Release 23.7.R1

Classic CLI Command Reference Guide

3HE 19215 AAAB TQZZA 01
Edition 01
July 2023

Nokia is committed to diversity and inclusion. We are continuously reviewing our customer documentation and consulting with standards bodies to ensure that terminology is inclusive and aligned with the industry. Our future customer documentation will be updated accordingly.

Table of contents

1 Getting started

This guide contains command descriptions for the classic SR OS CLI commands that are used to manage the SR OS.

In this guide, the term CLI refers to the classic CLI unless otherwise specified.

This guide does not include **clear**, **monitor**, **show**, or **tools** commands. These commands are documented in the *7450 ESS, 7750 SR, 7950 XRS, and VSR Clear, Monitor, Show, and Tools Command Reference Guide*.

Note:
This guide generically covers Release 23.*x*.R*x* content and may contain some content that will be released in later maintenance loads. In addition, some SR OS features are platform-specific and may not be available or visible on all platforms. See the *SR OS R23.x.Rx Software Release Notes*, part number 3HE 19269 000 *x* TQZZA, for information about the supported features and applicable platforms in each load of the Release 23.*x*.R*x* software.

The full set of CLI commands supported by the SR OS is documented in three related guides that are listed in the following table.

Table 1: Documentation for SR OS CLI commands

Guide title	Classic CLI commands	MD-CLI commands
7450 ESS, 7750 SR, 7950 XRS, and VSR Clear, Monitor, Show, and Tools Command Reference Guide	All **clear**, **monitor**, **show**, and **tools** commands	All **clear**, **monitor**, **show**, and **tools** commands
7450 ESS, 7750 SR, 7950 XRS, and VSR Classic CLI Command Reference Guide	All other commands	—
7450 ESS, 7750 SR, 7950 XRS, and VSR MD-CLI Command Reference Guide	—	All other commands

Note:
Unless explicitly noted otherwise, this guide uses the terminology defined in the following table to collectively designate the specified platforms.

Table 2: Platforms and Terminology

Platform	Collective platform designation
7450 ESS-7	All
7450 ESS-12	
7750 SR-1	
7750 SR-1-24D	

Platform	Collective platform designation
7750 SR-1-46S	
7750 SR-1-48D	
7750 SR-1-92S	
7750 SR-1x-48D	
7750 SR-1x-92S	
7750 SR-7	
7750 SR-12	
7750 SR-12e	
7750 SR-a4	
7750 SR-a8	
7750 SR-1e	
7750 SR-2e	
7750 SR-3e	
7750 SR-1s	
7750 SR-1se	
7750 SR-2s	
7750 SR-2se	
7750 SR-7s	
7750 SR-14s	
7950 XRS-20	
7950 XRS-20e	
7950 XRS-40	
VSR	
VSR-NRC	
7450 ESS-7	7450 ESS
7450 ESS-12	
7750 SR-1	7750 SR
7750 SR-1-24D	
7750 SR-1-46S	
7750 SR-1-48D	

Platform	Collective platform designation
7750 SR-1-92S	
7750 SR-1x-48D	
7750 SR-1x-92S	
7750 SR-7	
7750 SR-12

VSR	VSR
VSR-NRC	

1.1 Command tree

The SR OS CLI command tree is a hierarchical inverted tree. The highest level is the root level. Below this level are other tree levels with the major command groups; for example, **configuration** commands and **admin** commands are levels below root.

In the tree, you can click a command to link directly to the command description.

Note: Commands that are listed in the tree but are not linked to an associated description are available on one or more platforms but are not currently described in the guide.

1.2 Command descriptions

Command descriptions are listed in alphabetical order by command name.

The following figure shows an example of a command description.

Figure 1: Command description example

aa-sub-study

Syntax	as-sub-study *study-type*
Context	[Tree] (config>app-assure>group>statistics aa-sub-study)
Full Context	configure application-assurance group statistics aa-sub-study
Description	This command enables the context to configure accounting and statistics collection parameters per application assurance special study subscribers.
Parameters	*study-type* — Specifies special study protocol subscriber stats.
Values	application, protocol

sw3044

The following table describes the fields that may be shown for a command. Not all fields are applicable for all commands.

