with the priority level. The packets associated with the priority level share the burst tolerance of lower within the parent policer. As the parent policer PIR bucket depth increases during congestion, the lower priority packets eventually experience discard based on each priority's discard-unfair and discard-all thresholds. Assuming congestion continues when all the lower priority packets have been prevented from consuming bucket depth, the burst tolerance for the priority level will be consumed by its own packets and any packets associated with higher priorities.

The Effect of Fair and Unfair Child Policer Traffic at a Parent Policer Priority Level

The system continually monitors the offered rate of each child policer on each parent policer priority level and detects when the policer is in a congested state (the aggregate offered load is greater than the decrement rate defined on the parent policer). As previously stated, the result of congestion is that the parent policer's bucket depth will increase until it eventually hovers around either a discard-unfair or discard-all threshold belonging to one of the priority levels. This threshold is the point where enough packets are being discarded that the increment rate and decrement rate begin to even out. If only a single child policer is associated with the priority level, the discard-unfair threshold is not used since fairness is only applicable when multiple child policers are competing at the same priority level.

When multiple child policers are sharing the congested priority level, the system uses the offered rates and the parenting parameters of each child to determine the fair rate per child when the parent policer is unable to meet the bandwidth needs of each child. The fair rate represents the amount of bandwidth that each child at the priority level should receive relative to the other children at the same level according to the policer control policy instance managing the child policers. This fair rate is applied as the decrement rate for each child's FIR bucket. Changing a child's FIR rate does not modify the number of packets forwarded by the parent policer for the child's priority level. It just modifies the forwarded ratio between the children on that priority level. Since each child FIR bucket has some level of burst tolerance before marking its packets as unfair, the current parent policer bucket depth may at times rise above the discard-unfair threshold. The mbs-contribution value provides a means to define how much separation is provided between the priority level's discard-unfair and discard-all threshold to allow the parent policer to absorb some amount of FIR burst before reaching the priority's discard-all threshold.

This level of fair aggregate burst tolerance is based on the decrement rate of the parent policer's PIR bucket while the individual fair bursts making up the aggregate are based on each child's FIR decrement rate. The aggregate fair rate of the priority level is managed by the system with consideration of the current rate of traffic in higher priority levels. In essence, the system ensures that for each iteration of the child FIR rate calculation, the sum of the child FIR decrement rates plus the sum of the higher priority traffic increment rates equals the parent policers decrement rate. This means that dynamic amounts of higher priority traffic can be ignored when sizing a lower priority's fair aggregate burst tolerance. Consider the following:

- The parent policer decrement rate is set to 20 Mb/s (max-rate 20,000).
- A priority level's fair burst size is set to 30 kbytes (mbs-contribution 30 kbytes).
- Higher priority traffic is currently taking 12 Mb/s.
- The priority level has three child policers attached.
- Each child's PIR MBS is set to 10 kbytes, which makes each child's FIR MBS 10 kbytes.
- The children want 10 Mb/s, but only 8 Mb/s is available

- Based on weights, the children's FIR rates are set as follows.

Table 69: FIR Rates of the Children Based on Weights

	FIR Rate	FIR MBS
Child 1	4 Mb/s	10 kbytes
Child 2	3 Mb/s	10 kbytes
Child 3	1 Mb/s	10 kbytes

The 12 Mb/s of the higher priority traffic and the 8 Mb/s of fair traffic equal the 20 Mb/s decrement rate of the parent policer.

It is clear that the higher priority traffic is consuming 12 Mb/s of the parent policer’s decrement rate, leaving 8 Mb/s of decrement rate for the lower priority’s fair traffic.

- The burst tolerance of child 1 is based on 10 kbytes above 4 Mb/s.
- The burst tolerance of child 2 is based on 10 kbytes above 3 Mb/s.
- The burst tolerance of child 3 is based on 10 kbytes above 1 Mb/s.

If all three children burst simultaneously (unlikely), they will consume 30 kbytes above 8 Mb/s. This is the same as the remaining decrement rate after the higher priority traffic.

Parent Policer Total Burst Tolerance and Downstream Buffering

The highest in-use priority level’s discard-all threshold is the total burst tolerance of the parent policer. In some cases, the parent policer represents downstream bandwidth capacity and the max-rate of the parent policer is set to prevent overrunning the downstream bandwidth. The burst tolerance of the parent policer defines how much more traffic may be sent beyond the downstream scheduling capacity. In the worst-case scenario, when the downstream buffering is insufficient to handle the total possible burst from the parent policer, downstream discards based on lack of buffering may occur. However, in all likelihood, this is not the case.

In most cases, lower priority traffic in the policer will be responsible for the greater part of congestion above the parent policer rate. Since this traffic is discarded with a lower threshold, this lowers the effective burst tolerance even while the highest priority traffic is present.

Configuring a Priority Level's MBS Contribution Value

In the most conservative case, a priority level’s **mbs-contribution** value may be set to be greater than the sum of child policer’s mbs and one max-size-frame per child policer. This ensures that even in the absolute worst case where all the lower priority levels are simultaneously bursting to the maximum capacity of each child, enough burst tolerance for the priority’s children will exist if they also burst to their maximum capacity.

Since simply adding up all the child policer’s PIR MBS values may result in large overall burst tolerances that are not ever likely to be needed, consider some level of burst oversubscription when configuring the **mbs-contribution** value for each priority level. The amount of oversubscription should be determined based on the needs of each priority level.

Using the Fixed Keyword to Create Deterministic Parent Policer Discard Thresholds

In the default behavior, the system ignores the **mbs-contribution** values for a priority level on a subscriber or SAP parent policer when a child policer is not currently associated with the level. This prevents additional burst tolerance from being added to higher priority traffic within the parent policer.

This does cause fluctuations in the defined threshold values when child policers are added or removed from a parent policer instance. If this behavior is undesirable, the fixed keyword may be used that causes the **mbs-contribution** value to always be included in the calculation of parent policer's discard thresholds. The defined **mbs-contribution** value may be overridden on a subscriber sla-profile or on a SAP instance, but the fixed nature of the contribution cannot be overridden.

If the defined **mbs-contribution** value for the priority level is zero, the priority level will have no effect on the parent policer's defined discard thresholds. A packet associated with the priority level will use the next lower priority level's discard-unfair and discard-all thresholds.

The **no** form of this command returns the policy's priority level's MBS contribution to the default value. When changed, the thresholds for the priority level and all higher priority levels for all instances of the parent policer will be recalculated.

Parameters

size

The size parameter is required when executing the **mbs-contribution** command. It is expressed as an integer and specifies the priority's specific portion amount of accumulative MBS for the priority level. Setting this value has no effect on parent policer instances where the priority level's **mbs-contribution** value has been overridden.

Values 0 to 16777216 or **default**

Default 8

bytes | kilobytes:

This parameter indicates whether the size is expressed in bytes or kilobytes.

Default **kilobytes**

fixed

The optional fixed keyword is used to force the inclusion of the defined **mbs-contribution** value in the parent policer's discard threshold calculations. If the **mbs-contribution** command is executed without the **fixed** keyword, the fixed calculation behavior for the priority level is removed.

17.88 mbytes

mbytes

Syntax

mbytes {*mbytes* | **disable**}

no mbytes

Context

[Tree] (config>system>security>ssh>key-re-exchange>server mbytes)

[Tree] (config>system>security>ssh>key-re-exchange>client mbytes)

Full Context

configure system security ssh key-re-exchange server mbytes

configure system security ssh key-re-exchange client mbytes

Description

This command configures the maximum bytes to be transmitted before a key re-exchange is initiated by the server.

The **no** form of this command reverts to the default value.

Default

mbytes 1024

Parameters

mbytes

Specifies the number of megabytes, on a SSH session, after which the SSH client initiates the key-re-exchange.

Values 1 to 64000

Default 1024

disable

Specifies that a session will never timeout. To re-enable **mbytes**, enter the command without the **disable** option.

17.94 mc-maximum-routes

mc-maximum-routes

Syntax

mc-maximum-routes *number* [**log-only**] [**threshold** *threshold*]

Context

[Tree] (config>service>vprn mc-maximum-routes)

Full Context

configure service vprn mc-maximum-routes

Description

This command specifies the maximum number of multicast routes that can be held in the form of this command in a VPN routing or forwarding (VRF) context. When this limit is reached, a log and SNMP trap are sent. If the **log-only** parameter is not specified and the maximum-routes value is set below the existing number of routes in a VRF, then no new joins are processed.

The **no** form of this command disables the limit of multicast routes within a VRF context. Issue the **no** form of this command only when the VPRN instance is shutdown.

Default

no mc-maximum-routes

Parameters

number

Specifies the maximum number of routes to be held in a VRF context.

Values 1 to 2147483647

log-only

Specifies that if the maximum limit is reached, only log the event. **log-only** does not disable the learning of new routes.

threshold

Specifies the percentage at which a warning log message and SNMP trap should be sent.

Values 0 to 100

Default 10

17.96 mcast-ipv6-snooping-scope

mcast-ipv6-snooping-scope

Syntax

mcast-ipv6-snooping-scope {**mac-based** | **sg-based**}

no mcast-ipv6-snooping-scope

Context

[Tree] (config>service>vpls mcast-ipv6-snooping-scope)

Full Context

configure service vpls mcast-ipv6-snooping-scope

Description

This command specifies the forwarding scope used for IPv6 multicast traffic when PIM snooping for IPv6 is enabled.

By default, the scope is **mac-based**; IPv6 snooped multicast traffic is forwarded is based on the low-order 32 bits of the destination IPv6 address.

When the scope is configured as **sg-based**, the IPv6 snooped multicast traffic is forwarded based on both its full source (if specified in the join) and destination IPv6 address. SG-based forwarding is only supported on FP3- (or higher) based line cards.

PIM snooping for IPv6 must be disabled to change the forwarding mode within a VPLS service between **mac-based** and **sg-based**.

The **no** form of this command configures the router to use the default value.

Default

mcast-ipv6-snooping-scope mac-based

Parameters

mac-based

Sets forwarding for PIM-snooped IPv6 multicast traffic based on the low-order 32 bits of its destination IPv6 address.

sg-based

Sets forwarding for PIM-snooped IPv6 multicast traffic based on its full source (if specified in the join) and destination IPv6 address.

18 m Commands – Part II

18.1 md-auto-id

md-auto-id

Syntax

md-auto-id

Context

[Tree] (config>qos md-auto-id)

Full Context

configure qos md-auto-id

Description

This command automatically assigns numerical ID values for QoS policies in model-driven (MD) management interfaces.

Classic management interfaces use a numerical policy ID as the primary key for sap-ingress, sap-egress, and network QoS policies. In model-driven interfaces, SAP and network policies use string names as keys. The SAP and network policies can optionally be created in MD interfaces without having to explicitly select and specify a numerical policy ID. In this case, SR OS assigns an ID using the configured ID range.

Platforms

7705 SAR Gen 2

md-auto-id

Syntax

md-auto-id

Context

[Tree] (config>filter md-auto-id)

Full Context

configure filter md-auto-id

Description

This command automatically assigns numerical ID values for filter policies in model-driven management interfaces.

Classic management interfaces use a numerical filter ID as the primary key for IP filters, IPv6 filters, and MAC filters. In model-driven interfaces, IP, IPv6, and MAC filters use string names as keys. The filters can optionally be created in MD interfaces without having to explicitly select and specify a numerical filter ID. In this case, SR OS assigns an ID using the configured ID range.

Platforms

7705 SAR Gen 2

md-auto-id

Syntax

md-auto-id

Context

[Tree] (config>service md-auto-id)

Full Context

configure service md-auto-id

Description

This command automatically assigns numerical ID values for services, customers, and PW templates in model-driven (MD) management interfaces.

Classic management interfaces use a numerical service ID, customer ID, and PW template ID as the primary key for services, customers, and PW templates. In model-driven interfaces, services, customers, and PW templates use string names as keys. The services, customers, and PW templates can optionally be created in MD interfaces without having to explicitly select and specify a numerical ID. In this case, SR OS assigns an ID using the configured ID range.

md-cli-session

Syntax

md-cli-session {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization md-cli-session)

Full Context

configure system security profile grpc rpc-authorization md-cli-session

Description

This command configures the use of the MdCli Session RPC for the user profile.

The **no** form of this command reverts to the default value.

Default

md-cli-session permit

Parameters

deny

Specifies that the use of MdCli Session RPC is denied.

permit

Specifies that the use of MdCli Session RPC is permitted.

Platforms

7705 SAR Gen 2

18.4 md-interfaces

md-interfaces

Syntax

[**no**] **md-interfaces**

Context

[Tree] (config>system>security>management-interface>output-authorization md-interfaces)

Full Context

configure system security management-interface output-authorization md-interfaces

Description

This command controls output authorization of commands or RPCs for model-driven interfaces that display configuration or state.

When enabled, output authorization is performed for the following commands:

- MD-CLI **info** and **compare** commands
- NETCONF <get> and <get-config> RPCs
- gNMI Get RPC

When disabled, output authorization is not performed, which may significantly decrease the system response time by reducing command authorization requests, especially when remote AAA servers are used. Input to edit configuration is always authorized based on the AAA configuration.

By default, authorization checks are performed for configuration and state output.

The **no** form of this command disables authorization checks, allowing the output to be displayed immediately.

Description

This command configures an association between an MDA and the tunnel member pool.

The **no** form of this command removes the association between the MDA and the tunnel member pool.

Parameters

name

Specifies the name of the MDA, up to 32 characters.

Platforms

7705 SAR Gen 2

18.6 mda-type

mda-type

Syntax

mda-type *mda-type* [**level** *mda-level*]

no mda-type

Context

[Tree] (config>card>mda mda-type)

Full Context

configure card mda mda-type

Description

This mandatory command provisions a specific MDA type to the device configuration for the slot. The MDA can be preprovisioned but an MDA must be provisioned before ports can be configured. Ports can be configured once the MDA is properly provisioned.

A maximum of two MDAs can be provisioned on an IOM or XCM. To modify an MDA slot, shut down all port associations.

XMAs are provisioned using MDA commands. A medium severity alarm is generated if an MDA is inserted that does not match the MDA type configured for the slot. This alarm is cleared when the correct MDA is inserted or the configuration is modified. A high severity alarm is raised when an administratively enabled MDA is removed from the chassis. This alarm is cleared if the either the correct MDA type is inserted or the configuration is modified. A low severity trap is issued if an MDA is removed that is administratively disabled.

An MDA can only be provisioned in a slot if the MDA type is allowed in the MDA slot. An error message is generated when an MDA is provisioned in a slot where it is not allowed.

Some MDA hardware can support two different firmware loads. One load includes the base Ethernet functionality, including 10G WAN mode, but does not include 1588 port-based timestamping. The second load includes the base Ethernet functionality and 1588 port-based timestamping, but does not include 10G WAN mode. These are identified as two MDA types that are the same, except for a "-ptp” suffix to indicate the second loadset; for example, *x40-10gb-sfp* and *x40-10gb-sfp-ptp*. A hard reset of the MDA occurs when switching between the two provisioned types.

A medium severity alarm is generated if an MDA is inserted that does not match the MDA type configured for the slot. This alarm is cleared when the correct MDA is inserted or the configuration is modified.

A high severity alarm is raised when an administratively enabled MDA is removed from the chassis. This alarm is cleared if the either the correct MDA type is inserted or the configuration is modified. A low severity trap is issued if an MDA is removed that is administratively disabled.

An alarm is raised if partial or complete MDA failure is detected. The alarm is cleared when the error condition ceases.

All parameters in the MDA context remain and if non-default values are required then their configuration remains as it is on all existing MDAs.

New generations of XMAs include variants controlled through hardware and software licensing. For these XMAs, the license level must be provisioned in addition to the MDA type. An XMA cannot become operational unless the provisioned license level matches the license level of the XMA installed into the slot. The set of license levels varies by MDA type.

The provisioned level controls aspects related to connector provisioning and the consumption of hardware egress queues and egress policers. Changes to the provisioned license level may be blocked if configuration that would not be permitted with the new target license level exists.

If the license level is not specified, the level is set to the highest license level for that XMA.

The **no** form of this command deletes the MDA from the configuration. The MDA must be administratively shut down before it can be deleted from the configuration.

Parameters

mda-type

Specifies the type of MDA selected for the slot position. Values for this attribute vary by platform and release. The release notes include a listing of all supported mda-types and their CLI strings. In addition, the command can be queried to check which mda-types are relevant for the active platform type. Some examples include me6-10gb-spf+ and x4-100g-cfp2.

mda-level

Specifies the MDA level. Possible values vary by MDA type.

med-out

Syntax

med-out {*number* | **igp-cost**}

no med-out

Context

[Tree] (config>service>vprn>bgp>group med-out)

[Tree] (config>service>vprn>bgp med-out)

[Tree] (config>service>vprn>bgp>group>neighbor med-out)

Full Context

configure service vprn bgp group med-out

configure service vprn bgp med-out

configure service vprn bgp group neighbor med-out

Description

This command enables advertising the Multi-Exit Discriminator (MED) and assigns the value used for the path attribute for the MED advertised to BGP peers if the MED is not already set.

The specified value can be overridden by any value set via a route policy.

This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). The most specific value is used.

The **no** form of this command used at the global level reverts to default where the MED is not advertised.

The **no** form of this command used at the group level reverts to the value defined at the global level.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Default

no med-out

Parameters

number

Specifies the MED path attribute value, expressed as a decimal integer.

Values 0 to 4294967295

igp-cost

Specifies the MED is set to the IGP cost of the given IP prefix.

Platforms

7705 SAR Gen 2

med-out

Syntax

med-out {*number* | **igp-cost**}

no med-out

Context

[Tree] (config>router>bgp>group>neighbor med-out)

[Tree] (config>router>bgp med-out)

[Tree] (config>router>bgp>group med-out)

Full Context

configure router bgp group neighbor med-out

configure router bgp med-out

configure router bgp group med-out

Description

This command enables advertising the Multi-Exit Discriminator (MED) and assigns the value used for the path attribute for the MED advertised to BGP peers if the MED is not already set.

The specified value can be overridden by any value set via a route policy.

This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). The most specific value is used.

The **no** form of this command used at the global level reverts to default where the MED is not advertised.

The **no** form of this command used at the group level reverts to the value defined at the global level.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Default

no med-out

Parameters

number

Specifies the MED path attribute value, expressed as a decimal integer.

Values 0 to 4294967295

igp-cost

Sets MED to the IGP cost of the given IP prefix.

Platforms

7705 SAR Gen 2

18.9 member

member

Syntax

[**no**] **member** *interface-name*

Context

[Tree] (config>service>vprn>isis>link-group>level member)

Full Context

configure service vprn isis link-group level member

Description

This command adds or removes a links to the associated link-group. The interface name should already exist before it is added to a link-group.

The **no** form of this command removes the specified interface from the associated link-group.

Parameters

interface-name

Specifies the name of the interface to be added or removed from the associated link-group.

Platforms

7705 SAR Gen 2

member

Syntax

member *user-profile-name* [*user-profile-name*]

no member *user-profile-name*

Context

[Tree] (config>system>security>user>console member)

Full Context

configure system security user console member

Description

This command is used to associate the user with a local command authorization profile.

A user can be associated with up to eight profiles.

When a user is a member of multiple profiles, profiles are evaluated in the order that they are configured. Evaluation stops if there is a match, or when the default action of the a profile is **deny-all**, **permit-all** or **read-only-all**. When the profile default action is **none** and if no match conditions are met in the profile, the next profile is evaluated. When the default action of the last profile is **none** and no explicit match is found, the command is denied.

The **no** form of this command removes the association between the user and the profile.

Default

member default

Parameters

user-profile-name

Specifies up to eight user profile names, up to 32 characters.

Platforms

7705 SAR Gen 2

member

Syntax

[**no**] **member** *interface-name*

Context

[Tree] (config>router>isis>link-group>level member)

Full Context

configure router isis link-group level member

Description

This command adds or removes a link to the associated link-group. The interface name should already exist before it is added to a link-group.

The **no** form of this command removes the specified interface from the associated link-group.

Parameters

interface-name

Specifies the name of the interface to be added or removed from the associated link-group.

Platforms

7705 SAR Gen 2

18.10 member-pool

member-pool

Syntax

member-pool *name*

no member-pool

Context

[Tree] (config>isa>tunnel-grp member-pool)

Full Context

configure isa tunnel-group member-pool

Description

This command associates the tunnel group with a tunnel member pool. This tunnel group is used as the designated standby in an N:M IPsec redundancy configuration.

The **no** form of this command removes the tunnel member pool from the configuration.

Parameters

name

Specifies the name of the member pool, up to 32 characters.

Platforms

7705 SAR Gen 2

18.11 members

members

Syntax

[**no**] **members** *comm-id* [*comm-id*]

Context

[Tree] (config>router>policy-options>community members)

Full Context

configure router policy-options community members

Description

This command adds members to a route policy community list to use in route policy entries.

Each member of a community list is a standard, extended, or large community value or a regular expression that potentially matches many community values. A regular expression incorporates terms and operators that use the terms. An individual numerical digit is an elementary term in the community regular expression. More complex terms can be built from elementary terms. The following are key operators supported by SR OS:

- .
- *
- ?
- {n}
- {m,n}
- {m, }

To reverse the match criteria when specifying a list of ranges or single values using square brackets, use the non-match operator (^) before the elements within the square brackets.

The **no** version of this command deletes route policy community members.

Parameters

comm-id

Specifies a BGP community value, up to 72 characters. A community ID can be specified in different forms.

Values [*as-num*:*comm-val* | *reg-ex* | *ext-comm* | *well-known-comm* | *large-comm*]

where:

- *as-num* — 0 to 65535
- *comm-val* — 0 to 65535
- *reg-ex* — A regular expression string. Allowed values are any string up to 72 characters, composed of printable, 7-bit ASCII characters. If the string contains special characters (such as "#", "$", or spaces), the entire string must be enclosed within double quotes.
- *ext-comm* — The extended community, defined as one of the following:
  - {*target* | *origin*}:*ip-address*:*comm-val*
  - {*target* | *origin*}:*reg-ex1*&*reg-ex2*
  - {*target* | *origin*}:*ip-address*:*reg-ex2*
  - {*target* | *origin*}:*asnum*:*ext-comm-val*
  - {*target* | *origin*}:*ext-asnum*:*comm-val*
  - **bandwidth**:*asnum*:*val-in-mbps*
  - **ext:4300**:*ovstate*
  - **ext**:*value1*:*value2*
  - **flowspec-set**:*ext-asnum*:*group-id*
  - **flowspec-set-trans**:*ext-asnum*:*group-id*
  - **ipv6-redirect**: *ipv6-addr*
  - **color**:*co-bits*:*color-value*

  where:

  - *target* — route target
  - *origin* — route origin
  - *ip-address* — a.b.c.d
  - *ext-comm-val* — 0 to 4294967295
  - *ext-asnum* — 0 to 4294967295
  - *reg-ex1*, *reg-ex2* — A regular expression string. Allowed values are any string up to 63 characters, composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.
  - **bandwidth** — bandwidth
  - *val-in-mbps* — 0 to 16777215

- **ext:4300** — origin verification
- *ovstate* — 0, 1, or 2 (0 for valid, 1 for not found, 2 for invalid)
- **ext** — extended
- *value1* — 0000 to FFFF
- *value2* — 0 to FFFFFFFFFFFF
- **flowspec-set —** FlowSpec set
- **flowspec-set-trans —** FlowSpec set transitive
- *ipv6-addr* — x:x:x:x:x:x:x:x (eight 16-bit pieces)
- *group-id* — 0 to 16383
- *co-bits* — 00, 01, 10 or 11
- *color-value* — 0 to 4294967295

- *well-known-comm* — **null**, **no-export**, **no-export-subconfed**, **no-advertise**, **llgr-stale**, **no-llgr**, **blackhole**
- *large-comm* — large community, defined as one of the following:
  - *ext-asnum*:*ext-comm-val*:*ext-comm-val*
  - *reg-ex3*&*reg-ex3*&*reg-ex3*

  where:
  - *reg-ex3* — A regular expression string. Allowed values are any string up to 68 characters, composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

18.12 memory-use-alarm

memory-use-alarm

Syntax

memory-use-alarm rising-threshold *threshold* [**falling-threshold** *threshold*] **interval** *seconds* [*rmon-event-type*] [**startup-alarm** *alarm-type*]

no memory-use-alarm

Context

[Tree] (config>system>thresholds memory-use-alarm)

Full Context

configure system thresholds memory-use-alarm

Description

The memory thresholds are based on monitoring the TIMETRA-SYSTEM-MIB sgiMemoryUsed object. This object contains the amount of memory currently used by the system. The severity level is Alarm. The absolute sample type method is used.

The **no** form of this command removes the configured memory threshold warning.

Parameters

rising-threshold *threshold*

Specifies a threshold for the sampled statistic. When the current sampled value is greater than or equal to this threshold, and the value at the last sampling interval was less than this threshold, a single threshold crossing event will be generated. A single threshold crossing event will also be generated if the first sample taken is greater than or equal to this threshold and the associated startup-alarm is equal to rising or either.

After a rising threshold crossing event is generated, another such event will not be generated until the sampled value falls below this threshold and reaches less than or equal the falling-threshold value.

The threshold value represents units in bytes.

Values -2147483648 to 2147483647

Default 0

falling-threshold *threshold*

Specifies a threshold for the sampled statistic. When the current sampled value is less than or equal to this threshold, and the value at the last sampling interval was greater than this threshold, a single threshold crossing event will be generated. A single threshold crossing event will also be generated if the first sample taken is less than or equal to this threshold and the associated startup-alarm is equal to falling or either.

After a falling threshold crossing event is generated, another such event will not be generated until the sampled value rises above this threshold and reaches greater than or equal the rising-threshold value.

The threshold value represents units in bytes.

Values -2147483648 to 2147483647

Default 0

seconds

Specifies the polling period over which the data is sampled and compared with the rising and falling thresholds.

The threshold value represents units in bytes.

Values 1 to 2147483647

rmon-event-type

Specifies the type of notification action to be taken when this event occurs.

Values log — An entry is made in the RMON-MIB log table for each event occurrence. This does not create an OS logger entry. The RMON-MIB log table entries can be viewed using the CLI command.

trap — An SR OS logger event is generated. The SR OS logger utility then distributes the notification of this event to its configured log destinations which may be CONSOLE, telnet session, memory log, cflash file, syslog, or SNMP trap destinations logs.

both — Both an entry in the RMON-MIB logTable and an SR OS logger event are generated.

none — No action is taken.

Default both

alarm-type

Specifies the alarm that may be sent when this alarm is first created. If the first sample is greater than or equal to the rising threshold value and startup-alarm is equal to rising or either, then a single rising threshold crossing event is generated. If the first sample is less than or equal to the falling threshold value and startup-alarm is equal to falling or either, a single falling threshold crossing event is generated.

Values rising, falling, either

Default either

Configuration example

```
memory-use-alarm rising-threshold 50000000 falling-threshold 45999999
interval 500 rmon-event-type both start-alarm either
```

Platforms

7705 SAR Gen 2

18.13 memory-use-warn

memory-use-warn

Syntax

memory-use-warn rising-threshold *threshold* [**falling-threshold** *threshold*] **interval** *seconds* [*rmon-event-type*] [**startup-alarm** *alarm-type*]

no memory-use-warn

Context

[Tree] (config>system>thresholds memory-use-warn)

Full Context

configure system thresholds memory-use-warn

Description

The memory thresholds are based on monitoring MemoryUsed object. This object contains the amount of memory currently used by the system. The severity level is Alarm.

The absolute sample type method is used.

The **no** form of this command removes the configured compact flash threshold warning.

Parameters

rising-threshold *threshold*

Specifies a threshold for the sampled statistic. When the current sampled value is greater than or equal to this threshold, and the value at the last sampling interval was less than this threshold, a single threshold crossing event will be generated. A single threshold crossing event will also be generated if the first sample taken is greater than or equal to this threshold and the associated startup-alarm is equal to rising or either.

After a rising threshold crossing event is generated, another such event will not be generated until the sampled value falls below this threshold and reaches less than or equal the falling-threshold value.

The threshold value represents units in bytes.

Values -2147483648 to 2147483647

Default 0

falling-threshold *threshold*

Specifies a threshold for the sampled statistic. When the current sampled value is less than or equal to this threshold, and the value at the last sampling interval was greater than this threshold, a single threshold crossing event will be generated. A single threshold crossing event will also be generated if the first sample taken is less than or equal to this threshold and the associated startup-alarm is equal to falling or either.

After a falling threshold crossing event is generated, another such event will not be generated until the sampled value rises above this threshold and reaches greater than or equal the rising-threshold value.

The threshold value represents units in bytes.

Values -2147483648 to 2147483647

Default 0

seconds

Specifies the polling period over which the data is sampled and compared with the rising and falling thresholds.

Values 1 to 2147483647

rmon-event-type

Specifies the type of notification action to be taken when this event occurs.

Values log — An entry is made in the RMON-MIB log table for each event occurrence.

This does not create an SR OS logger entry. The RMON-MIB log table entries can be viewed using the **show>system>thresholds** CLI command.

trap — An SR OS logger event is generated. The SR OS logger utility then distributes the notification of this event to its configured log destinations which may be CONSOLE, telnet session, memory log, cflash file, syslog, or SNMP trap destinations logs.

both — Both an entry in the RMON-MIB logTable and an SR OS logger event are generated.

none — No action is taken.

Default both

startup-alarm *alarm-type*

Specifies the alarm that may be sent when this alarm is first created. If the first sample is greater than or equal to the rising threshold value and startup-alarm is equal to rising or either, then a single rising threshold crossing event is generated. If the first sample is less than or equal to the falling threshold value and startup-alarm is equal to falling or either, a single falling threshold crossing event is generated.

Default either

Values rising, falling, either

Configuration example

```
memory-use-warn rising-threshold 500000 falling-threshold 400000 interval 800
 rmon-
event-type log start-alarm falling
```

Platforms

7705 SAR Gen 2

18.14 mesh-group

mesh-group

Syntax

mesh-group {**value** | **blocked**}

no mesh-group

Context

[Tree] (config>service>vprn>isis>if mesh-group)

Full Context

configure service vprn isis interface mesh-group

Description

This command assigns an interface to a mesh group. Mesh groups limit the amount of flooding that occurs when a new or changed LSP is advertised throughout an area.

All routers in a mesh group should be fully meshed. When LSPs need to be flooded, only a single copy is received rather than a copy per neighbor.

To create a mesh group, configure the same mesh group value for each interface that is part of the mesh group. All routers must have the same mesh group value configured for all interfaces that are part of the mesh group.

To prevent an interface from flooding LSPs, the optional **blocked** parameter can be specified. Configure mesh groups carefully. It is easy to create isolated islands that do not receive updates as (other) links fail.

The **no** form of this command removes the interface from the mesh group. The interface does not belong to a mesh group.

Default

no mesh-group

Parameters

value

Specifies a unique decimal integer value distinguishes this mesh group from other mesh groups on this or any other router that is part of this mesh group.

Values 1 to 2000000000

blocked

Prevents an interface from flooding LSPs.

Platforms

7705 SAR Gen 2

mesh-group

Syntax

mesh-group {**value** | **blocked**}

no mesh-group

Context

[Tree] (config>router>isis>interface mesh-group)

18.15 mesh-sdp

mesh-sdp

Syntax

mesh-sdp *sdp-id*[*:vc-id*] [**vc-type** {**ether** | **vlan**}] [**create**]

mesh-sdp *sdp-id*[*:vc-id*] [**vc-type** {**ether** | **vlan**}] [**create**] **leaf-ac**

mesh-sdp *sdp-id*[*:vc-id*] [**vc-type** {**ether** | **vlan**}] [**create**] **root-leaf-tag**

no mesh-sdp *sdp-id*[*:vc-id*]

Context

[Tree] (config>service>vpls mesh-sdp)

Full Context

configure service vpls mesh-sdp

Description

This command binds a VPLS service to an existing service destination point (SDP).

Mesh SDPs bound to a service are logically treated like a single bridge "port" for flooded traffic where flooded traffic received on any mesh SDP on the service is replicated to other "ports" (spoke SDPs and SAPs) and not transmitted on any mesh SDPs.

Note:
This command creates a binding between a service and an SDP. The SDP has an operational state which determines the operational state of the SDP within the service. For example, if the SDP is administratively or operationally down, the SDP for the service is down.

The SDP must already be defined in the **config>service>sdp** context in order to associate the SDP with an Epipe or VPLS service. If the **sdp** *sdp-id* is not already configured, an error message is generated. If the *sdp-id* does exist, a binding between that *sdp-id* and the service is created.

SDPs must be explicitly associated and bound to a service. If an SDP is not bound to a service, no far-end router devices can participate in the service.

The **no** form of this command removes the SDP binding from the service. The SDP configuration is not affected; only the binding of the SDP to a service. Once removed, no packets are forwarded to the far-end router.

Default

No *sdp-id* is bound to a service.

Parameters

sdp-id

Specifies an SDP identifier.

Values 1 to 17407

vc-id

Specifies a virtual circuit identifier. This value is used to validate the VC ID portion of each mesh SDP binding defined in the service. The default value of this object is equal to the service ID. Any value may be used for the *vc-id* when there is no existing mesh SDP within the service; if a mesh SDP exists then all other mesh SDPs in the service must be configured with the same *vc-id*.

Values 1 to 4294967295

vc-type

Specifies to override the default VC type signaled for the spoke or mesh binding to the far end of the SDP. The VC type is a 15 bit-quantity containing a value which represents the type of VC. The actual signaling of the VC type depends on the signaling parameter defined for the SDP. If signaling is disabled, the **vc-type** command can still be used to define the dot1q value expected by the far-end provider equipment. A change of the binding's VC type causes the binding to signal the new VC type to the far end when signaling is enabled.

VC types are derived according to IETF *draft-martini-l2circuit-trans-mpls*.

The VC type value for Ethernet is 0x0005.

The VC type value for an Ethernet VLAN is 0x0004.

ether

Defines the VC type as Ethernet. The **vlan** keyword is mutually exclusive. When the VC type is not defined then the default is Ethernet for spoke SDP bindings. Defining Ethernet is the same as executing **no vc-type** and restores the default VC type for the spoke SDP binding (hex 5).

vlan

Defines the VC type as VLAN. The top VLAN tag, if a VLAN tag is present, is stripped from traffic received on the pseudowire, and a vlan-tag is inserted when forwarding into the pseudowire. The **ethernet** and **vlan** keywords are mutually exclusive. When the VC type is not defined then the default is Ethernet for mesh SDP bindings.

Note:
The system expects a symmetrical configuration with its peer, specifically it expects to remove the same number of VLAN tags from received traffic as it adds to transmitted traffic. As some of the related configuration parameters are local and not communicated in the signaling plane, an asymmetrical behavior cannot always be detected and so cannot be blocked. Consequently, protocol extractions will not necessarily function for asymmetrical configurations as they would with a symmetrical configurations resulting in an unexpected operation.

root-leaf-tag

Specifies a tagging mesh SDP under an E-Tree VPLS. When a tag SDP binding is required, it is created with a root-leaf-tag flag. Only VLAN tag SDP bindings are supported. The VLAN type must be set to VC VLAN type. The root-leaf-tag parameter indicates this SDP binding is a tag SDP that uses a default VID 1 for root and 2 for leaf. The SDP binding tags egress E-Tree traffic with root and leaf VIDs as appropriate. Root and leaf VIDs are

only significant between peering VPLS but the values must be consistent on each end. On ingress a tag SDP binding removes the VID tag on the interface between VPLS in the same E-Tree service. The tag SDP receives root tagged traffic and marks the traffic with a root indication internally. This option is not available on BGP EVPN-enabled E-Tree services.

leaf-ac

Specifies an access (AC) mesh SDP binding under a E-Tree VPLS as a leaf access (AC) SDP. The default E-Tree SDP type is a root AC if *leaf-ac* or *root-leaf-tag* is not specified at SDP binding creation. This option is only available when the VPLS is designated as an E-Tree VPLS. BGP EVPN-enabled E-Tree VPLS services support the **leaf-ac** option.

create

Keyword used to create the mesh SDP. The **create** keyword requirement can be enabled or disabled in the **environment>create** context.

18.17 message

message

Syntax

message {**eq** | **neq**} **pattern** *pattern* [**regexp**]

no message

Context

[Tree] (config>service>vprn>log>filter>entry>match message)

Full Context

configure service vprn log filter entry match message

Description

This command adds system messages as a match criterion.

The **no** form of this command removes messages as a match criterion.

Parameters

eq

Specifies if the matching criteria should be equal to the specified value.

neq

Specifies if the matching criteria should not be equal to the specified value.

pattern

Specifies a message, up to 400 characters, to be used in the match criteria.

regexp

Specifies the type of string comparison to use to determine if the log event matches the value of **message** command parameters. When the **regexp** keyword is not specified, the default matching algorithm used is a basic substring match.

Platforms

7705 SAR Gen 2

message

Syntax

message {**eq** | **neq**} **pattern** *pattern* [**regexp**]

Full Context

configure service vprn ospf area sham-link message-digest-key

configure service vprn ospf area interface message-digest-key

configure service vprn ospf area virtual-link message-digest-key

Description

This command configures a message digest key when MD5 authentication is enabled on the interface, virtual-link or sham-link. Multiple message digest keys can be configured.

This command is not valid in the OSPF3 context.

The **no** form of this command removes the message digest key identified by the *key-id*.

Default

No message digest keys are defined.

Parameters

keyid

Specifies the key ID. The *keyid* is expressed as a decimal integer.

Values 1 to 255

md5 *key*

Specifies the MD5 key. The *key* can be any alphanumeric string up to 16 characters in length.

md5 hash-key

Specifies the MD5 hash key. The key can be any combination of ASCII characters up to 32 characters in length (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided.

hash

Specifies the key is entered in an encrypted form. If the **hash** parameter is not used, the key is assumed to be in a non-encrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** parameter specified.

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

custom

Specifies the custom encryption to management interface.

Platforms

7705 SAR Gen 2

message-digest-key

Syntax

message-digest-key *key-id* **md5** [*key* | *hash-key* | *hash2-key*] [**hash** | **hash2** | **custom**]

no message-digest-key *key-id*

Context

[Tree] (config>router>ospf>area>interface message-digest-key)

[Tree] (config>router>ospf>area>virtual-link message-digest-key)

Full Context

configure router ospf area interface message-digest-key

configure router ospf area virtual-link message-digest-key

Description

This command configures a message digest key when MD5 authentication is enabled on the interface. Multiple message digest keys can be configured.

The **no** form of this command removes the message digest key identified by the *key-id*.

By default, no message keys are defined.

Parameters

key-id

Specifies the key ID. The *keyid* is expressed as a decimal integer.

Values 1 to 255

key

Specifies the MD5 key. The *key* can be any alphanumeric string up to 16 characters in length.

hash-key* | *hash2-key

Specifies the MD5 hash or hash2 key. the hash key. The key can be any combination of ASCII characters up to 32 (hash1-key) or 55 (hash2-key) characters in length (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided.

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

custom

Specifies the custom encryption to management interface.

18.22 message-interval

message-interval

Syntax

message-interval {[*seconds*] [**milliseconds** *milliseconds*]}

no message-interval

Context

[Tree] (config>service>ies>if>ipv6>vrrp message-interval)

Full Context

configure service ies interface ipv6 vrrp message-interval

Description

This command sets the advertisement timer and indirectly sets the master down timer on the virtual router instance. The message-interval setting must be the same for all virtual routers participating as a virtual router. Any VRRP advertisement message received with an Advertisement Interval field different than the virtual router instance configured message-interval value will be silently discarded.

The message-interval command is available in both non-owner and owner **vrrp** *virtual-router-id* nodal contexts. If the message-interval command is not executed, the default message interval of 1 second will be used.

The **no** form of this command restores the default message interval value of 1 second to the virtual router instance.

Default

message-interval 1

Parameters

seconds

The number of seconds that will transpire before the advertisement timer expires.

Values 1 to 255

Default 1

milliseconds ***milliseconds***

Specifies the time interval, in milliseconds, between sending advertisement messages.

Values 100 to 900

Platforms

7705 SAR Gen 2

[Tree] (config>router>if>ipv6>vrrp message-interval)

Full Context

configure router interface vrrp message-interval

configure router interface ipv6 vrrp message-interval

Description

This command configures the administrative advertisement message timer used by the master virtual router instance to send VRRP advertisement messages and to derive the master down timer as backup.

For an owner virtual router instance, the administrative advertisement timer directly sets the operational advertisement timer and indirectly sets the master down timer for the virtual router instance.

Non-owner virtual router instances usage of the **message-interval** setting is dependent on the state of the virtual router (master or backup) and the state of the **master-int-inherit** parameter.

- When a non-owner is operating as master for the virtual router, the configured **message-interval** is used as the operational advertisement timer similar to an owner virtual router instance. The **master-int-inherit** command has no effect when operating as master.
- When a non-owner is in the backup state with **master-int-inherit** disabled, the configured **message-interval** value is used to match the incoming VRRP advertisement message advertisement interval

field. If the locally configured message interval does not match the advertisement interval field, the VRRP advertisement is discarded.

- When a non-owner is in the backup state with **master-int-inherit** enabled, the configured **message-interval** is ignored. The master down timer is indirectly derived from the incoming VRRP advertisement message advertisement interval field value.

VRRP advertisements messages that are fragmented, or contain IP options (IPv4), or contain extension headers (IPv6) require a longer message interval to be configured.

The in-use value of the message interval is used to derive the master down timer to be used when the virtual router is operating in backup mode based on the following formula:

(3x (in-use message interval) + skew time)

The skew time portion is used to slow down virtual routers with relatively low priority values when competing in the master election process.

The command is available in both non-owner and owner **vrrp** nodal contexts.

By default, a **message-interval** of 1 second is used.

The **no** form of the command reverts to the default value.

Default

message-interval 1 — Advertisement timer set to 1 second.

Parameters

seconds

The number of seconds that will transpire before the advertisement timer expires expressed as a decimal integer.

Values IPv4: 1 to 255 IPv6: 1 to 40

milliseconds

Specifies the time interval, in milliseconds, between sending advertisement messages.

Values 100 to 900 IPv6: 10 to 990

Platforms

18.23 message-length

message-length

Syntax

message-length *message-length*

no message-length

Context

[Tree] (config>service>sdp>keep-alive message-length)

Full Context

configure service sdp keep-alive message-length

Description

This command configures the SDP monitoring keepalive request message length transmitted.

The **no** form of this command reverts the **message-length** *octets* value to the default setting.

Default

no message-length — The message length should be equal to the SDP's operating path MTU as configured in the **config>service>sdp path-mtu** command. If the default size is overridden, the actual size used will be the smaller of the operational SDP ID Path MTU and the size specified.

Parameters

message-length

Specifies the size of the keepalive request messages in octets, expressed as a decimal integer. The **size** keyword overrides the default keepalive message size.

Values 40 to 9198

Platforms

7705 SAR Gen 2

configure service vprn static-route-entry black-hole metric

configure service vprn static-route-entry next-hop metric

configure service vprn static-route-entry grt metric

configure service vprn static-route-entry indirect metric

Description

This command specifies the cost metric for the static route, expressed as a decimal integer. This value is used when importing the static route into other protocols such as OSPF. When the metric is configured as 0 then the metric configured in OSPF, default-import-metric, applies. When modifying the metric of an existing static route, the preference will not change unless specified. This value is also used to determine which static route to install in the forwarding table.

If there are multiple static routes with the same preference but different metrics then the lower cost (metric) route will be installed.

The **no** form of this command returns the metric to the default value

Default

metric 1

Parameters

metric-value

Specifies the cost metric value.

Values 0 to 65535

Platforms

7705 SAR Gen 2

[Tree] (config>router>mpls>lsp metric)

Full Context

configure router mpls static-lsp metric

configure router mpls lsp-template metric

configure router mpls lsp metric

Description

This command allows the user to override the LSP operational metric with a constant administrative value that will not change regardless of the actual path the LSP is using over its lifetime.

The LSP operational metric will match the metric the active path of this LSP is using at any given time. For a CSPF LSP, this metric represents the cumulative IGP metric of all the links the active path is using. If CSPF for this LSP is configured to use the TE metric, the LSP operational metric is set to the maximum value. For a non-CSPF LSP, the operational metric is the shortest IGP cost to the destination of the LSP.

The LSP operational metric is used by some applications to select an LSP among a set of LSPs that are destined to the same egress router. The LSP with the lowest operational metric will be selected. If more than one LSP with the same lowest LSP metric exists, the LSP with the lowest tunnel index will be selected. The configuration of a constant metric by the user will make sure the LSP always maintains its preference in this selection regardless of the path it is using at any given time. Applications that use the LSP operational metric include LDP-over-RSVP, VPRN auto-bind, and IGP, BGP and static route shortcuts.

The **no** form of this command disables the administrative LSP metric and reverts to the default setting in which the metric value will represent the LSP metric returned by MPLS. The same behavior is obtained if the user entered a metric of value zero (0).

Default

no metric. The LSP operational metric defaults to the metric returned by MPLS.

Parameters

metric

Specifies the integer value which specifies the value of the LSP administrative metric. A value of zero command reverts to the default setting and disables the administrative LSP metric.

Values 0 to 16777215

Platforms

7705 SAR Gen 2

no metric

Context

[Tree] (config>router>policy-options>policy-statement>entry>from metric)

Full Context

configure router policy-options policy-statement entry from metric

Description

This command matches BGP routes based on local preference (the value in the MULTI_EXIT_DISC attribute).

If no comparison qualifiers are present (**equal**, **or-higher**, **or-lower**), then **equal** is the implied default.

A non-BGP route does not match a policy entry if it contains the **metric** command. In addition, a BGP route without a MED attribute also does not match a policy entry if it contains a **metric** command.

Default

no metric

Parameters

metric

Specifies the MED value.

Values 0 to 4294967295, or a parameter name delimited by starting and ending at-sign (@) characters

equal

Specifies that matched routes should have the same MED as the value specified.

or-higher

Specifies that matched routes should have the same or a greater MED as the value specified.

or-lower

Specifies that matched routes should have the same or a lower MED as the value specified.

Full Context

configure router policy-options policy-statement entry action metric

configure router policy-options policy-statement default-action metric

Description

In a BGP import or export policy, this command assigns a MED value to routes matched by the policy statement entry. The MED value may be set to a fixed value (overriding the received value), set to the routing table cost of the route used to resolve the next hop of the BGP route, or modified by adding or subtracting a fixed value offset.

The **no** form of this command removes the MED attribute from the matched routes.

Default

no metric

Parameters

add

Specifies that an integer is added to any existing metric. If the result of the addition results in a number greater than 4294967295, the value 4294967295 is used.

subtract

Specified *integer* is subtracted from any existing metric. If the result of the subtraction results in a number less than 0, the value of 0 is used.

set

Specifies that *integer* replaces any existing metric.

igp

Sets the MED value to the routing table cost of the route used to resolve the next hop of the BGP route.

metric

Specifies the metric modifier expressed as a decimal integer.

Values 0 to 4294967295

param-name —Specifies the metric parameter variable name. Allowed values are any string up to 32 characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes. Policy parameters must start and end with at-signs (@); for example, "@variable@”

configure service vprn rip group neighbor metric-out

configure service vprn ripng group metric-out

configure service vprn ripng group neighbor metric-out

configure service vprn rip metric-out

configure service vprn ripng metric-out

Description

This command sets the metric added to routes exported into RIP and advertised to RIP neighbors.

The **no** form of this command removes the command from the config and resets the metric-in value back to the default.

Default

no metric-out

Parameters

metric

The value added to the metric for routes exported into RIP and advertised to RIP neighbors, expressed as a decimal integer.

Values 1 to 16

Platforms

7705 SAR Gen 2

metric-out

Syntax

metric-out *metric*

no metric-out

Context

configure router ripng group neighbor metric-out

configure router ripng metric-out

configure router rip group neighbor metric-out

configure router rip group metric-out

configure router ripng group metric-out

configure router rip metric-out

Description

This command configures the metric assigned to routes exported into RIP and advertised to RIP neighbors.

When applying an export policy to a RIP configuration, the policy overrides the metric values determined through calculations involving the **metric-in** and **metric-out** values.

The **no** form of the command reverts to the default value.

Default

metric-out 1

Parameters

metric

Specifies the value added to the metric for routes exported into RIP and advertised to RIP neighbors expressed as a decimal integer.

Values 1 to 16

Platforms

7705 SAR Gen 2

18.30 metric-type

metric-type

Syntax

metric-type *metric-type*

no metric-type

Context

[Tree] (config>router>mpls>lsp-template metric-type)

[Tree] (config>router>mpls>lsp metric-type)

Full Context

configure router mpls lsp-template metric-type

configure router mpls lsp metric-type

Description

This command configures the link metric type used by the local CSPF or the PCE controller in the SR-TE LSP path computation.

The **no** form of this command returns the link metric type to its default value.

Default

metric-type igp

Parameters

metric-type

Specifies the metric type for the LSP.

Values **igp** — Specifies use of the IGP metric.

te — Specifies use of the traffic-engineering metric. This is the default metric type.

delay — Specifies computation delay metrics.

Platforms

7705 SAR Gen 2

metric-type

Syntax

metric-type {**igp** | **te-metric** | **delay**}

no metric-type

Context

[Tree] (config>router>fad>flex-algo metric-type)

Full Context

configure router flexible-algorithm-definitions flex-algo metric-type

Description

This command configures the type of metric for the flexible algorithm. The topology graph assumes that all links are configured with the correct metric type.

For example, if the flexible algorithm definition instructs the use of **te-metric** keyword, it is assumed that all links have *te-metric* configured. Links without the *te-metric* configuration are excluded from the flexible algorithm topology graph.

The **no** form of this command removes the configured metric type and sets it to its default value.

Default

metric-type igp

Parameters

igp

Keyword to use the IGP metric for the flexible algorithm topology graph.

te-metric

Keyword to use the TE metric for the flexible algorithm topology graph.

delay

Keyword to use the delay metric for the flexible algorithm topology graph.

7705 SAR Gen 2

18.31 mfib-allowed-mda-destinations

mfib-allowed-mda-destinations

Syntax

mfib-allowed-mda-destinations

Context

[Tree] (config>service>vpls>mesh-sdp>egress mfib-allowed-mda-destinations)

[Tree] (config>service>vpls>spoke-sdp>egress mfib-allowed-mda-destinations)

Full Context

configure service vpls mesh-sdp egress mfib-allowed-mda-destinations

configure service vpls spoke-sdp egress mfib-allowed-mda-destinations

Description

Commands in this context configure MFIB-allowed MDA destinations.

The allowed-mda-destinations node and the corresponding **mda** command are used on spoke and mesh SDP bindings to provide a list of MDA destinations in the chassis that are allowed as destinations for multicast streams represented by [*,g] and [s,g] multicast flooding records on the VPLS service. The MDA list only applies to IP multicast forwarding when IGMP snooping is enabled on the VPLS service. The MDA list has no effect on normal VPLS flooding such as broadcast, L2 multicast, unknown destinations or non-snooped IP multicast.

At the IGMP snooping level, a spoke or mesh SDP binding is included in the flooding domain for an IP multicast stream when it has either been defined as a multicast router port, received a IGMP query through the binding or has been associated with the multicast stream through an IGMP request by a host over the binding. Due to the dynamic nature of the way that a spoke or mesh SDP binding is associated with one or more egress network IP interfaces, the system treats the binding as appearing on all network ports. This causes all possible network destinations in the switch fabric to be included in the multicast streams flooding domain. The MDA destination list provides a simple mechanism that narrows the IP multicast switch fabric destinations for the spoke or mesh SDP binding.

If no MDAs are defined within the allowed-mda-destinations node, the system operates normally and will forward IP multicast flooded packets associated with the spoke or mesh SDP binding to all switch fabric taps containing network IP interfaces.

The MDA inclusion list should include all MDAs that the SDP binding may attempt to forward through. A simple way to ensure that an MDA that is not included in the list is not being used by the binding is to define the SDP the binding is associated with as MPLS and use an RSVP-TE LSP with a strict egress hop. The MDA associated with the IP interface defined as the strict egress hop should be present in the inclusion list. If the inclusion list does not currently contain the MDA that the binding is forwarding through, the multicast packets will not reach the destination represented by the binding.

By default, the MDA inclusion list is empty.

If an MDA is removed from the list, the MDA is automatically removed from the flooding domain of any snooped IP multicast streams associated with a destination on the MDA unless the MDA was the last MDA on the inclusion list. Once the inclusion list is empty, all MDAs are eligible for snooped IP multicast flooding for streams associated with the SDP binding.

7705 SAR Gen 2

mfib-allowed-mda-destinations

Syntax

mfib-allowed-mda-destinations

Context

[Tree] (config>service>pw-template>egress mfib-allowed-mda-destinations)

Full Context

configure service pw-template egress mfib-allowed-mda-destinations

Description

Commands in this context configure MFIB-allowed XMA or MDA destinations.

The allowed-mda-destinations node and the corresponding **mda** command are used on spoke and mesh SDP bindings to provide a list of XMA or MDA destinations in the chassis that are allowed as destinations for multicast streams represented by [*,g] and [s,g] multicast flooding records on the VPLS service. The XMA or MDA list only applies to IP multicast forwarding when IGMP snooping is enabled on the VPLS service. The XMA or MDA list has no effect on normal VPLS flooding such as broadcast, Layer 2 multicast, unknown destinations or non-snooped IP multicast.

At the IGMP snooping level, a spoke or mesh SDP binding is included in the flooding domain for an IP multicast stream when it has either been defined as a multicast router port, received a IGMP query through the binding or has been associated with the multicast stream through an IGMP request by a host over the binding. Due to the dynamic nature of the way that a spoke or mesh SDP binding is associated with one or more egress network IP interfaces, the system treats the binding as appearing on all network ports. This causes all possible network destinations in the switch fabric to be included in the multicast streams flooding domain. The XMA or MDA destination list provides a simple mechanism that narrows the IP multicast switch fabric destinations for the spoke or mesh SDP binding.

If no XMAs or MDAs are defined within the allowed-mda-destinations node, the system operates normally and will forward IP multicast flooded packets associated with the spoke or mesh SDP binding to all switch fabric taps containing network IP interfaces.

The XMA or MDA inclusion list should include all XMAs or MDAs that the SDP binding may attempt to forward through. A simple way to ensure that an XMA or MDA that is not included in the list is not being used by the binding is to define the SDP the binding is associated with as MPLS and use an RSVP-TE LSP with a strict egress hop. The XMA or MDA associated with the IP interface defined as the strict egress hop should be present in the inclusion list.

If the inclusion list does not currently contain the XMA or MDA that the binding is forwarding through, the multicast packets will not reach the destination represented by the binding. By default, the XMA or MDA inclusion list is empty.

If an XMA or MDA is removed from the list, the XMA or MDA is automatically removed from the flooding domain of any snooped IP multicast streams associated with a destination on the XMA or MDA unless the XMA or MDA was the last XMA or MDA on the inclusion list. Once the inclusion list is empty, all XMAs or MDAs are eligible for snooped IP multicast flooding for streams associated with the SDP binding.

18.32 mfib-table-high-wmark

mfib-table-high-wmark

Syntax

[**no**] **mfib-table-high-wmark** *high-water-mark*

Context

[Tree] (config>service>vpls mfib-table-high-wmark)

Full Context

configure service vpls mfib-table-high-wmark

Description

This command specifies the multicast FIB high watermark. When the percentage filling level of the multicast FIB exceeds the configured value, a trap is generated and a log entry is added.

The **no** form of this command reverts to the default.

Default

mfib-table-high-wmark 95

Parameters

high-water-mark

Specifies the multicast FIB high watermark as a percentage.

Values 1 to 100

Platforms

7705 SAR Gen 2

18.33 mfib-table-low-wmark

mfib-table-low-wmark

Syntax

[**no**] **mfib-table-low-wmark** *low-water-mark*

Context

[Tree] (config>service>vpls mfib-table-low-wmark)

Full Context

configure service vpls mfib-table-low-wmark

Description

This command specifies the multicast FIB low watermark. When the percentage filling level of the multicast FIB drops below the configured value, the corresponding trap is cleared and a log entry is added.

The **no** form of this command reverts to the default.

Default

mfib-table-low-wmark

Parameters

low-water-mark

Specifies the multicast FIB low watermark as a percentage.

Values 1 to 100

Default 90

Platforms

7705 SAR Gen 2

18.34 mfib-table-size

mfib-table-size

Syntax

mfib-table-size *size*

no mfib-table-size

Context

[Tree] (config>service>vpls mfib-table-size)

Full Context

configure service vpls mfib-table-size

Description

This command specifies the maximum number of (s,g) entries in the multicast forwarding database (MFIB) for this VPLS instance.

The *mfib-table-size* parameter specifies the maximum number of multicast database entries for both learned and static multicast addresses for the VPLS instance. When a table-size limit is set on the mfib of a service which is lower than the current number of dynamic entries present in the mfib then the number of entries remains above the limit.

The **no** form of this command removes the configured maximum MFIB table size.

Default

no mfib-table-size

Parameters

size

Specifies the maximum number of (s,g) entries allowed in the Multicast FIB

Values 1 to 40959

Platforms

7705 SAR Gen 2

18.35 mh-mode

mh-mode

Syntax

mh-mode {**access** | **network**}

Context

[Tree] (config>service>vpls>bgp-evpn>mpls mh-mode)

Full Context

configure service vpls bgp-evpn mpls mh-mode

Description

This command configures each BGP-EVPN instance in a multi-instance EVPN VPLS service to behave as network or access.

You can only configure one network instance for the service. If the service has a provider tunnel enabled, it requires a network instance.

Default

mh-mode network

Parameters

access

Specifies that the BGP-EVPN instance does not participate in multihoming procedures, such as DF election processing or local bias forwarding.

network

Specifies that the BGP-EVPN instance participates in multihoming procedures, such as DF election processing or local bias forwarding.

In services with two instances, only one of the two instances can be configured as **network**.

Platforms

7705 SAR Gen 2

mh-mode

Syntax

mh-mode {**access** | **network**}

Context

[Tree] (config>service>epipe>bgp-evpn>mpls mh-mode)

Full Context

configure service epipe bgp-evpn mpls mh-mode

Description

This command configures each BGP-EVPN instance in a multi-instance Epipe service to behave as network or access.

You can only configure one network instance for the service. If the service has a provider tunnel enabled, it requires a network instance.

Default

mh-mode network

Parameters

access

Specifies that the BGP-EVPN instance does not participate in multihoming procedures, such as DF election processing or local bias forwarding.

network

Specifies that the BGP-EVPN instance participates in multihoming procedures, such as DF election processing or local bias forwarding.

In services with two instances, only one of the two instances can be configured as **network**.

18.36 micro-loop-avoidance

micro-loop-avoidance

Syntax

micro-loop-avoidance [**fib-delay** *fib-delay*]

no micro-loop-avoidance

Context

[Tree] (config>router>isis>segment-routing micro-loop-avoidance)

Full Context

configure router isis segment-routing micro-loop-avoidance

Description

This command enables, in the IGP instance, the microloop avoidance feature to prevent microloops from using segment routing (SR) loop-free tunnels for packets that are forwarded over SR IS-IS node SIDs.

This command enables microloop avoidance for MT0. Microloop avoidance for MT2 is enabled when this command is enabled along with SR-MPLS MT2 using the **configure router isis segment-routing multi-topology mt2** command.

When enabled, the behavior of the feature is triggered by the receipt of a single event on a P2P link or broadcast link with two neighbors:

- link addition or restoration
- link removal or failure
- link metric change

IGP then performs the following procedures:

1. IGP runs the main SPF and LFA SPFs.
2. For a node or a prefix in which the SPF resulted in no change to its next hops and metrics, IGP takes no action.
3. For a node or a prefix in which SPF resulted in a change to its next hops or metrics, IGP marks the route as eligible for microloop avoidance.
   a. Activate, for each node SID that uses a microloop avoidance eligible route with ECMP next hops, the common set of next hops between the previous and new SPF.
   b. Compute and activate, for each node SID which uses a microloop avoidance eligible route, with a single next hop loop-free SR tunnel that is applicable to the specific link event.

      This tunnel acts the microloop avoidance primary path for the route and uses the same outgoing interface as the new computed primary next hop.
   c. Program the TI-LFA, base LFA, or remote LFA backup path that protects the new primary next hop for the node SID.
4. Start the **fib-delay** timer to delay programming of new main and LFA SPF results into the FIB.
5. After the expiry of the **fib-delay** timer, program the new primary next hops for node SIDs routes that were marked eligible for microloop avoidance procedures.

The **no** form of this command disables the microloop avoidance feature.

Default

no micro-loop-avoidance

Parameters

fib-delay

Specifies the delay, in 100s of milliseconds, before the system programs the new next hops for the SR tunnel.

Values 1 to 300

Default 15

Platforms

7705 SAR Gen 2

micro-loop-avoidance

[no] micro-loop-avoidance

Context

[Tree] (config>router>isis>flex-algos>flex-algo micro-loop-avoidance)

Full Context

configure router isis flexible-algorithms flex-algo micro-loop-avoidance

Description

This command enables flexible algorithms-aware microloop avoidance. When enabled, the microloop configuration parameters are inherited from the base SPF.

This command enables microloop avoidance with flexible algorithms for MT0. Microloop avoidance with flexible algorithms for MT2 is enabled when this command is enabled along with SR-MPLS MT2 using the **configure router isis segment-routing multi-topology mt2** command.

The **no** form of this command disables the microloop avoidance for flexible algorithms.

Default

no micro-loop-avoidance

Platforms

7705 SAR Gen 2

micro-loop-avoidance

Syntax

[**no**] **micro-loop-avoidance**

Context

[Tree] (config>router>ospf>flex-algos>flex-algo micro-loop-avoidance)

Full Context

configure router ospf flexible-algorithms flex-algo micro-loop-avoidance

Description

This command enables microloop avoidance for an SR-OSPF flexible algorithm, and consequently, inherits the FIB delay timer from the SR-OSPF **configure router ospf segment-routing** context.

When enabled, FIB updates are delayed before programming new primary next hops to avoid microloops.

When enabled, the feature applies to the following contexts:

- OSPFv2 SR-OSPF IPv4 tunnel (node SID)
- IPv4 and IPv6 SR-TE LSPs that use a node SID in their segment list
- IPv4 and IPv6 SR policies that use a node SID in their segment list

The **no** form of this command disables microloop avoidance. When microloop avoidance is disabled, the system forces any running FIB delay to expire immediately and programs the new next hops for all impacted node SIDs. When disabled, microloop avoidance is disabled instantaneously and will be disabled for the next SPF runs. Microloop avoidance remains disabled until it is re-enabled.

Default

no micro-loop-avoidance

no micro-loop-avoidance

Context

[Tree] (config>router>ospf>segm-rtng micro-loop-avoidance)

Full Context

configure router ospf segment-routing micro-loop-avoidance

Description

This command enables microloop avoidance for SR-OSPF.

When enabled, the feature applies to the following contexts:

- SPFv2 SR-OSPF IPv4 tunnel (node SID)
- IPv4 and IPv6 SR-TE LSPs that use a node SID in their segment list
- IPv4 and IPv6 SR policies that use a node SID in their segment list

The **no** form of this command disables microloop avoidance. When microloop avoidance is disabled, the system forces any running FIB delay to expire immediately and programs the new next hops for all impacted node SIDs. When disabled, microloop avoidance is disabled instantaneously and will be disabled for the next SPF runs. Microloop avoidance remains disabled until it is re-enabled.

Default

no micro-loop-avoidance

Parameters

fib-delay

Specifies the FIB delay before programming new primary next hops. Configure the FIB delay timer to a value that corresponds to the worst-case IGP convergence in a network domain. The default FIB delay timer value corresponds to a network with a nominal convergence time.

Values 1 to 300

Default 15 (equal to 1.5 seconds or 15 units of 100 ms)

[Tree] (config>router>bgp>group min-route-advertisement)

Full Context

configure router bgp group neighbor min-route-advertisement

configure router bgp min-route-advertisement

configure router bgp group min-route-advertisement

Description

This command configures the minimum interval, in seconds, between successive updates of a prefix towards a peer.

This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group), or neighbor level (only applies to specified peer). The most specific value is used.

The **no** form of this command used at the global level reverts to default.

The **no** form of this command used at the group level reverts to the value defined at the global level.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

The **rapid-update** command can be used to override the peer-level **min-route-advertisement** time and applies the minimum setting (0 seconds) to routes belonging to address families specified by the **rapid-update** command; routes of other address families continue to be advertised according to the session-level MRAI setting.

The **rapid-update** and **rapid-withdrawal** commands may result in the routes being sent before the peer-level MRAI timer expires.

Default

min-route-advertisement 30

Parameters

seconds

Specifies the minimum route advertising interval, in seconds, expressed as a decimal integer.

Values 1 to 255

Platforms

7705 SAR Gen 2

18.42 min-threshold-separation

min-threshold-separation

Syntax

min-threshold-separation *size* [**bytes** | **kilobytes**]

no min-threshold-separation

Context

[Tree] (config>card>fp>ingress>network>queue-group>policer-control-override>priority-mbs-thresholds min-threshold-separation)

[Tree] (config>card>fp>ingress>access>queue-group>policer-control-override>priority-mbs-thresholds min-threshold-separation)

Full Context

configure card fp ingress network queue-group policer-control-override priority-mbs-thresholds min-threshold-separation

configure card fp ingress access queue-group policer-control-override priority-mbs-thresholds min-threshold-separation

Description

This command defines the minimum required separation between each in-use discard threshold maintained for each parent policer context associated with the policer-control-policy. The min-thresh-separation value may be overridden on each SAP or sub-profile to which the policy is applied.

The system uses the default or specified min-thresh-separation value in order to determine the minimum separation required between each of the of the parent policer discard thresholds. The system enforces the minimum separation based on the following behavior in two ways. The first is determining the size of the shared-portion for each priority level (when the **mbs-contribution** command's optional fixed keyword is not specified):

- When a parent policer instance's priority level has less than two child policers associated, the shared-portion for the level will be zero.
- When a parent policer instance's priority level has two or more child policers associated, the shared-portion for the level will be equal to the current value of **min-thresh-separation**.

The second function the system uses the **min-thresh-separation** value for is determining the value per priority level for the fair-portion:

- When a parent policer instance's priority level has no child policers associated, the fair-portion for the level will be zero.
- When a parent policer instance's priority level has one child policer associated, the fair-portion will be equal to the maximum of the min-thresh-separation value and the priority level's mbs-contribution value.
- When a parent policer instance's priority level has two or more child policers associated, the fair-portion will be equal to the maximum of the following:
  - **min-thresh-separation** value
  - The priority level's **mbs-contribution** value less **min-thresh-separation** value

When the **mbs-contribution** command's optional fixed keyword is defined for a priority level within the policy, the system will treat the defined **mbs-contribution** value as an explicit definition of the priority level's MBS. While the system will continue to track child policer associations with the parent policer priority levels, the association counters will have no effect. Instead the following rules will be used to determine a fixed priority level's shared-portion and fair-portion:

- If a fixed priority level's **mbs-contribution** value is set to zero, both the shared-portion and fair-portion will be set to zero
- If the **mbs-contribution** value is not set to zero:
  - The shared-portion will be set to the current **min-thresh-separation** value
  - The fair-portion will be set to the maximum of the following:
    - **min-thresh-separation** value
    - **mbs-contribution** value less **min-thresh-separation value**

Each time the **min-thresh-separation** value is modified, the thresholds for all instances of the parent policer created through association with this **policer-control-policy** are reevaluated except for parent policer instances that currently have a min-thresh-separation override.

Determining the Correct Value for the Minimum Threshold Separation Value

The minimum value for **min-thresh-separation** should be set equal to the maximum size packet that will be handled by the parent policer. This ensures that when a lower priority packet is incrementing the bucket, the size of the increment will not cause the bucket's depth to equal or exceed a higher priority threshold. It

also ensures that an unfair packet within a priority level cannot cause the PIR bucket to increment to the discard-all threshold within the priority.

When evaluating maximum packet size, each child policer's per-packet-offset setting should be taken into consideration. If the maximum size packet is 1518 bytes and a per-packet-offset parameter is configured to add 20 bytes per packet, min-thresh-separation should be set to 1538 due to the fact that the parent policer will increment its PIR bucket using the extra 20 bytes.

In most circumstances, a value larger than the maximum packet size is not necessary. Management of priority level aggregate burst tolerance is intended to be implemented using the priority level **mbs-contribution** command. Setting a value larger than the maximum packet size will not adversely affect the policer performance, but it may increase the aggregate burst tolerance for each priority level.

One thing to note is that a priority level's shared-portion of the parent policer's PIR bucket depth is only necessary to provide some separation between a lower priority's discard-all threshold and this priority's discard-unfair threshold. It is expected that the burst tolerance for the unfair packets is relatively minimal since the child policers feeding the parent policer priority level all have some amount of fair burst before entering into an FIR exceed or unfair state. The fair burst amount for a priority level is defined using the mbs-contribution command.

The **no** form of this command returns the policy's **min-thresh-separation** value to the default value. This has no effect on instances of the parent policer where **min-thresh-separation** is overridden unless the override is removed.

Default

no min-thresh-separation

Parameters

size

Specifies that the size parameter is required when executing the **min-thresh-separation** command. It is expressed as an integer and specifies the shared portion in bytes or kilobytes that is selected by the trailing bytes or kilobytes keywords. If both bytes and kilobytes are missing, kilobytes is the assumed value. Setting this value has no effect on parent policer instances where the **min-thresh-separation** value has been overridden. Clearing an override on parent policer instance causes this value to be enforced.

Values 0 to 16777216

bytes | kilobytes

Specifies that the **bytes** keyword is optional and is mutually exclusive with the **kilobytes** keyword. When specified, size is interpreted as specifying the size of **min-thresh-separation** in bytes.

The **kilobytes** keyword is optional and is mutually exclusive with the **bytes** keyword. When specified, size is interpreted as specifying the size of **min-thresh-separation** in kilobytes.

Values bytes or kilobytes

min-thresh-separation

Syntax

min-thresh-separation *size* [**bytes** | **kilobytes**]

Context

[Tree] (config>service>epipe>sap>egress>policy-ctrl-over>mbs-thrshlds min-thresh-separation)

[Tree] (config>service>epipe>sap>ingress>policy-ctrl-over>mbs-thrshlds min-thresh-separation)

Full Context

configure service epipe sap egress policer-control-override priority-mbs-thresholds min-thresh-separation

configure service epipe sap ingress policer-control-override priority-mbs-thresholds min-thresh-separation

Description

This command, within the SAP ingress and egress contexts, is used to override the root arbiter's parent policer min-thresh-separation parameter that is defined within the policer-control-policy applied to the SAP.

When the override is defined, modifications to the policer-control-policy min-thresh-separation parameter have no effect on the SAP's parent policer until the override is removed using the no min-thresh-separation command within the SAP.

The no form of this command removes the override and allows the min-thresh-separation setting from the policer-control-policy to control the root arbiter's parent policer's minimum discard threshold separation size.

Default

no min-thresh-separation

Parameters

size

The minimum discard threshold separation override value.

Values 1 to 16777216 | default

bytes

Signifies that *size* is expressed in bytes. The bytes and kilobytes keywords are mutually exclusive and optional. The default is kilobytes.

kilobytes

Signifies that *size* is expressed in kilobytes. The bytes and kilobytes keywords are mutually exclusive and optional. The default is kilobytes.

Context

[Tree] (config>qos>plcr-ctrl-plcy>root>priority-mbs-thresholds min-thresh-separation)

Full Context

configure qos policer-control-policy root priority-mbs-thresholds min-thresh-separation

Description

The **min-thresh-separation** command defines the minimum required separation between each in-use discard threshold maintained for each parent policer context associated with the policer-control-policy. The min-thresh-separation value may be overridden on each SAP or sub-profile to which the policy is applied.

The system uses the default or specified **min-thresh-separation** value in order to determine the minimum separation required between each of the of the parent policer discard thresholds. The system enforces the minimum separation based on the following behavior in two ways. The first is determining the size of the shared-portion for each priority level (when the **mbs-contribution** command's optional fixed keyword is not specified):

- When a parent policer instance's priority level has less than two child policers associated, the shared-portion for the level will be zero.
- When a parent policer instance's priority level has two or more child policers associated, the shared-portion for the level will be equal to the current value of **min-thresh-separation**.

The second function the system uses the **min-thresh-separation** value for is determining the value per priority level for the fair-portion:

- When a parent policer instance's priority level has no child policers associated, the fair-portion for the level will be zero.
- When a parent policer instance's priority level has one child policer associated, the fair-portion will be equal to the maximum of the min-thresh-separation value and the priority level's mbs-contribution value.
- When a parent policer instance's priority level has two or more child policers associated, the fair-portion will be equal to the maximum of the following:
  - **min-thresh-separation** value
  - **mbs-contribution** value less **min-thresh-separation** value

When the **mbs-contribution** command's optional fixed keyword is defined for a priority level within the policy, the system will treat the defined **mbs-contribution** value as an explicit definition of the priority level's MBS. While the system will continue to track child policer associations with the parent policer priority levels, the association counters will have no effect. Instead, the following rules will be used to determine a fixed priority level's shared-portion and fair-portion:

- If a fixed priority level's **mbs-contribution** value is set to zero, both the shared-portion and fair-portion will be set to zero

- If the **mbs-contribution** value is not set to zero:
  - The shared-portion will be set to the current **min-thresh-separation** value
  - The fair-portion will be set to the maximum of the following:

    min-thresh-separation value

    mbs-contribution value less **min-thresh-separation value**

Each time the **min-thresh-separation** value is modified, the thresholds for all instances of the parent policer created through association with this **policer-control-policy** are reevaluated.

Determining the Correct Value for the Minimum Threshold Separation Value

The minimum value for **min-thresh-separation** should be set equal to the maximum size packet that will be handled by the parent policer. This ensures that when a lower priority packet is incrementing the bucket, the size of the increment will not cause the bucket's depth to equal or exceed a higher priority threshold. It also ensures that an unfair packet within a priority level cannot cause the PIR bucket to increment to the discard-all threshold within the priority.

When evaluating maximum packet size, each child policer's per-packet-offset setting should be taken into consideration. If the maximum size packet is 1518 bytes and a per-packet-offset parameter is configured to add 20 bytes per packet, min-thresh-separation should be set to 1538 due to the fact that the parent policer will increment its PIR bucket using the extra 20 bytes.

In most circumstances, a value larger than the maximum packet size is not necessary. Management of priority level aggregate burst tolerance is intended to be implemented using the priority level **mbs-contribution** command. Setting a value larger than the maximum packet size will not adversely affect the policer performance, but it may increase the aggregate burst tolerance for each priority level.

Note:
A priority level's shared-portion of the parent policer's PIR bucket depth is only necessary to provide some separation between a lower priority's discard-all threshold and this priority's discard-unfair threshold. It is expected that the burst tolerance for the unfair packets is relatively minimal since the child policers feeding the parent policer priority level all have some amount of fair burst before entering into an FIR exceed or unfair state. The fair burst amount for a priority level is defined using the mbs-contribution command.

The **no** form of this command returns the policy's **min-thresh-separation** value to the default value.

Parameters

size

The *size* parameter is required when executing the **min-thresh-separation** command. It is expressed as an integer. Setting this value has no effect on parent policer instances where the **min-thresh-separation** value has been overridden.

Values 0 to 16777216 or **default**

Default 1536

bytes | kilobytes

This parameter indicates whether the size is expressed in bytes or kilobytes.

Default **kilobytes**

18.43 min-wait-to-advertise

min-wait-to-advertise

Syntax

min-wait-to-advertise *seconds*

no min-wait-to-advertise

Context

[Tree] (config>service>vprn>bgp>convergence min-wait-to-advertise)

Full Context

configure service vprn bgp convergence min-wait-to-advertise

Description

This command configures the minimum amount of time that BGP waits, after the first session establishment following a restart of the BGP instance, until it can start advertising IPv4-unicast and IPv6-unicast routes to its BGP peers, to allow time for re-convergence.

The time limit configured by this command should allow sufficient time for all important peers to re-establish their sessions with the restarting router.

The **no** form of this command implements the default time limit of 0 seconds, which disables all forms of delayed route advertisement. In other words, it causes IPv4-unicast and IPv6-unicast routes to be re-advertised as soon as possible after BGP instance restart.

Default

no min-wait-to-advertise

Parameters

seconds

Specifies the minimum amount of time, in seconds, that BGP waits until IPv4-unicast and IPv6-unicast routes can be advertised to peers.

Values 0 to 3600

Platforms

7705 SAR Gen 2

Full Context

configure service vprn dhcp6 local-dhcp-server pool prefix thresholds minimum-free minimum

configure router dhcp6 local-dhcp-server pool prefix thresholds minimum-free minimum

Description

This command configures a percentage-based or number-based threshold which represents the minimal available percentage or number of the prefix with a configured length in the provisioned prefix. The system sends out a warning if the actual percentage or number is lower than the configured threshold.

For example:

```
prefix 2001:0:0:ffe0::/50 pd wan-host create
   thresholds
       minimum-free prefix-length 64
           minimum number 3
```

With the above configuration, the system sends a warning when the number of available /64 in prefix 2001:0:0:ffe0::/50 is less than 3.

The **no** form of this command removes the command parameters from the configuration.

Parameters

percent

Specifies the percentage of used prefixes with the minimum free threshold length in the pool compared to the number of provisioned prefixes.

Values 0 to 100

number

Specifies the number of prefixes.

Values 0 to 4294967295

Context

[Tree] (config>service>vprn>dhcp6>server>pool>thresholds minimum-free)

[Tree] (config>router>dhcp6>server>pool>thresholds minimum-free)

Full Context

configure service vprn dhcp6 local-dhcp-server pool thresholds minimum-free

configure router dhcp6 local-dhcp-server pool thresholds minimum-free

Description

This command creates a threshold for a given prefix length on the pool level. Up to 128 thresholds could be created. For example, with **minimum-free prefix-length 64**, then the usage of /64 prefix in the pool is counted.

There are two types of thresholds that could be defined at the pool level:

- Depleted — The system sends out a warning when the prefix with the configured length is no long available in the pool.
- Minimum free — A percentage-based threshold which represents the minimal available percentage of prefix with the configured length in the pool. The system will send out warning if the actual percentage is lower than the configured percentage.

Configuring this command also enables the system stats collection for **configure prefix length**, which could be displayed with the **show router** *router-id* **dhcp6 local-dhcp-server** *dhcp6-server-name* **pool-threshold-stats** command.

The **no** form of this command removes the prefix-length from the configuration.

Parameters

prefix-length

Specifies the IPv6 prefix length.

Values 1 to 128

Platforms

7705 SAR Gen 2

18.50 minimum-length

minimum-length

Syntax

minimum-length *length*

no minimum-length

18.53 mirror-dest

mirror-dest

Syntax

mirror-dest *service-id* [**create**] [**type** *mirror-type*] [**name** *name*]

no mirror-dest *service-id*

Context

[Tree] (config>mirror mirror-dest)

Full Context

configure mirror mirror-dest

Description

This command creates a context to set up a service that is intended for packet mirroring. It is configured as a service to allow mirrored packets to be directed locally (within the same router) or remotely, over the core of the network and have a far-end decode mirror encapsulation.

The mirror destination service is comprised of destination parameters that define where the mirrored packets are to be sent. It also specifies whether the defined *service-id* will receive mirrored packets from far-end router over the network core.

The mirror destination service IDs are persistent between boots of the router and are included in the configuration saves. The local sources of mirrored packets for the service ID are defined within the **debug mirror mirror-source** command that references the same *service-id*. Up to 255 mirror destination service IDs can be created within a single system.

The **mirror-dest** command creates or edits a service ID for mirroring purposes. If the *service-id* does not exist within the context of all defined services, the mirror destination service is created and the context of the CLI is changed to that service ID. If the *service-id* exists within the context of defined mirror destination services, the CLI context is changed for editing parameters on that service ID. If the *service-id* exists within the context of another service type, an error message is returned and CLI context is not changed from the current context.

The **no** form of this command removes a mirror destination from the system. The mirror source associations with the mirror destination *service-id* do not need to be removed or shutdown first. The mirror destination *service-id* must be shutdown before the service ID can be removed. When the service ID is removed, all **mirror-source** commands that have the service ID defined will also be removed from the system.

Parameters

service-id

The service identification identifies the service in the service domain. This ID is unique to this service and cannot be used by any other service, regardless of service type. The same service ID must be configured on every router that this particular service is defined on.

If particular a service ID already exists for a service, then the same value cannot be used to create a mirror destination service ID with the same value. For example:

If an Epipe service ID **11** exists, then a mirror destination service ID **11** cannot be created. If a VPLS service ID **12** exists, then a mirror destination service ID **12** cannot be created.

If an IES service ID **13** exists, then a mirror destination service ID **13** cannot be created.

Values

service-id:	1 to 2147483647
svc-name:	64 characters maximum

create

Keyword used to create a mirror destination service.

mirror-type

The type describes the encapsulation supported by the mirror service.

Values ether, ip-only

name

Configures an optional service name identifier, up to 64 characters, to a given service. This service name can then be used in configuration references, display, and show commands throughout the system. A defined service name can help the service provider or administrator to identify and manage services within the SR OS platforms.

To create a service, you must assign a service ID; however, after it is created, either the service ID or the service name can be used to identify and reference a service.

If a name is not specified at creation time, then SR OS assigns a string version of the *service-id* as the name.