Table 3: Command description fields

Field	Description
Command Name	Name of the command
Syntax	Command syntax required to execute the command. See Table 4: Command syntax symbols for information about syntax symbols.
Context	Path to the command as it is displayed in the CLI prompt. Clicking on [Tree] links to the command in the CLI tree.
Full Context	Complete contextual path to perform the command
Description	Description of the command functionality and any restrictions
Default	Command default value

Field	Description
Parameters	Descriptions of command parameters
Values	Values allowed for the parameter
Default	Parameter default value
Platforms	Hardware platforms on which the command is available. See Table 2: Platforms and Terminology for more information about the platforms. **Note**: Some SR OS features are platform-specific and therefore may not be available or visible on all platforms. See the *SR OS R23.x.Rx Software Release Notes*, part number 3HE 19269 000 *x* TQZZA, for information about platform support.

Note: All options for enumerated types and numerical ranges are listed in the command descriptions; however, not all options or ranges are valid on all platforms.

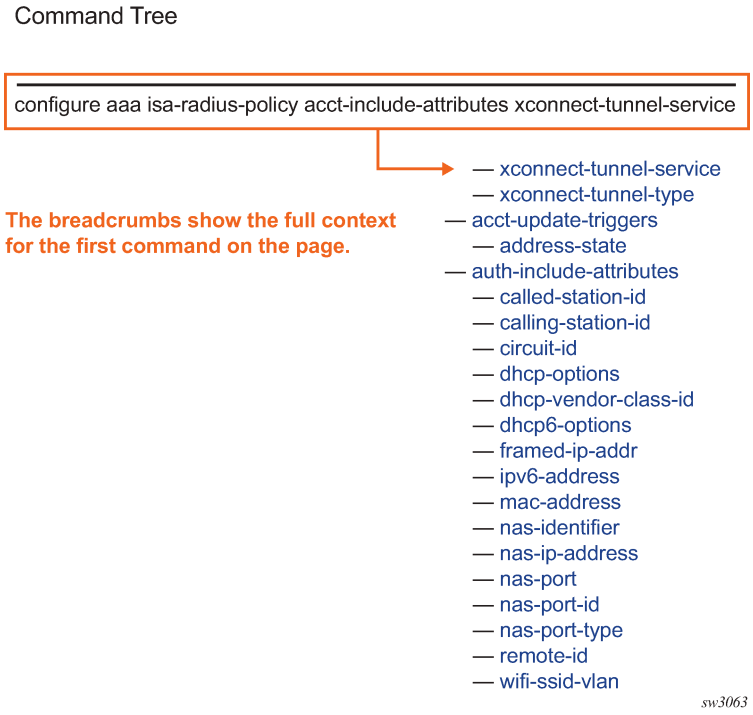
1.3 Navigational aids

The following aids help you navigate the guide and find specific commands.

1.3.1 Context path

In the CLI tree section, the complete contextual path to the first command on the page is shown at the top of the page, as shown in the following figure.

Figure 2: Command tree navigation



1.3.2 Searching

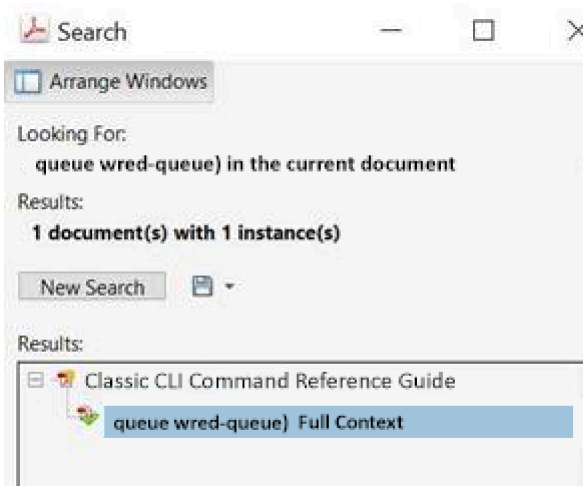
The Context field in each command description shows, in parentheses, the full path to the command as displayed in the CLI prompt. This form of the contextual path often abbreviates terms. For example:

(cfg>qos>qgrps>egr>qgrp>queue wred-queue)

To search this guide for a specific command using the Acrobat search function, enter the command name and append a closing parenthesis in the search window. For more efficient searching, add the previous level of the contextual path before the command name.

If you add the context and closing parenthesis, the resulting search returns only matching Context entries. It will not return instances of the same command found elsewhere in the guide. The following figure shows an example of a search.

Figure 3: Search window



1.3.3 Linking to the tree

Clicking on [Tree] in a command description context links directly to the command in the CLI tree. The following figure shows the [Tree] element.

Figure 4: Link to CLI tree

aa-sub-study

Syntax	as-sub-study *study-type*
Context	[Tree](config>app-assure>group>statistics aa-sub-study)
Full Context	configure application-assurance group statistics aa-sub-study
Description	This command enables the context to configure accounting and statistics collection parameters per application assurance special study subscribers.
Parameters	*study-type* — Specifies special study protocol subscriber stats.
Values	application, protocol

sw3061

2 Classic CLI overview

In this chapter, "CLI" refers to the classic CLI unless otherwise specified.