Service names may not begin with an integer (0 to 9).

Platforms

7705 SAR Gen 2

18.54 mirror-source

mirror-source

Syntax

[**no**] **mirror-source** *service-id*

Context

[Tree] (config>mirror mirror-source)

Full Context

configure mirror mirror-source

Description

This command configures mirror source parameters for a mirrored service.

The **mirror-source** command is used to enable mirroring of packets specified by the association of the **mirror-source** to sources of packets defined within the context of the *mirror-dest-service-id*. The mirror destination service must already exist within the system.

A mirrored packet cannot be mirrored to multiple destinations. If a packet matches multiple mirror source entries (for example, a SAP on one **mirror-source** and a port on another **mirror-source**), then the packet is mirrored to a single *mirror-dest-service-id* based on the following precedence:

1. Filter entry
2. SAP
3. Physical port

The precedence is structured so the most specific match criteria has precedence over a less specific match. For example, if a **mirror-source** defines a port and a SAP on that port, then a packet arriving on

the SAP will be mirrored using the SAP mirror (and not mirrored using the Port mirror) because the SAP is more specific than the port.

The **no** form of this command deletes all related source commands within the context of the **mirror-source** *service-id*. The command does not remove the service ID from the system.

Parameters

service-id

Specifies the service identification identifies the service in the service domain. This ID is unique to this service and cannot be used by any other service, regardless of service type. The same service ID must be configured on every router that this particular service is defined on.

Values

service-id: 1 to 2147483647

svc-name: 64 characters maximum

Platforms

7705 SAR Gen 2

mirror-source

Syntax

[**no**] **mirror-source** *service-id*

Context

[Tree] (debug mirror-source)

Full Context

debug mirror-source

Description

This command configures mirror source parameters for a mirrored service.

The **mirror-source** command is used to enable mirroring of packets specified by the association of the **mirror-source** to sources of packets defined within the context of the *mirror-dest-service-id*. The mirror destination service must already exist within the system.

A mirrored packet cannot be mirrored to multiple destinations. If a packet matches multiple mirror source entries (for example, a SAP on one **mirror-source** and a port on another **mirror-source**), then the packet is mirrored to a single *mirror-dest-service-id* based on the following precedence:

1. Filter entry
2. SAP
3. Physical port

The precedence is structured so the most specific match criteria has precedence over a less specific match. For example, if a **mirror-source** defines a port and a SAP on that port, then a packet arriving on

the SAP will be mirrored using the SAP mirror (and not mirrored using the Port mirror) because the SAP is more specific than the port.

The **mirror-source** configuration is not saved when a configuration is saved. A **mirror-source** manually configured within an ASCII configuration file will not be preserved if that file is overwritten by a **save** command. Define the **mirror-source** within a file associated with a **config exec** command to make a **mirror-source** persistent between system reboots.

By default, all mirror destination service IDs have a **mirror-source** associated with them. The **mirror-source** is not technically created with this command. Instead the service ID provides a contextual node for storing the current mirroring sources for the associated mirror destination service ID. The **mirror-source** is created for the mirror service when the operator enters the **debug>mirror-source** *svcId* for the first time. The **mirror-source** is also automatically removed when the mirror destination service ID is deleted from the system.

The **no** form of this command deletes all related source commands within the context of the **mirror-source** *service-id*. The command does not remove the service ID from the system.

Parameters

service-id

Specifies the mirror destination service ID for which match criteria will be defined. The *service-id* must already exist within the system.

Values *service-id*: 1 to 2147483647

svc-name: 64 characters maximum

mixed-lsp-mode

Syntax

[**no**] **mixed-lsp-mode**

Context

[Tree] (config>service>sdp mixed-lsp-mode)

Full Context

configure service sdp mixed-lsp-mode

Description

This command enables the use by an SDP of the mixed-LSP mode of operation. This command indicates to the service manager that it must allow a primary LSP type and a backup LSP type in the same SDP configuration. For example, the **lsp** and **ldp** commands are allowed concurrently in the SDP configuration. The user can configure one or two types of LSPs under the same SDP. Without this command, these commands are mutually exclusive.

The user can configure an RSVP LSP as a primary LSP type with an LDP LSP as a backup type. The user can also configure an RFC 8277 BGP LSP as a backup LSP type.

If the user configures an LDP LSP as a primary LSP type, then the backup LSP type must be an RFC 8277 BGP labeled route.

At any given time, the service manager programs only one type of LSP in the linecard that will activate it to forward service packets according to the following priority order:

- RSVP LSP type. Up to 16 RSVP LSPs can be entered by the user and programmed by the service manager in ingress linecard to load balance service packets. This is the highest priority LSP type.
- LDP LSP type. One LDP FEC programmed by the service manager but the ingress card can use up to 16 LDP ECMP paths for the FEC to load balance service packets when ECMP is enabled on the node.
- BGP LSP type. One RFC 8277-labeled BGP prefix programmed by the service manager. The ingress card can use more than one next-hop for the prefix.

In the case of the RSVP/LDP SDP, the service manager will program the NHLFE(s) for the active LSP type preferring the RSVP LSP type over the LDP LSP type. If no RSVP LSP is configured or all configured RSVP LSPs go down, the service manager will re-program the card with the LDP LSP if available. If not, the SDP goes operationally down.

When a higher priority type LSP becomes available, the service manager reverts back to this LSP at the expiry of the sdp-revert-time timer or the failure of the currently active LSP, whichever comes first. The service manager then re-programs the card accordingly. If the infinite value is configured, then the SDP reverts to the highest priority type LSP only if the currently active LSP failed.

Note:
LDP uses a tunnel down damp timer which is set to three seconds by default. When the LDP LSP fails, the SDP will revert to the RSVP LSP type after the expiry of this timer. For an immediate

switchover, this timer must be set to zero. Use the **config>router>ldp>tunnel-down-damp-time** command.

If the user changes the value of the sdp-revert-time timer, it will take effect only at the next use of the timer. Any timer which is outstanding at the time of the change will be restarted with the new value.

If class based forwarding is enabled for this SDP, the forwarding of the packets over the RSVP LSPs will be based on the FC of the packet as in current implementation. When the SDP activates the LDP LSP type, then packets are forwarded over the LDP ECMP paths using the regular hash routine.

In the case of the LDP/BGP SDP, the service manager will prefer the LDP LSP type over the BGP LSP type. The service manager will re-program the card with the BGP LSP if available otherwise it brings down the SDP operationally.

Also note the following difference in behavior of the LDP/BGP SDP compared to that of an RSVP/LDP SDP. For a given /32 prefix, only a single route will exist in the routing table: the IGP route or the BGP route. Thus, either the LDP FEC or the BGP label route is active at any given time. The impact of this is that the tunnel table needs to be re-programmed each time a route is deactivated and the other is activated. Furthermore, the SDP revert-time cannot be used since there is no situation where both LSP types are active for the same /32 prefix.

The **no** form of this command disables the mixed-LSP mode of operation. The user first has to remove one of the LSP types from the SDP configuration or the command will fail.

configure service vprn interface urpf-check mode

configure service ies interface urpf-check mode

Description

This command specifies the mode of unicast RPF check.

The **no** form of this command reverts to the default (strict) mode.

Default

mode strict

Parameters

strict

When specified, uRPF checks whether incoming packet has a source address that matches a prefix in the routing table, and whether the interface expects to receive a packet with this source address prefix.

loose

In **loose** mode, uRPF checks whether incoming packet has source address with a corresponding prefix in the routing table. However, the loose mode does not check whether

the interface expects to receive a packet with a specific source address prefix. This object is valid only when **urpf-check** is enabled.

strict-no-ecmp

When a packet is received on an interface in this mode and the SA matches an ECMP route the packet is dropped by uRPF.

mode {**access** | **network** | **hybrid**}

no mode

Context

[Tree] (config>lag mode)

[Tree] (config>port>ethernet mode)

Full Context

configure lag mode

configure port ethernet mode

Description

This command configures an Ethernet port, TDM channel, or SONET/SDH path (sub-port) for **access**, **network**, or **hybrid** mode operation.

An **access** port or channel is used for customer facing traffic on which services are configured. A Service Access Point (SAP) can only be configured on an access port or channel. When a port is configured for access mode, the appropriate **encap-type** must be specified to distinguish the services on the port or SONET path. Once an Ethernet port, a TDM channel or a SONET path has been configured for access mode, multiple services can be configured on the Ethernet port, a TDM channel or SONET path.

A network port or channel participates in the service provider transport or infrastructure network when a network mode is selected. When the network option is configured, the encap-type cannot be configured for the port/channel.

When network mode is selected on a SONET/SDH path, the appropriate control protocols are activated when the need arises. For example, configuring an IP interface on the SONET path activates IPCP while the removal of the IP interface causes the IPCP to be removed. The same applies for MPLS, MPLSCP, and OSICP. When configuring a SONET/SDH port, the mode command must be entered in the channel context or an error message is generated.

A hybrid Ethernet port allows the combination of network and access modes of operation on a per-VLAN basis and must be configured as either dot1q or QinQ encapsulation.

When the hybrid port is configured to the dot1q encapsulation, the user configures a SAP inside a service simply by providing the SAP ID which must include the port-id value of the hybrid mode port and an unused VLAN tag value. The format is <*port-id*>:*qtag1*. A SAP of format <*port-id*>:* also supported.

The user configures a network IP interface under **config>router>if>port** by providing the port name which consists of the port-id of the hybrid mode port and an unused VLAN tag value. The format is <*port-id*>:*qtag1*. The user must explicitly enter a valid value for qtag1. The <*port-id*>:* value is not supported on a network IP interface. The 4096 VLAN tag space on the port is shared among VLAN SAPs and VLAN network IP interfaces.

When the hybrid port is configured to QinQ encapsulation, the user configures a SAP inside a service simply by providing the SAP ID which must include the port-id value of the hybrid mode port and the outer and inner VLAN tag values. The format is <port-id>:qtag1.qtag2. A SAP of format <*port-id*>: *qtag1*.* is also supported. The outer VLAN tag value must not have been used to create an IP network interface on this port. In addition, the qtag1.qtag2 value combination must not have been used by another SAP on this port.

The user configures a network IP interface under **config>router>if>port** by providing the port name which consists of the port-id of the hybrid mode port and a VLAN tag value. The format is <*port-id*>:*qtag1*.*. An outer VLAN tag qtag2 of * creates an IP network interface. In addition, the qtag1.qtag2 value combination must not have been used on another SAP or IP network interface on this port.

The **no** form of this command restores the default.

Default

mode network — For Ethernet ports

mode access — For TDM channel or SONET paths

Parameters

access

Configures the Ethernet port, TDM channel or SONET path as service access.

network

Configures the Ethernet port, TDM channel or SONET path for transport network use.

hybrid

Configures the Ethernet port for hybrid use.

Platforms

configure router interface ipv6 urpf-check mode

configure router interface urpf-check mode

Description

This command specifies the mode of unicast RPF check.

The **no** form of this command reverts to the default (strict) mode.

Default

mode strict

Parameters

strict

When specified, uRPF checks whether incoming packet has a source address that matches a prefix in the routing table, and whether the interface expects to receive a packet with this source address prefix.

loose

In **loose** mode, uRPF checks whether incoming packet has source address with a corresponding prefix in the routing table. However, the loose mode does not check whether

the interface expects to receive a packet with a specific source address prefix. This object is valid only when **urpf-check** is enabled.

strict-no-ecmp

When a packet is received on an interface in this mode and the SA matches an ECMP route the packet is dropped by uRPF.

Platforms

7705 SAR Gen 2

mode

Syntax

mode {**ecmp-protected** | **linear**}

no mode

Context

[Tree] (config>router>segment-routing>maintenance-policy mode)

Full Context

configure router segment-routing maintenance-policy mode

Description

This command specifies the data path programming and protection mechanism for SR policy candidate paths to which the maintenance policy is applied.

In both the **linear** mode and **ecmp-protected** modes, if two or more candidate paths of the same {headend, color, endpoint} and also have the same mode, then the best preference path is treated as the primary while the next best preference path is the standby. If a third path is present in the linear mode, then this is treated as a tertiary and also programmed in the IOM.

If the currently active path goes unavailable due to S-BFD, the system failovers to the next best preference available candidate path. If S-BFD is down on all segment lists of all programmed candidate paths of an SR Policy, then the SR Policy is marked as down in TTM.

If the default mode is specified, the router only programs the segment lists of the best preference paths in the IOM.

The **no** form of this command removes the configured mode.

Default

no mode

Parameters

ecmp-protected

Specifies only the top two routes (paths) are programmed in the IOM. Up to 32 segment lists can be programmed for each path.

linear

Specifies the top three routes are programmed in the IOM. Only one segment list is allowed per path.

The **no** form of this command removes the association from the configuration.

Default

no monitor-oper-group

Parameters

name

Specifies a character string, up to 32 ASCII characters, identifying the group instance.

Platforms

7705 SAR Gen 2

monitor-oper-group

Syntax

monitor-oper-group *group-name* **family** {**ipv4** | **ipv6**} **add** [*1..4294967295*]

monitor-oper-group *group-name* **family** {**ipv4** | **ipv6**} **set** [*1..4294967295*]

monitor-oper-group *group-name* **family** {**ipv4** | **ipv6**} **subtract** [*1..4294967295*]

no monitor-oper-group [**family** {**ipv4** | **ipv6**}]

Context

[Tree] (config>service>vprn>pim>if monitor-oper-group)

Full Context

configure service vprn pim interface monitor-oper-group

Description

This command configures PIM to monitor the state of an operational group to provide a redundancy mechanism. PIM monitors the operational group and changes its DR priority to the specified value when the status of the operational group is up. This enables the router to become the PIM DR only when the operational group is up. If the operational group status changes to down, PIM changes its DR priority to the default or the value configured with **priority** under **config**>**service**>**vprn**>**pim**>**if**. The **oper-group** *group-name* must already be configured under the **config**>**service** context before its name is referenced in this command. Two operational groups are supported per PIM interface.

The **no** form of this command removes the operational group from the configuration.

Parameters

group-name

Specifies the operational group identifier up to 32 characters in length.

family

Specifies the address family.

ipv4

Specifies the IPv4 designated router priority.

ipv6

Specifies the IPv6 designated router priority.

add

Specifies that the value is to be added to the existing priority to become the designated router.

subtract

Specifies that the value is to be subtracted from the existing priority to become the designated router.

set

Specifies the priority to become the designated router.

value

Specifies the priority modifier expressed as a decimal integer.

Values 1 to 4294967295

Platforms

7705 SAR Gen 2

monitor-oper-group

Syntax

monitor-oper-group *group-name* **family** {**ipv4** | **ipv6**} **add** [*value*]

monitor-oper-group *group-name* **family** {**ipv4** | **ipv6**} **set** [*value*]

monitor-oper-group *group-name* **family** {**ipv4** | **ipv6**} **subtract** [*value*]

no monitor-oper-group [**family** {**ipv4** | **ipv6**}]

Context

[Tree] (config>router>pim>if monitor-oper-group)

Full Context

configure router pim interface monitor-oper-group

Description

This command configures PIM to monitor the state of an operational group to provide a redundancy mechanism. PIM monitors the operational group and changes its DR priority to the specified value when the status of the operational group is up. This enables the router to become the PIM DR only when the operational group is up. If the operational group status changes to down, PIM changes its DR priority to the default or the value configured with **priority** under **config**>**router**>**pim**>**if**. The **oper-group** *group-name* must already be configured under the **config**>**service** context before its name is referenced in this command. Two operational groups are supported per PIM interface.

The **no** form of this command removes the operational group from the configuration.

Parameters

group-name

Specifies the operational group identifier, up to 32 characters.

family

Specifies the address family.

ipv4

Specifies the IPv4 designated router priority.

ipv6

Specifies the IPv6 designated router priority.

add

Specifies that the value is to be added to the existing priority to become the designated router.

subtract

Specifies that the value is to be subtracted from the existing priority to become the designated router.

set

Specifies the priority to become the designated router.

value

Specifies the priority modifier expressed as a decimal integer.

monitor-oper-group

Syntax

monitor-oper-group *group-name*

no monitor-oper-group

Context

[Tree] (config>port monitor-oper-group)

Full Context

configure port monitor-oper-group

Description

This command configures the operational group to monitor the operational group state. The state of the operational group affects the state of this port. When the operational group is inactive, the state of the port goes down and powers off the port to signal the CE that the connected port is not available.

Default

no monitor-oper-group

Parameters

group-name

Specifies operational group name to monitor, up to 32 characters.

Platforms

7705 SAR Gen 2

18.63 month

month

Syntax

month {*month-number* [*..month-number*] | *month-name* [*..month-name*] | **all**}

no month

Context

[Tree] (config>system>cron>sched month)

Full Context

configure system cron schedule month

Description

This command specifies the month when the event should be executed. Multiple months can be specified. When multiple months are configured, each of them will cause the schedule to trigger. If a month is configured without configuring the month, weekday, day-of-month, and minute, the event will not execute.

The **no** form of this command removes the specified month from the configuration.

Default

no month

Parameters

month-number

Specifies a month number.

Values 1 to 12 (maximum 12 month-numbers)

month-name

Specifies a month by name.

Values january, february, march, april, may, june, july, august, september, october, november, december (maximum 12 month names)

all

Specifies all months.

18.65 motd

motd

Syntax

motd {**url** *url-prefix*: *source-url* | **text** *motd-text-string*}

no motd

Context

[Tree] (config>system>login-control motd)

Full Context

configure system login-control motd

Description

This command creates the message of the day displayed after a successful console login. Only one message can be configured.

The **no** form of this command removes the message.

Default

no motd

Parameters

url *url-prefix*: *source-url*

When the message of the day is present as a text file, provide both url-prefix and the source-url of the file containing the message of the day. The URL prefix can be local or remote.

text *motd-text-string*

Specifies the text of the message of the day. The *motd-text-string* must be enclosed in double quotes. Multiple text strings are not appended to one another.

Some special characters can be used to format the message text. The \n character can be used to create multi-line messages. A \n in the message moves to the beginning of the next line by sending ASCII/UTF-8 chars 0xA (LF) and 0xD (CR) to the client terminal. An \r in the message sends the ASCII/UTF-8 char 0xD (CR) to the client terminal.

7705 SAR Gen 2

18.66 move

move

Syntax

move *old-file-url new-file-url* [**force**] [**no-redirect**] [**client-tls-profile** *profile*] [**proxy** *proxy-url*]

Context

[Tree] (file move)

Full Context

file move

Description

This command moves a local file, system file, or a directory. If the target already exists, the command fails and an error message displays.

The following prompt appears if the destination file already exists:

"Overwrite destination file (y/n)?”

Parameters

old-file-url

Specifies the file or directory to be moved.

Values		
	local-url	[*cflash-id*/][*file-path*] up to 200 characters, including cflash-id directory length up to 99 each
	remote-url	[{ftp:// | tftp:// | http:// | https://}*login*:*pswd*@*remote-locn*/][*file-path*]
		up to 247 characters
		directory length up to 99 characters each
	remote-locn	[hostname | ipv4-address | [ipv6-address]]
	ipv4-address	*a.b.c.d*
	ipv6-address	*x:x:x:x:x:x:x:x*[-*interface*]
		x:x:x:x:x:x:d.d.d.d[-*interface*]
		x - [0 to FFFF]H
		d - [0 to 255]D
		interface - up to 32 characters, for link local addresses 255
	cflash-id	cf1:, cf1-A:, cf1-B:, cf2:, cf2-A:, cf2-B:, cf3:, cf3-A:, cf3-B:

new-file-url

Specifies the new destination to place the old-file-url.

Values		
	local-url	[*cflash-id*/][*file-path*] up to 200 characters, including cflash-id directory length up to 99 each
	remote-url	[{ftp:// | tftp://}*login*:*pswd*@*remote-locn*/][*file-path*]
		up to 247 characters
		directory length up to 99 characters each

remote-locn	[hostname | ipv4-address | [ipv6-address]]
ipv4-address	*a.b.c.d*
ipv6-address	*x:x:x:x:x:x:x:x*[-*interface*]
	x:x:x:x:x:x:d.d.d.d[-*interface*]
	x - [0 to FFFF]H
	d - [0 to 255]D
	interface - up to 32 characters, for link local addresses 255
cflash-id	cf1:, cf1-A:, cf1-B:, cf2:, cf2-A:, cf2-B:, cf3:, cf3-A:, cf3-B:

force

Forces an immediate move of the specified file(s).

The **file move force** command moves the specified file(s) without displaying a user prompt message. This command also automatically accepts HTTP redirects unless overridden by the **no-redirect** parameter.

profile

Specifies the TLS client profile configured under **config**>**system**>**security**>**tls**>**client-tls-profile** to use.

proxy-url

Specifies the URL of an HTTP proxy. For example, http://proxy.mydomain.com:8000. This URL must be an HTTP URL and not an HTTPS URL.

no-redirect

Specifies to automatically refuse any HTTP redirects without prompting the user.

Platforms

7705 SAR Gen 2

18.67 move-frequency

move-frequency

Syntax

move-frequency *frequency*

no move-frequency

Context

[Tree] (config>service>vpls>mac-move move-frequency)

[Tree] (config>service>template>vpls-template>mac-move move-frequency)

Full Context

configure service vpls mac-move move-frequency

configure service template vpls-template mac-move move-frequency

Description

This command indicates the maximum rate at which MACs can be relearned in the VPLS service before the SAP where the moving MAC was last seen is automatically disabled to protect the system against undetected loops or duplicate MACs. The rate (relearns per second) is measured in a 5-second window.

The **no** form of this command reverts to the default value.

Default

2 (relearns per second, when mac-move is enabled). For example, the value 2 requires 10 MAC relearns in a 5-second period for the MAC to be considered duplicate.

Parameters

frequency

Specifies the rate, in relearns per second.

Values 1 to 10

Platforms

7705 SAR Gen 2

18.68 mp-bgp-keep

mp-bgp-keep

Syntax

[**no**] **mp-bgp-keep**

Context

[Tree] (config>router>bgp mp-bgp-keep)

Full Context

configure router bgp mp-bgp-keep

Description

As a result of enabling this command, route refresh messages are no longer needed, or issued when VPN route policy changes are made; RIB-IN will retain all MP-BGP routes.

The **no** form of this command is used to disable this feature.

Default

no mp-bgp-keep

Platforms

7705 SAR Gen 2

18.69 mpls

mpls

Syntax

mpls [**bgp** *bgp*] [**endpoint** *endpoint-name*]

no mpls [**bgp** *bgp*]

Context

[Tree] (config>service>vprn>bgp-evpn mpls)

[Tree] (config>service>epipe>bgp-evpn mpls)

[Tree] (config>service>vpls>bgp-evpn mpls)

Full Context

configure service vprn bgp-evpn mpls

configure service epipe bgp-evpn mpls

configure service vpls bgp-evpn mpls

Description

Commands in this context configure the BGP EVPN MPLS parameters. In VPLS, either instance BGP 1 or BGP 2 can be configured, but not both simultaneously in the same service. Epipe and VPRN services only support instance 1. If the **bgp** *bgp* parameter is not specified, the instance is set to 1.

The **endpoint** option is only supported for Epipe services. When configured, the same endpoint name can be configured for the **bgp-evpn>mpls** context and an additional spoke SDP. An EVPN MPLS destination always has higher preference than a spoke SDP.

The **no** form of this command removes the MPLS instance from the service.

Parameters

bgp

Indicates the BGP instance identifier.

Values 1, 2

endpoint-name

Specifies the endpoint name for Epipe services, up to 32 characters.

Platforms

7705 SAR Gen 2

mpls

Syntax

mpls

Context

[Tree] (config>service>vprn>bgp-ipvpn mpls)

Full Context

configure service vprn bgp-ipvpn mpls

Description

Commands in this context configure the BGP IPVPN parameters.

Platforms

7705 SAR Gen 2

mpls

Syntax

[**no**] **mpls**

Context

[Tree] (config>router mpls)

Full Context

configure router mpls

Description

Commands in this context configure MPLS parameters. MPLS is not enabled by default and must be explicitly enabled (**no shutdown**).

The **no** form of this command deletes this MPLS protocol instance and removes all configuration parameters for this MPLS instance.

You must remove all SDP bindings and use the **shutdown** command to administratively disable the MPLS instance before deleting it.

Platforms

7705 SAR Gen 2

mpls

Syntax

mpls [**lsp** *lsp-name*] [**sender** *source-address*] [**endpoint** *endpoint-address*] [**tunnel-id** *tunnel-id*] [**lsp-id** *lsp-id*]

no mpls

Context

[Tree] (debug>router mpls)

Full Context

debug router mpls

Description

This command enables and configures debugging for MPLS.

Parameters

lsp *lsp-name*

Specifies the LSP name up to 64 characters in length.

sender *source-address*

Specifies the IP address of the sender.

endpoint *endpoint-address*

Specifies the far-end IP address.

tunnel-id *tunnel-id*

Specifies the MPLS SDP ID.

Values 0 to 4294967295

lsp-id *lsp-id*

Specifies the LSP ID.

Values 1 to 65535

Platforms

7705 SAR Gen 2

mpls

Syntax

[**no**] **mpls**

Context

[Tree] (config>oam-pm>session>ip>tunnel mpls)

Full Context

configure oam-pm session ip tunnel mpls

Description

Commands in this context configure the MPLS packet tunneling options for the session. Configure the **tunnel oam-pm session ip router-instance** to Base to configure commands in the MPLS context. When entering a context under MPLS, the system removes any previous configuration of any sibling context. You can only configure one of the contexts for each OAM-PM session.

The **no** form of this command deletes the **mpls** context and all configurations under it.

Platforms

7705 SAR Gen 2

18.70 mpls-echo-request-downstream-map

mpls-echo-request-downstream-map

Syntax

mpls-echo-request-downstream-map {**dsmap** | **ddmap**}

Context

[Tree] (config>test-oam mpls-echo-request-downstream-map)

Full Context

configure test-oam mpls-echo-request-downstream-map

Description

This command specifies which format of the downstream mapping TLV to use in all LSP trace packets and LDP tree trace packets originated on this node. The Downstream Mapping (DSMAP) TLV is the original format in RFC 4379 (obsoleted by RFC 8029) and is the default value. The new Downstream Detailed Mapping (DDMAP) TLV is the new enhanced format specified in RFC 6424 and RFC 8029.

This command applies to LSP trace of an RSVP P2P LSP, a MPLS-TP LSP, or LDP unicast FEC, and to LDP tree trace of a unicast LDP FEC. It does not apply to LSP trace of an RSVP P2MP LSP which always uses the DDMAP TLV.

The global DSMAP/DDMAP setting impacts the behavior of both OAM LSP trace packets and SAA test packets of type **lsp-trace** and is used by the sender node when one of the following events occurs:

1. An SAA test of type **lsp-trace** is created (not modified) and no value is specified for the per-test **downstream-map-tlv** {**dsmap** | **ddmap** | **none**} option. In this case, the SAA test **downstream-map-tlv** value defaults to the global **mpls-echo-request-downstream-map** value.
2. An OAM test of type **lsp-trace** test is executed and no value is specified for the per-test **downstream-map-tlv** {**dsmap** | **ddmap** | **none**} option. In this case, the OAM test **downstream-map-tlv** value defaults to the global **mpls-echo-request-downstream-map** value.

A consequence of the rules above is that a change to the value of **mpls-echo-request-downstream-map** option does not affect the value inserted in the downstream mapping TLV of existing tests.

Following are the details of the processing of the new DDMAP TLV:

1. When either the DSMAP TLV or the DDMAP TLV is received in an echo request message, the responder node includes the same type of TLV in the echo reply message with the proper downstream interface information and label stack information.
2. If an echo request message without a Downstream Mapping TLV (DSMAP or DDMAP) expires at a node which is not the egress for the target FEC stack, the responder node always includes the DSMAP TLV in the echo reply message. This can occur in the following cases:
   a. The user issues a LSP trace from a sender node with a **min-ttl** value higher than 1 and a **max-ttl** value lower than the number of hops to reach the egress of the target FEC stack. This is the sender node behavior when the global configuration or the per-test setting of the DSMAP/DDMAP is set to DSMAP.
   b. The user issues a LSP ping from a sender node with a **ttl** value lower than the number of hops to reach the egress of the target FEC stack. This is the sender node behavior when the global configuration of the DSMAP/DDMAP is set to DSMAP.
   c. The behavior in (a) is changed when the global configuration or the per-test setting of the Downstream Mapping TLV is set to DDMAP. The sender node includes in this case the DDMAP TLV with the Downstream IP address field set to the all-routers multicast address as per Section 3.4 of RFC 8029. The responder node then bypasses the interface and label stack validation and replies with a DDMAP TLV with the correct downstream information for the target FEC stack.
3. A sender node never includes the DSMAP or DDMAP TLV in an lsp-ping message.

In addition to performing the same features as the DSMAP TLV, the new DDMAP TLV addresses the following scenarios:

1. Full validation of an LDP FEC stitched to a BGP IPv4 label route. In this case, the LSP trace message is inserted from the LDP LSP segment or from the stitching point.
2. Full validation of a BGP IPv4 label route stitched to an LDP FEC. This includes the case of explicit configuration of the LDP-BGP stitching in which the BGP label route is active in Route Table Manager (RTM) and the case of a BGP IPv4 label route resolved to the LDP FEC due to the IGP route of the same prefix active in RTM. In this case, the LSP trace message is inserted from the BGP LSP segment or from the stitching point.
3. Full validation of an LDP FEC which is stitched to a BGP LSP and stitched back into an LDP FEC. In this case, the LSP trace message is inserted from the LDP segments or the or from the stitching points.
4. Full validation of an LDP FEC tunneled over an RSVP LSP using LSP trace.

To properly check a target FEC which is stitched to another FEC (stitching FEC) of the same or a different type, or which is tunneled over another FEC (tunneling FEC), it is necessary for the responding nodes to provide details about the FEC manipulation back to the sender node. This is achieved via the use of the new FEC stack change sub-TLV in the Downstream Detailed Mapping TLV (DDMAP) defined in RFC 6424.

When the user configures the use of the DDMAP TLV on a trace for an LSP that does not undergo stitching or tunneling operation in the network, the procedures at the sender and responder nodes are the same as in the case of the DSMAP TLV.

This feature however introduces changes to the target FEC stack validation procedures at the sender and responder nodes in the case of LSP stitching and LSP hierarchy. These changes pertain to the processing of the new FEC stack change sub-TLV in the new DDMAP TLV and the new return code of value 15 `Label switched with FEC change`.

The **no** form of this command reverts to the default behavior of using the DSMAP TLV in a LSP trace packet and LDP tree trace packet.

Default

mpls-echo-request-downstream-map dsmap

Parameters

dsmap

Specifies that the DSMAP TLV should be used in all LSP trace packets and LDP tree trace packets originating on the node.

ddmap

Specifies that the DDMAP TLV should be used in all LSP trace packets and LDP tree trace packets originating on the node.

Platforms

7705 SAR Gen 2

Output

The following output is an example of mpls-echo-request-downstream-map information.

Output Example: LDP-over-RSVP

18.71 mpls-label

mpls-label

Syntax

mpls-label *value*

no mpls-label

Context

[Tree] (conf>router>segment-routing>sr-policies>policy>seg-list>segment mpls-label)

Full Context

configure router segment-routing sr-policies static-policy segment-list segment mpls-label

Description

This command configures the MPLS label value this is associated with a segment.

The **no** form of this command removes the label value.

Default

no mpls-label

Parameters

value

Specifies the MPLS label value.

Values 0 to 1048575

Platforms

7705 SAR Gen 2

18.72 mpls-labels

mpls-labels

Syntax

mpls-labels

Context

[Tree] (config>router mpls-labels)

Full Context

configure router mpls-labels

Description

This command creates a context for the configuration of global parameters related to MPLS labels.

Platforms

7705 SAR Gen 2

18.73 mpls-time-stamp-format

mpls-time-stamp-format

Syntax

mpls-time-stamp-format {**rfc4379** | **unix**}

Context

[Tree] (config>test-oam mpls-time-stamp-format)

Full Context

configure test-oam mpls-time-stamp-format

Description

This command configures the format of the timestamp used by for lsp-ping, lsp-trace, p2mp-lsp-ping and p2mp-lsp-trace, vccv-ping, vccv-trace, and lsp-trace.

If **rfc4379** is selected, then the timestamp is in seconds and microseconds since 1900, otherwise it is in seconds and microseconds since 1970.

Changing this system-wide setting does not affect tests that are currently in progress, but SAAs starts to use the new timestamp when they are restarted. When an SR OS receives an echo request, it replies with the locally configured timestamp format, and does not try to match the timestamp format of the incoming echo request message.

Default

mpls-time-stamp-format unix

Parameters

rfc4379

Specifies the RFC 4379 (obsoleted by RFC 8029) time stamp format. The timestamp's **seconds** field holds the integral number of seconds since 1-Jan-1900 00:00:00 UTC. The

timestamp's **microseconds** field contains a microseconds value in the range 0 to 999999. This setting is used to inter-operate with network elements which are fully compliant with RFC 4379, *Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures*, (such as an SR OS system with the same setting, or any other RFC 4379 compliant router).

unix

Specifies the Unix time stamp format. The time stamps **seconds** field holds a Unix time, the integral number of seconds since 1-Jan-1970 00:00:00 UTC. The time stamps **microseconds** field contains a microseconds value in the range 0 to 999999. This setting is used to inter-operate with network elements which send and expect a 1970-based timestamp in MPLS Echo Request/Reply PDUs (such as an SR OS system with the same setting, or an SR OS system running software earlier than R8.0 R4).

[Tree] (config>service>vpls>bind>mld-snooping mrouter-port)

[Tree] (config>service>vpls>spoke-sdp>igmp-snooping mrouter-port)

[Tree] (config>service>vpls>sap>igmp-snooping mrouter-port)

[Tree] (config>service>vpls>mesh-sdp>igmp-snooping mrouter-port)

Full Context

configure service vpls spoke-sdp mld-snooping mrouter-port

configure service vpls allow-ip-int-bind mld-snooping mrouter-port

configure service vpls spoke-sdp igmp-snooping mrouter-port

configure service vpls sap igmp-snooping mrouter-port

configure service vpls mesh-sdp igmp-snooping mrouter-port

Description

This command specifies whether a multicast router is attached behind this SAP, SDP, or routed VPLS IP interface.

Configuring these objects as an mrouter-port will have a double effect. Firstly, all multicast traffic received on another SAP, SDP, or routed VPLS IP interface will be copied to this SAP, SDP, or routed VPLS IP interface. Secondly, IGMP/MLD reports generated by the system as a result of a router joining or leaving a multicast group, will be sent to this SAP, SDP, or routed VPLS IP interface.

If two multicast routers exist in the network, one of them will become the active querier. While the other multicast router (non-querier) stops sending IGMP queries, it should still receive reports to keep its multicast trees up-to-date. To support this, the mrouter-port should be enabled on all SAPs, SDPs, or routed VPLS IP interfaces connecting to a multicast router.

Note:
The IGMP version to be used for the reports (v1, v2, or v3) can only be determined after an initial query has been received. Until such time, no reports are sent on the SAP, spoke-SDP, or routed VPLS IP interface, even if **mrouter-port** is enabled.

If the **send-queries** command is enabled on this SAP or spoke-SDP, the **mrouter-port** parameter cannot be set.

When PIM-snooping is enabled within a VPLS service, all IP multicast traffic and PIM messages will be sent to any SAP or SDP binding configured with an IGMP-snooping mrouter port. This occurs even without IGMP-snooping enabled, but is not supported in a BGP-VPLS or M-VPLS service.

The **no** form of this command reverts to the default.

Default

no mrouter-port

Platforms

7705 SAR Gen 2

18.76 msap-defaults

msap-defaults

Syntax

msap-default

Context

[Tree] (config>service>vpls>sap msap-defaults)

Context

[Tree] (config>router mss-adjust-group)

[Tree] (config>service>vprn mss-adjust-group)

Full Context

configure router mss-adjust-group

configure service vprn mss-adjust-group

Description

This command associates the MSS adjust group consisting of multiple ISAs with the routing context in which the application requiring TCP MSS adjust resides.

Parameters

bb-group-id

Specifies the group used for TCP MSS adjust

segment-size

Specifies the value to put into the TCP Maximum Segment Size (MSS) option if it is not already present, or if the present value is higher

Values 160 to 10240

Platforms

7705 SAR Gen 2

18.80 mst-instance

mst-instance

Syntax

mst-instance *mst-inst-number*

Context

[Tree] (config>service>vpls>sap>stp mst-instance)

Full Context

configure service vpls sap stp mst-instance

Description

Commands in this context configure MSTI related parameters at SAP level. This context can be open only for existing mst-instances defined at the service level (see **config>service>vpls>stp mst-instance**).

Parameters

mst-inst-number

Specifies an existing Multiple Spanning Tree Instance number.

Values 1 to 4094

Platforms

7705 SAR Gen 2

mst-instance

Syntax

mst-instance *mst-inst-number* [**create**]

no mst-instance [*mst-inst-number*]

Context

[Tree] (config>service>vpls>stp mst-instance)

Full Context

configure service vpls stp mst-instance

Description

This command creates the context to configure MST instance (MSTI) related parameters. Up to 16 instances will be supported by MSTP. The instance 0 is mandatory by protocol and therefore, it cannot be created by the CLI. The software will maintain this instance automatically.

Parameters

mst-inst-number

Specifies the Multiple Spanning Tree instance

Values 1 to 4094

Platforms

7705 SAR Gen 2

18.81 mst-max-hops

mst-max-hops

Syntax

mst-max-hops *hops-count*

no mst-max-hops

Context

[Tree] (config>service>vpls>stp mst-max-hops)

Full Context

configure service vpls stp mst-max-hops

Description

This command specifies the number of hops in the region before BPDU is discarded and the information held for the port is aged out. The root bridge of the instance sends a BPDU (or M-record) with remaining-hop-count set to configured <*max-hops*>. When a bridge receives the BPDU (or M-record), it decrements the received remaining-hop-count by 1 and propagates it in BPDU (or M-record) it generates.

The **no** form of this command sets the *hops-count* to its default value.

Default

mst-max-hops 20

Parameters

hops-count

Specifies the maximum number of hops.

Values 1 to 40

Platforms

7705 SAR Gen 2

18.82 mst-name

mst-name

Syntax

mst-name *region-name*

no mst-name

Context

[Tree] (config>service>vpls>stp mst-name)

Full Context

configure service vpls stp mst-name

Description

This command defines an MST region name. Two bridges are considered as a part of the same MST region as soon as their configuration of the MST region name, the MST-revision and VLAN-to-instance assignment is identical.

The **no** form of this command removes *region-name* from the configuration.

Default

no mst-name

Parameters

region-name

Specifies an MST-region name up to 32 characters in length.

Platforms

7705 SAR Gen 2

18.83 mst-path-cost

mst-path-cost

Syntax

mst-path-cost *inst-path-cost*

no mst-path-cost

Context

[Tree] (config>service>vpls>sap>stp>mst-instance mst-path-cost)

Full Context

configure service vpls sap stp mst-instance mst-path-cost

Description

This commands specifies path-cost within a specified instance, expressing probability that a specified port will be put into the forwarding state in case a loop occurs (the highest value expresses lowest priority).

The **no** form of this command sets port-priority to its default value.

Default

The path-cost is proportional to link speed.

Parameters

inst-path-cost

Specifies the contribution of this port to the MSTI path cost of paths toward the spanning tree regional root that include this port.

Values 1 to 200000000

Platforms

7705 SAR Gen 2

18.84 mst-port-priority

mst-port-priority

Syntax

mst-port-priority *stp-priority*

no mst-port-priority

Context

[Tree] (config>service>vpls>sap>stp>mst-instance mst-port-priority)

Full Context

configure service vpls sap stp mst-instance mst-port-priority

Description

This commands specifies the port priority within a specified instance, expressing probability that a specified port will be put into the forwarding state if a loop occurs.

The **no** form of this command sets port-priority to its default value.

Default

mst-port-priority 128

Parameters

stp-priority

Specifies the value of the port priority field.

Platforms

7705 SAR Gen 2

18.85 mst-priority

mst-priority

Syntax

mst-priority *bridge-priority*

no mst-priority

Context

[Tree] (config>service>vpls>stp>mst-instance mst-priority)

Full Context

configure service vpls stp mst-instance mst-priority

Description

This command specifies the bridge priority for this specific Multiple Spanning Tree Instance for this service. The *bridge-priority* value reflects likelihood that the switch will be chosen as the regional root switch (65535 represents the least likely). It is used as the highest 4 bits of the Bridge ID included in the MSTP BPDUs generated by this bridge.

The priority can only take on values that are multiples of 4096 (4k). If a value is specified that is not a multiple of 4K, then the value will be replaced by the closest multiple of 4K, which is lower than the value entered.

All instances created by the **configure service vpls stp mst-instance vlan-range** command and not having explicit definition of bridge-priority inherit the default value.