2.1 CLI structure

The SR OS CLI is a command-driven interface accessible through the console, Telnet, or secure shell (SSH). The CLI can be used for the configuration and management of routers.

The SR OS CLI command tree is a hierarchical inverted tree. The operational root level is the highest level of this tree. When the user enters a CLI session, the user is in the operational root context. Below this level are other tree levels for the major command groups; for example, **configure** commands and **show** commands are levels below the operational root level.

The CLI is organized so that related commands with the same scope are at the same level or in the same context. Sublevels or subcontexts have related commands with a more refined scope.

Note: The CLI engine used to execute scripts is the primary CLI engine configured with **config**>**system**>**management-interface**>**cli**>**cli-engine** {[**classic-cli**] [**md-cli**]}.

2.2 Navigating in the CLI

The following table describes command syntax symbols used in this guide.

Table 4: Command syntax symbols

Symbol	Description
|	A vertical line indicates that only one of the parameters within the brackets or braces can be selected.
[ ]	Brackets indicate optional parameters.
{ }	Braces indicate that one of the parameters must be selected.
[{ }]	Braces within square brackets indicate that the parameters are optional, but if one is selected, the information within the braces is required.
Bold	**Bold** indicates commands and keywords.
Italic	*Italics* indicates that you must enter text for the parameter.

2.2.1 CLI contexts

Use the CLI to access, configure, and manage Nokia routers. CLI commands are entered at the command line prompt. Access to specific CLI commands is controlled by the permissions set by your system administrator. Entering a CLI command makes navigation possible from one command context (or level) to another.

When the user enters a CLI session, the user is in the operational root context. Navigate to another level by entering the name of successively lower contexts. For example, at the command prompt (#), enter **configure** or **config**. See Command completion for alternative syntax for the same command. The active context displays in the command prompt.

```
A:cses-E11# config
A:cses-E11>config#
```

In a CLI context, enter commands at that context level by entering the text. Press <Enter> to move to a lower context. The user can also include commands from lower context at one context level as long as the command and parameter syntax is correct.

The following example shows two methods to navigate to a service SDP ingress level.

Method 1:

```
A:cses-E11# configure service epipe 6 spoke-sdp 2:6 ingress
*A:cses-E11>config>service>epipe>spoke-sdp>ingress#
```

Method 2:

```
A:cses-E11>config# service
A:cses-E11>config>service# epipe 6
*A:cses-E11>config>service>epipe# spoke-sdp 2:6
*A:cses-E11>config>service>epipe>spoke-sdp# ingress
*A:cses-E11>config>service>epipe>spoke-sdp>ingress#
```

The CLI returns an error message if the syntax is incorrect. For example, if the user enters **rooter** for the **root** command, it would result in an error.

```
*A:cses-E11>config# rooter
Error: Bad command.
```

The command parameter is the means by which a value is passed to the command processing program. The user must enter the value according to the syntax rules and, where applicable, the defined range. In the previous example, "6" and "2:6" are the parameter values that the user must enter to execute the command. The value "6" is the value for the Epipe service identifier parameter. For the value "2:6", "2" is the value for the SDP identifier parameter and "6" is the value for the virtual circuit identifier.

2.2.2 Operational root and global commands

The commands in the following table are available at the operational root level of the CLI hierarchy. For the command descriptions, see the respective command sections in this guide. For descriptions of the **clear**, **monitor**, **show**, and **tools** commands, see the *7450 ESS, 7750 SR, 7950 XRS, and VSR Clear, Monitor, Show, and Tools Command Reference Guide*.

Table 5: Operational root commands

Command	Description
admin	Enters the administrative context for system operations
bof	Enters the context to configure the boot options file
clear	Clears statistics or resets the operational state
configure	Enters the configuration context
[**no**] **debug**	Enters the context to enable or disable debugging and specify debug options
environment	Enters the environment configuration context
file	Enters the context for file system commands
help	Displays help in the CLI
monitor	Enters the context to monitor statistics
password	Enters the context to change the user CLI login password
show	Shows operational information
tools	Enters the tools context for troubleshooting and debugging

Global commands are commands that can be entered at any level in the CLI hierarchy. To display the list of all system global commands, enter **help globals** in the CLI.

The global commands are listed in the following table. For the command descriptions, see the respective command sections in this guide.

Table 6: Global commands

Command	Description
back	Navigates to the parent context
candidate	Enters the context to configure candidate parameters
echo	Echoes the text that is typed in. The primary use is to display messages to the screen within an exec file.
enable-admin	Enables the user to become a system administrator
exec	Executes the contents of a text file as if they were CLI commands entered at the console
exit	Returns to the previous higher context
help	Displays help in the CLI

Command	Description
history	Displays a list of the most recently entered commands
logout	Terminates the CLI session
mrinfo	Requests multicast router information
mstat	Traces a multicast path from a source to a receiver and displays multicast packet rate and loss information (IGMP-based)
mstat2	Traces a multicast path from a source to a receiver and displays multicast packet rate and loss information (UDP-based)
mtrace	Traces a multicast path from a source to a receiver (IGMP-based)
mtrace2	Traces a multicast path from a source to a receiver (UDP-based)
oam	Provides OAM test suite options. See the *7450 ESS, 7750 SR, 7950 XRS, and VSR OAM and Diagnostics Guide*.
ping	Verifies the reachability of a remote host
pwc	Displays the present or previous working context of the CLI session
sleep	Causes the console session to pause operation (sleep) for 1 s or for the specified number of seconds. The primary use is to introduce a pause in the execution of an exec file.
ssh	Opens a secure shell connection to a host
telnet	Connects to a host using Telnet
traceroute	Determines the route to a destination address
tree	Displays a list of all commands at the current level and all sublevels
write	Sends a console message to a specific user or to all users with active console sessions

2.2.3 CLI environment commands

The CLI **environment** commands listed in the following table are found in the **environment** context of the operational root of the CLI tree. These commands control session preferences for a single CLI session. For more information on the commands, see the respective command sections in this guide.

Table 7: CLI environment commands

Command	Description
alias	Enables the substitution of a command line by an alias
create	Enables or disables the use of a create parameter check

Command	Description
kernel	Enables or disables the kernel
more	Enables the CLI output to be displayed one screen at a time, awaiting user input to continue
reduced-prompt	Configures the maximum number of higher-level CLI context nodes to display by name in the CLI prompt for the current CLI session
saved-ind-prompt	Saves the indicator in the prompt
shell	Enables or disables the shell
suggest-internal-objects	Enables the suggestion of internally created objects while auto-completing
terminal	Configures the terminal screen length for the current CLI session
time-display	Specifies whether time should be displayed in local time or UTC
time-stamp	Specifies whether the timestamp should be displayed before the prompt

2.3 Getting help in the CLI

The **help** system commands and the **?** key display different types of help in the CLI. The following table lists the help commands.

Table 8: Online help commands

Command	Description
help	Describes the help system
help globals	Displays information about global commands
help edit	Displays information about all editing keystrokes
help special-characters	Displays information about all special characters that can be entered at the command prompt
?	Displays context-sensitive help information and displays a full list of options and commands available from the current context When entered at the root context, displays a full list of top-level contexts and global commands
command ? *command parameter* ? *command* **keyword** ?	Displays the available syntax options for the command, lists the associated parameters and keywords, and lists all commands available from the *command* context

Command	Description
string?	Lists all commands available in the current context that start with *string*
command string? *command parameter string*? *command* **keyword** *string*?	Lists all commands, parameters, or keywords available in the *command* context that start with *string*
*string***Tab**	Completes a partial command name (auto-completion) or lists available commands that match *string*

The **tree** and **tree detail** system commands are useful when searching for a command in a lower-level context.

The following example shows a partial list of the **tree** and **tree detail** command outputs on a 7750 SR.

Example: tree and tree detail command outputs

```
*A:cses-E11>config# tree

+---router
| +---aggregate
| +---allow-icmp-redirect
| +---allow-icmp6-redirect
| +---autonomous-system
| +---bfd
| | +---abort
| | +---begin
| | +---bfd-template
| | | +---echo-receive
| | | +---multiplier
| | | +---receive-interval

| | +---advertise-inactive
| | | no advertise-inactive
| | +---aggregator-id-zero
| | | no aggregator-id-zero
| | +---auth-keychain <name>
| | +---authentication-key <authentication-key|hash-key> [hash|hash2|custom]
```

2.4 The CLI command prompt

By default, the CLI command prompt indicates the device being accessed, the active CPM, and the current CLI context. For example, the prompt: **A:cses-E11>config>router>if#** indicates that the active CPM is CPM A, the user is on the device with the hostname **cses-E11**, and the current context **config**>**router**>**interface**. In the prompt, the separator used between contexts is the ">" symbol. The active CPM can be A or B on the 7750 SR, and A, B, C, or D on the 7950 XRS.