The **no** form of this command sets the bridge-priority to its default value.

Default

mst-priority 32768

Parameters

bridge-priority

Specifies the priority of this specific Multiple Spanning Tree Instance for this service.

Values 0 to 65535

Platforms

7705 SAR Gen 2

18.86 mst-revision

mst-revision

Syntax

mst-revision *revision-number*

no mst-revision

Context

[Tree] (config>service>vpls>stp mst-revision)

Full Context

configure service vpls stp mst-revision

Description

This command defines the MST configuration revision number. Two bridges are considered as a part of the same MST region as soon as their configuration of MST-region name, MST-revision and VLAN-to-instance assignment is identical.

The **no** form of this command returns MST configuration revision to its default value.

Default

mst-revision 0

Parameters

revision-number

Specifies the MSTP region revision number to define the MSTP region.

Values 0 to 65535

Platforms

7705 SAR Gen 2

18.87 mtu

configure service vprn router-advertisement interface mtu

configure router router-advertisement interface mtu

Description

This command specifies the value to be placed in link MTU options sent by the router on this interface.

The **no** form of this command reverts to the default.

Default

no mtu — The MTU option is not sent in the router advertisement messages.

Parameters

bytes

Specifies the advertised MTU value in bytes for this interface.

Values 1280 to 9800 (for **config**>**router**>**router-advert**>**if** and **config**>**service**>**vprn**>**router-advert**>**if** contexts only)

1280 to 9212 (for **subscriber management** context, **ies** and **vprn service subscriber-interface** contexts)

Platforms

7705 SAR Gen 2

mtu

Syntax

mtu *mtu-bytes*

no mtu

Context

[Tree] (config>port>ethernet mtu)

Full Context

configure port ethernet mtu

Description

This command configures the maximum payload MTU size for an Ethernet port, PPP-enabled port or sub-port and Frame Relay-enabled port or subport. The Ethernet port level MTU parameter indirectly defines

the largest physical packet the port can transmit or the far-end Ethernet port can receive. Packets that cannot be fragmented at egress and exceed the MTU are discarded.

The value specified for the MTU includes the destination MAC address, source MAC address, the Ethertype or Length field and the complete Ethernet payload. The MTU value does not include the preamble, start of frame delimiter or the trailing CRC.

PoS channels use the MTU to define the largest PPP payload a PoS frame may contain. A significant difference between SONET/SDH PoS channel and Ethernet physical MTU values the overhead considered part of the framing method and the overhead considered to be part of the application using the frame. In Ethernet, the preamble, start of frame delimiter and the CRC are considered part of the framing overhead and not part of the frame payload. For a PoS channel, the HDLC framing overhead is not included in the physical MTU; only the PPP and PPP payload are included. If the port mode or encapsulation type is changed, the MTU assumes the default values of the new mode or encapsulation type.

The **no** form of this command restores the default values.

Default

The default MTU value depends on the (sub-)port type, mode and encapsulation and are listed in Table 70: Default MTU Values:

Table 70: Default MTU Values

Type	Mode	Encap Type	Default (Bytes)
10/100, Gig, or 10GigE	Access	null	1514
10/100, Gig, or 10GigE	Access	dot1q	1518
10/100, Gig, or 10GigE	Access	q-in-q	1522
SONET/SDH or TDM	Access	mpls	1506
SONET/SDH or TDM	Access	bcp-null	1518
SONET/SDH or TDM	Access	bcp-dot1q	1522
SONET/SDH or TDM	Access	ipcp	1502
SONET/SDH or TDM	Access	frame-relay	1578
ATM, SONET/SDH or TDM	Access	atm	1524
10/100 or 100FX Ethernet	Network	null	1514
10/100 or 100FX Ethernet	Network	dot1q	1518
SONET/SDH	Network	ppp-auto	1524

Parameters

mtu-bytes

Sets the maximum allowable size of the MTU, expressed as an integer.

Values	512 to 9212	config>port>ethernet
	512 to 9800	config>port>ethernet (for FP4-based connector ports)
	512 to 9208	config>port>sonet-sdh>path
	512 to 9208	config>port>tdm>ds1>channel-group
	512 to 9208	config>port>tdm>ds3
	512 to 9208	config>port>tdm>e1>channel-group
	512 to 9208	config>port>tdm>e3

Context

[Tree] (config>service>vprn>ospf3>area>if mtu)

[Tree] (config>service>vprn>ospf>area>if mtu)

Full Context

configure service vprn ospf3 area interface mtu

configure service vprn ospf area interface mtu

Description

This command configures the OSPF packet size used on this interface. If this parameter is not configured, OSPF derives the MTU value from the MTU configured (default or explicitly) in the following contexts:

config>**port**>**ethernet**, **config**>**port**>**sonet-sdh**>**path**, **config**>**port**>**tdm**>**t3-e3**, **config**>**port**>**tdm**>**t1-e1**>**channel-group**

If this parameter is configured, the smaller value between the value configured here and the MTU configured (default or explicitly) in an above-mentioned contexts is used.

To determine the actual packet size, add 14 bytes for an Ethernet packet and 18 bytes for a tagged Ethernet packet to the size of the OSPF (IP) packet MTU configured in this command.

The **no** form of this command reverts to default value derived from the MTU configured in the **config>port** context.

Default

no mtu

Parameters

mtu-bytes

Specifies the MTU to be used by OSPF for this logical interface, in bytes.

Values 512 to 9786

Platforms

7705 SAR Gen 2

mtu

Syntax

mtu *value*

no mtu

Context

[Tree] (config>service>vprn>nat>outside mtu)

Full Context

configure service vprn nat outside mtu

Description

This command configures the Maximum Transmission Unit (MTU) for downstream traffic flowing through this router (as outside NAT router). The system fragments IP datagrams exceeding the MTU.

The **no** form of the command reverts to the default.

Default

no mtu

Parameters

value

Specifies the MTU for downstream traffic.

Values 512 to 9000

Platforms

7705 SAR Gen 2

mtu

Syntax

mtu *mtu-size*

no mtu

Context

[Tree] (config>router>nat>outside mtu)

mtu

Syntax

mtu *bytes*

no mtu

Context

[Tree] (config>router>ospf3>area>interface mtu)

[Tree] (config>router>ospf>area>interface mtu)

Full Context

configure router ospf3 area interface mtu

configure router ospf area interface mtu

Description

This command configures the OSPF packet size used on this interface. If this parameter is not configured OSPF derives the MTU value from the MTU configured (default or explicitly) in the following contexts:

- **config>port>ethernet**
- **config>port>sonet-sdh>path**
- **config>port>tdm>t3-e3**
- **config>port>tdm>t1-e1>channel-group**

If this parameter is configured, the smaller value between the value configured here and the MTU configured (default or explicitly) in an above-mentioned context is used.

To determine the actual packet size, add 14 bytes for an Ethernet packet and 18 bytes for a tagged Ethernet packet to the size of the OSPF (IP) packet MTU configured in this command.

The **no** form of this command reverts to the default derived from the MTU configured in the **config>port** context.

Default

no mtu

Parameters

bytes

Specifies the MTU to be used by OSPF for this logical interface in bytes.

Values 512 to 9786 in the **config**>**router**>**ospf**>**area**>**interface** context.

1280 to 9786 in the **config**>**router**>**ospf3**>**area**>**interface** context.

configure service vprn pim mtu-over-head

Description

This commands subtracts the specified value from the MVPN MTU to allow a BIER header to be added without exceeding the network MTU.

Default

no mtu-over-head

Parameters

mtu-value

Specifies the value subtracted from the MVPN MTU.

Values 44, 76, 140, 268, 536

Platforms

7705 SAR Gen 2

18.89 multi-active

multi-active

Syntax

[**no**] **multi-active**

Context

[Tree] (config>isa>tunnel-grp multi-active)

Full Context

configure isa tunnel-group multi-active

Description

This command enables configuring multiple active MS-ISA in the tunnel-group. IPsec traffic will be load balanced to configured active MS-ISAs.

Operational notes:

- A shutdown of group and removal of all existing configured tunnels of the tunnel-group are needed before provisioning command "multi-active".
- If the tunnel-group is admin-up with "multi-active" configured then the configuration of "primary" and "backup" are not allowed.
- The active-mda-number must be =< total number of ISA configured.
  - If active-mda-number is less than total number of ISA configured then the delta number of ISA will become backup ISA.

Default
no multi-active

18.93 multi-homed-prefix

multi-homed-prefix

Syntax

[**no**] **multi-homed-prefix**

Context

[Tree] (config>router>ospf>lfa multi-homed-prefix)

Full Context

configure router ospf loopfree-alternates multi-homed-prefix

Description

This command enables multi-homed prefix LFA for OSPF routes (IP FRR) and SR-OSPF node SID tunnels.

This feature makes use of the multi-homed prefix model described in RFC 8518 to compute a backup IP next hop using an alternate ABR or ASBR for external prefixes and to an alternate router owner for local anycast prefixes.

This feature further enhances the multi-homed prefix backup path calculation beyond RFC 8518 with the addition of repair tunnels that make use of a PQ node or a P-Q set to reach the alternate exit ABR or ASBR of external prefixes or the alternate owner router of local anycast prefixes.

The computed IP next-hop based backup path is added to OSPF routes of external /32 prefixes (OSPFv2 routes types 3, 4, 5, and 7) and local /32 anycast prefixes in the RTM if the prefix is not protected by base LFA or if the user set leaf preference value to **all**. The user must enable the **ip-fast-reroute** leaf to have these backup paths programmed into the FIB in data path.

The computed IP next hop or repair tunnel based backup path is also programmed for SR-OSPF node SID tunnels of external /32 prefixes and to /32 prefixes in same area as the computing node S and which are advertised by multiple routers (anycast prefix) in both algorithm 0 and flexible-algorithm numbers.

The **no** form of this command disables multi-homed prefix LFA.

Default

no multi-homed-prefix

Platforms

7705 SAR Gen 2

multi-homed-prefix

Syntax

[**no**] **multi-homed-prefix**

Context

[Tree] (config>router>isis>lfa multi-homed-prefix)

Full Context

configure router isis loopfree-alternates multi-homed-prefix

Description

This command enables multihomed prefix LFA for IS-IS routes (IP FRR), SR-ISIS tunnels, and SRv6-ISIS tunnels.

This feature uses the multihomed prefix model described in RFC 8518 to compute a backup IP next hop using an alternate ABR or ASBR for external prefixes and to an alternate router owner for local anycast prefixes.

This feature further enhances the multihomed prefix backup path calculation beyond RFC 8518 with the addition of repair tunnels that make use of a PQ node or a P-Q set to reach the alternate exit ABR or ASBR of external prefixes or the alternate owner router of intra-area anycast prefixes.

The computed IP next hop-based backup path is added to IS-IS routes of external /32 or /128 prefixes and intra-area /32 or /128 anycast prefixes in the RTM if the prefix is not protected by base LFA or if the user set leaf **preference** command option to **all**. The user must enable the **ip-fast-reroute** leaf to have these backup paths programmed into the FIB in datapath.

The computed IP next hop or repair tunnel-based backup path is also programmed for:

1. SR-ISIS node SID tunnels of external /32 IPv4 prefixes and /128 IPv6 prefixes, and node SID tunnels of intra-area /32 IPv4 anycast prefixes and /128 anycast IPv6 prefixes, in both algorithm 0 and flexible-algorithms

2. SRv6-ISIS locator routes and tunnels of external prefixes and of intra-area anycast prefixes of any size, in both algorithm 0 and flexible algorithm numbers

As a result, an SR-TE LSP, an SR-MPLS policy, or an SRv6 policy which uses an SR-ISIS SID or an SRv6-ISIS SID of those same prefixes in its configured or computed SID list benefits from the multi-homed prefix LFA protection.

Once the IP next-hop based multihomed prefix LFA is enabled, the extensions to compute an SR-TE repair tunnel for the multihomed prefix LFA in the case of SR-ISIS and SRv6-ISIS are automatically enabled if the user also enabled TI-LFA or Remote LFA. The computation reuses the SID list of the primary path or of the TI-LFA or Remote LFA backup path of the alternate ABR or ASBR or alternate owner router.

The **no** form of this command disables multihomed prefix LFA.

Default

no multi-homed-prefix

18.96 multi-service-site

multi-service-site

Syntax

[**no**] **multi-service-site** *customer-site-name*

Context

[Tree] (config>service>ies>if>sap multi-service-site)

Full Context

configure service ies interface sap multi-service-site

Description

This command creates a new customer site or edits an existing customer site with the *customer-site-name* parameter. A customer site is an anchor point to create an ingress and egress virtual scheduler hierarchy. When a site is created, it must be assigned to a chassis slot or port. When scheduler policies are defined for ingress and egress, the scheduler names contained in each policy are created according to the parameters defined in the policy. Multi-service customer sites exist for the sole purpose of creating a virtual scheduler hierarchy and making it available to queues on multiple Service Access Points (SAPs).

The scheduler policy association with the customer site normally prevents the scheduler policy from being deleted until after the scheduler policy is removed from the customer site. The multi-service-site object generates a log message indicating that the association was deleted due to scheduler policy removal.

When the multi-service customer site is created, an ingress and egress scheduler policy association does not exist. This does not prevent the site from being assigned to a chassis slot or prevent service SAP assignment. After the site has been created, the ingress and egress scheduler policy associations can be assigned or removed at any time.

The **no** form of this command removes the value from the configuration.

Default

n/a — Each customer site must be explicitly created.

Parameters

customer-site-name

Each customer site must have a unique name within the context of the customer. If *customer-site-name* already exists for the customer ID, the CLI context changes to that site name for the purpose of editing the site scheduler policies or assignment. Any modifications made to an existing site affects all SAPs associated with the site. Changing a scheduler policy association may cause new schedulers to be created and existing policers and queues on the SAPs to no longer be orphaned. Existing schedulers on the site may cease to exist, causing policers and queues relying on that scheduler to be orphaned.

If the *customer-site-name* does not exist, it is assumed that an attempt is being made to create a site of that name in the customer ID context. The success of the command execution depends on the following:

The maximum number of customer sites defined for the chassis slot has not been met.

The *customer-site-name* is valid.

The **create** keyword is included in the command line syntax (if the system requires it).

When the maximum number of customer sites has been exceeded a configuration error occurs, the command will not execute and the CLI context will not change.

If the *customer-site-name* is invalid, a syntax error occurs, the command will not execute and the CLI context will not change.

Values Valid names consist of any string, up to 32 characters, composed of printable, 7-bit ASCII characters excluding double quotes. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

[Tree] (config>service>vpls>sap multi-service-site)

Full Context

configure service vprn interface sap multi-service-site

configure service vpls sap multi-service-site

Description

This command associates the SAP with a *customer-site-name*. If the specified *customer-site-name* does not exist in the context of the service customer ID an error occurs and the command is not executed. If *customer-site-name* exists, the current and future defined queues on the SAP (ingress and egress) attempts to use the scheduler hierarchies created within *customer-site-name* as parent schedulers.

This command is mutually exclusive with the SAP ingress and egress scheduler policy commands. If a scheduler policy has been applied to either the ingress or egress nodes on the SAP, the **multi-service-site** command fails without executing. The locally applied scheduler policies must be removed prior to executing the **multi-service-site** command.

The **no** form of this command removes the SAP from any multi-service customer site the SAP belongs to. Removing the site can cause existing or future policers and queues to enter an orphaned state.

Parameters

customer-site-name

Specifies an existing customer site name, up to 32 characters. If the *customer-site-name* exists and local scheduler policies have not been applied to the SAP, the current and future policers queues defined on the SAP looks for their parent schedulers within the scheduler hierarchies defined in the customer-site-name.

multi-service-site *customer-site-name* [**create**]

no multi-service-site *customer-site-name*

Context

[Tree] (config>service>cust multi-service-site)

Full Context

configure service customer multi-service-site

Description

This command creates a new customer site or edits an existing customer site with the *customer-site-name* parameter. A customer site is an anchor point to create an ingress and egress virtual scheduler hierarchy. When a site is created, it must be assigned to a chassis slot or port. When scheduler policies are defined for ingress and egress, the scheduler names contained in each policy are created according to the parameters defined in the policy. Multi-service customer sites exist for the sole purpose of creating a virtual scheduler hierarchy and making it available to queues on multiple Service Access Points (SAPs).

The scheduler policy association with the customer site normally prevents the scheduler policy from being deleted until after the scheduler policy is removed from the customer site. The multi-service-site object will generate a log message indicating that the association was deleted due to scheduler policy removal.

When the multi-service customer site is created, an ingress and egress scheduler policy association does not exist. This does not prevent the site from being assigned to a chassis slot or prevent service SAP assignment. After the site has been created, the ingress and egress scheduler policy associations can be assigned or removed at any time.

Parameters

customer-site-name

Specifies the customer site name. Each customer site must have a unique name within the context of the customer. If *customer-site-name* already exists for the customer ID, the CLI context changes to that site name for the purpose of editing the site scheduler policies or assignment. Any modifications made to an existing site will affect all SAPs associated with the site. Changing a scheduler policy association may cause new schedulers to be created and existing policers and queues on the SAPs to no longer be orphaned. Existing schedulers on the site may cease to exist, causing policers and queues relying on that scheduler to be orphaned.

If the *customer-site-name* does not exist, it is assumed that an attempt is being made to create a site of that name in the customer ID context. The success of the command execution depends on the following:

- The maximum number of customer sites defined for the chassis has not been met.

- The *customer-site-name* is valid.
- The **create** keyword is included in the command line syntax (if the system requires).

When the maximum number of customer sites has been exceeded a configuration error occurs; the command will not execute and the CLI context will not change.

If the *customer-site-name* is invalid, a syntax error occurs; the command will not execute and the CLI context will not change.

Values Valid names consist of any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

multicast

Syntax

multicast [**key-id** *key-id* | **authentication-keychain** *keychain-name*] [**version** *version*]

no multicast

Context

[Tree] (config>system>time>ntp multicast)

Full Context

configure system time ntp multicast

Description

This command configures NTP the node to transmit multicast packets on the CPM/CCM MGMT port. Broadcast and multicast messages can easily be spoofed; authentication is strongly recommended.

The **no** form of this command removes the multicast address from the configuration.

Parameters

key-id

Specifies the configured authentication key and authentication type used by this version to transmit NTP packets. If this command is omitted from the configuration, packets are sent unencrypted.

Values 1 to 255

keychain-name

Identifies the keychain name, up to 32 characters.

version

Specifies the NTP version number that is generated by this node. This parameter does not need to be configured when in client mode in which case all three versions are accepted.

Values 2 to 4

Default 4

Platforms

7705 SAR Gen 2

18.99 multicast-import

multicast-import

Syntax

[**no**] **multicast-import**

Context

[Tree] (config>service>vprn>isis multicast-import)

Full Context

configure service vprn isis multicast-import

Description

This command enables ISIS to submit routes into the multicast Route Table Manager (RTM).

The **no** form of this command disables the submission of routes into the multicast RTM.

Default

no multicast-import

Platforms

7705 SAR Gen 2

multicast-import

Syntax

configure router isis multicast-import

Description

This command enables the submission of routes into the multicast Route Table Manager (RTM) by IS-IS.

The **no** form of this command disables the submission of routes into the multicast RTM.

Default

no multicast-import

Parameters

both

Allows submission of both IPv4 and IPv6 routes.

ipv4

Allows submission of IPv4 routes only.

ipv6

Allows submission of IPv6 routes only.

Platforms

7705 SAR Gen 2

multicast-import

Syntax

[**no**] **multicast-import**

Context

Description

This command enables the submission of routes into the multicast Route Table Manager (RTM) by OSPF.

The **no** form of this command disables the submission of routes into the multicast RTM.

Default

no multicast-import

Platforms

7705 SAR Gen 2

18.100 multicast-leave-sync-propagation

multicast-leave-sync-propagation

Syntax

multicast-leave-sync-propagation *time*

Context

[Tree] (config>service>system>bgp-evpn multicast-leave-sync-propagation)

Full Context

configure service system bgp-evpn multicast-leave-sync-propagation

Description

This command configures the additional amount of time that the system waits before removing a multicast state that was synchronized in an Ethernet Segment via Multicast Join or Leave Synch routes. This value represents a delta corresponding to the time it takes for a BGP advertisement to propagate to ES peers.

The node triggering the route computes the maximum response time as the product of the locally configured values, Last Member Query Count and Last Member Query Interval (this value is taken from the **config**>**service**>**vpls**>**sap**>**igmp-snooping**>**last-member-query-interval** or **config**>**service**>**vpls**>**spoke-sdp**>**igmp-snooping**> **last-member-query-interval** commands depending on the Ethernet Segment being used), and adds the delta value to the Maximum Response Time. Increasing the Maximum Response Time by this value can help minimize the churn of removing and recreating the state on the node.

The maximum response time value should be configured consistently in all ES peers. For example, in a scenario where a maximum response time of five seconds is advertised by PE-A and there is a delay of four seconds in the BGP propagation to PE-B, the timer could already expire on PE-A while PE-B is still in LMQ time and can still receive joins (which would recreate state in A after a join synch route from B). To minimize this situation, adding an extra delta timer on PE-A, reduces the potential churn of PE-A removing and recreating the state.

Default

multicast-leave-sync-propagation 5

Parameters

time

Specifies the multicast leave sync propagation delay time, in seconds.

Values 0 to 300

Default 5

Platforms

7705 SAR Gen 2

18.101 multicast-network-domain

multicast-network-domain

Syntax

multicast-network-domain *multicast-network-domain*

no multicast-network-domain

Context

[Tree] (config>service>ies>if multicast-network-domain)

Full Context

configure service ies interface multicast-network-domain

Description

This command is used to enable efficient multicast replication over a spoke SDP. Multicast traffic is copied to only a subset of network interfaces that may be used as egress for a spoke SDP. A network domain is defined by associating multiple interfaces to a logical group that may participate in multicast replication for a spoke SDP.

The **no** form of command disables efficient multicast replication to a network domain for a spoke SDP and traffic is replicated to all forwarding complexes.

Default

no multicast-network-domain

Platforms

7705 SAR Gen 2

18.102 multicast-policer

multicast-policer

Syntax

multicast-policer *policer-id* [**fp-redirect-group**]

no multicast-policer

Context

[Tree] (config>qos>sap-ingress>fc multicast-policer)

Full Context

configure qos sap-ingress fc multicast-policer

Description

Within a **sap-ingress** QoS policy forwarding class context, the **multicast-policer** command is used to map packets that match the forwarding class and are considered multicast in nature to the specified policer-id. The specified policer-id must already exist within the **sap-ingress** QoS policy. While the system is determining the forwarding class of a packet, it is also looking up its forwarding destination based on the ingress service type and the service instance forwarding records. Two basic types of services support multicast packets: routed services (IES and VPRN) and L2 multipoint services (VPLS, I-VPLS, and B-VPLS). For the routed service types, a multicast packet is destined to an IPv4 or IPv6 multicast address. For the L2 multipoint services, a multicast packet is a packet destined to a multicast MAC address (multicast bit set in the destination MAC address but not the ff:ff:ff:ff:ff:ff broadcast address). The VPLS services also support two other multipoint forwarding types (broadcast and unknown), which are considered separate from the multicast forwarding type.

If ingress forwarding logic has resolved a packet to the multicast forwarding type within the forwarding class, it will be mapped to either an ingress multipoint queue (using the **multicast** *queue-id* or **multicast** *queue-id* **group** *ingress-queue-group* commands) or an ingress policer (**multicast-policer** *policer-id*). The **multicast** and **multicast-policer** commands within the forwarding class context are mutually exclusive. By default, the multicast forwarding type is mapped to the SAP ingress default multipoint queue. If the **multicast-policer** *policer-id* command is executed, any previous policer mapping or queue mapping for the multicast forwarding type within the forwarding class is overridden if the policer mapping is successful.

A policer defined within the **sap-ingress** policy is not actually created on an ingress SAP or a subscriber using an **sla-profile** where the policy is applied until at least one forwarding type (unicast, broadcast, unknown, or multicast) from one of the forwarding classes is mapped to the policer. If insufficient policer resources exist to create the policer for a SAP or subscriber or multiservice site, or ingress policing is not

supported on the port associated with the SAP or subscriber or multiservice site, the initial forwarding class forwarding type mapping will fail.

The **multicast-policer** command is ignored for instances of the policer applied to SAPs subscribers or multiservice site where broadcast packets are not supported.

When the multicast forwarding type within a forwarding class is mapped to a policer, the multicast packets classified to the subclasses within the forwarding class are also mapped to the policer.

The **no** form of this command is used to restore the mapping of the multicast forwarding type within the forwarding class to the default multipoint queue. If all forwarding class forwarding types had been removed from the default multipoint queue, the queue will not exist on the SAPs subscribers or multiservice site associated with the QoS policy, and the **no multicast-policer** command will cause the system to attempt to create the default multipoint queue on each object. If the system cannot create the queue on each instance, the **no multicast-policer** command will fail and the multicast forwarding type within the forwarding class will continue its mapping to the existing *policer-id*. If the **no multicast-policer** command results in a policer without any current mappings, the policer will be removed from the SAPs and subscribers associated with the QoS policy. All statistics associated with the policer on each SAP and subscriber will be lost.

Parameters

policer-id

When the forwarding class **multicast-policer** command is executed, a valid *policer-id* must be specified. The parameter *policer-id* references a *policer-id* that has already been created within the **sap-ingress** QoS policy.

Values 1 to 63

fp-redirect-group

Redirects a forwarding class to a forwarding plane queue-group as specified in a SAP QoS policy.

Platforms

7705 SAR Gen 2

18.103 multicast-queue

multicast-queue

Syntax

multicast-queue *queue-id* [**group** *queue-group-name*]

no multicast-queue

Context

[Tree] (config>qos>sap-ingress>fc multicast-queue)

Full Context

configure qos sap-ingress fc multicast-queue

Description

This command overrides the default multicast forwarding type queue mapping for **fc** *fc-name*. The specified *queue-id* must exist within the policy as a multipoint queue before the mapping can be made. When the forwarding class mapping is executed, all multicast traffic on a SAP using this policy is forwarded using the *queue-id*.

The multicast forwarding type includes the **unknown** unicast forwarding type and the **broadcast** forwarding type unless each is explicitly defined to a different multipoint queue. When the unknown and broadcast forwarding types are left as default, they will track the defined queue for the multicast forwarding type.

The **no** form of this command sets the multicast forwarding type *queue-id* back to the default queue for the forwarding class. If the **broadcast** and **unknown** forwarding types were not explicitly defined to a multipoint queue, they will also be set back to the default multipoint queue (queue 11).

Parameters

queue-id

The *queue-id* parameter specified must be an existing, multipoint queue defined in the config>qos>sap-ingress context.

Values Any valid multipoint queue-ID in the policy including 2 through 32.

Default 11

group *queue-group-name*

This optional parameter is used to redirect the forwarding type within the forwarding class to the specified queue-id within the queue-group-name. When the policy is applied, all packets matching the forwarding class and forwarding type will be redirected to the queue within the specified queue group. The *queue-group-name* are configured in the **config>qos>queue-group-templates** egress and ingress contexts.

Platforms

7705 SAR Gen 2

multicast-queue

Syntax

multicast-queue *queue-id*

no multicast-queue

Context

[Tree] (config>qos>network-queue>fc multicast-queue)

Full Context

configure qos network-queue fc multicast-queue

Description

This command overrides the default multicast forwarding type queue mapping for **fc** *fc-name*. The specified *queue-id* must exist within the policy as a multipoint queue before the mapping can be made. When the forwarding class mapping is executed, all multicast traffic using this policy is forwarded using the *queue-id*.

The multicast forwarding type includes the **unknown** unicast forwarding type and the **broadcast** forwarding type, unless each is explicitly defined to a different multipoint queue. When the unknown and broadcast forwarding types are left as default, they will track the defined queue for the multicast forwarding type.

The **no** form of this command sets the multicast forwarding type *queue-id* back to the default queue for the forwarding class. If the **broadcast** and **unknown** forwarding types were not explicitly defined to a multipoint queue, they will also be set back to the default multipoint queue (queue 11).

Resource Utilization

When a multipoint queue is created and at least one forwarding class is mapped to the queue using the **multipoint-queue** command, a single ingress multipoint hardware queue is created per instance of the applied network-queue policy, using the queue-policy command at the ingress network FP level. Multipoint queues are not created at egress and the multipoint queues defined in the network-queue policy are ignored when the policy is applied to an egress port.

Parameters

queue-id

Specifies any valid multipoint queue-ID in the policy. The *queue-id* parameter specified must be an existing, multipoint queue defined in the **config>qos>network-queue>queue** context.

Values 1 to 16

Default 11

Platforms

7705 SAR Gen 2

18.104 multicast-senders

multicast-senders

Syntax

multicast-senders {**auto** | **always** | **never**}

no multicast-senders

Context

[Tree] (config>service>vprn>pim>if multicast-senders)

Full Context

configure service vprn pim interface multicast-senders

Description

This command configures the way subnet matching is done for incoming data packets on this interface. An IP multicast sender is an user entity to be authenticated in a receiving host.

Parameters

auto

Subnet matching is automatically performed for incoming data packets on this interface.

always

Subnet matching is always performed for incoming data packets on this interface.

never

Subnet matching is never performed for incoming data packets on this interface.

Platforms

7705 SAR Gen 2

multicast-senders

Syntax

multicast-senders {**auto** | **always** | **never**}

no multicast-senders

Context

[Tree] (config>router>pim>interface multicast-senders)

Full Context

configure router pim interface multicast-senders

Description

This command configures how traffic from directly-attached multicast sources should be treated on broadcast interfaces. It can also be used to treat all traffic received on an interface as traffic coming from a directly-attached multicast source. This is particularly useful if a multicast source is connected to a point-to-point or unnumbered interface.

The **no** form of this command reverts to the default value.

Default

multicast-senders auto

Parameters

auto

Specifies that, on broadcast interfaces, the forwarding plane performs subnet-match check on multicast packets received on the interface to determine if the packet is from a directly-attached source. On unnumbered/point-to-point interfaces, all traffic is implicitly treated as coming from a remote source.

always

Treats all traffic received on the interface as coming from a directly-attached multicast source.

never

Specifies that, on broadcast interfaces, traffic from directly-attached multicast sources will not be forwarded; however, traffic from a remote source will still be forwarded if there is a multicast state for it. On unnumbered/point-to-point interfaces, it means that all traffic received on that interface must not be forwarded.

Platforms

7705 SAR Gen 2

18.105 multicastclient

multicastclient

Syntax

multicastclient [**authenticate**]

no multicastclient

Context

[Tree] (config>system>time>ntp multicastclient)

Full Context

configure system time ntp multicastclient

Description

This command configures the node to receive multicast NTP messages on the CPM MGMT port. If **multicastclient** is not configured, received NTP multicast traffic will be ignored. Use the **show** command to view the state of the configuration.

The **no** construct of this message removes the multicast client for the specified interface from the configuration.

Parameters

authenticate

Specifies to make authentication a requirement (optional). If authentication is required, the authentication key-id received must have been configured in the **authentication-key** command, and that key-id type and key value must also match.

Platforms

7705 SAR Gen 2

18.107 multipath-eligible

multipath-eligible

Syntax

[**no**] **multipath-eligible**

Context

[Tree] (config>service>vprn>bgp>group multipath-eligible)

Full Context

configure service vprn bgp group multipath-eligible

Description

This command specifies that a BGP neighbor or the set of BGP neighbors in a peer group should be part of a selective multipath set. Selective multipaths are only supported by the ipv4, label-ipv4, ipv6, and label-ipv6 address families.

If no candidate multipath route for an IP prefix came from a multipath-eligible peer, multipaths are selected without further constraints.

If the best route for an IP prefix is received from a neighbor marked as multipath-eligible, other routes for the same prefix are not eligible to be used as multipaths unless they also came from peers marked as multipath-eligible.

If the best route for an IP prefix did not come from a multipath-eligible peer but there is at least one candidate multipath route for the same prefix from a multipath-eligible peer, multipath is not used.

The **no** form of this command marks a neighbor or group as non-multipath eligible. The effect of this depends on whether other neighbors and groups are marked as multipath eligible.

Default

no multipath-eligible

Platforms

7705 SAR Gen 2

Syntax

multiple-option {**true** | **false**}

no multiple-option

Context

[Tree] (config>filter>ip-filter>entry>match multiple-option)

Full Context

configure filter ip-filter entry match multiple-option

Description

This command configures matching packets that contain one or more than one option fields in the IP header as an IP filter match criterion.

The **no** form of the command removes the checking of the number of option fields in the IP header as a match criterion.

Default

no multiple-option

Parameters

true

Specifies matching on IP packets that contain more than one option field in the header.

false

Specifies matching on IP packets that do not contain multiple option fields present in the header.

Platforms

7705 SAR Gen 2

18.109 multiplier

multiplier

Syntax

multiplier *multiplier*

no multiplier

Context

[Tree] (config>router>bfd>bfd-template multiplier)

Full Context

configure router bfd bfd-template multiplier

Description

This command specifies the detect multiplier for a BFD session. If a BFD control packet is not received for a period of *multiplier* x *receive-interval* (the parameter value of the **receive-interval** command), the session is declared down.

The **no** form of this command reverts to the default value.

Default

multiplier 3

Parameters

multiplier

Specifies the multiplier.

Values 3 to 20

Default 3

7705 SAR Gen 2

18.110 mvpn-rtcache

mvpn-rtcache

Syntax

mvpn-rtcache [**group** *grp-ip-address*] [**peer** *ip-address*]

no mvpn-rtcache

Context

[Tree] (debug>router>pim mvpn-rtcache)

Full Context

debug router pim mvpn-rtcache

Description

This command enables debugging for the PIM MVPN route cache.

The **no** form of this command disables debugging for the PIM MVPN route cache.

Parameters

grp-ip-address

Debugs information associated with the specified group.

Values multicast group address (ipv4, ipv6) or zero

peer-ip-address

Debugs information associated with the specified peer.

Values peer address (ipv4, ipv6)

Platforms

7705 SAR Gen 2

18.111 mvrp-control

mvrp-control

Syntax

[**no**] **mvrp-control**

Context

[Tree] (config>service>vpls>vpls-group mvrp-control)

Full Context

configure service vpls vpls-group mvrp-control

Description

This command enables MVRP control in the VPLS instances instantiated using the templates for the specified vpls-group. That means the flooding FDB will be created empty and will be populated with endpoints whenever MVRP receives a declaration and a registration on a specific endpoint. Also the VLAN ID associated by the control VPLS with the instantiated VPLS will be declared on service activation by MVRP on all virtual MVRP ports in the control VPLS. Service activation takes place when at least one other SAP is provisioned and brought up under the data VPLS. This is usually a customer facing SAP or a SAP leading outside of the MVRP controlled domain.

The **no** form of this command disallows MVRP control over this VPLS. The VPLS will be created with a regular FDB and will become as a result active upon creation time. Command change is allowed only when the related vpls-group is in shutdown state.

Default

no mvrp-control

Platforms

7705 SAR Gen 2

7705 SAR Gen 2

19.2 name

name

Syntax

name *system-name*

no name

Context

[Tree] (config>system name)

Full Context

configure system name

Description

This command creates a system name string for the device.

For example, system-name parameter ALA-1 for the **name** command configures the device name as ALA-1.

```
ABC>config>system# name "ALA-1"
ALA-1>config>system#
```

Only one system name can be configured. If multiple system names are configured, the last one encountered overwrites the previous entry.

The **no** form of the command reverts to the default value.

Default

no name

Parameters

system-name

Specifies the system name as a character string. The string may be up to 64 characters. Any printable, seven-bit ASCII characters can be used within the string. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

Platforms

7705 SAR Gen 2

Context

[Tree] (config>router>policy-options>policy-statement>entry>from>policy-variables name)

[Tree] (config>router>policy-options>global-variables name)

Full Context

configure router policy-options policy-statement entry from policy-variables name

configure router policy-options global-variables name

Description

This command configures routing policies that are often reused across BGP peers of a common type (transit, peer, customer, and so on). Using global variables allows a user to have a single variable that is consistent across all peers of a type, while retaining the flexibility to reference different policy functions (prefixes, prefix-lists, community lists, and so on) with unique names.

Depending on the parameter referenced, specify the correct type as follows:

- value-string: **as-path, as-path-group, community, prefix-list, damping**
- ip-address: **next-hop**
- value-number: **aigp-metric, as-path-prepend, local-preference, metric, origin, origin-validation, preference, tag, type**

The **no** form of this command removes the global variable.

Parameters

name-string

Specifies the name of the global variable, with the variable delimited by at-signs (@) at the beginning and the end of the name. Allowed values are any string up to 32 characters, composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

value-string

The value of the policy variable. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

value-number

Specifies the numerical value of the policy variable.

Values 0 to 4294967295

ip-address

Specifies the IP address of the policy variable.

Values		
	ipv4-address	a.b.c.d
	ipv6-address	x:x:x:x:x:x:x:x (eight 16-bit pieces)
		x:x:x:x:x:x:d.d.d.d
		x - [0 to FFFF]H

d - [0 to 255]D

decimal

Specifies the decimal value of the policy variable.

Values 0.000 to 4294967295.000

ip-prefix/ip-prefix-length

Specifies the IP prefix and prefix length of the policy variable.

Values		
	ip-prefix/ip-prefix-length	*ipv4-prefix*/*ipv4-prefix-length* | *ipv6-prefix*/*ipv6-prefix-length*
	ipv4-prefix	a.b.c.d (host bits must be 0)
	ipv4-prefix-length	[0 to 32]
	ipv6-prefix	x:x:x:x:x:x:x:x (eight 16-bit pieces)
		x:x:x:x:x:x:d.d.d.d
		x - [0 to FFFF]H
		d - [0 to 255]D
	ipv6-prefix-length	[0 to 128]

Full Context

configure ipsec radius-authentication-policy include-radius-attribute nas-ip-addr

configure ipsec radius-accounting-policy include-radius-attribute nas-ip-addr

Description

This command enables the generation of the NAS IP address attribute.

Default

no nas-ip-addr

Platforms

7705 SAR Gen 2

19.5 nas-port-id

nas-port-id

Syntax

[**no**] **nas-port-id**

Context

[Tree] (config>ipsec>rad-acct-plcy>include nas-port-id)

[Tree] (config>ipsec>rad-auth-plcy>include nas-port-id)

Full Context

configure ipsec radius-accounting-policy include-radius-attribute nas-port-id

configure ipsec radius-authentication-policy include-radius-attribute nas-port-id

Description

This command enables the generation of the **nas-port-id** RADIUS attribute. Optionally, the value of this attribute (the SAP-id) can be prefixed by a fixed string and suffixed by the circuit-id or the remote-id of the client connection. If a suffix is configured, but no corresponding data is available, the suffix used will be 0/0/0/0/0/0.

Default

no nas-port-id

Platforms

7705 SAR Gen 2

19.6 nat

nat

Syntax

[**no**] **nat**

Context

[Tree] (config>router nat)

[Tree] (config>service>vprn nat)

Full Context

configure router nat

configure service vprn nat

Description

This command enables a NAT instance for the specified router or service.

The **no** form of this command disables the NAT instance.

Platforms

7705 SAR Gen 2

nat

Syntax

nat [**nat-policy** *nat-policy-name*]

Context

[Tree] (config>filter>ip-filter>entry>action nat)

Full Context

configure filter ip-filter entry action nat

Description

This command enables NAT traffic diversion based on IPv4 filters (LSN44) or IPv6 filters (DS-Lite, NAT64). The filter contains a matching condition based on any combination of the 5 tuple. Traffic is diverted to NAT based on such defined matching condition. Filter fields outside of the 5 tuples are not valid and it will be ignored in filter based traffic diversion to NAT.

The pool selection for the outside IP address and port along with other mapping characteristics can be specified by the means on the NAT policy.

Parameters

nat-type

Specifies the NAT type.

nat-policy-name

Specifies the NAT policy name, up to 32 characters.

Platforms

7705 SAR Gen 2

19.7 nat-group

nat-group

Syntax

nat-group *nat-group-id* [**create**]

no nat-group *nat-group-id*

Context

[Tree] (config>isa nat-group)

Full Context

configure isa nat-group

Description

This command configures an ISA NAT group.

The **no** form of the command removes the ID from the configuration.

Parameters

nat-group-id

Specifies the ISA NAT group ID.

Values 1 to 4

create

Keyword used to create the NAT group.

Platforms

7705 SAR Gen 2

19.8 nat-policy

nat-policy

Syntax

nat-policy *nat-policy-name*

no nat-policy

Context

[Tree] (config>router>nat>inside nat-policy)

[Tree] (config>service>vprn>nat>inside nat-policy)

Full Context

configure router nat inside nat-policy

configure service vprn nat inside nat-policy

Description

This command configures the NAT policy that is used for large-scale NAT in this service. If a **nat-policy** is not configured, then the default **nat-policy** is used.