At the end of the prompt, there is either a pound sign (#) or a dollar sign ($). A "#" at the end of the prompt indicates the context is an existing context. A "$" at the end of the prompt indicates the context has been newly created. Contexts are newly created for logical entities when the user first navigates into the context.

Because there can be a large number of sublevels in the CLI, the **environment** command **reduced-prompt** *no of nodes in prompt* allows the user to control the number of levels displayed in the prompt.

WARNING:
In CLI command configurations, allowed values in parameter strings are printable, 7-bit ASCII characters. If the string contains special characters, (#, $, space), the entire string must be enclosed within double quotes ("). Double quotes within a string are not supported. Parameter strings input by the user must follow this format. This rule supersedes all related parameter descriptions found in this guide.

When changes are made to the configuration file, a "*" appears in the prompt string (*A:cses-E11), indicating that the changes have not been saved. When an **admin save** command is executed, the "*" disappears. This behavior is controlled by the **saved-ind-prompt** command in the **environment** context.

2.5 Displaying configuration contexts

The **info**, **info detail**, and **objective** commands display the configuration for the current level. The **info** command shows non-default configurations. The **info detail** command shows the entire configuration for the current level, including defaults. The **info objective** command provides an output objective that controls the configuration parameters to be displayed.

Example: info and info detail command outputs

The following example displays the output from the **info** command and the **info detail** command.

```
*A:cses-E11>config>router# interface system
*A:cses-E11>config>router>if# info
----------------------------------------------
            address 10.10.0.1/32
----------------------------------------------
*A:cses-E11>config>router>if#

*A:cses-E11>config>router>if# info detail
----------------------------------------------
            address 10.10.10.103/32 broadcast host-ones
            no description
            no arp-timeout
            no allow-directed-broadcasts
            tos-marking-state trusted
            no local-proxy-arp
            no proxy-arp
```

```
            icmp
                mask-reply
                redirects 100 10
                unreachables 100 10
                ttl-expired 100 10
            exit
            no mac
            no cflowd
            no shutdown
-----------------------------------------------
*A:cses-E11>config>router>if#
```

2.6 exec Files

The **exec** command allows you to execute a text file of CLI commands as if it were typed at a console device.

The **exec** command and the associated exec files can be used to conveniently execute a number of commands that are always executed together in the same order. For example, an **exec** command can be used to define a set of commonly used standard command aliases.

The **echo** command can be used within an exec command file to display messages on screen while the file executes.

Arguments can be specified with the **exec** command. These arguments are passed in to be used inside the text file that includes the CLI commands. The passing of arguments with the **exec** command only works in the classic CLI. The passing of arguments with the **exec** command cannot be used in the MD-CLI.

For example, if the file `cf3/Test.txt` contains the following set of CLI commands:

```
echo $(1)
echo $(2)
echo $(3)
```

then executing the following commands:

 # exec cf3:/Test.txt -arguments var1=10 var2=20 var3=30

or

 # exec cf3:/Test.txt -arguments 10 20 30

produces the following output:

```
10
20
30
```

2.7 CLI script control

SR OS provides centralized script management for CLI scripts that are used by CRON and the Event Handling System (EHS). A set of script policies and script objects can be configured to control such things as:

- where scripts are located (local compact FTP server)

- where to store the output of the results
- how long to keep historical script result records
- how long a script may run

If the scripts are located on local compact flash devices, the user must ensure that the scripts are on the compact flash devices of both CPMs so that operation of EHS continues as expected if a CPM switchover occurs.

Only one script can execute at a time. An SNMP table (smRunTable in the DISMAN-SCRIPT-MIB) is used as both an input queue of scripts waiting to be executed and for storage of records for completed scripts. If the input queue is full, the script request is discarded.

2.8 Entering CLI commands

The following sections outline the steps to entering CLI commands.

2.8.1 Command completion

The CLI supports both command abbreviation and command completion. If the keystrokes entered are enough to match a valid command, the CLI displays the remainder of the command syntax when **Tab** or **Spacebar** is pressed. When typing a command, **Tab** or **Spacebar** invokes auto-completion. If the keystrokes entered are sufficient to identity a specific command, auto-completion completes the command. If the letters are not sufficient to identify a specific command, pressing **Tab** or **Spacebar** displays commands matching the letters entered.

System commands are available in all CLI contexts.

2.8.2 Unordered and unnamed parameters

In a command context, the CLI accepts command parameters in any order as long as the command is formatted in the proper command keyword and parameter syntax. Command completion works as long as enough recognizable characters of the command are entered.

The following output shows the command syntax for **static-route-entry**.

```
*A:cses-E11>config>router# static-route-entry ?
 - no static-route-entry <ip-prefix/prefix-length> [mcast]
 - static-route-entry <ip-prefix/prefix-length> [mcast]

<ip-prefix/prefix-*> : ipv4-prefix    - a.b.c.d (host bits must be 0)
                       ipv4-prefix-le - [0..32]
                       ipv6-prefix    - x:x:x:x:x:x:x:x   (eight 16-bit pieces)
                                        x:x:x:x:x:x:d.d.d.d
                                        x - [0..FFFF]H
                                        d - [0..255]D
                       ipv6-prefix-le - [0..128]
<mcast>              : keyword - Indicates that static-route being configured
                       is used for mcast table only

 [no] backup-tag      - Create/Configure or Delete/Deconfigure backup tag for
                        static-route-entry
 [no] black-hole      + Create/Configure or Delete/Deconfigure blackhole
```

```
                        nexthop for static-route-entry
[no] community        - Create/Configure or Delete/Deconfigure community for
                        static-route-entry
[no] indirect         + Create/Configure or Delete/Deconfigure indirect
                        next-hop for static-route-entry
[no] next-hop         + Create/Configure or Delete/Deconfigure next-hop for
                        static-route-entry
[no] tag              - Create/Configure or Delete/Deconfigure tag for
                        static-route-entry
```

Some SR OS CLI commands have multiple unnamed parameters. For example, the **subrate** *csu-mode rate-step* command has both a *csu-mode* parameter and a *rate-step* parameter that do not have leading keywords. SR OS uses a best-match algorithm to select which parts of the user input are intended to be used for each unnamed parameter. This best-match algorithm depends on the specific command.

In some cases, it is not possible for the algorithm to be 100% accurate, and SR OS may assign an unintended value to a parameter when two unnamed parameters have similar constraints and syntax. For example, the **environment alias** *alias-name alias-command-name* command may reverse the *alias-name* and *alias-command-name* parameters if the first parameter entered is more than 80 characters.

2.8.3 Using editing keystrokes

When entering a command, special keystrokes allow for editing of the command. The following table lists the command editing keystrokes.

Table 9: Command editing keystrokes

Editing action	Keystrokes
Stop the current command	**Ctrl-C**
Delete current character	**Ctrl-D**
Delete text up to cursor	**Ctrl-U**
Delete text after cursor	**Ctrl-K**
Move to beginning of line	**Ctrl-A**
Move to end of line	**Ctrl-E**
Get prior command from history	**Ctrl-P**
Get next command from history	**Ctrl-N**
Move cursor left	**Ctrl-B**
Move cursor right	**Ctrl-F**
Move back one word	**Alt-B** or **Esc+B**
Move forward one word	**Alt-F** or **Esc+F**
Convert rest of word to uppercase	**Alt-C** or **Esc+C**

Editing action	Keystrokes
Convert rest of word to lowercase	**Alt-L** or **Esc+L**
Delete remainder of word	**Alt-D** or **Esc+D**
Delete word up to cursor	**Ctrl-W**
Transpose current and previous character	**Ctrl-T**
Enter command and return to operational root prompt	**Ctrl-Z**
Refresh input line	**Ctrl-L**

2.8.4 Entering absolute paths

CLI commands can be executed in any context by specifying the full path from the CLI root. To execute an out-of-context command, enter a forward slash (**/**) or backward slash (\) at the beginning of the command line. The commands are interpreted as absolute paths. Spaces between the slash and the first command return an error.

```
*A:cses-E11# configure router
*A:cses-E11>config>router# interface system address 10.2.3.4
*A:cses-E11>config>router# /admin save
*A:cses-E11>config>router# \clear router interface
*A:cses-E11>config>router#
```

The "**/**" or "****" cannot be used as an absolute path at the beginning of the command string of the **environment alias** command. The command may change the current context depending on whether it is a leaf command. This is the same behavior the CLI performs when CLI commands are entered individually; for example:

```
*A:cses-E11# admin
*A:cses-E11>admin# save
```

or

```
*A:cses-E11# admin save
*A:cses-E11#
```

An absolute path command behaves in the same way as manually entering a series of command line instructions and parameters.