The **no** form of the command removes the policy name from the configuration.

Parameters

nat-policy-name

Specifies the NAT policy name, up to 32 characters.

Platforms

7705 SAR Gen 2

nat-policy

Syntax

nat-policy *nat-policy-name* [**create**]

no nat-policy *nat-policy-name*

Context

[Tree] (config>service>nat nat-policy)

Full Context

configure service nat nat-policy

Description

This command configures a NAT policy.

Parameters

nat-policy-name

Specifies the NAT policy name, up to 32 characters.

create

Keyword used to create the NAT policy.

Platforms
7705 SAR Gen 2

19.9 nat-port-forwarding

nat-port-forwarding

Syntax
nat-port-forwarding

Context

19.10 nat-traversal

nat-traversal

Syntax
nat-traversal [**force**] [**keep-alive-interval** *keep-alive-interval*] [**force-keep-alive**]
no nat-traversal

Context
[Tree] (config>ipsec>ike-policy nat-traversal)

Full Context
configure ipsec ike-policy nat-traversal

Description
This command specifies whether NAT-T (Network Address Translation Traversal) is enabled, disabled or in forced mode.

The **no** form of this command reverts the parameters to the default.

Default

no nat-traversal

Parameters

force

Forces to enable NAT-T

keep-alive-interval *keep-alive-interval*

Specifies the keep-alive interval in seconds.

Values 120 to 600

force-keep-alive

When specified, the keep-alive does not expire.

Platforms

7705 SAR Gen 2

19.11 nbr

nbr

Syntax

nbr [**detail**]

no nbr

Context

[Tree] (debug>router>rsvp>event nbr)

Full Context

debug router rsvp event nbr

Description

This command debugs neighbor events.

The **no** form of the command disables the debugging.

Parameters

detail

Displays detailed information about neighbor events.

Platforms
7705 SAR Gen 2

19.14 nd-learn-unsolicited

nd-learn-unsolicited

Syntax

nd-learn-unsolicited {**global** | **link-local** | **both**}

no nd-learn-unsolicited

Context

[Tree] (config>service>ies>if>ipv6 nd-learn-unsolicited)

Full Context

configure service ies interface ipv6 nd-learn-unsolicited

Description

This command enables the ability to learn neighbor entries out of received unsolicited Neighbor Advertisement messages with or without the solicited flag set. The command can be enabled for global addresses, link-local addresses, or for both.

The **no** form of this command makes the router use standard RFC 4861 behavior, as described below, for learning of neighbor entries.

- If an unsolicited NA, regardless of the S flag, is received from a neighbor that is not yet in the ND cache, the NA is ignored.
- If an NS, RS, RA, or Redirect message with a Link Layer Address (MAC) is received from a neighbor that is not yet in the ND cache, a new neighbor entry is created in the cache to store the received Link Layer MAC. The neighbor is put in the stale state.

Parameters

global

Learns global neighbor entries out of received unsolicited Neighbor Advertisement messages.

link-local

Learns link local neighbor entries out of received unsolicited Neighbor Advertisement messages.

both

Learns both global and link local neighbor entries out of received unsolicited Neighbor Advertisement messages.

Platforms

7705 SAR Gen 2

nd-learn-unsolicited

Syntax

nd-learn-unsolicited {**global** | **link-local** | **both**}

no nd-learn-unsolicited

Context

[Tree] (config>service>vprn>if>ipv6 nd-learn-unsolicited)

Full Context

configure service vprn interface ipv6 nd-learn-unsolicited

Description

This command enables the ability to learn neighbor entries out of received unsolicited Neighbor Advertisement messages, with or without the solicited flag set. The command can be enabled for global addresses, link-local addresses, or for both.

The **no** form of this command makes the router follow standard RFC 4861 behavior for learning of neighbor entries.

- If an unsolicited NA (regardless of the S flag) is received from a neighbor that is not yet in the ND cache, the NA is ignored in line with RFC 4861.
- If an NS, RS, RA, or Redirect message with a Link Layer Address (MAC) is received from a neighbor that is not yet in the ND cache, a new neighbor entry is created in the cache to store the received Link Layer MAC. The neighbor is put in the STALE state. This is the standard RFC behavior.

Parameters

global

Learns global neighbor entries out of received unsolicited Neighbor Advertisement messages.

link-local

Learns link local neighbor entries out of received unsolicited Neighbor Advertisement messages.

both

Learns both global and link local neighbor entries out of received unsolicited Neighbor Advertisement messages.

Platforms

7705 SAR Gen 2

nd-learn-unsolicited

Syntax

nd-learn-unsolicited {**global** | **link-local** | **both**}

no nd-learn-unsolicited

Context

[Tree] (config>router>if>ipv6 nd-learn-unsolicited)

Full Context

configure router interface ipv6 nd-learn-unsolicited

Description

This command enables the ability to learn neighbor entries out of received unsolicited Neighbor Advertisement messages, with or without the solicited flag set. The command can be enabled for global addresses, link-local addresses, or for both.

The **no** form of this command makes the router follow standard RFC 4861 behavior for learning of neighbor entries.

- If an unsolicited NA (regardless of the S flag) is received from a neighbor that is not yet in the ND cache, the NA is ignored in line with RFC 4861.
- If an NS, RS, RA, or Redirect message with a Link Layer Address (MAC) is received from a neighbor that is not yet in the ND cache, a new neighbor entry is created in the cache to store the received Link Layer MAC. The neighbor is put in the STALE state. This is the standard RFC behavior.

Parameters

global

Learns global neighbor entries out of received unsolicited Neighbor Advertisement messages. This parameter is relevant only to global IPv6 addresses.

link-local

Learns link local neighbor entries out of received unsolicited Neighbor Advertisement messages.

both

Learns both global and link local neighbor entries out of received unsolicited Neighbor Advertisement messages.

Platforms

7705 SAR Gen 2

19.15 nd-proactive-refresh

nd-proactive-refresh

Syntax

nd-proactive-refresh {**global** | **link-local** | **both**}

no nd-proactive-refresh

Context

[Tree] (config>service>ies>if>ipv6 nd-proactive-refresh)

Full Context

configure service ies interface ipv6 nd-proactive-refresh

Description

This command enables a proactive refresh of the neighbor entries. When enabled, at the stale timer expiration, the router sends a NUD message to the host (regardless of the existence of traffic to the IP address on the IOM), so the entry can be refreshed or removed.

This behavior is different from ARP, where the refresh is sent 30 seconds prior to the entry's age out time. The refresh can be optionally enabled for global addresses, link-local addresses, or both.

The **no** form of this command disables the proactive behavior and the router only refreshes an entry if there is traffic that needs to be sent to the IP address.

Parameters

global

Refreshes global neighbor entries.

link-local

Refreshes link local neighbor entries.

both

Refreshes both global and link local neighbor entries.

Platforms

7705 SAR Gen 2

nd-proactive-refresh

Syntax

19.16 nd-router-preference

nd-router-preference

Syntax

nd-router-preference {**medium** | **high** | **low**}

no nd-router-preference

Context

[Tree] (config>service>vprn>router-advert>if nd-router-preference)

[Tree] (config>router>router-advert>if nd-router-preference)

Full Context

configure service vprn router-advertisement interface nd-router-preference

configure router router-advertisement interface nd-router-preference

Description

This command configures the default router preference for Router Advertisement (RA) and allows IPv6 hosts to discover and select a default gateway address by listening to RAs.

This feature provides basic traffic engineering functionality for host devices. When this command is applied, the router advertises the respective router preference to the connected host to assist in its selection of the most appropriate default gateway on a link.

This extension is backward compatible, both for routers (setting the router preference bits) and hosts (interpreting the router preference bits). These bits are ignored by hosts that do not implement the RFC 4191 functionality by configuring this command. Similarly, hosts that do not implement the RFC 4191 functionality interpret the values sent by devices that do not implement the RFC 4191 extension with the **medium** preference option.

The **no** form of this command configures this command to the default value.

Default

nd-router-preference medium

Parameters

medium

Specifies the router advertises a medium default gateway preference.

high

Specifies the router advertises a high default gateway preference.

low

Specifies the router advertises a low default gateway preference.

Platforms

7705 SAR Gen 2

19.17 neid

neid

Syntax

neid *hex-string*

no neid

Context

[Tree] (config>system>ned>profile neid)

Full Context

configure system network-element-discovery profile neid

Description

This command configures the NEID for this profile.

The **no** form of this command deletes the NEID for this profile.

Parameters

hex-string

A hexadecimal string that consists of a subnet ID and basic ID. The first 8 high-order bits indicate the subnet ID and range from 0x1 to 0xFE. The 16 low-order bits indicate the basic ID and ranges from 0x0001 to 0xFFFE. The NEID cannot be configured as 0x90006 to 0x9FF06 or 0x9bff0.

Values 0x10001 to 0xFEFFFE

Platforms

7705 SAR Gen 2

19.18 neighbor

neighbor

Syntax

[**no**] **neighbor** *ip-int-name*

Context

[Tree] (config>router>rip>group neighbor)

[Tree] (config>router>ripng>group neighbor)

[Tree] (config>service>vprn>rip>group neighbor)

Full Context

configure router rip group neighbor

configure router ripng group neighbor

configure service vprn rip group neighbor

Description

This command creates a context for configuring a RIP neighbor interface. By default, group interfaces are not activated with RIP, unless explicitly configured. The BNG only learns RIP routes from IPv4 host on the group interface. The RIP neighbor group interface defaults to **none**. The send operation is unchangeable for group-interface.

The **no** form of this command deletes the RIP interface configuration for this group interface. The shutdown command in the **config>router>rip>group group-name>neighbor** context can be used to disable an interface without removing the configuration for the interface.

Default

no neighbor

Parameters

ip-int-name

Specifies the IP interface name. Interface names must be unique within the group of defined IP interfaces for **config router interface** and **config service ies interface** commands. An interface name cannot be in the form of an IP address. Interface names can be any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

If the IP interface name does not exist or does not have an IP address configured, an error message will be returned.

Platforms

7705 SAR Gen 2

neighbor

Syntax

neighbor *ipv6-address mac-address*

no neighbor *ipv6-address*

Context

[Tree] (config>service>ies>if>ipv6 neighbor)

Full Context

configure service ies interface ipv6 neighbor

Description

This command configures IPv6-to-MAC address mapping on the IES interface.

Parameters

ipv6-address

The IPv6 address of the interface for which to display information.

Values		
	ipv6-address:	x:x:x:x:x:x:x:x (eight 16-bit pieces)
		x:x:x:x:x:x:d.d.d.d
		x - [0..FFFF]H
		d - [0..255]D

mac-address

Specifies the 48-bit MAC address for the IPv6-to-MAC address mapping in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.

Platforms

7705 SAR Gen 2

neighbor

Syntax

[**no**] **neighbor** *ip-address*

Context

[Tree] (config>router>bgp>group neighbor)

Full Context

configure router bgp group neighbor

Description

This command creates a BGP peer/neighbor instance within the context of the BGP group.

This command can be issued repeatedly to create multiple peers and their associated configuration.

The **no** form of this command is used to remove the specified neighbor and the entire configuration associated with the neighbor. The neighbor must be administratively **shutdown** before attempting to delete it. If the neighbor is not shutdown, the command will not result in any action except a warning message on the console indicating that neighbor is still administratively up.

Default

no neighbor

Parameters

ip-address

Specifies the IP address of the BGP peer router in dotted decimal notation.

Values ipv4-address:

- a.b.c.d (host bits must be 0)

ipv6-address:

- x:x:x:x:x:x:x:x [-interface]
- x:x:x:x:x:x:d.d.d.d [-interface]
- x: [0 to FFFF]H
- d: [0 to 255]D

- interface: 32 characters maximum, mandatory for link local addresses

Platforms

7705 SAR Gen 2

neighbor

Syntax

[**no**] **neighbor** *ip-address*

Context

[Tree] (config>service>vprn>bgp>group neighbor)

Full Context

configure service vprn bgp group neighbor

Description

This command creates a BGP peer/neighbor instance within the context of the BGP group.

This command can be issued repeatedly to create multiple peers and their associated configuration.

The **no** form of this command is used to remove the specified neighbor and the entire configuration associated with the neighbor. The neighbor must be administratively **shutdown** before attempting to delete it. If the neighbor is not shut down, the command will not result in any action except a warning message on the console indicating that neighbor is still administratively up.

Parameters

ip-address

The IP address of the BGP peer router in dotted decimal notation.

Values

ipv4-address	a.b.c.d (host bits must be 0)
ipv6-address	x:x:x:x:x:x:x:x[-interface]
	x:x:x:x:x:x:d.d.d.d[-interface]
	x: [0 to FFFF]H
	d: [0 to 255]D
	interface: 32 characters maximum, mandatory for link local addresses

Platforms

7705 SAR Gen 2

neighbor

Syntax

neighbor *ipv6-address mac-address*

no neighbor *ipv6-address*

Context

[Tree] (config>service>vprn>if>ipv6 neighbor)

Full Context

configure service vprn interface ipv6 neighbor

Description

This command configures IPv6-to-MAC address mapping on the interface.

Parameters

ipv6-address

Specifies the IPv6 address on the interface.

Values

ipv6-address	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x [0 to FFFF]H
	d [0 to 255]D

mac-address

Specifies the 48-bit MAC address for the static ARP in the form *aa*:*bb*: *cc*:*dd*:*ee*:*ff* or *aa-bb-cc -dd-ee-ff* where *aa*, *bb*, *cc*, *dd*, *ee* and *ff* are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.

Platforms

7705 SAR Gen 2

neighbor

Syntax

[**no**] **neighbor** *ip-address*

Context

[Tree] (config>service>vprn>ospf>area>if neighbor)

[Tree] (config>service>vprn>ospf3>area>if neighbor)

Full Context

configure service vprn ospf area interface neighbor

configure service vprn ospf3 area interface neighbor

Description

This command configures an OSPF non-broadcast multi-access (NBMA) neighbor. The OSPF interface must be configured as an NBMA interface with the **interface-type non-broadcast** command. An NBMA network has no broadcast or multicast capabilities, so the router cannot discover its neighbors dynamically. All neighbors must be configured statically with the **neighbor** command.

In addition to configuring the OSPF NBMA neighbor's IP address, the neighbor's MAC address may need to be configured with the **config>service>vprn>interface>static-arp** command for OSPFv2 neighbors using its IPv4 address, and the **config>service>vprn>interface>ipv6>neighbor** command for OSPFv3 neighbors using its IPv6 link-local address.

The **no** form of this command removes the **neighbor** configuration.

Default

No OSPF NBMA neighbors are configured.

Parameters

ip-address

Specifies the OSPFv2 neighbor's IPv4 address or the OSPFv3 neighbor's IPv6 link-local address.

Values

ipv4-address:	a.b.c.d
ipv6-address:	x:x:x:x:x:x:x:x [-interface]
	x:x:x:x:x:x:d.d.d.d [-interface]
	x: [0..FFFF]H
	d: [0..255]D
	interface —32 characters max, for link local addresses.

Platforms

7705 SAR Gen 2

neighbor

Syntax

neighbor *ipv6-address mac-address*

no neighbor *ipv6-address*

Context

[Tree] (config>router>if>ipv6 neighbor)

Full Context

configure router interface ipv6 neighbor

Description

This command configures an IPv6-to-MAC address mapping on the interface. Use this command if a directly attached IPv6 node does not support ICMPv6 neighbor discovery, or for some reason, a static address must be used. This command can only be used on Ethernet media.

The *ipv6-address* must be on the subnet that was configured from the IPv6 **address** command or a link-local address.

Parameters

ipv6-address

The IPv6 address assigned to a router interface.

Values

ipv6-address:	x:x:x:x:x:x:x:x (eight 16-bit pieces)	
	x:x:x:x:x:x:d.d.d.d	
	x:	[0 to FFFF]H
	d:	[0 to 255]D

mac-address

Specifies the MAC address for the neighbor in the form of xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx.

Platforms

7705 SAR Gen 2

Context

[Tree] (config>router>ospf3>area>interface neighbor)

[Tree] (config>router>ospf>area>interface neighbor)

Full Context

configure router ospf3 area interface neighbor

configure router ospf area interface neighbor

Description

This command configures an OSPF non-broadcast multi-access (NBMA) neighbor. The OSPF interface must be configured as an NBMA interface with the **interface-type non-broadcast** command. An NBMA network has no broadcast or multicast capabilities, so the router cannot discover its neighbors dynamically. All neighbors must be configured statically with the **neighbor** command.

In addition to configuring the IP address of the OSPF NBMA neighbor, the MAC address of the neighbor may need to be configured with the **config>router>interface>static-arp** command for OSPFv2 neighbors using its IPv4 address, and the **config>router>interface>ipv6>neighbor** command for OSPFv3 neighbors using its IPv6 link-local address.

The **no** form of this command removes the **neighbor** configuration.

Default

no neighbor

Parameters

ipv4-address

Specifies the IPv4 address of the OSPFv2 neighbor.

Values ipv4-address — a.b.c.d

ipv6-address

Specifies the IPv6 link-local address of the OSPFv3 neighbor.

Values

ipv6-address: x:x:x:x:x:x:x:x [-interface]

x:x:x:x:x:x:d.d.d.d [-interface]

x: [0..FFFF]H

d: [0..255]D

interface — 32 characters maximum for link local addresses.

[Tree] (config>router>policy-options>policy-statement>entry>from neighbor)

Full Context

configure router policy-options policy-statement entry to neighbor

configure router policy-options policy-statement entry from neighbor

Description

This command specifies the neighbor address as found in the source address of the actual join and prune message as a filter criterion. If no neighbor is specified, any neighbor is considered a match.

The **no** form of the of the command removes the neighbor IP match criterion from the configuration.

Default

no neighbor

Parameters

ip-address

Specifies the neighbor IP address in dotted decimal notation.

Values ipv4-address:

- a.b.c.d

ipv6-address:

- x:x:x:x:x:x:x:x [-interface]
- x:x:x:x:x:x:d.d.d.d [-interface]
- x: [0 to FFFF]H

- d: [0 to 255]D
- interface: 32 characters maximum, mandatory for link local addresses

prefix-list *name*

Specifies the prefix-list name. Allowed values are any string up to 64 characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

The *name* specified must already be defined.

19.19 neighbor-limit

neighbor-limit

Syntax

neighbor-limit *limit* [**log-only**] [**threshold** *percent*]

no neighbor-limit

Context

[Tree] (config>service>ies>if>ipv6 neighbor-limit)

Full Context

configure service ies interface ipv6 neighbor-limit

Description

This command configures the maximum amount of dynamic IPv6 neighbor entries that can be learned on an IP interface.

When the number of dynamic neighbor entries reaches the configured percentage of this limit, an SNMP trap is sent. When the limit is exceeded, no new entries are learned until an entry expires and traffic to these destinations is dropped. Entries that have already been learned is refreshed.

The **no** form of this command removes the **neighbor-limit**.

Default

no neighbor-limit

Parameters

log-only

Enables the warning message to be sent at the specified threshold percentage, and also when the limit is exceeded. However, entries above the limit is learned.

percent

The threshold value (as a percentage) that triggers a warning message to be sent.

Values 0 to 100

limit

The number of entries that can be learned on an IP interface expressed as a decimal integer. If the limit is set to 0, dynamic neighbor learning is disabled and no dynamic neighbor entries are learned.

Values 0 to 102400

Platforms

7705 SAR Gen 2

Syntax

neighbor-limit *limit* [**log-only**] [**threshold** *percent*]

no neighbor-limit

Context

[Tree] (config>service>vprn>if>ipv6 neighbor-limit)

Full Context

configure service vprn interface ipv6 neighbor-limit

Description

This command configures the maximum amount of dynamic IPv6 neighbor entries that can be learned on an IP interface.

When the number of dynamic neighbor entries reaches the configured percentage of this limit, an SNMP trap is sent. When the limit is exceeded, no new entries are learned until an entry expires and traffic to these destinations will be dropped. Entries that have already been learned will be refreshed.

The **no** form of this command removes the **neighbor-limit**.

Default

neighbor-limit 90

Parameters

log-only

Enables the warning message to be sent at the specified threshold percentage, and also when the limit is exceeded. However, entries above the limit will be learned.

percent

The threshold value (as a percentage) that triggers a warning message to be sent.

Values 0 to 100

limit

The number of entries that can be learned on an IP interface expressed as a decimal integer. If the limit is set to 0, dynamic neighbor learning is disabled and no dynamic neighbor entries are learned.

Values 0 to 102400

19.20 neighbor-liveness-time

neighbor-liveness-time

Syntax

neighbor-liveness-time *interval*

no neighbor-liveness-time

Context

[Tree] (config>router>ldp>graceful-restart neighbor-liveness-time)

Full Context

configure router ldp graceful-restart neighbor-liveness-time

Description

This command configures the neighbor liveness time.

The **no** form of this command returns the default value.

Default

no neighbor-liveness (which equals a value of 120 seconds)

Parameters

interval

Specifies the length of time in seconds.

Values 5 to 300

Platforms

7705 SAR Gen 2

19.21 neighbor-trust

neighbor-trust

Syntax

neighbor-trust [**vpn-ipv4**] [**vpn-ipv6**] [**evpn**]

no neighbor-trust

Context

[Tree] (config>router>bgp neighbor-trust)

Full Context

configure router bgp neighbor-trust

Description

This command enables a label security feature for prefixes of a VPN family at an inter-AS boundary.

This label security feature allows the configuration of a router, acting in a PE, ASBR, or both roles, to accept packets of VPN-IP or EVPN prefixes only from direct EBGP neighbors to which it advertised a service label.

The untrusted state identifies the participating interfaces. The router supports a maximum of 15 network interfaces that can participate in this feature.

At a high level, BGP tracks each direct EBGP neighbor over an untrusted interface to which it sent a prefix label. For each of those prefixes, BGP programs a bitmap in the ILM record that indicates, on per-untrusted interface basis, whether the matching received packets must be forwarded or dropped.

The **no** form of this command disables the inter-AS security feature for the VPN family.

Parameters

vpn-ipv4

Keyword to enable the inter-AS label security for VPN IPv4 family.

vpn-ipv6

Keyword to enable the inter-AS label security for VPN IPv6 family.

evpn

Keyword to enable the inter-AS label security for EVPN family.

Full Context

configure subscriber-mgmt local-user-db ipoe host options netbios-name-server

configure service vprn dhcp local-dhcp-server pool options netbios-name-server

configure router dhcp local-dhcp-server pool options netbios-name-server

Description

This command configures up to four Network Basic Input/Output System (NetBIOS) name server IP addresses for a DHCP client.

The **no** form of this command removes the IP address from the netbios-name-server configuration.

Parameters

ip-address

Specifies up to four NetBIOS name server IP addresses. The address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).

Platforms

7705 SAR Gen 2

19.24 netbios-node-type

[Tree] (config>subscr-mgmt>loc-user-db>ipoe>host>options netbios-node-type)

[Tree] (config>router>dhcp>server>pool>options netbios-node-type)

Full Context

configure service vprn dhcp local-dhcp-server pool options netbios-node-type

configure subscriber-mgmt local-user-db ipoe host options netbios-node-type

configure router dhcp local-dhcp-server pool options netbios-node-type

Description

This command configures the Network Basic Input/Output System (NetBIOS) node type.

The **no** form of this command removes the NetBIOS node type parameters from the configuration.

Parameters

netbios-node-type

Specifies the netbios node type.

Values B — Broadcast node uses broadcasting to query nodes on the network for the owner of a NetBIOS name.

P — Peer-to-peer node uses directed calls to communicate with a known NetBIOS name server for the IP address of a NetBIOS machine name.

M — Mixed node uses broadcast queries to find a node, and if that fails, queries a known P-node name server for the address.

H — Hybrid node is the opposite of the M-node action so that a directed query is executed first, and if that fails, a broadcast is attempted.

19.26 netconf-stream

netconf-stream

Syntax
netconf-stream *stream-name*
no netconf-steam

Context
[Tree] (config>log>log-id netconf-stream)

Full Context
configure log log-id netconf-stream

Description

This command is used to associate a NETCONF stream name with a log ID. The NETCONF stream name must be unique per SR OS device. For the same log ID, **to netconf** must be configured for a subscription to that NETCONF stream name to be accepted. A **netconf-stream** cannot be set to "NETCONF" as "NETCONF" is reserved for log-id 101. If a **netconf-stream** is changed, active subscriptions to the changed stream name are terminated by SR OS.

The **no** form of this command removes a NETCONF stream name from a log ID. Active subscriptions to the removed stream name are terminated by SR OS.

Parameters

stream-name

Specifies a NETCONF stream name, up to 32 characters.

Platforms

7705 SAR Gen 2

Syntax

network *network-policy-id* [**create**] [**name** *name*]

no network *network-policy-id*

Context

[Tree] (config>qos network)

Full Context

configure qos network

Description

This command creates or edits a QoS network policy. The network policy defines the treatment that IP or MPLS packets receive as they ingress and egress the network port.

The QoS network policy consists of an ingress and egress component. The ingress component of the policy defines how DiffServ code points and MPLS EXP bits are mapped to internal forwarding class and profile state. The forwarding class and profile state define the Per Hop Behavior (PHB) or the QoS treatment through the router. The mapping on each network interface defaults to the mappings defined in the default network QoS policy until an explicit policy is defined for the network interface.

The egress component of the network QoS policy defines the queuing parameters associated with each forwarding class. Each of the forwarding classes defined within the system automatically creates a queue on each network interface. This queue gets all the parameters defined within the default network QoS policy 1 until an explicit policy is defined for the network interface access uplink port. If the egressing packet originated on an ingress SAP, or the remarking parameter is defined for the egress interface, the egress QoS policy also defines the IP DSCP, dot1p/DE, or MPLS EXP bit marking based on the forwarding class and the profile state.

Network **policy-id 1** exists as the default policy that is applied to all network interfaces by default. The network **policy-id 1** cannot be modified or deleted. It defines the default DSCP-to-FC mapping and MPLS EXP-to-FC mapping for the ingress. For the egress, it defines six forwarding classes that represent individual queues and the packet marking criteria.

Network **policy-id 1** exists as the default policy that is applied to all network ports by default. This default policy cannot be modified or deleted. It defines the default DSCP-to-FC mapping and default unicast meters for ingress IP traffic. For the egress, it defines the forwarding class to dot1p and DSCP values and the packet marking criteria.

If a new network policy is created (for instance, policy-id 3), only the default action and egress forwarding class parameters are identical to the default policy. A new network policy does not contain the default DSCP-to-FC and MPLS-EXP-to-FC mapping for network QoS policy of type **ip-interface** or the DSCP-to-FC mapping (for network QoS policy of type **port**). The default network policy can be copied (use the copy command) to create a new network policy that includes the default ingress DSCP-to-FC and MPLS EXP-to-FC mapping (as appropriate). Parameters can be modified, or the **no** form of this command can be used to remove an object from the configuration.

Any changes made to an existing policy, using any of the sub-commands, will be applied immediately to all network interfaces where this policy is applied. For this reason, when many changes are required on a policy, it is highly recommended that the policy be copied to a work area policy-id. That work-in-progress policy can be modified until complete, then written over the original policy-id. Use the config qos copy command to maintain policies in this manner.

The **no** form of this command deletes the network policy. A policy cannot be deleted until it is removed from all entities where it is applied. The default network **policy** *policy-id* 1 cannot be deleted.

Default

network 1 — System Default Network Policy 1

Parameters

network-policy-id

The policy-id uniquely identifies the policy on the router.

Values 1 to 65535

Default 1

create

Required parameter when creating a QoS network policy.

name name

A name that is saved as part of the configuration data. If a name is not specified at creation time, then SR OS assigns a string version of the network policy identifier as the name.

Values A string up to 64 characters

configure service vprn network-interface

Description

This command configures a network interface in a VPRN that acts as a CSC interface to a CSC-CE in a Carrier Supporting Carrier IP VPN deployment model.

Parameters

interface-name

Specifies the name of the interface to be added.

create

Keyword used to create the network interface.

Platforms

7705 SAR Gen 2

19.32 network-queue

network-queue

Syntax

network-queue *policy-name* [**create**]

no network-queue *policy-name*

Context

[Tree] (config>qos network-queue)

Full Context

configure qos network-queue

Description

This command creates a context to configure a network queue policy. Network queue policies define the ingress network queuing at the FP network node level and on the Ethernet port and SONET/SDH path level to define network egress queuing.

Default

network-queue "default”

Parameters

policy-name

The name of the network queue policy.

Values Valid names consist of any string up to 32 characters, composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, etc.), the entire string must be enclosed within double quotes.

create

Required keyword when creating a network queue policy.

Platforms

7705 SAR Gen 2

19.35 next-header

next-header

Syntax
next-header *next-header*

no next-header

Context

[Tree] (config>system>security>mgmt-access-filter>ipv6-filter>entry next-header)

Full Context

configure system security management-access-filter ipv6-filter entry next-header

Description

This command specifies the next header to match. The protocol type such as TCP, UDP or OSPF is identified by its respective protocol number. Well-known protocol numbers include ICMP(1), TCP(6), UDP(17). IPv6 Extension headers are identified by the next header IPv6 numbers as per RFC 2460.

Parameters

next-header

Specifies for IPv4 MAF the IP protocol field, and for IPv6 the next header type to be used in the match criteria for this Management Access Filter Entry.

Values

next-header:	0 to 255, protocol numbers accepted in DHB
keywords:	none, crtp, crudp, egp, eigrp, encap, ether-ip, gre, icmp, drp, igmp, igp, ip, ipv6, ipv6-icmp, ipv6-no-nxt, isis, iso-ip, l2tp, spf-igp, pim, pnni, ptp, rdp, rsvp, stp, tcp, udp, vrrp

19.36 next-hop

next-hop

Syntax

next-hop {*ip-address* | *ip-int-name* | *ipv6 address*}

Context

[Tree] (config>service>vprn>static-route-entry next-hop)

Full Context

configure service vprn static-route-entry next-hop

Description

This command specifies the directly connected next hop IP address or interface used to reach the destination. If the next hop is over an unnumbered interface or a point-to-point interface, the *ip-int-name* of the unnumbered or point-to-point interface (on this node) can be configured.

The configured *ip-address* can be either on the network side or the access side on this node. The address must be associated with a network directly connected to a network configured on this node.

Default

no next-hop

Parameters

ip-int-name, ipv4-address, ipv6-address

the IP-INT, IPv4, and IPv6 addresses

Values

ip-int-name	32 characters max
ipv4-address	a.b.c.d
ipv6-address	x:x:x:x:x:x:x:x-[interface]
	x:x:x:x:x:x:d.d.d.d[-interface]
	x: [0 to FFFF]H
	d: [0 to 255]D
	interface: 32 characters maximum, mandatory for link local addresses

Platforms

7705 SAR Gen 2

next-hop

Syntax

next-hop *ip-address*

no next-hop

Context

[Tree] (config>router>mpls>fwd-policies>fwd-policy>nh-grp>pri next-hop)

[Tree] (config>router>mpls>fwd-policies>fwd-policy>nh-grp>bkup next-hop)

Full Context

configure router mpls forwarding-policies forwarding-policy next-hop-group primary-next-hop next-hop

configure router mpls forwarding-policies forwarding-policy next-hop-group backup-next-hop next-hop

Description

This command configures the address of primary or backup next hop of an NHG entry in a forwarding policy.

The **no** form of this command removes the address of primary or backup next hop of an NHG entry in a forwarding policy.

Parameters

ip-address

Specifies the destination IPv4 or IPv6 address.

Values		
	ipv4-address	a.b.c.d
	ipv6-address	x:x:x:x:x:x:x:x (eight 16-bit pieces)
		x:x:x:x:x:x:d.d.d.d
		x - [0..FFFF]H
		d - [0..255]D

Platforms

7705 SAR Gen 2

next-hop

Syntax

next-hop {*ip-int-name* | *ip-address* | *ipv6-address*}

Context

[Tree] (config>router>static-route-entry next-hop)

Full Context

configure router static-route-entry next-hop

Description

This command specifies the directly connected next hop IP address or interface used to reach the destination. If the next hop is over a point-to-point unnumbered interface, the **ip-int-name** of the unnumbered point-to-point interface (on this node) can be configured.

The configured *ip-address* can be either on the network side or the access side on this node. The address must be associated with a network directly connected to a network configured on this node.

Default

no next-hop

Parameters

ip-int-name* | *ip-address* | *ipv6-address

Specifies the interface or IPv4/IPv6 address of the next hop.

Values

ip-int-name	32 characters max
ipv4-address	a.b.c.d
ipv6-address	x:x:x:x:x:x:x:x-[interface]
	x:x:x:x:x:x:d.d.d.d[-interface]
	x: [0..FFFF]H
	d: [0..255]D
	interface: 32 characters maximum, mandatory for link local addresses

Platforms

7705 SAR Gen 2

next-hop

Syntax

[**no**] **next-hop** *ip-address*

Context

[Tree] (config>vrrp>policy>priority-event>route-unknown next-hop)

Full Context

configure vrrp policy priority-event route-unknown next-hop

Description

This command enables an allowed next hop IP address to match the IP route prefix for a route-unknown priority control event.

If the next-hop IP address does not match one of the defined *ip-address*, the match is considered unsuccessful and the **route-unknown** event transitions to the set state.

The **next-hop** command is optional. If no **next-hop** *ip-address* commands are configured, the comparison between the RTM prefix return and the **route-unknown** IP route prefix are not included in the next hop information.

When more than one next hop IP addresses are eligible for matching, a **next-hop** command must be executed for each IP address. Defining the same IP address multiple times has no effect after the first instance.

The **no** form of the command removes the *ip-address* from the list of acceptable next hops when looking up the **route-unknown** prefix. If this *ip-address* is the last next hop defined on the **route-unknown** event, the returned next hop information is ignored when testing the match criteria. If the *ip-address* does not exist, the **no next-hop** command returns a warning error, but continues to execute if part of an **exec** script.

Default

no next-hop — No next hop IP address for the route unknown priority control event is defined.

Parameters

ip-address

The IP address for an acceptable next hop IP address for a returned route prefix from the RTM when looking up the **route-unknown** route prefix.

Values

ipv4-address:	a.b.c.d	
ipv6-address:	x:x:x:x:x:x:x:x[-interface]	
	x:	[0..FFFF]H
	interface:	32 chars maximum, mandatory for link local addresses

The link-local IPv6 address must have an interface name specified. The global IPv6 address must not have an interface name specified.

Platforms

7705 SAR Gen 2

next-hop

Syntax

next-hop *ip-address*

next-hop prefix-list *name*

no next-hop

Context

[Tree] (config>router>policy-options>policy-statement>entry>from next-hop)

Full Context

configure router policy-options policy-statement entry from next-hop

Description

This command enables BGP routes to be matched based on the BGP next-hop address. The match condition is evaluated against the IPv4 or IPv6 address in the NEXT_HOP or MP_REACH_NLRI attribute.

When the next-hop match is applied to VPN-IP routes, the Route Distinguisher (RD) is ignored.

A non-BGP route does not match a policy entry if it contains the **next-hop** command.

Default

no next-hop

Parameters

ip-address

An IPv4 or IPv6 address.

Values a.b.c.d or x:x:x:x:x:x:x:x or x:x:x:x:x:x:d.d.d.d

name

Specifies the name of a prefix-list (up to 64 characters).

prefix-list

Specifies that the BGP next hop should be matched against a prefix-list instead of an individual IP address.

Platforms

7705 SAR Gen 2

next-hop

Syntax

next-hop {*ip-address* | **peer-address**}

no next-hop

Context

[Tree] (config>router>policy-options>policy-statement>entry>action next-hop)

[Tree] (config>router>policy-options>policy-statement>default-action next-hop)

Full Context

configure router policy-options policy-statement entry action next-hop

configure router policy-options policy-statement default-action next-hop

Description

This command assigns the specified next hop IP address to routes matching the policy statement entry.

If a next-hop IP address is not specified, the next-hop attribute is not changed.

The **no** form of this command disables assigning a next hop address in the route policy entry.

Default

no next-hop

Parameters

ip-address

Specifies the next hop IP address in dotted decimal notation.

Values

ipv4-address:	a.b.c.d	
ipv6-address:	x:x:x:x:x:x:x:x	
	x:x:x:x:x:x:d.d.d.d	
	x:	[0 to FFFF]H
	d:	[0 to 255]D
param-name:	The next-hop parameter variable name.	
	Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes. Policy parameters must start and end with at-signs (@); for example, "@variable@”.	

peer-address

configure router mpls forwarding-policies forwarding-policy next-hop-group

Description

This command configures an NHG entry in an MPLS forwarding policy.

Each NHG can have primary and backup next hops of the same type.

The **no** form of this command removes the NHG from the MPLS forwarding policy.

Parameters

index

Specifies the index value.

Values 1 to 32

direct

Specifies the direct resolution type.

indirect

Specifies the indirect resolution type.

configure service vprn bgp group bfd-strict-mode next-hop-reachability

configure service vprn bgp group neighbor bfd-strict-mode next-hop-reachability

configure router bgp group bfd-strict-mode next-hop-reachability

Description

This command configures the router to consider next-hop self routes belonging to specific address families received from a peer within scope of this command as having an unresolved next hop, provided that the following requirements are met:

- The BFD session to the peer is in a down state.
- There is a valid interface BFD configuration that applies to the peer.
- There is a valid BFD liveness configuration that applies to the peer.

The unresolved state is maintained until the BFD session state changes to up or administratively down, even if there is a resolving route or tunnel that matches the BGP next-hop address.

Routes received from one peer with a BGP next-hop address equal to the address of another peer are not affected by the BFD session to the other peer.

The behavior of the router when this command is enabled does not depend on whether Strict-BFD is used, as both features are independent.

Enabling this command only affects routes belonging to the following address families:

- IPv4
- IPv6
- IPv4 VPN
- IPv6 VPN
- labeled unicast IPv4
- labeled unicast IPv6
- EVPN
- IPv4 multicast
- IPv6 multicast
- IPv4 VPN multicast
- IPv6 VPN multicast

The **no** form of this command prevents the router from considering next-hop self routes belonging to the preceding address families as having an unresolved next hop if the BFD session goes down.

Default

no next-hop-reachability

[Tree] (config>service>vprn>bgp>group next-hop-self)

Full Context

configure service vprn bgp group neighbor next-hop-self

configure service vprn bgp group next-hop-self

Description

This command configures the group or neighbor to always set the NEXTHOP path attribute to its own physical interface when advertising to a peer.

This is primarily used to avoid third-party route advertisements when connected to a multi-access network.

The **no** form of this command used at the group level allows third-party route advertisements in a multi-access network.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Default

no next-hop-self — Third-party route advertisements are allowed.

Platforms

7705 SAR Gen 2

next-hop-self

Syntax

[**no**] **next-hop-self**

Context

[Tree] (config>router>bgp>group next-hop-self)

[Tree] (config>router>bgp>group>neighbor next-hop-self)

Full Context

configure router bgp group next-hop-self

configure router bgp group neighbor next-hop-self

Description

This command enables BGP to advertise routes to members of a group or to a specific neighbor using a local address of the BGP instance as the BGP next-hop address. Note that **next-hop-self** is set without exception, regardless of the route source (EBGP or IBGP) or its family. When used with VPN-IPv4 and VPN-IPv6 routes the **enable-rr-vpn-forwarding** command should also be configured.

The **no** form of this command uses protocol standard behavior to decide whether or not to set **next-hop-self** in advertised routes.

Default

no next-hop-self

Platforms

7705 SAR Gen 2

next-hop-self

Syntax

Context

[Tree] (config>router>policy-options>policy-statement>default-action next-hop-self)

[Tree] (config>router>policy-options>policy-statement>entry>action next-hop-self)

Full Context

configure router policy-options policy-statement default-action next-hop-self

configure router policy-options policy-statement entry action next-hop-self

Description

This command configures BGP to advertise routes that match a policy entry (or that match no other policy entry and, therefore, to which the default action applies) using a local address of the BGP instance as the BGP next-hop address. The command applies to IPv4, IPv6, label-IPv4, and label-IPv6 routes. It also applies to VPN-IPv4 and VPN-IPv6 routes, but only when used in conjunction with the **enable-rr-vpn-forwarding** command.

This command affects how routes are advertised to IBGP peers, regardless of whether or not they were learned from an IBGP or EBGP peer

The **no** form of this command uses protocol standard behavior to decide whether or not to set **next-hop-self** in advertised routes.

Default

no next-hop-self

Platforms

next-hop-unchanged

Syntax

next-hop-unchanged [**label-ipv4**] [**label-ipv6**] [**vpn-ipv4**] [**vpn-ipv6**] [**evpn**]

no next-hop-unchanged

Context

[Tree] (config>router>bgp>group next-hop-unchanged)

[Tree] (config>router>bgp>group>neighbor next-hop-unchanged)

Full Context

configure router bgp group next-hop-unchanged

configure router bgp group neighbor next-hop-unchanged

Description

This command enables unchanged BGP next-hops when sending BGP routes to peers in this group or neighbor.