For example, beginning in an IES context service ID 4 (IES 4):

```
config>service>ies> /clear card 1
```

behaves in the way same as the following series of commands:

```
config>service>ies>exit all
clear card 1
configure service ies 4 (returns you to your starting point)
config>service>ies
```

If the command takes you to a different context, the following occurs:

```
config>service>ies>/configure service vpls 5 create
```

becomes:

```
config>service>ies>exit all
configure service vpls 5 create
config>service>vpls>
```

2.8.5 Displaying the command history

The CLI maintains a history of the most recently entered commands. The **history** command shows the most recently entered CLI commands.

```
*A:cses-E11# history
   1 environment terminal length 48
   2 environment no create
   3 show version
   4 configure port 1/1/1
   5 info
   6 \configure router isis
   7 \port 1/1/2
   8 con port 1/1/2
   9 \con port 1/1/2
  10 \configure router bgp
  11 info
  12 \configure system login-control
  13 info
  14 history
  15 show version
  16 history
*A:cses-E11# !3

A:cses-E11# show version

```

2.8.6 Entering numerical ranges

The SR OS CLI allows the use of a single numerical range as an argument in the command line. This range can be a set or a sequence of numbers, or a combination of both.

A set is a range of numerical values, from a minimum to a maximum, incremented by 1. For example:

```
configure service vpls [1..10] create customer 1
```

A sequence is a list of discrete integer elements, in any order. For example:

```
configure service vpls [1,2,3] no shutdown
```

A sequence can contain sets as well as integer elements. For example:

```
configure service vpls [4..6,7,8..10] no shutdown
```

For example, it is possible to shut down ports 1 through 10 on an XMA/MDA 1 in chassis slot 1. A port can be denoted by "*slot*/*mda*/*port*", where *slot* is the slot number, *mda* is the XMA/MDA number and *port* is the port number. To shut down ports 1 through 10 on an XMA/MDA 1 in slot 1, the command is entered as follows:

```
configure port 1/1/[1..10] shutdown
```

Ctrl-C can be used to abort the execution of a range command.

CLI commands can contain ranges of hexadecimal values. This allows ranges to be used when working with data normally expressed in hexadecimal instead of decimal, such as IPv6 or MAC addresses. For example:

```
#config>service>vpls>sap$ static-mac aa:bb:[0x19..0x21]:dd:ee:ff create
#config>service>vpls>sap$ info
----------------------------------------------
                static-mac aa:bb:19:dd:ee:ff create
                static-mac aa:bb:1a:dd:ee:ff create
                static-mac aa:bb:1b:dd:ee:ff create
                static-mac aa:bb:1c:dd:ee:ff create
                static-mac aa:bb:1d:dd:ee:ff create
                static-mac aa:bb:1e:dd:ee:ff create
                static-mac aa:bb:1f:dd:ee:ff create
                static-mac aa:bb:20:dd:ee:ff create
                static-mac aa:bb:21:dd:ee:ff create
----------------------------------------------
```

A range can also be a reference to a previous range in the same command. This reference takes the form [$*x*], where *x* is an integer between 0 and 5. For example:

```
configure service vprn [11..20] router-id 10.20.[$0].1
```

This gives vprn 11 the router-id "10.20.11.1", vprn 12 the router-id "10.20.12.1", and so on.

Specifying a range in the CLI does have limitations. These limitations are summarized in the following table.

Table 10: CLI range use limitations

Limitation	Description
Up to 6 ranges (including references) with 20 range elements in each range may be specified in a single command, and they may not combine to more than 1000 iterations of the command.	For example, ports on two adapter cards can be shut down in one command by using two ranges: **configure port 1/[1..2]/[1..10]**
Ranges within quotation marks are interpreted literally.	In the CLI, enclosing a string in quotation marks ("*string*") causes the string to be treated literally and as a single parameter. For example, several commands in the CLI allow the configuration of a descriptive string. If the string is more than one word and includes spaces, it must be enclosed in quotation marks.

Limitation	Description
	A range that is enclosed in quotes is also treated literally. For example, **configure router interface "A[1..10]" no shutdown** creates a single router interface with the name "A[1..10]". However, a command such as: **configure router interface A[1..10] no shutdown** creates 10 interfaces with names A1, A2 .. A10.
Command completion does not work when entering a range.	After entering a range in a CLI command, command and key completion, which normally occurs by pressing **Tab** or **Spacebar**, does not work. If the command line entered is correct and unambiguous, the command works properly; otherwise, an error is returned.

2.8.6.1 Using regular expressions in numerical ranges

The user can include a regular expression inside the numerical ranges of any **clear**, **config**, **show**, or **tools** CLI commands. The beginning and ending of the regular expression must be delimited with the "/" symbol.