The **no** form of this command disables unchanged BGP next-hops.

Default

no next-hop-unchanged

Parameters

evpn

Specifies BGP next hops are unchanged for the evpn address family.

label-ipv4

Specifies BGP next hops are unchanged for the label-ipv4 address family.

label-ipv6

Specifies BGP next hops are unchanged for the label-ipv6 address family.

vpn-ipv4

Specifies BGP next hops are unchanged for the vpn-ipv4 address family.

vpn-ipv6

Specifies BGP next hops are unchanged for the vpn-ipv6 address family.

19.42 nh-type

nh-type

Syntax

nh-type {**ip** | **tunnel**}

no nh-type

Context

[Tree] (config>router>route-next-hop-policy>template nh-type)

Full Context

configure router route-next-hop-policy template nh-type

Description

This command configures the next-hop type constraint into the route next-hop policy template.

The user can select if tunnel backup next-hop or IP backup next-hop is preferred. The default in SR OS implementation is to prefer IP next-hop over tunnel next-hop. The implementation will fall back to the other type if no LFA next-hop of the preferred type is found.

When the route next-hop policy template is applied to an IP interface, all prefixes using this interface as a primary next-hop will follow the next-hop type preference specified in the template.

The **no** form deletes the next-hop type constraint from the route next-hop policy template.

Default

nh-type ip

Parameters

{ip | tunnel}

Specifies the two possible values for the next-hop type.

Default ip

Full Context

configure router mpls lsp fast-reroute node-protect

configure router mpls lsp-template fast-reroute node-protect

Description

This command enables or disables node and link protection on the specified LSP. Node protection ensures that traffic from an LSP traversing a neighboring router will reach its destination even if the neighboring router fails.

Default

node-protect (for a provisioned LSP)

no node-protect (for a P2P LSP template)

Platforms

7705 SAR Gen 2

node-protect

Syntax

node-protect [**max-pq-nodes** *value*]

no node-protect

Context

[Tree] (config>router>isis>loopfree-alternates>remote-lfa node-protect)

Full Context

configure router isis loopfree-alternates remote-lfa node-protect

Description

This command enables node-protect in which the router prefers a node-protect over a link-protect repair tunnel for a given prefix if both are found in the Remote LFA or TI-LFA SPF computations. The SPF computations may only find a link-protect repair tunnel for prefixes owned by the protected node.

The **no** form of this command disables node-protect.

Default

no node-protect

Parameters

value

Specifies the maximum number of PQ nodes found in the LFA SPFs for which the node protection check is performed. The node-protect condition means the router must run the

original Remote LFA algorithm plus one extra forward SPF on behalf of each PQ node found, potentially after applying the **max-pq-cost** parameter, to check if the path from the PQ node to the destination does not traverse the protected node. Setting this parameter to a lower value means the LFA SPFs will use less computation time and resources but may result in not finding a node-protect repair tunnel.

19.47 node-sid

node-sid

Syntax

node-sid index *index-value* [**clear-n-flag**]

node-sid label *label-value* [**clear-n-flag**]

no node-sid

Context

[Tree] (config>router>ospf>area>interface node-sid)

Full Context

configure router ospf area interface node-sid

Description

This command assigns a node SID index or label value to the prefix representing the primary address of a network interface of type system or loopback. A separate SID value can be configured for each IPv4 and IPv6 primary address of the interface. The secondary address of an IPv4 interface cannot be assigned a node SID index and does not inherit the SID of the primary IPv4 address.

In OSPFv2 and OSPFv3, the node SID is configured in the primary area but is inherited in any other area in which the interface is added as secondary.

This command fails if the network interface is not of type loopback or if the interface is defined in an IES or VPRN context. Assigning the same SID index or label value to the same interface in two different IGP instances is not allowed within the same node.

The value of the label or index SID is taken from the range configured for this IGP instance. When using the global mode of operation, the segment routing module checks that the same index or label value is not assigned to more than one loopback interface address. When using the per-instance mode of operation, this check is not required because the index, and therefore, the label ranges of IGP instances are not allowed to overlap.

The **clear-n-flag** option allows the user to clear the N-flag (node-sid flag) in an OSPF or OSPF3 prefix SID sub-TLV originated for the prefix of a loopback interface on the system. By default, the prefix SID sub-TLV for the prefix of a loopback interface is tagged as a node SID; that is, it belongs to this node only. However, to configure and advertise an anycast SID using the same loopback interface prefix on multiple nodes, the user must clear the N-flag to assure interoperability with third-party implementations, which may perform a strict check on the receive end and drop duplicate prefix SID sub-TLVs when the N-flag is set.

The SR OS implementation is relaxed on the receive end and accepts duplicate prefix SIDs with the N-flag set or clear. SR OS will resolve to the closest owner, or owners if ECMP, of the prefix SID cost-wise.

Parameters

index-value

Specifies the node SID index value.

Values 0 to 4294967295

label-value

Specifies the node SID label value.

Values 0 to 4294967295

clear-n-flag

Clears the node SID flag.

Default no clear-n-flag

non-dr-attract-traffic

Syntax

[**no**] **non-dr-attract-traffic**

Context

[Tree] (config>service>vprn>pim non-dr-attract-traffic)

Full Context

configure service vprn pim non-dr-attract-traffic

Description

This command specifies whether the router should ignore the designated router state and attract traffic even when it is not the designated router.

An operator can configure an interface (router or IES or VPRN interfaces) to IGMP and PIM. The interface IGMP state will be synchronized to the backup node if it is associated with the redundant peer port. The interface can be configured to use PIM which will cause multicast streams to be sent to the elected DR only. The DR will also be the router sending traffic to the DSLAM. Since it may be required to attract traffic to both routers a flag non-dr-attract-traffic can be used in the PIM context to have the router ignore the DR state and attract traffic when not DR. While using this flag, the router may not send the stream down to the DSLAM while not DR.

When enabled, the designated router state is ignored. When disabled, **no non-dr-attract-traffic**, the designated router value is honored.

configure filter redirect-policy notify-dest-change

Description

This command instructs the system to send notifications (Log, SNMP, …) when the active destination of a redirect policy changes. No notification is sent when there are no more active destinations (as this is covered by a specific other notification). Notifications can be controlled (using the **config**>**log**>**event-control** command) using application ID *2017* and event-name *tFilterRPActiveDstChangeEvent*.

The **no** form of the command disables notification generation.

Default

no notify-dest-change

19.59 nssa

nssa

Syntax

[**no**] **nssa**

Context

[Tree] (config>service>vprn>ospf3>area nssa)

[Tree] (config>service>vprn>ospf>area nssa)

Full Context

configure service vprn ospf3 area nssa

configure service vprn ospf area nssa

Description

This command creates the context to configure an OSPF Not So Stubby Area (NSSA) and adds/removes the NSSA designation from the area.

NSSAs are similar to stub areas in that no external routes are imported into the area from other OSPF areas. The major difference between a stub area and an NSSA is that an NSSA has the capability to flood external routes that it learns throughout its area and via an ABR to the entire OSPF domain.

Existing virtual links of a non-stub or NSSA area are removed when the designation is changed to NSSA or stub.

An area can be designated as stub or NSSA but never both at the same time.

By default, an area is not configured as an NSSA area.

The **no** form of this command removes the NSSA designation and configuration context from the area.

Default

no nssa — The OSPF area is not an NSSA.

Platforms

7705 SAR Gen 2

19.61 ntp

ntp

Syntax

[**no**] **ntp**

Context

[Tree] (config>service>vprn ntp)

Full Context

configure service vprn ntp

Description

Commands in this context configure Network Time Protocol (NTP) and its operation. It also enables NTP server mode within the VPRN routing instance so that the router will respond to NTP requests from external clients received inside the VPRN.

The **no** form of this command stops the execution of NTP and removes its configuration.

Platforms

7705 SAR Gen 2

ntp

Syntax

[**no**] **ntp**

Context

[Tree] (config>system>time ntp)

Full Context

configure system time ntp

Description

Commands in this context configure Network Time Protocol (NTP) and its operation. This protocol defines a method to accurately distribute and maintain time for network elements. Furthermore, this capability allows for the synchronization of clocks between the various network elements.

The **no** form of the command stops the execution of NTP and remove its configuration.

Default

ntp

Platforms

7705 SAR Gen 2

ntp

Syntax

ntp [**router** *router-instance*] [**interface** *ip-int-name*]

Context

[Tree] (debug>system ntp)

Full Context

debug system ntp

Description

This command enables and configures debugging for NTP.

The **no** form of the command disables debugging for NTP.

Parameters

router-instance

Specifies the router name or CPM router instance.

Values *router-name* | *vprn-svc-id*

router-name – "Base", "management"

vprn-svc-id – 1 to 2147483647

Default Base

ip-int-name

Specifies the name of the IP interface. The name can be up to 32 characters and must begin with a letter. If the string contains special characters (#, $, spaces, etc.), the entire string must be enclosed within double quotes.

19.63 ntp-server

ntp-server

Syntax

ntp-server [**authenticate**]

no ntp-server

Context

[Tree] (config>system>time>ntp ntp-server)

Full Context

configure system time ntp ntp-server

Description

This command configures the node to assume the role of an NTP server. Unless the **server** command is used, this node will function as an NTP client only and will not distribute the time to downstream network elements.

Default

no ntp-server

Parameters

authenticate

Specifies to make authentication a requirement (optional). If authentication is required, the authentication key-id received in a message must have been configured in the **authentication-key** command, and that key-id type and key value must also match.

The authentication key from the received messages will be used for the transmitted messages.

19.64 number

number

Syntax

number {**eq** | **neq** | **lt** | **lte** | **gt** | **gte**} *event-id*

no number

Context

[Tree] (config>service>vprn>log>filter>entry>match number)

Full Context

configure service vprn log filter entry match number

Description

This command adds an SR OS application event number as a match criterion.

SR OS event numbers uniquely identify a specific logging event within an application.

Only one **number** command can be entered per event filter entry. The latest **number** command overwrites the previous command.

The **no** form of this command removes the event number as a match criterion.

Default

no event-number — No event ID match criterion is specified.

Parameters

eq | neq | lt | lte | gt | gte

Specifies the type of match. Valid operators are listed below.

Values

Table 71: Valid Operators

Operator	Note
eq	equal to
neq	not equal to
lt	less than
lte	less than or equal to
gt	greater than
gte	greater than or equal to

event-id

Specifies the event ID, expressed as a decimal integer.

Values 1 to 4294967295

19.65 number-down

number-down

Syntax

[**no**] **number-down** *number-of-lag-ports-down*

Context

[Tree] (config>vrrp>policy>priority-event>lag-port-down number-down)

Full Context

configure vrrp policy priority-event lag-port-down number-down

Description

This command creates a context to configure an event set threshold within a lag-port-down priority control event.

The **number-down** command defines a sub-node within the **lag-port-down** event and is uniquely identified with the *number-of-lag-ports-down* parameter. Each **number-down** node within the same **lag-port-down** event node must have a unique *number-of-lag-ports-down* value. Each **number-down** node has its own **priority** command that takes effect whenever that node represents the current threshold.

The total number of sub-nodes (uniquely identified by the *number-of-lag-ports-down* parameter) allowed in a single **lag-port-down** event is equal to the total number of possible physical ports allowed in a LAG.

A **number-down** node is not required for each possible number of ports that could be down. The active threshold is always the closest lower threshold. When the number of ports down equals a given threshold, that is the active threshold.

The **no** form of the command deletes the event set threshold. The threshold may be removed at any time. If the removed threshold is the current active threshold, the event set thresholds must be re-evaluated after removal.

Default

no number-down — No threshold for the LAG priority event is created.

Parameters

number-of-lag-ports-down

The number of LAG ports down to create a set event threshold. This is the active threshold when the number of down ports in the LAG equals or exceeds *number-of-lag-ports-down*, but does not equal or exceed the next highest configured *number-of-lag-ports-down*.

Values 1 to 64 (applies to 64-link LAG) 1 to 32 (applies to other LAGs)

Syntax

oam-pm session *session-name* {**dm** | **dmm** | **lmm** | **slm** | **twamp-light**} { **start** | **stop**}

Context

[Tree] (oam oam-pm)

Full Context

oam oam-pm

Description

This command allows the operator to start and stop on-demand OAM-PM sessions.

Parameters

session-name

Identifies the session name, up to 32 characters, that the test is associated with.

dm

Specifies the MPLS delay measurement test that is affected by the command.

dmm

Specifies the DMM test that is affected by the command.

lmm

Specifies the LMM test that is affected by the command.

slm

Specifies the SLM test that is affected by the command.

twamp-light

Specifies the TWAMP-light test that is affected by the command.

start

Manually starts the test.

stop

Manually stops the test.

Platforms

20.8 open

open

Syntax
open [**neighbor** *ip-address* | **group** *name*]
no open

Context
[Tree] (debug>router>bgp open)

Full Context
debug router bgp open

Description

This command decodes and logs all sent and received open messages in the debug log.

The **no** form of this command disables debugging.

Parameters

neighbor *ip-address*

Debugs only events affecting the specified BGP neighbor.

Values ipv4-address:

- a.b.c.d (host bits must be 0)

ipv6-address:

- x:x:x:x:x:x:x:x [-interface] (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d [-interface]
- x: [0 to FFFF]H
- d: [0 to 255]D
- interface: up to 32 characters for link local addresses

group *name*

Debugs only events affecting the specified peer group name, up to 64 characters, and associated neighbors.

Platforms

7705 SAR Gen 2

20.9 oper-group

oper-group

Syntax

oper-group *name*

no oper-group

Context

[Tree] (config>service>epipe oper-group)

Full Context

configure service epipe oper-group

Description

This command associates an operational group to the status of the Epipe. When this oper-group is used in Epipes with static VXLAN or BGP-EVPN, the oper-group behaves as follows:

- The Epipe (and the oper-group) goes down if a SAP or spoke SDP goes operationally down because of an administrative shutdown, service shutdown, or non-DF status as a result of EVPN multi-homing single-active election.
- The Epipe (and oper-group) goes down if the Epipe's EVPN destination is removed (because of an EVPN AD per-EVI route withdrawal, for example).
- The Epipe (and oper-group) does not go down if a static VXLAN destination exists and the egress VTEP is not in the global route table.

The operational group must be monitored in a different service and not in the service where it is defined.

The **no** version of this command removes the oper-group association.

Parameters

name

Specifies the name of the **oper-group**, up to 32 characters.

Platforms

7705 SAR Gen 2

oper-group

Syntax

oper-group *name*

no oper-group

Context

[Tree] (config>service>vpls>bgp-evpn>mpls oper-group)

[Tree] (config>service>epipe>bgp-evpn>mpls oper-group)

Full Context

configure service vpls bgp-evpn mpls oper-group

configure service epipe bgp-evpn mpls oper-group

Description

This command adds the BGP EVPN MPLS, SRv6, or VXLAN instance or Ethernet Segment (ES) as a member of the operational group.

When configured on an ES, the state of the operational group depends on the state of the SAPs contained in the ES. The operational group transitions to up if at least one SAP in the ES is up. The operational group goes down when all the associated SAPs are operationally down. The ES operational group should be monitored on the LAG associated with the ES, along with single-active multi-homing, so that the NDF state can be signaled to the CE by LAG standby signaling.

When configured on a BGP EVPN instance, the operational group is up when it is either empty (meaning that the operational group has no members) or at least an EVPN destination is created under the EVPN instance added as member. When configured, no other SAP, SDP binding, or BGP EVPN instance can be added to the same operational group within the same or a different service.

The operational group is down when the following apply:

- on a BGP EVPN instance
- the service is disabled
- the BGP EVPN MPLS, VXLAN or SRv6 instance are disabled
- all the EVPN destinations in the instance are removed

Default

no oper-group

Parameters

name

Specifies the name of the operational group, up to 32 characters.

Platforms

7705 SAR Gen 2

oper-group

Syntax

oper-group *group-name*

no oper-group

Context

[Tree] (config>service>epipe>sap oper-group)

Full Context

configure router interface ipv6 vrrp oper-group

configure router interface vrrp oper-group

Description

This command configures VRRP to associate with an operational group. When associated, VRRP notifies the operational group of its state changes so that other protocols can monitor it to provide a redundancy mechanism. When VRRP is the master router (MR), the operational group is up; the operational group is down for all other VRRP states.

The **no** form of the command removes the association.

Default

no oper-group — No operational group is configured.

Parameters

group-name

Specifies the operational group identifier, up to 32 characters.

Platforms

7705 SAR Gen 2

oper-group

Syntax

oper-group *group-name* [**create**]

no oper-group *group-name*

Context

[Tree] (config>service oper-group)

Full Context

configure service oper-group

Description

This command creates a system-wide group (operational group) name which can be used to associate a number of service objects (for example, SAPs or pseudowires). The status of the group is derived from the status of its members. The status of the group can then be used to influence the status of non-member objects. For example, when a group status is marked as down, the object(s) that monitor the group change their status accordingly.

The **no** form of the command removes the group. All the object associations need to be removed before the no form of the command can be executed.

Default

no oper-group

Parameters

group-name

Specifies the operational group identifier up to 32 characters in length.

create

This keyword is required when first creating the configuration context. Once the context is created, it is possible to navigate into the context without the **create** keyword.

no option

Context

[Tree] (config>filter>dhcp-filter>entry option)

Full Context

configure filter dhcp-filter entry option

Description

This command configures match criteria for the DHCP filter policy entry.

The **no** form of this command reverts to the default.

Parameters

dhcp-option-number

Specifies the DHCP option number.

Values 0 to 255

present

Specifies that the related DHCP option must be present.

absent

Specifies that the related DHCP option must be absent.

hex-string

Specifies that the option must partially match a specified hex string.

Values 0x0 to 0xFFFFFFFF (up to 254 hex nibbles)

ascii-string

Specifies that the option must partially match a specified ASCII string, up to 127 characters.

exact

Specifies that this option requires an exact match of a hex or ASCII string.

invert-match

Requires the option not to partially match.

Platforms

7705 SAR Gen 2

option

Syntax

option *dhcp6-option-number* {**present** | **absent**}

option *dhcp6-option-number* **match hex** *hex-string* [**exact**] [**invert-match**]

option *dhcp6-option-number* **match string** *ascii-string* [**exact**] [**invert-match**]

no option

Context

[Tree] (config>filter>dhcp6-filter>entry option)

Full Context

configure filter dhcp6-filter entry option

Description

This command configures match criteria for the DHCP6 filter policy entry.

The **no** form of this command reverts to the default.

Parameters

dhcp-option-number

Specifies the DHCP6 option number.

Values 0 to 255

present

Specifies that the related DHCP6 option must be present.

absent

Specifies that the related DHCP6 option must be absent.

match hex *hex-string*

Specifies that the option must (partially) match a specified hex string.

Values 0x0 to 0xFFFFFFFF (up to 254 hex nibbles)

match string *ascii-string*

Specifies that the option must partially match a specified ASCII string, up to 127 characters.

exact

Specifies that this option requires an exact match of a hex or ASCII string.

invert-match

Requires the option not to partially match.

configure filter ip-filter entry match option-present

Description

This command configures matching packets that contain any IP options in the IP header as an IP filter match criterion.

The **no** form of the command removes the checking of IP options in the IP header as a match criterion.

Default

no option-present

Parameters

true

Specifies matching on all IP packets that contain any IP options in the IP header. A match occurs for all packets that have any IP option present. An option field of zero is considered as no option present.

false

Specifies matching on IP packets that do not have any IP option present in the IP header. (an option field of zero). An option field of zero is considered as no option present.

option60 string *ascii-string*

no option60

Context

[Tree] (config>subscr-mgmt>loc-user-db>ipoe>host>host-ident option60)

Full Context

configure subscriber-mgmt local-user-db ipoe host host-identification option60

Description

This command specifies the Vendor-Identifying Vendor Option to match. Option 60 is encoded as Type-Length-Value (TLV). The *hex-string* portion of Option 60 in the received DHCP request is used for matching. Only the first 32 bytes can be defined here. If Option 60 from the message is longer, those bytes are ignored.

Note:
This command is only used when **option60** is configured as one of the **match-list** parameters.

The **no** form of this command removes **option60** from the configuration.

Parameters

hex-string

Specifies the hexadecimal format for this option.

Values 0x0 to 0xFFFFFFFF(maximum 64 hex nibbles)

ascii-string

Specifies the string format for this option, up to 32 characters.

20.19 origin

origin

Syntax

origin {**igp** | **egp** | **incomplete** | **any** | **aaa** | **dynamic** | **static** | **bonding | pfcp**}

no origin

Context

[Tree] (config>router>policy-options>policy-statement>entry>from origin)

Full Context

configure router policy-options policy-statement entry from origin

Description

This command configures the match criteria for the origin attribute of the route. The origin attribute is applicable to BGP routes and to the following subscriber-management routes.

- Host routes (for example, IPv4 /32 address, or IPv6 SLAAC prefix) carry the origin attribute with the **aaa**, **dynamic**, or **static** options, depending on the address assignment method. For CUPS hosts, the

pfcp option is used for the origin attribute. Host routes can also be distinguished using the **sub-mgmt** option for the **protocol** command.

- Dynamically provisioned prefixes or loopback addresses carry the origin attribute with the **aaa** or **pfcp** options, depending on the protocol that provides the prefix and address. Dynamic routes can also be distinguished using the **direct** option for the **protocol** command.
- Statically configured prefixes under the subscriber interface do not have an origin attribute.These routes can be distinguished using the **direct** option for the **protocol** command.
- Framed routes for non-CUPS hosts do not have an origin attribute. Framed routes for CUPS hosts use the **pfcp** option for the origin attribute. Alternatively, framed routes can be distinguished using the **managed** option for the **protocol** command.

These values that are specific to subscriber-management routes are never carried in BGP updates as part of the BGP origin attribute and are not visible within the BGP process.

Default

no origin

Parameters

igp

Specifies path-matching information that originates within the local AS.

egp

Specifies path-matching information that originates in another AS.

incomplete

Configures path-matching information learned by another method.

any

Specifies to ignore this criteria.

aaa

Specifies to use the subscriber-host address that originates from AAA.

Values IPv4 — subscriber-management /32 host routes that originate from the RADIUS framed-ip-address VSA other than 255.255.255.254. The 255.255.255.254 returned by the RADIUS indicates that the BNG (NAS) should assign an IP address from its own pool.

IPv6 — subscriber-management routes that originate through framed-ipv6-prefix (SLAAC), delegated-ipv6-prefix (IA_PD) or alc-ipv6-address (IA_NA) RADIUS attributes. It is also applicable to VSA Alc-IPv6-Sub-If-Prefix, where the subscriber interface prefix can originate from RADIUS. This is valid for IPoE and PPPoE type hosts.

dynamic

Specifies to use the subscriber host address that originates from DHCP, DHCPv6, or the local address server.

Values IPv4 — subscriber-management /32 host routes that originate from the DHCP server (local or remote) or RADIUS framed-ip-address=255.255.255.254 (RFC 2865).

IPv6 — subscriber-management routes that are assigned via local DHCPv6 server pools whose name is obtained through the Alc-Delegated-IPv6-Pool (PD pool) and Framed-IPv6-Pool (NA pool) RADIUS attributes, or the local address server whose name is obtained through the Alc-SLAAC-IPv6-Pool (SLAAC pool) RADIUS attribute. This is valid for IPoE and PPPoE type hosts.

For IPoEv6 only, the pool name can also be obtained from ipv6-delegated-prefix-pool (PD pool) and ipv6-wan-address-pool (NA pool) from the LUDB.

static

Specifies to use the subscriber-host address that originates from the local user database.

Values IPv4 — subscriber-management /32 host routes that originate from the LUDB and also covers the RADIUS fallback category (RADIUS falls back to system defaults or to the LUDB).

IPv6 — subscriber-management routes that originate from the LUDB from ipv6-address (IA_NA) or ipv6-prefix (IA_PD), or ipv6-slaac-prefix (SLAAC).

bonding

Specifies to use bonding.

pfcp

Specifies to use routes learned using the PFCP protocol.

Platforms

7705 SAR Gen 2

origin

Syntax

origin {**igp** | **egp** | **incomplete** | *param-name*}

Context

[Tree] (config>router>policy-options>policy-statement>default-action origin)

[Tree] (config>router>policy-options>policy-statement>entry>action origin)

Full Context

configure router policy-options policy-statement default-action origin

configure router policy-options policy-statement entry action origin

Description

This command sets the BGP origin assigned to routes exported into BGP.

If the routes are exported into protocols other than BGP, this option is ignored.

The **no** form of this command disables setting the BGP origin for the route policy entry.

Default

no origin

Parameters

igp

Sets the path information as originating within the local AS.

egp

Sets the path information as originating in another AS.

incomplete

Sets the path information as learned by some other means.

param-name

The origin parameter variable name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes. Policy parameters must start and end with at-signs (@); for example, "@variable@”.

Full Context

configure router policy-options policy-statement default-action origin-validation-state

configure router policy-options policy-statement entry action origin-validation-state

Description

This command is used to mark BGP IPv4 and IPv6 routes matching the **default-action** or a specific entry of a route policy with one of the 3 following origin validation states:

- Valid (0)
- Not-Found (1)
- Invalid (2)

Default

no origin-validation-state

Parameters

state

Specifies the default operational origin validation state for this policy statement.

Values valid — Marks the route as having an origin validation state of valid.

notFound — Marks the route as having an origin validation state of Not Found.

invalid — Marks the route as having an origin validation state of invalid.

param-name

Specifies the origin parameter variable name. Allowed values are any string up to 32 characters, composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes. Policy parameters must start and end with at-signs (@); for example, "@variable@”.

no originate-default-route

Context

[Tree] (config>service>vprn>ospf>area>nssa originate-default-route)

[Tree] (config>service>vprn>ospf3>area>nssa originate-default-route)

Full Context

configure service vprn ospf area nssa originate-default-route

configure service vprn ospf3 area nssa originate-default-route

Description

This command specifies whether when configuring an NSSA with no summaries, the Area Border Router (ABR) injects a type-7 LSA default route into the NSSA area. The default behavior is to inject a type-3 LSA default route, but some older implementations expect a type-7 LSA default route.

When configuring an NSSA with no summaries, the ABR will inject a type 3 LSA default route into the NSSA area. Some older implementations expect a type 7 LSA default route.

The **no** form of this command disables origination of a default route.

Default

no originate-default-route — A default route is not originated.

Parameters

type-nssa

Specifies that a type 7 LSA should be used for the default route.

Configure this parameter to inject a type 7 LSA default route into an NSSA configured with no summaries, instead of a type 3 LSA.

To revert to a type 3 LSA, execute the **originate-default-route** command without the **type-nssa** parameter.

Default type 3 LSA default route

adjacency-check

Specifies whether adjacency checks are performed before originating a default route. If this parameter is configured, then no area 0 adjacency is required for the ABR to advertise the default route.

Default Adjacency checks are performed, and an area 0 adjacency is required for the ABR to advertise the default route

Platforms

7705 SAR Gen 2

originate-default-route

Syntax

originate-default-route [**type-7**] [**no-adjacency-check**]

originate-default-route [**type-nssa**] [**no-adjacency-check**]

no originate-default-route

Context

[Tree] (config>router>ospf>area>nssa originate-default-route)

[Tree] (config>router>ospf3>area>nssa originate-default-route)

Full Context

configure router ospf area nssa originate-default-route

configure router ospf3 area nssa originate-default-route

Description

This command enables the generation of a default route and its LSA type (3 or 7) into a Not So Stubby Area (NSSA) by an NSSA Area Border Router (ABR).

When configuring an NSSA with no summaries, the ABR will inject a type 3 LSA default route into the NSSA area. Some older implementations expect a type 7 LSA default route.

The **no** form of this command disables origination of a default route.

Default

no originate-default-route

Parameters

type-7

Specifies a type 7 LSA should be used for the default route in the **config**>**router**>**ospf**>**area**>**nssa** context.

Configure this parameter to inject a type-7 LSA default route instead the type 3 LSA into the NSSA configured with no summaries.

To revert to a type 3 LSA, enter **originate-default-route** without the **type-7** parameter.

Default Type 3 LSA default route.

type-nssa

Specifies an NSSA-LSA type should be used for the default route in the **config**>**router**>**ospf3**>**area**>**nssa** context.

no-adjacency-check

Specifies whether adjacency checks are performed before originating a default route. If this parameter is configured, then no area 0 adjacency is required for the ABR to advertise the default route.

Default Adjacency checks are performed, and an area 0 adjacency is required for the ABR to advertise the default route.

20.25 orphan-override

orphan-override

Syntax

orphan-override [**level** *priority-level*] [**weight** *weight*] [**cir-level** *cir-level*] [**cir-weight** *cir-weight*]

no orphan-override

Context

[Tree] (config>qos>port-scheduler-policy orphan-override)

Full Context

configure qos port-scheduler-policy orphan-override

Description

This command overrides the default orphan behavior for port schedulers created using the port scheduler policy. The default orphan behavior is to give all orphan queues and schedulers bandwidth after all other properly parented queues and schedulers. Orphans by default do not receive any within-CIR bandwidth and receive above-CIR bandwidth after priority levels 8 through 1 have been allocated. The orphan-override command accepts the same parameters as the port-parent command in the SAP egress and network queue policy contexts. The defined parameters are used as a default port-parent association for any queue or scheduler on the port that the port scheduler policy is applied.

Orphan queues and schedulers are identified as:

- Any queue or scheduler that does not have a port-parent or parent command applied
- Any queue that has a parent command applied, but the specified scheduler name does not exist on the queue's SAP, MSS, or SLA Profile instance.

A queue or scheduler may be properly parented to an upper level scheduler, but that scheduler may be orphaned. In this case, the queue or scheduler receives bandwidth from its parent scheduler based on the parent schedulers ability to receive bandwidth as an orphan.

Within-CIR Priority Level Parameters

The within-CIR parameters define which port priority level the orphan queues and schedulers should be associated with when receiving bandwidth for the queue or schedulers within-CIR offered load. The within-CIR offered load is the amount of bandwidth the queue or schedulers could use that is equal to or less than its defined or summed CIR value. The summed value is only valid on schedulers and is the sum of the within-CIR offered loads of the children attached to the scheduler. The parameters that control within-CIR bandwidth allocation for orphans are the orphan-override commands cir-level and cir-weight keywords. The cir-level keyword defines the port priority level that the scheduler or queue uses to receive bandwidth for its within-CIR offered load. The cir-weight is used when multiple queues or schedulers exist at the same port priority level for within-CIR bandwidth. The weight value defines the relative ratio that is used to distribute bandwidth at the priority level when more within-CIR offered load exists than the port priority level has bandwidth.

A cir-weight equal to zero (the default value) has special meaning and informs the system that the orphan queues and schedulers do not receive bandwidth from the within-CIR distribution. Instead, all bandwidth for the orphan queues and schedulers must be allocated from the port scheduler's above-CIR pass.

Above-CIR Priority Level Parameters

The above-CIR parameters define which port priority level the orphan queues and schedulers should be associated with when receiving bandwidth for the queue or schedulers above-CIR offered load. The above-CIR offered load is the amount of bandwidth the queue or schedulers could use that is equal to or less than its defined PIR value (based on the queue or schedulers rate command) less any bandwidth that was given to the queue or scheduler during the above-CIR scheduler pass. The parameters that control above-CIR bandwidth allocation for orphans are the orphan-override commands level and weight keywords. The **level** keyword defines the port priority level that the scheduler or queue uses to receive bandwidth for its above-CIR offered load. The weight is used when multiple queues or schedulers exist at the same port priority level for above-CIR bandwidth. The weight value defines the relative ratio that is used to distribute bandwidth at the priority level when more above-CIR offered load exists than the port priority level has bandwidth.

The **no** form of this command removes the orphan override port parent association for the orphan queues and schedulers on port schedulers created with the port scheduler policy. Any orphan queues and schedulers on a port associated with the port scheduler policy will revert to default orphan behavior.

Parameters

level *priority-level*

Defines the port priority the orphan queues and schedulers will use to receive bandwidth for their above-CIR offered-load.

Values 1 to 8 (8 is the highest priority)

Default 1

weight *weight*

Defines the weight the orphan queues and schedulers will use in the above-CIR port priority level (defined by the level parameter).

Values 1 to 100

Default 1

cir-level *cir-level*

Defines the port priority the orphan queues and schedulers will use to receive bandwidth for their within-CIR offered-load. If the cir-weight parameter is set to a value of 0 (the default value), the orphan queues and schedulers do not receive bandwidth during the port scheduler's within-CIR pass and the cir-level parameter is ignored. If the cir-weight parameter is 1 or greater, the cir-level parameter comes into play.

Values 1 to 8 (8 is the highest level)

cir-weight *cir-weight*

Defines the weight the orphan queues and schedulers will use in the within-CIR port priority level (defined by the cir-level parameter). When the cir-weight parameter is set to a value of 0 (the default value), the orphan queues and schedulers do not receive bandwidth

during the port scheduler's within-CIR pass and the cir-level parameter is ignored. If the cir-weight parameter is 1 or greater, the cir-level parameter comes into play.

Values 1 to 100 (100 is the highest weight)

Platforms

7705 SAR Gen 2

20.26 ospf

ospf

Syntax

ospf [*router-id*]

no ospf

Context

[Tree] (config>service>vprn ospf)

Full Context

configure service vprn ospf

Description

This command enables access to the context to enable an OSPF protocol instance.

OSPF instances are **shutdown** when created, so that all parameters can be configured prior to the instance being enabled.

The **no** form of this command deletes the OSPF protocol instance removing all associated configuration parameters.

Default

no ospf

Parameters

router-id

Specifies the OSPF router ID to be used with the associated OSPF instance. The *router-id* must be given a dot decimal notation format.

Values a.b.c.d

Platforms

7705 SAR Gen 2

ospf

Syntax

ospf *ospf-instance* [*router-id*]

[**no**] **ospf** *ospf-instance*

Context

[Tree] (config>router ospf)

Full Context

configure router ospf

Description

This command creates an OSPF routing instance and then enters the associated context to configure the associated protocol parameters.

Additionally, the router ID can be specified as another parameter of the OSPF command. This parameter is required for all non-base OSPF instances.

The default value for the base instance is inherited from the configuration in the **config**>**router** context. When that is not configured, the following apply:

1. the system uses the system interface address (which is also the loopback address)
2. if a system interface address is not configured, it uses the last 32 bits of the chassis MAC address

This is a required command when configuring multiple instances and the instance being configured is not the base instance. When configuring multiple instances of OSPF, there is a risk of loops because networks are advertised by multiple domains configured with multiple interconnections to one another. To prevent this from happening, all routers in a domain should be configured with the same domain ID. Each domain (OSPF-instance) should be assigned a specific bit value in the 32-bit tag mask.

The default value for non-base instances is 0.0.0.0 and is invalid; in this case, the instance of OSPF will not start. When configuring a new router ID, the instance is not automatically restarted with the new router ID. The next time the instance is initialized, the new router ID is used.

Issue the shutdown and no shutdown commands for the instance for the new router ID to be used, or reboot the entire router.

OSPF instances are **shutdown** when created, so that all parameters can be configured prior to the instance being enabled.

The **no** form of this command to reverts to the default value.

Default

no ospf

Parameters

ospf-instance

Specifies a unique integer that identifies a specific instance of a version of the OSPF protocol running in the router instance specified by the router ID.

Values 1 to 31

router-id

Specifies the OSPF router ID to be used with the associated OSPF instance. This IP address must be given a dot decimal notation format.

Platforms

7705 SAR Gen 2

ospf

Syntax

ospf [*ospf-instance*]

no ospf [*ospf-instance*]

Context

[Tree] (debug>router ospf)

Full Context

debug router ospf

Description

Indicates the OSPF instance for debugging purposes.

Parameters

ospf-instance

Debugs the specified OSPF instance.

Values 0 to 31

Platforms

20.27 ospf-dynamic-hostnames

ospf-dynamic-hostnames

Syntax

[**no**] **ospf-dynamic-hostnames**

Context

[Tree] (config>system ospf-dynamic-hostnames)

Full Context

configure system ospf-dynamic-hostnames

Description

This command enables OSPF dynamic hostnames.

The router receiving the new Dynamic Hostname within the OSPF Router Information (RI) LSA is instructed to process the received dynamic hostname information.

The **no** form of this command disables OSPF dynamic hostnames.

Default

no ospf-dynamic-hostnames

Platforms

7705 SAR Gen 2

20.28 ospf3

ospf3

Syntax

ospf3 [*instance-id*] [*router-id*]

[**no**] **ospf3** *instance-id*

Context

[Tree] (config>service>vprn ospf3)

Full Context

configure service vprn ospf3

Description

This command creates an OSPFv3 routing instance and then enters the associated context to configure associated protocol parameters.

OSPF instances are **shutdown** when created, so that all parameters can be configured before the instance is enabled.

The **no** form of this command deletes the OSPFv3 protocol instance, removing all associated configuration parameters.

Default

no ospf3

Parameters

instance-id

Specifies the instance ID for the OSPFv3 instance being created or modified. The instance ID must match the specified range based on the address family.

Values 0 to 31: IPv6 unicast

64 to 95: IPv4 unicast

router-id

Specifies the IP address.

Platforms

7705 SAR Gen 2

20.36 out-remark

out-remark

Syntax

out-remark {**dscp** *dscp-name* | **prec** *ip-prec-value*}

no out-remark

Context

[Tree] (config>qos>sap-ingress>fc out-remark)

Full Context

configure qos sap-ingress fc out-remark

Description

This command is used in a SAP ingress QoS policy to define an explicit out-of-profile remark action for a forwarding class or subclass. While the SAP ingress QoS policy may be applied to any SAP, the remarking functions are only enforced when the SAP is associated with an IP or subscriber interface (in an IES or VPRN). When the policy is applied to a Layer 2 SAP (for example, Epipe or VPLS), the remarking definitions are silently ignored.

In the case where the policy is applied to a Layer 3 SAP, the out-of-profile remarking definition will be applied to packets that have been classified to the forwarding class or subclass. It is possible for a packet to match a classification command that maps the packet to a particular forwarding class or subclass, only to have a more explicit (higher priority match) override the association. Only the highest priority match forwarding class or subclass association will drive the out-of-profile marking.

The out-remark command is only applicable to ingress IP routed packets that are considered out-of-profile. The profile of a SAP ingress packet is affected by either the explicit in-profile/out-of-profile definitions or the ingress policing function applied to the packet. Table 73: Out-remark Command Effect describes the effect of the out-remark command on received SAP ingress packets. Within the out-of-profile IP packet's ToS field, either the six DSCP bits or the three precedence bits are remarked.

Table 73: Out-remark Command Effect

SAP Ingress Packet State	out-remark Command Effect
Non-Routed, Policed In-Profile	No Effect (non-routed packet)
Non-Routed, Policed Out-of-Profile	No Effect (non-routed packet)
Non-Routed, Explicit In-Profile	No Effect (non-routed packet)
Non-Routed, Explicit Out-of-Profile	No Effect (non-routed packet)
IP Routed, Policed In-Profile	No Effect (in-profile packet)
IP Routed, Policed Out-of-Profile	out-remark value applied to IP header ToS field
IP Routed, Explicit In-Profile	No Effect (in-of-profile packet)
IP Routed, Explicit Out-of-Profile	out-remark value applied to IP header ToS field

A packet that is explicitly remarked at ingress will not be affected by any egress remarking decision. Explicit ingress remarking has highest priority.

An explicit dscp name or precedence value must be specified for out-of-profile remarking to be applied.

The **no** form of this command disables ingress remarking of out-of-profile packets classified to the forwarding class or subclass.

Default

no out-remark

Parameters

dscp *dscp-name*

Specifies that the matching packet's DSCP bits should be overridden with the value represented by *dscp-name*.

The *dscp-name* parameter is a 6-bit value. It must be one of the predefined DSCP names defined on the system.

Values be, cp1, cp2, cp3, cp4, cp5, cp6, cp7, cs1, cp9, af11, cp11, af12, cp13, af13, cp15, cs2, cp17, af21, cp19, af22, cp21, af23, cp23, cs3, cp25, af31, cp27, af32, cp29, af33, cp31, cs4, cp33, af41, c p35, af42, cp37, af43, cp39, cs5, cp41, cp42, cp43, cp44, cp45, e f, cp47, nc1, cp49, cp50, cp51, cp52, cp53, cp54, cp55, nc2, cp57, cp58, cp59, cp60, cp61, cp62, cp63

prec *ip-prec-value*

Specifies that the matching packet's precedence bits should be overridden with the value represented by *ip-prec-value*.

The value specified by *ip-prec-value* is used to overwrite the precedence bits within a matching routed packets IP header ToS field.

Values 0 to 7

Platforms

7705 SAR Gen 2

20.37 outband

outband

Syntax

outband *service-id*

no outband

Context

[Tree] (config>system>security>vprn-aaa-server outband)

Full Context

configure system security vprn-aaa-server outband

Description

This command configures TACACS+ and RADIUS servers in a VPRN to be used for AAA by that VPRN and by sessions on the console or out-of-band (OOB) Ethernet ports.

The **no** form of this command disables the use of servers in out-of-band management.

Default

no outband

Parameters

service-id

Specifies the VPRN server for AAA to use for OOB sessions.

Values *service-id*: 1 to 2147483648

svc-name: 64 characters maximum

Platforms

7705 SAR Gen 2

20.38 outbound-max-sessions

outbound-max-sessions

Syntax

outbound-max-sessions *number-of-sessions*

no outbound-route-filtering

Platforms

7705 SAR Gen 2

outbound-route-filtering

Syntax

[**no**] **outbound-route-filtering**

Context

[Tree] (debug>router>bgp outbound-route-filtering)

Full Context

debug router bgp outbound-route-filtering

Description

This command enables debugging for all BGP outbound route filtering (ORF) packets. ORF is used to inform a neighbor of targets (using target-list) that it is willing to receive.

Platforms

7705 SAR Gen 2

20.40 outer-tag

outer-tag

Syntax

outer-tag *value* [*vid-mask*]

no outer-tag

Context

[Tree] (config>qos>sap-ingress>mac-criteria>entry>match outer-tag)

Full Context

configure qos sap-ingress mac-criteria entry match outer-tag

Description

This command configures the matching of the first tag that is carried transparently through the service. Service delimiting tags are stripped from the frame and the outer tag on ingress is the first tag after any service delimiting tags. The outer tag is the first tag before any service delimiting tags on egress. This allows matching VLAN tags for explicit filtering or QoS setting when using default or null encapsulations.

On dot1Q SAPs, the outer tag is the only tag that can be matched. On dot1Q SAPs with exact match (sap 2/1/1:50), the outer tag will be populated with the next tag that is carried transparently through the service or 0 if there is no additional VLAN tags on the frame.

On QinQ SAPs that strip a single service delimiting tag, the outer tag will contain the next tag (which is still the first tag carried transparently through the service.) On SAPs with two service delimiting tags (two tags stripped), the **outer-tag** will contain 0 even if there are more than two tags on the frame.

The optional *vid_mask* is defaulted to 4095 (exact match) but may be specified to allow pattern matching. The masking operation is ((value & vid-mask) = = (tag & vid-mask)). A value of 6 and a mask of 7 would match all VIDs with the lower 3 bits set to 6.

For QoS, the VID type cannot be specified on the default QoS policy.

The default vid-mask is set to 4095 for exact match.

configure system security management-interface output-authorization

Description

This command configures the authorization of the configuration and state output in model-driven interfaces and telemetry. When enabled, commands that display configuration or state output authorize every element in the output. If a remote AAA server is configured, this can cause delays in displaying output while it is authorized. If a large amount of output is displayed, for example, when displaying the system configuration, the remote AAA server receives a large number of authorization requests.

Input to edit the configuration is not affected by this command, and is always authorized.

[Tree] (config>router>nat>inside>deterministic>address-map outside-range)

Full Context

configure service vprn nat inside deterministic address-map outside-range

configure router nat inside deterministic address-map outside-range

Description

This command configures the mapping of the inside address range of deterministic NAT subscribers to the first IP address in the outside IP address range in the NAT pool.

The last outside IP address is determined by the number of subscribers mapped to an outside IP address via the **configure router nat outside pool subscriber-limit** and **configure service vprn nat outside pool subscriber-limit** commands.

The **no** form of this command removes the configuration.

Default

no outside-range

Parameters

outside-ip-address

Specifies an outside IPv4 address.

Values a.b.c.d

Platforms

7705 SAR Gen 2

20.44 overlapping-reverse-route

overlapping-reverse-route

Syntax

[**no**] **overlapping-reverse-route**

Context

[Tree] (config>service>vprn>ipsec overlapping-reverse-route)

Full Context

configure service vprn ipsec overlapping-reverse-route

Description

This command configures the router to accept overlapping DL2L tunnel reverse routes from different tunnels and install the routes based on the preference, metric, or ECMP configuration.

This command is mutually exclusive with the **configure service vprn ipsec allow-reverse-route-override-type** command.

The **no** form of this command disables the acceptance of overlapping reverse routes. The router handles the overlapping route according to the **allow-reverse-route-override-type** command configuration. See the *7705 SAR Gen 2 Multiservice ISA and ESA Guide* for more information.

Default

no overlapping-reverse-route

Platforms

7705 SAR Gen 2

20.45 overload

overload

Syntax

overload [**timeout** *seconds*] [**max-metric**]

no overload

Context

[Tree] (config>service>vprn>isis overload)

Full Context

configure service vprn isis overload

Description

This command administratively sets the IS-IS router to operate in the overload state for a specific time period, in seconds, or indefinitely.

During normal operation, the router may be forced to enter an overload state due to a lack of resources. When in the overload state, the router is only used if the destination is reachable by the router and will not be used for other transit traffic.

If a time period is specified, the overload state persists for the configured length of time. If no time is specified, the overload state operation is maintained indefinitely.

The **overload** command can be useful in circumstances where the router is overloaded or used prior to executing a **shutdown** command to divert traffic around the router.

The **max-metric** parameter can be set to advertise transit links with the maximum metric of 0xffffffe (wide metrics) or 0x3f (regular metrics), instead of setting the overload bit when placing the router in overload.

The **no** form of this command causes the router to exit the overload state.

Default

no overload

Parameters

seconds

Specifies the time, in seconds, that this router must operate in overload state.

Values 60 to 1800

Default infinity (overload state maintained indefinitely)

max-metric

Set the maximum metric instead of overload.

Platforms

7705 SAR Gen 2

overload

Syntax

overload [**timeout** *seconds*]

no overload

Context

[Tree] (config>service>vprn>ospf overload)

[Tree] (config>service>vprn>ospf3 overload)

Full Context

configure service vprn ospf overload

configure service vprn ospf3 overload

Description

This command changes the overload state of the local router so that it appears to be overloaded. When overload is enabled, the router can participate in OSPF routing, but is not used for transit traffic. Traffic destined for directly attached interfaces continue to reach the router.

To put the IGP in an overload state, enter a **timeout** value. The IGP enters the overload state until the **timeout** timer expires or a **no overload** command is executed.

If the **overload** command is performed during the execution of an **overload-on-boot** command, the **overload** command takes precedence. This could occur as a result of a saved configuration file in which both parameters are saved. When the file is saved by the system, the **overload-on-boot** command is saved after the **overload** command.

Use the **no** form of this command to return to the default. When the **no overload** command is executed, the overload state is terminated, regardless the reason the protocol entered overload state.

Default

no overload

Parameters

timeout seconds

Specifies the number of seconds to reset overloading.

Values 60 to1800

Default 60

Platforms

7705 SAR Gen 2

overload

Syntax

overload [**timeout** *seconds*] [**max-metric**]

no overload

Context

[Tree] (config>router>isis overload)

Full Context

configure router isis overload

Description

This command administratively sets the IS-IS router to operate in the overload state for a specific time period, in seconds, or indefinitely.

During normal operation, the router may be forced to enter an overload state because of a lack of resources. When in the overload state, the router is only used if the destination is reachable by the router and is not used for other transit traffic.

If a time period is specified, the overload state persists for the configured length of time. If no time is specified, the overload state operation is maintained indefinitely.

The overload command is cleared from the configuration after a reboot if **overload-on-boot** is configured with or without a timeout value. To keep the IS-IS router in the overload state indefinitely after rebooting, configure **overload-on-boot** with no timeout value or configure the **overload** command with **no overload-on-boot** command.

The **overload** command can be useful in circumstances where the router is overloaded or used before executing a **shutdown** command to divert traffic around the router.

The **max-metric** parameter can be set to advertise transit links with the maximum metric of 0xfffffffe (wide metrics) or 0x3f (regular metrics), instead of setting the overload bit when placing the router in overload.

The **no** form of this command causes the router to exit the overload state.

Default

no overload

Parameters

seconds

Specifies the time, in seconds, that this router must operate in overload state.

Default infinity (overload state maintained indefinitely)

Values 60 to 1800

max-metric

Sets the maximum metric instead of overload.

Platforms

7705 SAR Gen 2

overload

Syntax

overload [**timeout** *seconds*]

no overload

Context

[Tree] (config>router>ospf3 overload)

[Tree] (config>router>ospf overload)

Full Context

configure router ospf3 overload

configure router ospf overload

Description

This command changes the overload state of the local router so that it appears to be overloaded. When overload is enabled, the router can participate in OSPF routing, but is not used for transit traffic. Traffic destined to directly attached interfaces continues to reach the router.

To put the IGP in an overload state enter a timeout value. The IGP will enter the overload state until the timeout timer expires or a **no overload** command is executed.

If the **overload** command is encountered during the execution of an **overload-on-boot** command then this command takes precedence. This could occur as a result of a saved configuration file where both parameters are saved. When the file is saved by the system the **overload-on-boot** command is saved after the **overload** command. **However**, when **overload-on-boot** is configured under OSPF with no timeout value configured, the router will remain in overload state indefinitely after a reboot.

The **no** form of this command reverts to the default. When the **no overload** command is executed, the overload state is terminated regardless of the reason the protocol entered overload state.

Default

no overload

Parameters

timeout seconds

Specifies the number of seconds to reset overloading.

Values 1 to 1800 in the following context.

```
configure router ospf
```

60 to 1800 in the following context.

```
configure router ospf3
```

[Tree] (config>service>vprn>isis overload-fib-error-notify-only)

Full Context

configure router isis overload-fib-error-notify-only

configure service vprn isis overload-fib-error-notify-only

Description

This command configures the IS-IS router to send a notification when an overload condition occurs when programming the FIB, instead of advertising the overload condition of the router in the IS-IS LSP.

Note: Nokia recommends being careful using this command. When you configure the router not to advertise the IS-IS overload state in the IS-IS LSP, other routers are not instructed to take the overloaded router out of the IS-IS forwarding topology and this will cause suboptimal forwarding and non-deterministic behavior on the overloaded router. To avoid changing the default IS-IS overflow behavior, leave this command disabled.

When this command is configured, the IS-IS router enters a suboptimal state where it only sends a notification trap; the router can still be used by transit traffic in this state. The IS-IS router tracks the segment routing prefix SIDs where FIB programming failed. With the **retry** parameter configured, the router retries programming the segment routing prefix SIDs in the FIB using this tracked information.

When this command is not configured, during normal operation, the system may force the router to enter an overload state because of a lack of FIB resources. In this state, the router is used to terminate traffic and is not used to transit traffic.

The removal of the **overload-fib-error-notify-only** command configuration causes the system to program the failed entries in the FIB by triggering an immediate SPF.

The **no** form of this command causes the router to enter the full overload state.

Default

no overload-fib-error-notify-only

Parameters

seconds

Specifies the time, in seconds, this router uses to retry programming the failed entries in the FIB when **overload-fib-error-notify-only** is configured. The **overload-fib-error-notify-only** command must be configured to use the retry timer.

Values 10 to 1800

no overload-on-boot

Context

[Tree] (config>service>vprn>isis overload-on-boot)

Full Context

configure service vprn isis overload-on-boot

Description

When the router is in an overload state, it is used only if there is no other router to reach the destination. This command configures the IGP upon bootup in the overload state until one of the following events occur:

- The timeout timer expires.
- A manual override of the current overload state is entered with the **config>router>isis>no overload** command.

  The **no overload** command does not affect the **overload-on-boot** function.

If no timeout is specified, IS-IS will go into overload indefinitely after a reboot. After the reboot, the IS-IS status will display a permanent overload state:

- L1 LSDB Overload : Manual on boot (Indefinitely in overload)
- L2 LSDB Overload : Manual on boot (Indefinitely in overload)

This state can be cleared with the **config>router>isis>no overload** command.

When specifying a timeout value, IS-IS will go into overload for the configured timeout after a reboot. After the reboot, the IS-IS status will display the remaining time the system stays in overload:

- L1 LSDB Overload : Manual on boot (Overload Time Left : 17)
- L2 LSDB Overload : Manual on boot (Overload Time Left : 17)

The overload state can be cleared before the timeout expires with the **config>router>isis>no overload** command.

The **no** form of this command removes the overload-on-boot functionality from the configuration.

Use the **show router isis status** command to display the administrative and operational state as well as all timers.

Default

no overload-on-boot

Parameters

timeout *seconds*

Configure the timeout timer for overload-on-boot in seconds.

Values 60 to 1800

max-metric

Set the maximum metric instead of overload.

Platforms

21 p Commands – Part I

21.1 p2p-active-path-fast-retry

p2p-active-path-fast-retry

Syntax

p2p-active-path-fast-retry *seconds*

no p2p-active-path-fast-retry

Context

[Tree] (config>router>mpls p2p-active-path-fast-retry)

Full Context

configure router mpls p2p-active-path-fast-retry

Description

This command configures a global parameter to allow the user to apply a shorter retry timer for the first try after an active LSP path went down due to a local failure or the receipt of a ResvTear. This timer is used only in the first try. Subsequent retries will continue to be governed by the existing LSP level retry-timer.

The **no** form of this command disables the timer.

Default

no p2p-active-path-fast-retry

Parameters

seconds

Specifies the length of time for retry timer, in seconds

Values 1 to 10 seconds

Platforms

7705 SAR Gen 2

21.2 p2p-merge-point-abort-timer

p2p-merge-point-abort-timer

Syntax

p2p-merge-point-abort-timer *seconds*

no p2p-merge-point-abort-timer

Context

[Tree] (config>router>rsvp p2p-merge-point-abort-timer)

Full Context

configure router rsvp p2p-merge-point-abort-timer

Description

This command configures a timer to abort Merge-Point (MP) node procedures for a P2P LSP path. When a value higher than zero is configured for this timer, it will enter into effect anytime this node activates Merge-Point procedures for one or more P2P LSP paths. As soon an ingress interface goes operationally down, the Merge-Point node starts the abort timer. Upon expiry of the timer, MPLS will clean up all P2P LSP paths which ILM is on the failed interface and which have not already received a Path refresh over the bypass LSP.

The **no** form of this command disables the timer.

Default

no p2p-merge-point-abort-timer

Parameters

seconds

Specifies the length of the abort timer in seconds

Values 1 to 65535

Platforms

7705 SAR Gen 2

21.3 packet

packet

Syntax

packet [**query** | **v1-report** | **v2-report** | **v3-report** | **v2-leave**] [*ip-int-name* | *ip-address*] [**mode** {**dropped-only** | **ingr-and-dropped** | **egr-ingr-and-dropped**}]

packet [**query** | **v1-report** | **v2-report** | **v3-report** | **v2-leave**] [**mode** { **dropped-only** | **ingr-and-dropped** | **egr-ingr-and-dropped**}] **group-interface** *ip-int-name*

packet [**query** | **v1-report** | **v2-report** | **v3-report** | **v2-leave**] **host** *ip-address* [**mode** {**dropped-only** | **ingr-and-dropped** | **egr-ingr-and-dropped**}]

no packet [**query** | **v1-report** | **v2-report** | **v3-report** | **v2-leave**] [*ip-int-name* | *ip-address*]

Context

[Tree] (debug>router>igmp packet)

Full Context

debug router igmp packet

Description

This command enables/disables debugging for IGMP packets.

Parameters

query

Specifies to log the IGMP group- and source-specific queries transmitted and received on this interface.

v1-report

Specifies to debug IGMP V1 reports transmitted and received on this interface.

v2-report

Specifies to debug IGMP V2 reports transmitted and received on this interface.

v3-report

Specifies to debug IGMP V3 reports transmitted and received on this interface.

v2-leave

Specifies to debug the IGMP Leaves transmitted and received on this interface.

ip-int-name

Debugs the information associated with the specified IP interface name.

Values IP interface address

ip-address

Debugs the information associated with the specified IP address.

Platforms

7705 SAR Gen 2

packet

Syntax

packet [**detail**]

no packet

Context

[Tree] (debug>router>ldp>if packet)

[Tree] (debug>router>ldp>peer packet)

Full Context

debug router ldp interface packet

debug router ldp peer packet

Description

This command enables debugging for specific LDP packets.

The **no** form of the command disables the debugging output.

Parameters

detail

Displays detailed information.

Platforms

7705 SAR Gen 2

packet

Syntax

[**no**] **packet**

Context

[Tree] (debug>router>rsvp packet)

Full Context

debug router rsvp packet

Description

Commands in this context debug packets.

Platforms

7705 SAR Gen 2

packet

Syntax

packet [**hello** | **register** | **register-stop** | **jp** | **bsr** | **assert** | **crp** | **mdt-tlv** | **auto-rp-announcement** | **auto-rp-mapping** | **graft** | **graft-ack**] [*ip-int-name* | *mt-int-name* | *int-ip-address* | *mpls-if-name*] [**family** {**ipv4** | **ipv6**}] [**send** | **receive**]

no packet

Context

[Tree] (debug>router>pim packet)

Full Context

debug router pim packet

Description

This command enables debugging for PIM packets.

The **no** form of this command disables debugging for PIM packets.

Parameters

hello | register | register-stop | jp | bsr | assert | crp | mdt-tlv | auto-rp-announcement | auto-rp-mapping | graft | graft-ack

Specifies PIM packet types.

ip-int-name

Debugs the information associated with the specified IP interface name, up to 32 characters.

mt-int-name

Debugs the information associated with the specified VPRN ID and group address.

Values *vprn-id*-mt-*grp-ip-address*

int-ip-address

Debugs the information associated with the specified IP address.

ipv4

Specifies to display IPv4 packets.

ipv6

Specifies to display IPv6 packets.

mpls-if-name

Debugs the information associated with the specified MPLS interface.

Values mpls-if-*index*

receive

Specifies to display received packets.

send

Specifies to display sent packets.

family

Debugs database packet information.

Values ipv4, ipv6

Platforms

7705 SAR Gen 2

packet

Syntax

packet [{*ip-int-name* | *ip-address*}] [**headers**] [*protocol-id*]

no packet [{*ip-int-name* | *ip-address*}]

Context

Full Context

debug router ip packet

Description

This command enables debugging for IP packets.

Parameters

ip-int-name

Only displays the interface information associated with the specified IP interface name.

Values 32 characters maximum

ip-address

Only displays the interface information associated with the specified IP address.

headers

Only displays information associated with the packet header.

protocol-id

Specifies the decimal value representing the IP protocol to debug. Well-known protocol numbers include ICMP(1), TCP(6), UDP(17). The **no** form the command removes the protocol from the criteria.

Values 0 to 255 (values can be expressed in decimal, hexadecimal, or binary)

Context

[Tree] (debug>router>isis packet)

Full Context

debug router isis packet

Description

This command enables debugging for IS-IS packets.

The **no** form of the command disables debugging.

Parameters

ip-address

When specified, only packets with the specified interface address are debugged.

Values ipv4-address:

- a.b.c.d (host bits must be 0)

ipv6-address:

- x:x:x:x:x:x:x:x (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d
- x: [0 to FFFF]H
- d: [0 to 255]D

ip-int-name

When specified, only packets with the specified interface name are debugged.

packet-type

When specified, only packets of the specified type are debugged.

Values ptop-hello | l1-hello | l2-hello | l1-psnp | l2-psnp | l1-csnp | l2-csnp | l1-lsp | l2-lsp

21.4 packet-byte-offset

packet-byte-offset

Syntax

packet-byte-offset {**add** *add-bytes* | **subtract** *sub-bytes*}

no packet-byte-offset

Context

[Tree] (config>card>fp>ingress>access>qgrp>policer-over>plcr packet-byte-offset)

[Tree] (config>card>fp>ingress>network>qgrp>policer-over>plcr packet-byte-offset)

Full Context

configure card fp ingress access queue-group policer-override policer packet-byte-offset

configure card fp ingress network queue-group policer-override policer packet-byte-offset

Description

This command modifies the size of each packet handled by the policer by adding or subtracting a number of bytes. The actual packet size is not modified; only the size used to determine the bucket depth impact is changed. The **packet-byte-offset** command is meant to be an arbitrary mechanism the can be used to either add downstream frame encapsulation or remove portions of packet headers. Both the policing metering and profiling throughput is affected by the offset as well as the stats associated with the policer.

When child policers are adding to or subtracting from the size of each packet, the parent policer's **min-thresh-separation** value should also need to be modified by the same amount.

The policer's **packet-byte-offset** defined in the QoS policy may be overridden on an **sla-profile** or SAP where the policy is applied.

The **no** form of this command removes per packet size modifications from the policer.

Parameters

add-bytes

The **add** keyword is mutually exclusive to the **subtract** keyword. Either **add** or **subtract** must be specified. When **add** is defined the corresponding bytes parameter specifies the number of bytes that is added to the size each packet associated with the policer for rate

metering, profiling and accounting purposes. From the policer's perspective, the maximum packet size is increased by the amount being added to the size of each packet.

Values 1 to 31

sub-bytes

The **subtract** keyword is mutually exclusive to the **add** keyword. Either **add** or **subtract** must be specified. When b is defined the corresponding bytes parameter specifies the number of bytes that is subtracted from the size of each packet associated with the policer for rate metering, profiling and accounting purposes. From the policer's perspective, the maximum packet size is reduced by the amount being subtracted from the size of each packet. Note that the minimum resulting packet size used by the system is 1 byte.

Values 0 to 32

Platforms

7705 SAR Gen 2

packet-byte-offset

Syntax

packet-byte-offset {**add** *add-bytes* | **subtract** *sub-bytes*}

no packet-byte-offset

Full Context

configure service epipe sap ingress policer-override policer packet-byte-offset

configure service epipe sap egress policer-override policer packet-byte-offset

Description

This command, within the SAP ingress and egress policer-overrides contexts, is used to override the sap-ingress and sap-egress QoS policy configured packet-byte-offset parameter for the specified policer-id. Packet byte offset settings are not included in the applied rate when (queue) frame based accounting is configured; however, the offsets are applied to the statistics.

The **no** packet-byte-offset command is used to restore the policer's packet-byte-offset setting to the policy defined value.

Default

no packet-byte-offset

Parameters

add-bytes

Specifies the number of bytes that are added to the size each packet associated with the policer for rate metering, profiling and accounting purposes. From the policer's perspective, the maximum packet size is increased by the amount being added to the size of each packet.

Values 1 to 31

sub-bytes

Specifies the number of bytes that are subtracted from the size of each packet associated with the policer for rate metering, profiling and accounting purposes. From the policer's perspective, the maximum packet size is reduced by the amount being subtracted from the size of each packet.

Values 1 to 64

Context

[Tree] (config>qos>sap-ingress>queue packet-byte-offset)

Full Context

configure qos sap-ingress queue packet-byte-offset

Description

This command modifies the size of each packet handled by the queue by adding or subtracting the specified number of bytes. The actual packet size is not modified, only the size used to determine the ingress scheduling and profiling is changed. The **packet-byte-offset** command is an arbitrary mechanism that can be used to either add downstream frame encapsulation or remove portions of packet headers. Both the scheduling and profiling throughput is affected by the offset as well as the statistics (accounting) associated with the queue. The **packet-byte-offset** does not apply to drop statistics, received valid statistics, or the offered managed and unmanaged statistics used by Ingress Multicast Path Management.

The **no** form of this command removes per-packet size modifications from the queue.

Parameters

add-bytes

Specifies the number of bytes added to the size of each packet associated with the queue for scheduling, profiling, and accounting purposes. From the queue's perspective, the packet size is increased by the amount specified.

Values 0 to 30, in increments of 2

sub-bytes

Specifies the number of bytes subtracted from the size of each packet associated with the queue for scheduling, profiling, and accounting purposes. From the queue's perspective, the packet size is reduced by the amount specified. The minimum resulting packet size used by the system is 1 byte.

Values 0 to 64, in increments of 2

packet-byte-offset

Syntax

packet-byte-offset {**add** *add-bytes* | **subtract** *sub-bytes*}

no packet-byte-offset

Context

[Tree] (config>qos>sap-egress>queue packet-byte-offset)

Full Context

configure qos sap-egress queue packet-byte-offset

Description

This command is used to modify the size of each packet handled by the queue by adding or subtracting a number of bytes. The actual packet size is not modified; only the size used to determine the bucket depth impact is changed.

The packet-byte-offset command is meant to be an arbitrary mechanism the can be used to either add downstream frame encapsulation or remove portions of packet headers.

When a packet-byte-offset value is applied to a queue instance, it adjusts the immediate packet size. This means that the queue rates, in other words, operational PIR and CIR, and queue bucket updates use the adjusted packet size. In addition, the queue statistics also reflects the adjusted packet size. Scheduler policy rates, which are data rates, uses the adjusted packet size.

The port scheduler max-rate and the priority level rates and weights, if a Weighted Scheduler Group is used, are always on-the-wire rates and uses the actual frame size. The same applies for the agg-rate-limit on a SAP, a subscriber, or a multiservice Site (MSS) when the queue is port-parented.

When the user enables frame-based-accounting in a scheduler policy or queue-frame-based-accounting with agg-rate-limit in a port scheduler policy, the queue rate will be capped to a user-configured on-the-wire rate and the packet-byte-offset is not included. However, the offsets are applied to the statistics.

The **no** form of this command is used to remove per packet size modifications from the queue.

Parameters

add-bytes

The **add** keyword is mutually exclusive to the **subtract** keyword. Either parameter must be specified. When **add** is defined, the corresponding bytes parameter specifies the number of bytes that is added to the size of each packet associated with the queue for scheduling and accounting purposes.

Values 0 to 32

Full Context

configure service ies interface ipv6 icmp6 packet-too-big

Description

This command specifies whether packet-too-big ICMP messages should be sent. When enabled, ICMPv6 packet-too-big messages are generated by this interface.

The **no** form of this command disables the sending of ICMPv6 packet-too-big messages.

Default

packet-too-big 100 10

Parameters

number

Specifies the number of ICMP messages that are too large to send in the time frame specified by the *seconds* parameter.

Values 10 to 1000

Default 100

seconds

Specifies the time frame, in seconds, that is used to limit the number of "packet-too-big" ICMP messages issued.

Values 1 to 60

Default 10

Platforms

7705 SAR Gen 2

packet-too-big

Syntax

packet-too-big [*number seconds*]

no packet-too-big

Context

[Tree] (config>service>vprn>if>ipv6>icmp6 packet-too-big)

Full Context

configure service vprn interface ipv6 icmp6 packet-too-big

Description

This command configures the rate for Internet Control Message Protocol version 6 (ICMPv6) packet-too-big messages.

Parameters

number

Specifies the number of packet-too-big messages to send in the time frame specified by the *seconds* parameter.

Values 10 to 1000

Default 100

seconds

Specifies the time frame, in seconds, that is used to limit the number of packet-too-big messages issued.

Values 1 to 60

Default 10

Platforms

7705 SAR Gen 2

packet-too-big

Syntax

packet-too-big

packet-too-big number [**10..1000**] **seconds** [**1..60**]

no packet-too-big

Context

[Tree] (config>service>vprn>if>sap>ip-tunnel>icmp6-gen packet-too-big)

Full Context

configure service vprn interface sap ip-tunnel icmp6-generation packet-too-big

Description

This command enables the system to send ICMPv6 PTB (Packet Too Big) messages on the private side and optionally specifies the rate.

With this command configured, the system sends PTB back if it received an IPv6 packet on the private side that is bigger than 1280 bytes and also exceeds the private MTU of the tunnel.

The **ip-mtu** command (under **ipsec-tunnel** or **tunnel-template**) specifies the private MTU for the ipsec-tunnel or dynamic tunnel.

The **no** form of this command reverts **interval** and **message-count** values to their default values.

Platforms

7705 SAR Gen 2

packet-too-big

Syntax

packet-too-big [*number seconds*]

no packet-too-big

Context

[Tree] (config>router>if>ipv6>icmp6 packet-too-big)

Full Context

configure router interface ipv6 icmp6 packet-too-big

Description

This command configures the rate for ICMPv6 packet-too-big messages.

Parameters

number

Limits the number of packet-too-big messages issued per time frame specified in the *seconds* parameter.

Values 10 to 1000

seconds

Determines the time frame, in seconds, that is used to limit the number of packet-too-big messages issued per time frame.

Values 1 to 60

Context

[Tree] (debug>router>vrrp packets)

Full Context

debug router vrrp packets

Description

This command enables or disables debugging for VRRP packets.

Parameters

ip-int-name

Specifies the interface name, up to 32 characters.

virtual-router-id

Specifies the router ID.

Values 1 to 255

ipv6

Debugs the specified IPv6 VRRP interface.

Platforms

7705 SAR Gen 2

packets

Syntax

packets [**neighbor** *ip-address* | **group** *name*]

no packets

Context

[Tree] (debug>router>bgp packets)

Full Context

debug router bgp packets

Description

This command decodes and logs all sent and received BGP packets in the debug log.

The **no** form of this command disables debugging.

Parameters

neighbor *ip-address*

Debugs only events affecting the specified BGP neighbor.

Values ipv4-address:

- a.b.c.d (host bits must be 0)

ipv6-address:

- x:x:x:x:x:x:x:x [-interface] (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d [-interface]
- x: [0 to FFFF]H
- d: [0 to 255]D
- interface: up to 32 characters for link local addresses

group *name*

Debugs only events affecting the specified peer group name, up to 64 characters, and associated neighbors.

Platforms

7705 SAR Gen 2

packets

Syntax

[**no**] **packets** [**neighbor** *ip-int-name* | *ip-addr*]

Context

[Tree] (debug>router>rip packets)

Full Context

debug router rip packets

Description

This command enables debugging for RIP packets.

Parameters

ip-int-name* | *ip-address

Debugs the RIP packets sent on the neighbor IP address or interface.

Platforms

7705 SAR Gen 2

packets

Syntax

[**no**] **packets** [**neighbor** *ip-int-name* | *ipv6-address*]

Context

[Tree] (debug>router>ripng packets)

Full Context

debug router ripng packets

Description

This command enables debugging for RIPng packets.

Parameters

ip-int-name*| *ipv6-address

Debugs the RIPng packets sent on the neighbor IP address or interface.

Platforms

7705 SAR Gen 2

21.9 pad-size

pad-size

Syntax

pad-size *octets*

no pad-size

Context

[Tree] (config>oam-pm>session>ip>twamp-light pad-size)

Full Context

configure oam-pm session ip twamp-light pad-size

Description

This command defines the amount by which the TWAMP Light packet is padded. TWAMP session controller packets are 27 bytes smaller than TWAMP session reflector packets. If symmetrical packet sizes in the forward and backward direction are required, the pad size must be configured to a minimum of 27 bytes.

The **no** form of this command removes all padding.

Default

pad-size 0

Parameters

octets

Specifies the value, in octets, to pad the TWAMP Light packet.

Values 0 to 2000

Default 0

Platforms

7705 SAR Gen 2

21.10 pad-tlv-size

pad-tlv-size

Syntax

pad-tlv-size *octets* [**create**]

no pad-tlv-size

Context

[Tree] (config>oam-pm>session>ip>twamp-light pad-tlv-size)

Full Context

configure oam-pm session ip twamp-light pad-tlv-size

Description

This command configures the PAD TLV to be included in the STAMP test packet with a total byte count equivalent to the value of this leaf.

TWAMP Light does not support TLVs. To pad the size of the TWAMP Light test packet the user must configure the **pad-size** command. STAMP test packets (the standard form of TWAMP Light) introduces TLVs for padding. Therefore, STAMP test packets must use the pad-tlv-size value.

The **no** form of this command removes the TWAMP Light test function from the OAM-PM session.

Parameters

test-id

Specifies the value of the 4-byte local test identifier not sent in the TWAMP Light packets.

Values 0 to 2147483647

create

Creates the test.

Platforms

7705 SAR Gen 2

21.11 padding-size

padding-size

Syntax

padding-size *padding-size*

no padding-size

Context

[Tree] (config>service>vprn>static-route-entry>indirect>cpe-check padding-size)

[Tree] (config>service>vprn>static-route-entry>next-hop>cpe-check padding-size)

Full Context

configure service vprn static-route-entry indirect cpe-check padding-size

configure service vprn static-route-entry next-hop cpe-check padding-size

Description

This optional parameter specifies the amount of padding to add to the ICMP packet in bytes. The parameter is only applicable when the **cpe-check** option is used with the associated static route.

Default

padding-size 56

Parameters

padding-size

An integer value.

Values 0 to 16384 bytes

Platforms

7705 SAR Gen 2

padding-size

Syntax

padding-size *padding-size*

no padding-size

Context

[Tree] (config>router>static-route-entry>indirect>cpe-check padding-size)

[Tree] (config>router>static-route-entry>next-hop>cpe-check padding-size)

Full Context

configure router static-route-entry indirect cpe-check padding-size

configure router static-route-entry next-hop cpe-check padding-size

Description

This command specifies the amount of padding to add to the ICMP packet in bytes. The parameter is only applicable when the **cpe-check** option is used with the associated static route.

Default

padding-size 56

Parameters

padding-size

Specifies the integer value.

Values 0 to 16384 bytes

Platforms

7705 SAR Gen 2

padding-size

Syntax

padding-size *size*

no padding-size

Context

[Tree] (config>vrrp>policy>priority-event>host-unreachable padding-size)

Full Context

configure vrrp policy priority-event host-unreachable padding-size

Description

This command allows the operator to increase the size of IP packet by padding the PDU.

The **no** form of the command reverts to the default.

Default

padding-size 0

Parameters

size

Specifies amount of increase to the ICMP PDU.

Values 0 to 16384

Platforms

7705 SAR Gen 2

21.12 parallel

parallel

Syntax

parallel [**no-advertise**]

no parallel

Context

[Tree] (config>router>ospf>segm-rtng>adjacency-set parallel)

[Tree] (config>router>isis>segm-rtng>adjacency-set parallel)

Full Context

configure router ospf segment-routing adjacency-set parallel

configure router isis segment-routing adjacency-set parallel

Description

This command indicates that all members of the adjacency set must terminate on the same neighboring node. The system raises a trap if a user attempts to add an adjacency terminating on a neighboring node that differs from the existing members of the adjacency set. In addition, the system stops advertising the adjacency set in IS-IS or OSPF and locally deprograms it.

By default, parallel adjacency sets are advertised in the IGP. The **no-advertise** option prevents an adjacency set from being advertised in the IGP. It is only allowed in CLI and SNMP if the **parallel** command is configured.

The **no** form of this command indicates that the adjacency set can include adjacencies to different next hop nodes.

Default

parallel

Platforms

7705 SAR Gen 2

21.14 parent

parent

Syntax

parent [**weight** *weight*] [**cir-weight** *cir-weight*]

no parent

Context

[Tree] (config>port>ethernet>access>egr>qgrp>qover>q parent)

Full Context

configure port ethernet access egress queue-group queue-overrides queue parent

Description

This command, when used in the *queue-overrides* context for a queue group queue, defines an optional **weight** and **cir-weight** for the queue treatment by the parent scheduler that further governs the available bandwidth for the queue aside from the queue PIR setting. When multiple schedulers and or queues share a child status with the parent scheduler, the weight or level parameters define how this queue contends with the other children for the parent bandwidth.

Parameters

weight

Specifies the relative weight of this queue in comparison to other child schedulers and queues while vying for bandwidth on the parent scheduler-name. Any queues or schedulers defined as weighted receive no parental bandwidth until all strict queues and schedulers on the parent have reached their maximum bandwidth or are idle. In this manner, weighted children are considered to be the lowest priority.

Values 0 to 100

Default 1

cir-weight

Specifies the weight the queue uses at the within-cir port priority level. The weight is specified as an integer value from 0 to 100 with 100 being the highest weight. When the cir-weight parameter is set to a value of 0 (the default value), the queue or scheduler does not receive bandwidth during the port schedulers within-cir pass and the cir-level parameter is ignored. If the cir-weight parameter is 1 or greater, the cir-level parameter comes into play.

Values 0 to 100

Platforms

7705 SAR Gen 2

parent

Syntax

parent [**weight** *weight*] [**cir-weight** *cir-weight*]

no parent

Context

[Tree] (config>port>ethernet>access>ing>qgrp>sched-override>scheduler parent)

[Tree] (config>port>ethernet>access>egr>qgrp>sched-override>scheduler parent)

Full Context

configure port ethernet access ingress queue-group scheduler-override scheduler parent

configure port ethernet access egress queue-group scheduler-override scheduler parent

Description

This command can be used to override the scheduler's parent weight and CIR weight. The weights apply to the associated level/cir-level configured in the applied scheduler policy. The scheduler name must exist in the applied scheduler policy.

The override weights are ignored if the scheduler does not have a parent command configured in the scheduler policy - this allows the parent of the scheduler to be removed from the scheduler policy without having to remove all of the queue group overrides. If the parent scheduler does not exist, causing the configured scheduler to be fostered on an egress port scheduler, the override weights will be ignored and the default values used; this avoids having non-default weightings for fostered schedulers.

The **no** form of this command returns the scheduler's parent weight and cir-weight to the value configured in the applied scheduler policy.

Default

no parent

Parameters

weight

Specifies the relative weight of this scheduler in comparison to other child schedulers and queues at the same strict level defined by the level parameter in the applied scheduler policy. Within the level, all weight values from active children at that level are summed and the ratio of each active child's weight to the total distributes the available bandwidth at that level. A weight is considered to be active when the queue or scheduler the weight pertains to has not reached its maximum rate and still has packets to transmit.

A 0 (zero) weight value signifies that the child scheduler will receive bandwidth only after bandwidth is distributed to all other non-zero weighted children in the strict level.

Values 0 to 100

cir-weight

Specifies the relative weight of this scheduler in comparison to other child schedulers and queues at the same cir-level defined by the cir-level parameter in the applied scheduler policy. Within the strict cir-level, all cir-weight values from active children at that level are summed and the ratio of each active child's cir-weight to the total distributes the available bandwidth at that level. A cir-weight is considered to be active when the policer, queue, or scheduler that the cir-weight pertains to has not reached the CIR and still has packets to transmit.

A 0 (zero) cir-weight value signifies that the child scheduler will receive bandwidth only after bandwidth is distributed to all other non-zero weighted children in the strict cir-level.

Values 0 to 100

Platforms

7705 SAR Gen 2

parent

Syntax

parent {[**weight** *weight*] [**cir-weight** *cir-weight*]}

no parent

Context

[Tree] (config>service>epipe>sap>egress>queue-override>queue parent)

[Tree] (config>service>epipe>sap>ingress>queue-override>queue parent)

Full Context

configure service epipe sap egress queue-override queue parent

configure service epipe sap ingress queue-override queue parent

Description

This command defines an optional parent scheduler that further governs the available bandwidth given the queue aside from the queue's PIR setting. When multiple schedulers and/or queues share a child status with the parent scheduler, the **weight** or **level** parameters define how this queue contends with the other children for the parent's bandwidth.

Checks are not performed to see if a *scheduler-name* exists when the parent command is defined on the queue. Scheduler names are configured in the **config>qos>scheduler-policy>tier** *level* context. Multiple schedulers can exist with the *scheduler-name* and the association pertains to a scheduler that should exist on the egress SAP as the policy is applied and the queue created. When the queue is created on the egress SAP, the existence of the *scheduler-name* is dependent on a scheduler policy containing the *scheduler-name* being directly or indirectly applied (through a multi-service customer site) to the egress SAP. If the *scheduler-name* does not exist, the queue is placed in the orphaned operational state. The queue will accept packets but will not be bandwidth limited by a virtual scheduler or the scheduler hierarchy applied to the SAP. The orphaned state must generate a log entry and a trap message. The SAP which the queue belongs to must also depict an orphan queue status. The orphaned state of the queue is automatically cleared when the *scheduler-name* becomes available on the egress SAP.

The parent scheduler can be made unavailable due to the removal of a scheduler policy or scheduler. When an existing parent scheduler is removed or inoperative, the queue enters the orphaned state and automatically returns to normal operation when the parent scheduler is available again.

When a parent scheduler is defined without specifying weight or strict parameters, the default bandwidth access method is weight with a value of 1.

The **no** form of this command removes a child association with a parent scheduler. If a parent association does not currently exist, the command has no effect and returns without an error. Once a parent association has been removed, the former child queue attempts to operate based on its configured rate parameter. Removing the parent association on the queue within the policy takes effect immediately on all queues using the SAP egress QoS policy.

Parameters

weight

These optional keywords are mutually exclusive to the **level** keyword. Specifies the relative weight of this queue in comparison to other child schedulers, policers, and queues while vying for bandwidth on the parent *scheduler-name*. Any policers, queues, or schedulers defined as weighted receive no parental bandwidth until all policers, queues, and schedulers with a higher (numerically larger) priority on the parent have reached their maximum bandwidth or are idle.

All **weight** values from all weighted active policers, queues, and schedulers with a common parent scheduler are added together. Then, each individual active weight is divided by the total, deriving the percentage of remaining bandwidth provided to the policer, queue, or scheduler. A weight is considered to be active when the pertaining policer, queue, or scheduler has not reached its maximum rate and still has packets to transmit. All child policers, queues, and schedulers with a weight of 0 are considered to have the lowest priority level and are not serviced until all non-zero weighted policers, queues, and schedulers at that level are operating at the maximum bandwidth or are idle.

Values 0 to 100

Default 1

cir-weight

Specifies the weight the queue or scheduler will use at the within-cir port priority level (defined by the cir-level parameter). The weight is specified as an integer value from 0 to 100 with 100 being the highest weight. When the cir-weight parameter is set to a value of 0 (the default value), the policer, queue, or scheduler does not receive bandwidth during the port schedulers within-cir pass and the cir-level parameter is ignored. If the cir-weight parameter is 1 or greater, the cir-level parameter comes into play.

Values 0 to 100

Platforms

7705 SAR Gen 2

parent

[Tree] (config>service>epipe>sap>ingress>sched-override>scheduler parent)

Full Context

configure service epipe sap egress scheduler-override scheduler parent

configure service epipe sap ingress scheduler-override scheduler parent

Description

This command can be used to override the scheduler's parent weight and cir-weight information. The weights apply to the associated level/cir-level configured in the applied scheduler policy. The scheduler name must exist in the scheduler policy applied to the ingress or egress of the SAP or multi-service site.

The override weights are ignored if the scheduler does not have a parent command configured in the scheduler policy – this allows the parent of the scheduler to be removed from the scheduler policy without having to remove all of the SAP/MSS overrides. If the parent scheduler does not exist causing the configured scheduler to be fostered on an egress port scheduler, the override weights will be ignored and the default values used; this avoids having non-default weightings for fostered schedulers.

The **no** form of this command returns the scheduler's parent weight and cir-weight to the value configured in the applied scheduler policy.

Default

no parent

Parameters

weight

Specifies the relative weight of this scheduler in comparison to other child schedulers, policers, and queues at the same strict **level** defined by the level parameter in the applied scheduler policy. Within the level, all weight values from active children at that level are summed and the ratio of each active child's weight to the total is used to distribute the available bandwidth at that level. A weight is considered to be active when the policer, queue, or scheduler the weight pertains to has not reached its maximum rate and still has packets to transmit.

A 0 (zero) weight value signifies that the child scheduler will receive bandwidth only after bandwidth is distributed to all other non-zero weighted children in the strict level.

Values 0 to 100

cir-weight

Specifies the relative weight of this scheduler in comparison to other child schedulers, policers, and queues at the same *cir-level* defined by the **cir-level** parameter in the applied scheduler policy. Within the strict **cir-level**, all **cir-weight** values from active children at that level are summed and the ratio of each active child's **cir-weight** to the total is used to distribute the available bandwidth at that level. A **cir-weight** is considered to be active when the policer, queue, or scheduler that the **cir-weight** pertains to has not reached the CIR and still has packets to transmit.

A 0 (zero) **cir-weight** value signifies that the child scheduler will receive bandwidth only after bandwidth is distributed to all other non-zero weighted children in the strict cir-level.

Full Context

configure service vpls sap egress queue-override queue parent

configure service vpls sap ingress queue-override queue parent

Description

This command defines an optional parent scheduler that further governs the available bandwidth given the queue aside from the queue's PIR setting. When multiple schedulers and/or queues share a child status with the parent scheduler, the **weight** or **level** parameters define how this queue contends with the other children for the parent's bandwidth.

Checks are not performed to see if a *scheduler-name* exists when the parent command is defined on the queue. Scheduler names are configured in the **config>qos>scheduler-policy>tier** *level* context. Multiple schedulers can exist with the *scheduler-name* and the association pertains to a scheduler that should exist on the egress SAP as the policy is applied and the queue created. When the queue is created on the egress SAP, the existence of the *scheduler-name* is dependent on a scheduler policy containing the *scheduler-name* being directly or indirectly applied (through a multi-service customer site) to the egress SAP. If the *scheduler-name* does not exist, the queue is placed in the orphaned operational state. The queue will accept packets but will not be bandwidth limited by a virtual scheduler or the scheduler hierarchy applied to the SAP. The orphaned state must generate a log entry and a trap message. The SAP which the queue belongs to must also depict an orphan queue status. The orphaned state of the queue is automatically cleared when the *scheduler-name* becomes available on the egress SAP.

The parent scheduler can be made unavailable due to the removal of a scheduler policy or scheduler. When an existing parent scheduler is removed or inoperative, the queue enters the orphaned state mentioned above and automatically return to normal operation when the parent scheduler is available again.

When a parent scheduler is defined without specifying weight or strict parameters, the default bandwidth access method is weight with a value of 1.

The **no** form of this command removes a child association with a parent scheduler. If a parent association does not currently exist, the command has no effect and returns without an error. Once a parent association has been removed, the former child queue attempts to operate based on its configured rate parameter. Removing the parent association on the queue within the policy takes effect immediately on all queues using the SAP egress QoS policy.

Parameters

weight

These optional keywords are mutually exclusive to the **level** keyword. The weight defines the relative weight of this queue in comparison to other child schedulers, policers, and queues while vying for bandwidth on the parent *scheduler-name*. Any policers, queues, or schedulers defined as weighted receive no parental bandwidth until all policers, queues, and schedulers with a higher (numerically larger) priority on the parent have reached their maximum bandwidth or are idle.

All **weight** values from all weighted active policers, queues, and schedulers with a common parent scheduler are added together. Then, each individual active weight is divided by the total, deriving the percentage of remaining bandwidth provided to the policer, queue, or scheduler. A weight is considered to be active when the pertaining policer, queue, or scheduler has not reached its maximum rate and still has packets to transmit. All child policers, queues, and schedulers with a weight of 0 are considered to have the lowest priority level and are not serviced until all non-zero weighted policers, queues, and schedulers at that level are operating at the maximum bandwidth or are idle.

Values 0 to 100

Default 1

cir-weight

Specifies the weight the queue or scheduler will use at the within-cir port priority level (defined by the cir-level parameter). The weight is specified as an integer value from 0 to 100 with 100 being the highest weight. When the cir-weight parameter is set to a value of 0 (the default value), the policer, queue, or scheduler does not receive bandwidth during the port schedulers within-cir pass and the cir-level parameter is ignored. If the cir-weight parameter is 1 or greater, the cir-level parameter comes into play.

[Tree] (config>service>vpls>sap>egress>sched-override>scheduler parent)

Full Context

configure service vpls sap ingress scheduler-override scheduler parent

configure service vpls sap egress scheduler-override scheduler parent

Description

This command can be used to override the scheduler's parent weight and cir-weight information. The weights apply to the associated level/cir-level configured in the applied scheduler policy. The scheduler name must exist in the scheduler policy applied to the ingress or egress of the SAP or multi-service site.

The override weights are ignored if the scheduler does not have a parent command configured in the scheduler policy – this allows the parent of the scheduler to be removed from the scheduler policy without having to remove all of the SAP/MSS overrides. If the parent scheduler does not exist causing the configured scheduler to be fostered on an egress port scheduler, the override weights will be ignored and the default values used; this avoids having non-default weightings for fostered schedulers.

The **no** form of this command returns the scheduler's parent weight and cir-weight to the value configured in the applied scheduler policy.

Default

no parent

Parameters

weight

Specifies the relative weight of this scheduler in comparison to other child schedulers and queues at the same strict **level** defined by the level parameter in the applied scheduler policy. Within the level, all weight values from active children at that level are summed and the ratio of each active child's weight to the total is used to distribute the available bandwidth at that level. A weight is considered to be active when the policer, queue, or scheduler the weight pertains to has not reached its maximum rate and still has packets to transmit.

A 0 (zero) weight value signifies that the child scheduler will receive bandwidth only after bandwidth is distributed to all other non-zero weighted children in the strict level.

Values 0 to 100

cir-weight

Specifies the relative weight of this scheduler in comparison to other child schedulers and queues at the same *cir-level* defined by the **cir-level** parameter in the applied scheduler policy. Within the strict **cir-level**, all **cir-weight** values from active children at that level are summed and the ratio of each active child's **cir-weight** to the total is used to distribute the available bandwidth at that level. A **cir-weight** is considered to be active when the policer, queue, or scheduler that the **cir-weight** pertains to has not reached the CIR and still has packets to transmit.

A 0 (zero) **cir-weight** value signifies that the child scheduler will receive bandwidth only after bandwidth is distributed to all other non-zero weighted children in the strict cir-level.

Values 0 to 100

Platforms

7705 SAR Gen 2

configure service ies interface sap ingress scheduler-override scheduler parent

configure service ies interface sap ingress queue-override queue parent

configure service ies interface sap egress queue-override queue parent

configure service ies interface sap egress scheduler-override scheduler parent

Description

This command can be used to override the scheduler's parent weight and cir-weight information. The weights apply to the associated level/cir-level configured in the applied scheduler policy. The scheduler name must exist in the scheduler policy applied to the ingress or egress of the SAP or multi-service site.

The override weights are ignored if the scheduler does not have a parent command configured in the scheduler policy – this allows the parent of the scheduler to be removed from the scheduler policy without having to remove all of the SAP/MSS overrides. If the parent scheduler does not exist causing the configured scheduler to be fostered on an egress port scheduler, the override weights will be ignored and the default values used; this avoids having non default weightings for fostered schedulers.

The **no** form of this command returns the scheduler's parent weight and cir-weight to the value configured in the applied scheduler policy.

Default

no parent

Parameters

weight *weight*

Specifies the relative weight of this scheduler in comparison to other child schedulers and queues at the same strict **level** defined by the level parameter in the applied scheduler policy. Within the level, all weight values from active children at that level are summed and the ratio of each active child's weight to the total is used to distribute the available bandwidth at that level. A weight is considered to be active when the queue or scheduler the weight pertains to has not reached its maximum rate and still has packets to transmit.

A 0 (zero) weight value signifies that the child scheduler will receive bandwidth only after bandwidth is distributed to all other non-zero weighted children in the strict level.

Values 0 to 100

cir-weight ***cir-weight***

Specifies the relative weight of this scheduler in comparison to other child schedulers and queues at the same *cir-level* defined by the **cir-level** parameter in the applied scheduler policy. Within the strict **cir-level**, all **cir-weight** values from active children at that level are summed and the ratio of each active child's **cir-weight** to the total is used to distribute the available bandwidth at that level. A **cir-weight** is considered to be active when the policer, queue, or scheduler that the **cir-weight** pertains to has not reached the CIR and still has packets to transmit.

A 0 (zero) **cir-weight** value signifies that the child scheduler will receive bandwidth only after bandwidth is distributed to all other non-zero weighted children in the strict cir-level.

parent

Syntax

parent {**root** | *arbiter-name*} [**level** *priority-level*] [**weight** *weight-within-level*]

no parent

Context

[Tree] (config>qos>plcr-ctrl-plcy>tier>arbiter parent)

Full Context

configure qos policer-control-policy tier arbiter parent

Description

This command is used to define from where the tiered arbiter receives bandwidth. Both tier 1 and tier 2 arbiters default to parenting to the root arbiter. Tier 2 arbiters may be modified to parent to a tier 1 arbiter. The tier 1 arbiter parent cannot be changed.

The **no** form of this command is used to return the tiered arbiter to the default parenting behavior.

Default

parent root level 1 weight 1

Parameters

root

In tier 1, *arbiter-name* is not allowed and only **root** is accepted. When **root** is specified, the arbiter will receive all bandwidth directly from the root arbiter. This is the default parent for tiered arbiters.

arbiter-name

In tier 1, *arbiter-name* is not allowed and only **root** is accepted. The specified *arbiter-name* must exist within the policer-control-policy at tier 1 or the parent command will fail. When a tiered arbiter is acting as a parent for another tiered arbiter, the parent arbiter cannot be removed from the policy. The child arbiter will receive all bandwidth directly from its parent arbiter (that receives bandwidth from the root arbiter).

priority-level

Each child arbiter attaches to its parent on one of the parent's eight strict levels. Level 1 is the lowest and 8 is the highest. The level attribute is used to define which level the child arbiter uses on its parent. The parent distributes its available bandwidth based on strict priority starting with priority level 8 and proceeding towards level 1.

Values 1 to 8

Default 1

weight-within-level

The **weight** attribute is used to define how multiple children at the same parent strict level compete when insufficient bandwidth exists on the parent for that level. Each child's weight is divided by the sum of the active children's weights and the result is multiplied by the available bandwidth. If a child cannot receive its entire weighted fair share of bandwidth due to a defined child rate limit, the remainder of its bandwidth is distributed between the other children based on their weights.

Values 1 to 100

[Tree] (config>qos>sap-ingress>policer parent)

[Tree] (config>qos>sap-egress>policer parent)

Full Context

configure qos sap-ingress policer parent

configure qos sap-egress policer parent

Description

This command is used to create a child-to-parent mapping between each instance of the policer and either the **root** arbiter or a specific tiered **arbiter** on the object where the policy is applied. Defining a parent association for the policer causes the policer to compete for the parent policer's available bandwidth with other child policers mapped to the policer control hierarchy.

Policer control hierarchies may be created on SAPs or on a subscriber or multiservice site context. To create a policer control hierarchy on an ingress or egress SAP context, a **policer-control-policy** must be applied to the SAP. When applied, the system will create a parent policer that is bandwidth limited by the policy's **max-rate** value under the root arbiter. The root arbiter in the policy also provides the information used to determine the various priority-level discard-unfair and discard-all thresholds. Besides the root arbiter, the policy may also contain user-defined tiered arbiters that provide arbitrary bandwidth control for subsets of child policers that are either directly or indirectly parented by the arbiter.

When the QoS policy containing the policer with a **parent** mapping to an arbiter name exists on the SAP, the system will scan the available arbiters on the SAP. If an arbiter exists with the appropriate name, the policer to arbiter association is created. If the specified arbiter does not exist either because a **policer-control-policy** is not currently applied to the SAP or the arbiter name does not exist within the applied

policy, the policer is placed in an orphan state. Orphan policers operate as if they are not parented and are not subject to any bandwidth constraints other than their own PIR. When a policer enters the orphan state, it is flagged as operationally degraded due to the fact that it is not operating as intended and a trap is generated. Whenever a **policer-control-policy** is added to the SAP or the existing policy is modified, the SAP's policer's parenting configurations must be reevaluated. If an orphan policer becomes parented, the degraded flag is cleared, and a resulting trap is generated.

For subscribers, the policer control hierarchy is created through the **policer-control-policy** applied to the **sub-profile** used by the subscriber. A unique policer control hierarchy is created for each subscriber associated with the **sub-profile**. The QoS policy containing the policer with the parenting command comes into play through the subscriber **sla-profile**, which references the QoS policy. The combining of the **sub-profile** and the **sla-profile** at the subscriber level provides the system with the proper information to create the policer control hierarchy instance for the subscriber.

Executing the **parent** command will fail if:

- The policer’s stat-mode in the QoS policy is set to no-stats
- A stat-mode no-stats override exists on an instance of the policer on a SAP or subscriber or multiservice site context

A policer with a **parent** command applied cannot be configured with **stat-mode no-stats** in either the QoS policy or as an override on an instance of the policer.

When a policer is successfully parented to an arbiter, the **parent** commands **level** and **weight** parameters are used to determine at what priority level and at which weight in the priority level that the child policer competes with other children (policers or other arbiters) for bandwidth.

The **no** form of this command is used to remove the parent association from all instances of the policer.

Parameters

{root | *arbiter-name*}

When the **parent** command is executed, either the keyword **root** or an *arbiter-name* must be specified.

root

Specifies that the policer is intended to become a child to the **root** arbiter where an instance of the policer is created. If the **root** arbiter does not exist, the policer will be placed in the orphan state.

Default **root**

arbiter-name

Specifies that the policer is intended to become a child to one of the tiered arbiters with the given arbiter-name where an instance of the policer is created. If the specified *arbiter-name* does not exist, the policer will be placed in the orphan state.

weight *weight-within-level*

The **weight** *weight-within-level* keyword and parameter are optional when executing the **parent** command. When **weight** is not specified, a default level of 1 is used in the parent arbiter’s priority level. When **weight** is specified, the *weight-within-level* parameter must be specified as an integer value from 1 through 100.

Default 1

Platforms

7705 SAR Gen 2

parent

Syntax

parent *scheduler-name* [**weight** *weight*] [**level** *level*] [**cir-weight** *cir-weight*] [**cir-level** *cir-level*]

no parent

Context

[Tree] (config>qos>sap-ingress>queue parent)

[Tree] (config>qos>sap-egress>queue parent)

Full Context

configure qos sap-ingress queue parent

configure qos sap-egress queue parent

Description

This command defines an optional parent scheduler that further governs the available bandwidth given the queue aside from the queue's PIR setting. When multiple schedulers, policers (at egress only), and/or queues share a child status with the parent scheduler, the **weight** or **level** parameters define how this queue contends with the other children for the parent's bandwidth.

Checks are not performed to see if a *scheduler-name* exists when the parent command is defined on the queue. Scheduler names are configured in the **config>qos>scheduler-policy>tier** *level* context. Multiple schedulers can exist with the *scheduler-name* and the association pertains to a scheduler that should exist on the egress SAP as the policy is applied and the queue created. When the queue is created on the egress SAP, the existence of the *scheduler-name* is dependent on a scheduler policy containing the *scheduler-name* being directly or indirectly applied (through a multiservice customer site) to the egress SAP. If the *scheduler-name* does not exist, the queue is placed in the orphaned operational state. The queue will accept packets but will not be bandwidth limited by a virtual scheduler or the scheduler hierarchy applied to the SAP. The SAP that the queue belongs to also depicts an orphan queue status. The orphaned state of the queue is automatically cleared when the *scheduler-name* becomes available on the egress SAP.

The parent scheduler can be made unavailable due to the removal of a scheduler policy or scheduler. When an existing parent scheduler is removed or inoperative, the queue enters the orphaned state and automatically returns to normal operation when the parent scheduler is available again.

When a parent scheduler is defined without specifying the weight parameter, the default is a weight of 1.

The **no** form of this command removes a child association with a parent scheduler. If a parent association does not currently exist, the command has no effect and returns without an error. When a parent association has been removed, the former child queue attempts to operate based on its configured rate parameter. Removing the parent association on the queue within the policy takes effect immediately on all queues using the SAP egress QoS policy.

Parameters

scheduler-name

The defined *scheduler-name* conforms to the same input criteria as the schedulers defined within a scheduler policy. Scheduler names are configured in the config>qos>scheduler-policy>tier *level* context. There are no checks performed at the time of definition to ensure that the *scheduler-name* exists within an existing scheduler policy. For the queue to use the defined *scheduler-name*, the scheduler exists on each egress SAP that the queue is eventually created on. For the duration where *scheduler-name* does not exist on the egress SAP, the queue operates in an orphaned state.

Values Any string up to 32 characters, composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, etc.), the entire string must be enclosed within double quotes.

weight

Specifies the relative weight of this queue in comparison to other child schedulers, policers, and queues, while vying for bandwidth on the parent *scheduler-name*. Any queues, policers, or schedulers defined as weighted receive no parental bandwidth until all policers, queues, and schedulers with a higher (numerically larger) priority on the parent have reached their maximum bandwidth or are idle.

All **weight** values from all weighted active queues, policers, and schedulers with a common parent scheduler are added together. Then, each individual active weight is divided by the total, deriving the percentage of remaining bandwidth provided to the queue, policer, or scheduler. A weight is considered to be active when the pertaining queue, policer, or scheduler has not reached its maximum rate and still has packets to transmit. All child queues, policers, and schedulers with a weight of 0 are considered to have the lowest priority level and are not serviced until all non-zero weighted queues, policers, and schedulers at that level are operating at the maximum bandwidth or are idle.

Values 0 to 100

Default 1

level

The optional **level** parameter defines the level of hierarchy when compared to other schedulers and queues competing for bandwidth on the parent *scheduler-name*. Queues or schedulers will not receive parental bandwidth until all queues, policers, and schedulers with a higher (numerically larger) priority on the parent have reached their maximum bandwidth or are idle.

Children of the parent scheduler with a lower strict priority will not receive bandwidth until all children with a higher strict priority have either reached their maximum bandwidth or are idle. Children with the same strict level are serviced in relation to their relative weights.

Values 1 to 8

Default 1

cir-weight

Specifies the weight that the queue or scheduler uses at the within-CIR port priority level (defined by the cir-level parameter). The weight is specified as an integer value from 0 to

100 with 100 being the highest weight. When the cir-weight parameter is set to a value of 0 (the default value), the queue or scheduler does not receive bandwidth during the port schedulers within-CIR pass and the cir-level parameter is ignored. If the cir-weight parameter is 1 or greater, the cir-level parameter comes into play.

Values 0 to 100

Default 1

cir-level

Specifies the port priority that the queue or scheduler will use to receive bandwidth for its within-CIR offered-load. If the cir-weight parameter is set to a value of 0 (the default value), the queue or scheduler does not receive bandwidth during the port schedulers within-CIR pass and the cir-level parameter is ignored. If the cir-weight parameter is 1 or greater, the cir-level parameter comes into play.

Values 0 to 8 (8 is the highest priority)

Default 0

Platforms

7705 SAR Gen 2

parent

parent {**root** | *arbiter-name*} [**level** *level*] [**weight** *weight-within-level*]

no parent

Context

[Tree] (config>qos>qgrps>ing>qgrp>policer parent)

[Tree] (config>qos>qgrps>egr>qgrp>policer parent)

Full Context

configure qos queue-group-templates ingress queue-group policer parent

configure qos queue-group-templates egress queue-group policer parent

Description

This command is used to create a child-to-parent mapping between each instance of the policer and either the **root** arbiter or a specific tiered **arbiter** on the object where the policy is applied. Defining a parent association for the policer causes the policer to compete for the parent policer's available bandwidth with other child policers mapped to the policer control hierarchy.

Policer control hierarchies may be created on SAPs or on a subscriber or multiservice site context. To create a policer control hierarchy on an ingress or egress SAP context, a **policer-control-policy** must be applied to the SAP. When applied, the system will create a parent policer that is bandwidth limited by the policy's **max-rate** value under the root arbiter. The root arbiter in the policy also provides the information

used to determine the various priority level discard-unfair and discard-all thresholds. Besides the root arbiter, the policy may also contain user-defined tiered arbiters that provide arbitrary bandwidth control for subsets of child policers that are either directly or indirectly parented by the arbiter.

When the QoS policy containing the policer with a **parent** mapping to an arbiter name exists on the SAP, the system will scan the available arbiters on the SAP. If an arbiter exists with the appropriate name, the policer to arbiter association is created. If the specified arbiter does not exist either because a **policer-control-policy** is not currently applied to the SAP or the arbiter name does not exist within the applied policy, the policer is placed in an orphan state. Orphan policers operate as if they are not parented and are not subject to any bandwidth constraints other than their own PIR. When a policer enters the orphan state, it is flagged as operationally degraded due to the fact that it is not operating as intended and a trap is generated. Whenever a **policer-control-policy** is added to the SAP or the existing policy is modified, the SAP's policer's parenting configurations must be reevaluated. If an orphan policer becomes parented, the degraded flag is cleared and a resulting trap is generated.

For subscribers, the policer control hierarchy is created through the **policer-control-policy** applied to the **sub-profile** used by the subscriber. A unique policer control hierarchy is created for each subscriber associated with the **sub-profile**. The QoS policy containing the policer with the parenting command comes into play through the subscriber **sla-profile** that references the QoS policy. The combining of the **sub-profile** and the **sla-profile** at the subscriber level provides the system with the proper information to create the policer control hierarchy instance for the subscriber.

Executing the **parent** command will fail if:

- The policer’s stat-mode in the QoS policy is set to no-stats
- A stat-mode no-stats override exists on an instance of the policer on a SAP or subscriber or multiservice site context

A policer with a **parent** command applied cannot be configured with **stat-mode no-stats** in either the QoS policy or as an override on an instance of the policer.

When a policer is successfully parented to an arbiter, the **parent** commands **level** and **weight** parameters are used to determine at what priority level and at which weight in the priority level that the child policer competes with other children (policers or other arbiters) for bandwidth.

The **no** form of this command is used to remove the parent association from all instances of the policer.

Parameters

{root | *arbiter-name*}

When the **parent** command is executed, either the keyword **root** or an *arbiter-name* must be specified.

Default **root**

root

The **root** keyword specifies that the policer is intended to become a child to the **root** arbiter where an instance of the policer is created. If the **root** arbiter does not exist, the policer will be placed in the orphan state.

arbiter-name

The *arbiter-name* parameter specifies that the policer is intended to become a child to one of the tiered arbiters with the given arbiter-name where an instance of the policer is created. If the specified arbiter-name does not exist, the policer will be placed in the orphan state.

weight *weight-within-level*

The **weight** *weight-within-level* keyword and parameter are optional when executing the **parent** command. When **weight** is not specified, a default level of 1 is used in the parent arbiters priority level. When **weight** is specified, the *weight-within-level* parameter must be specified as an integer value from 1 through 100.

Default 1

[Tree] (config>qos>qgrps>ing>qgrp>queue parent)

Full Context

configure qos queue-group-templates egress queue-group queue parent

configure qos queue-group-templates ingress queue-group queue parent

Description

This command defines an optional parent scheduler that further governs the available bandwidth given the queue aside from the queue's PIR setting. When multiple schedulers, policers (at egress only), and/or queues share a child status with the parent scheduler, the **weight** or **level** parameters define how this queue contends with the other children for the parent's bandwidth.

Checks are not performed to see if a *scheduler-name* exists when the parent command is defined on the queue. Scheduler names are configured in the config>qos>scheduler-policy>tier *level* context. Multiple schedulers can exist with the *scheduler-name* and the association pertains to a scheduler that should exist on the egress SAP as the policy is applied and the queue created. When the queue is created on the egress SAP, the existence of the *scheduler-name* is dependent on a scheduler policy containing the *scheduler-name* being directly or indirectly applied (through a multiservice customer site) to the egress SAP. If the *scheduler-name* does not exist, the queue is placed in the orphaned operational state. The queue will accept packets but will not be bandwidth limited by a virtual scheduler or the scheduler hierarchy applied to the SAP. The SAP that the queue belongs to must also depict an orphan queue status. The orphaned state of the queue is automatically cleared when the *scheduler-name* becomes available on the egress SAP.

The parent scheduler can be made unavailable due to the removal of a scheduler policy or scheduler. When an existing parent scheduler is removed or inoperative, the queue enters the orphaned state and automatically returns to normal operation when the parent scheduler is available again.

When a parent scheduler is defined without specifying weight or strict parameters, the default bandwidth access method is weight with a value of 1.

The **no** form of this command removes a child association with a parent scheduler. If a parent association does not currently exist, the command has no effect and returns without an error. When a parent association has been removed, the former child queue attempts to operate based on its configured rate parameter. Removing the parent association on the queue within the policy takes effect immediately on all queues using the SAP egress QoS policy.

Parameters

scheduler-name

The defined *scheduler-name* conforms to the same input criteria as the schedulers defined within a scheduler policy. Scheduler names are configured in the config>qos>scheduler-policy>tier *level* context. There are no checks performed at the time of definition to ensure that the *scheduler-name* exists within an existing scheduler policy. For the queue to use the defined *scheduler-name*, the scheduler exists on each egress SAP the queue is eventually created on. For the duration where *scheduler-name* does not exist on the egress SAP, the queue operates in an orphaned state.

Values Any string up to 32 characters, composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, etc.), the entire string must be enclosed within double quotes.

weight *weight*

weight defines the relative weight of this queue in comparison to other child schedulers and queues while vying for bandwidth on the parent *scheduler-name*. Any queues or schedulers defined as weighted receive no parental bandwidth until all policers, queues, and schedulers with a higher (numerically larger) priority on the parent have reached their maximum bandwidth or are idle.

All **weight** values from all weighted active queues, policers, and schedulers with a common parent scheduler are added together. Then, each individual active weight is divided by the total, deriving the percentage of remaining bandwidth provided to the queue, policer, or scheduler. A weight is considered to be active when the pertaining queue or scheduler has not reached its maximum rate and still has packets to transmit. All child policers, queues, and schedulers with a weight of 0 are considered to have the lowest priority level and are not serviced until all non-zero weighted queues, policers, and schedulers at that level are operating at the maximum bandwidth or are idle.

Values 0 to 100

Default 1

level *level*

The optional **level** parameter defines the level of hierarchy when compared to other schedulers and queues when vying for bandwidth on the parent *scheduler-name*. Queues or schedulers will not receive parental bandwidth until all queues and schedulers with a higher (numerically larger) priority on the parent have reached their maximum bandwidth or are idle.

Children of the parent scheduler with a lower strict priority will not receive bandwidth until all children with a higher strict priority have either reached their maximum bandwidth or are idle. Children with the same strict level are serviced relative to their weights.

Values 1 to 8

Default 1

cir-weight ***cir-weight***

Specifies the weight the queue or scheduler will use at the within-CIR port priority level (defined by the cir-level parameter). The weight is specified as an integer value from 0 to 100 with 100 being the highest weight. When the cir-weight parameter is set to a value of 0 (the default value), the queue or scheduler does not receive bandwidth during the port schedulers within-CIR pass and the cir-level parameter is ignored. If the cir-weight parameter is 1 or greater, the cir-level parameter comes into play.

Values 0 to 100

Default 1

cir-level ***cir-level***

Specifies the port priority the queue or scheduler will use to receive bandwidth for its within-CIR offered-load. If the cir-weight parameter is set to a value of 0 (the default value), the queue or scheduler does not receive bandwidth during the port schedulers within-CIR pass and the cir-level parameter is ignored. If the cir-weight parameter is 1 or greater, the cir-level parameter comes into play.

Values 0 to 8 (8 is the highest priority)

Default 0

Platforms

parent

Syntax

parent *scheduler-name* [**weight** *weight*] [**level** *level*] [**cir-weight** *cir-weight*] [**cir-level** *cir-level*]

no parent

Context

[Tree] (config>qos>scheduler-policy>tier>scheduler parent)

Full Context

configure qos scheduler-policy tier scheduler parent

Description

This command defines an optional parent scheduler that is higher up the policy hierarchy. Only schedulers in tier levels 2 and 3 can have a parental association. When multiple schedulers, policers (at egress only), and/or queues share a child status with the scheduler on the parent, the weight or strict parameters define

how this scheduler contends with the other children for the parent's bandwidth. The parent scheduler can be removed or changed at any time and is immediately reflected on the schedulers created by association of this scheduler policy.

When a parent scheduler is defined without specifying weight or strict parameters, the default bandwidth access method is weight with a value of 1.

The **no** form of this command removes a child association with a parent scheduler. If a parent association does not currently exist, the command has no effect and returns without an error. When a parent association has been removed, the former child scheduler attempts to operate based on its configured rate parameter. Removing the parent association on the scheduler within the policy will take effect immediately on all schedulers with *scheduler-name* that have been created using the *scheduler-policy-name*.

Parameters

scheduler-name

Specifies a scheduler name. The *scheduler-name* must already exist within the context of the scheduler policy in a tier that is higher (numerically lower).

Values Any valid *scheduler-name* existing on a higher tier within the scheduler policy.

weight *weight*

Specifies the relative weight of this scheduler in comparison to other child schedulers and queues at the same strict level defined by the **level** parameter. Within the level, all weight values from active children at that level are summed and the ratio of each active child's weight to the total is used to distribute the available bandwidth at that level. A weight is considered to be active when the queue or scheduler the weight pertains to has not reached its maximum rate and still has packets to transmit.

A zero (0) weight value signifies that the child scheduler will receive bandwidth only after bandwidth is distributed to all other non-zero weighted children in the strict level.

Values 0 to 100

Default 1

level *level*

Specifies the strict priority level of this scheduler in comparison to other child schedulers and queues vying for bandwidth on the parent scheduler-name during the above-CIR distribution phase of bandwidth allocation. During the above-CIR distribution phase, any queues or schedulers defined at a lower strict level receive no parental bandwidth until all queues and schedulers defined with a higher (numerically larger) strict level on the parent have reached their maximum bandwidth or have satisfied their offered load requirements.

When the similar **cir-level** parameter default (undefined) are retained for the child scheduler, bandwidth is only allocated to the scheduler during the above-CIR distribution phase.

Children of the parent scheduler with a lower strict priority level will not receive bandwidth until all children with a higher strict priority level have either reached their maximum bandwidth or are idle. Children with the same strict level are serviced in relation to their relative weights.

Values 1 to 8

Default 1

cir-weight ***cir-weight***

Specifies the relative weight of this scheduler in comparison to other child schedulers and queues at the same **cir-level** defined by the **cir-level** parameter. Within the strict **cir-level**, all **cir-weight** values from active children at that level are summed and the ratio of each active child's **cir-weight** to the total is used to distribute the available bandwidth at that level. A **cir-weight** is considered to be active when the queue or scheduler that the **cir-weight** pertains to has not reached the CIR and still has packets to transmit.

A zero (0) **cir-weight** value signifies that the child scheduler will receive bandwidth only after bandwidth is distributed to all other non-zero weighted children in the strict cir-level.

Values 0 to 100

Default 1

cir-level ***cir-level***

Specifies the strict priority CIR level of this scheduler in comparison to other child schedulers and queues vying for bandwidth on the parent *scheduler-name* during the within-CIR distribution phase of bandwidth allocation. During the within-CIR distribution phase, any queues or schedulers defined at a lower strict CIR level receive no parental bandwidth until all queues and schedulers defined with a higher (numerically larger) strict CIR level on the parent have reached their CIR bandwidth or have satisfied their offered load requirements.

If the scheduler's **cir-level** parameter retains the default (undefined) state, bandwidth is only allocated to the scheduler during the above-CIR distribution phase.

Children with the same strict cir-level are serviced according to their cir-weight.

Values 0 to 8

Default 0

Platforms

parent

Syntax

parent [**weight** *weight*] [**cir-weight** *cir-weight*]

no parent

Context

[Tree] (config>service>cust>multi-service-site>egress>sched-override>scheduler parent)

[Tree] (config>service>cust>multi-service-site>ingress>sched-override>scheduler parent)

Full Context

configure service customer multi-service-site egress scheduler-override scheduler parent

configure service customer multi-service-site ingress scheduler-override scheduler parent

Description

This command overrides the scheduler's parent weight and CIR weight information. The weights apply to the associated level or cir-level configured in the applied scheduler policy. The scheduler name must exist in the scheduler policy applied to the ingress or egress of the SAP or multi-service site.

The override weights are ignored if the scheduler does not have a **parent** command configured in the scheduler policy. This allows the parent of the scheduler to be removed from the scheduler policy without having to remove all of the SAP/MSS overrides. If the parent scheduler does not exist causing the configured scheduler to be fostered on an egress port scheduler, the override weights will be ignored and the default values used; this avoids having non-default weightings for fostered schedulers.

The **no** form of the command returns the scheduler's parent weight and CIR weight to the value configured in the applied scheduler policy.

Default

no parent

Parameters

weight

Specifies the relative weight of this scheduler in comparison to other child schedulers and queues at the same strict **level** defined by the level parameter in the applied scheduler policy. Within the level, all weight values from active children at that level are summed and the ratio of each active child's weight to the total is used to distribute the available bandwidth at that level. A weight is considered to be active when the policer, queue or scheduler the weight pertains to has not reached its maximum rate and still has packets to transmit. A 0 (zero) weight value signifies that the child scheduler will receive bandwidth only after bandwidth is distributed to all other non-zero weighted children in the strict level.

Values 0 to 100

Default 1

cir-weight

Specifies the relative weight of this scheduler in comparison to other child schedulers and queues at the same *cir-level* defined by the **cir-level** parameter in the applied scheduler policy. Within the strict **cir-level**, all **cir-weight** values from active children at that level are summed and the ratio of each active child's **cir-weight** to the total is used to distribute the available bandwidth at that level. A **cir-weight** is considered to be active when the policer, queue or scheduler that the **cir-weight** pertains to has not reached the CIR and still has packets to transmit. A 0 (zero) **cir-weight** value signifies that the child scheduler will receive bandwidth only after bandwidth is distributed to all other non-zero weighted children in the strict cir-level.

21.15 parent-location

parent-location

Syntax

parent-location {**none** | **sub** | **vport**}

no parent-location

Context

[Tree] (config>qos>scheduler-policy>tier parent-location)

Full Context

configure qos scheduler-policy tier parent-location

Description

This command determines the expected location of the parent schedulers for the tier 1 schedulers configured with a parent command within the scheduler-policy. The parent schedulers must be configured within a scheduler-policy applied at the location corresponding to the parent-location parameter.

If a parent scheduler name does not exist at the specified location, the schedulers will not be parented and will be orphaned.

The configuration of **parent-location** and **frame-based-accounting** in a scheduler policy is mutually exclusive in order to ensure consistency between the different scheduling levels.

The **no** form of this command reverts to the default.

Default

parent-location none

Parameters

none

This parameter indicates that the tier 1 schedulers do not have a parent scheduler and the configuration of the parent under a tier 1 scheduler is blocked. Conversely, this parameter is blocked when any tier 1 scheduler has a parent configured.

sub

When the scheduler-policy is applied to an sla-profile for a subscriber, the parent schedulers of the tier 1 schedulers need to be configured in the scheduler-policy applied to the subscriber's sub-profile.

If this parameter is configured within a scheduler-policy that is applied to any object except for the egress of an sla-profile, the configured parent schedulers will not be found and so the tier 1 schedulers will not be parented and will be orphaned.

vport

When the scheduler-policy is applied to an sla-profile, a sub-profile for a subscriber, or to the egress of a pseudowire SAP, the parent schedulers of the tier 1 schedulers need to be configured in the scheduler-policy applied to the Vport to which the subscriber will be assigned.

If this parameter is configured within a scheduler-policy that is applied to any object except for the egress of an sla-profile or sub-profile, or to the egress of a PW SAP, the configured parent schedulers will not be found and so the tier 1 schedulers will not be parented and will be orphaned.

configure service vprn dhcp6 local-dhcp-server failover partner-down-delay

configure router dhcp local-dhcp-server pool failover partner-down-delay

configure service vprn dhcp6 local-dhcp-server pool failover partner-down-delay

configure service vprn dhcp local-dhcp-server pool failover partner-down-delay

configure service vprn dhcp local-dhcp-server failover partner-down-delay

configure router dhcp6 local-dhcp-server failover partner-down-delay

Description

This command configures the partner down delay time. Since the DHCP lease synchronization failure can be caused by the failure of the intercommunication link (and not necessary the entire node), there is a possibility the redundant DHCP servers become isolated in the network. In other words, they can serve DHCP clients but they cannot synchronize the lease. This can lead to duplicate assignment of IP addresses, since the servers have configured overlapping IP address ranges but they are not aware of each other's leases.

The purpose of the partner down delay is to prevent the IP lease duplication during the intercommunication link failure by not allowing new IP addresses to be assigned from the remote IP address range. This timer is intended to provide the operator with enough time to remedy the failed situation and to avoid duplication of IP addresses or prefixes during the failure.

During the partner-down-delay time, the prefix designated as remote is eligible only for renewals of the existing DHCP leases that have been synchronized by the peering node. Only after the sum of the partner-down-delay and the maximum-client-lead-time will the prefix designated as remote be eligible for delegation of the new DHCP leases. When this occurs, we say that the remote IP address range has been taken over.

It is possible to expedite the takeover of a remote IP address range so that the new IP leases can start being delegated from that range shortly after the intercommunication failure is detected. This can be achieved by configuring the partner-down-delay timer to 0 seconds, along with enabling the ignore-mclt-on-takeover CLI flag. Caution must be taken before enabling this functionality. It is safe to bypass safety timers (partner-down-delay + MCLT) only in cases where the operator is certain that the intercommunication between the nodes has failed due to the entire node failure and not due to the intercommunication (MCS) link failure. Failed intercommunication due to the nodal failure would ensure that only one node is present in the network for IP address delegation (as opposed to two isolated nodes with overlapping IP address ranges where address duplication can occur). For this reason, the operator must ensure that there are redundant paths between the nodes to ensure uninterrupted synchronization of DHCP leases.

In access-driven mode of operation, partner-down-delay has no effect.

The **no** form of this command reverts to the default.

Default

partner-down-delay hrs 23 min 59 sec 59

Parameters

partner-down-delay

Specifies the partner down delay time.

Values	**hrs** *hours*	1 to 23
	min *minutes*	1 to 59
	sec *seconds*	0 to 59

[Tree] (config>service>vprn>bgp>group passive)

Full Context

configure service vprn bgp group neighbor passive

configure service vprn bgp group passive

Description

This command enables passive mode for the BGP group or neighbor.

When in passive mode, BGP will not attempt to actively connect to the configured BGP peers but responds only when it receives a connect open request from the peer.

The **no** form of this command used at the group level disables passive mode where BGP actively attempts to connect to its peers.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Default

no passive — BGP will actively try to connect to all the configured peers.