SR OS performs the following steps:

- auto-completes the command to get all the possible names
- performs a match of the regular expression against all the names
- executes the command for the names for which the match was successful

Note:
The order of execution is the same as the order in which the names are listed in the output display of the CLI **info** command or in the output display when you invoke the auto-complete function using **Tab**. If the execution of the command fails for one of the matching object names, the execution is aborted and the remaining matching object names are not processed.

For example, the following SR-TE LSP names are configured on the router:

```
*A:bkvm35# show router mpls sr-te-lsp
===============================================================================
MPLS SR-TE LSPs (Originating)
===============================================================================
LSP Name                        To              Tun      Protect     Adm    Opr
                                                Id       Path
-------------------------------------------------------------------------------
sr-te-pce                       192.0.2.198     1        N/A         Up     Dwn
RENO194_DET190_LSP1_Profile10   192.0.2.190     2        N/A         Up     Dwn
RENO194_DET190_LSP3             192.0.2.190     3        N/A         Up     Dwn
RENO194_ATL224_LSP1             192.0.2.224     4        N/A         Up     Dwn
-------------------------------------------------------------------------------
LSPs : 4
===============================================================================
```

The following command displays the subset of all SR-TE LSPs with names that include the expression "LSP":

show router mpls sr-te-lsp [/LSP/]

The SR OS expands this command into the following individual commands:

show router mpls sr-te-lsp RENO194_DET190_LSP1_Profile10

show router mpls sr-te-lsp RENO194_DET190_LSP3

show router mpls sr-te-lsp RENO194_ATL224_LSP1

The output of the three **show** commands is displayed in the following example:

```
*A:bkvm35# show router mpls sr-te-lsp [/LSP/]
===============================================================================
MPLS SR-TE LSPs (Originating)
===============================================================================
LSP Name                            To              Tun     Protect   Adm  Opr
                                                    Id      Path
-------------------------------------------------------------------------------
RENO194_DET190_LSP1_Profile10       192.0.2.190     2       N/A       Up   Dwn
-------------------------------------------------------------------------------
LSPs : 1
===============================================================================
===============================================================================
MPLS SR-TE LSPs (Originating)
===============================================================================
LSP Name                            To              Tun     Protect   Adm  Opr
                                                    Id      Path
-------------------------------------------------------------------------------
RENO194_DET190_LSP3                 192.0.2.190     3       N/A       Up   Dwn
-------------------------------------------------------------------------------
LSPs : 1
===============================================================================
===============================================================================
MPLS SR-TE LSPs (Originating)
===============================================================================
LSP Name                            To              Tun     Protect   Adm  Opr
                                                    Id      Path
-------------------------------------------------------------------------------
RENO194_ATL224_LSP1                 192.0.2.224     4       N/A       Up   Dwn
-------------------------------------------------------------------------------
```

2.8.6.1.1 Regular expression symbols in a regular expression match operation

The user can use all the regular expression symbols listed in Table 12: Regular expression symbols and Table 13: Character class expressions inside the regular expression to match.

For example, the user can list all LSP names that begin with the string "RENO194_" followed by the string "ATL" as follows:

```
*A:bkvm35# show router mpls sr-te-lsp [/^RENO194_\['ATL'\]/]
===============================================================================
MPLS SR-TE LSPs (Originating)
===============================================================================
LSP Name                        To              Tun      Protect     Adm    Opr
                                                Id       Path
-------------------------------------------------------------------------------
RENO194_ATL224_LSP1             38.120.48.224   4        N/A         Up     Dwn
-------------------------------------------------------------------------------
```

```
LSPs : 1
===============================================================================
```

Note:
The following conventions are used in the previous example.

- Use the character "^", which matches the start of the string, directly inside the regular expression to indicate a match at the start of the string. However, if you want to match it as a character, enter it as "\\^".
- Use the range delimiter with the escape symbol in front "\[" inside the regular expression because the range delimiter encloses the regular expression.

The following table summarizes special rules governing the use of some of the regular expression symbols inside a regular expression match operation. Any symbol from Table 12: Regular expression symbols or Table 13: Character class expressions that is not listed in Table 11: Rules governing regular expression symbols can be used directly inside a regular expression match operation.

Table 11: Rules governing regular expression symbols

String	Description
?	[/\?/] if using as a regular expression and [/\\\?/] if using to match the character ?
[ ]	[/\[\]/] if using as a regular expression and [/\\\[\\\]/] if using to match the characters []
$	[/$/] if using as a regular expression and [/\\$/] if using to match the character $
\	[/\\\\/] if using to match the character \
/	[/\/] if using to match the character /
'	[/\'/] if using to match the character '
*	[/*/] if using to match the character *
.	[/\./] if using as a regular expression and [/\\\./] if using to match the character .
+	[/\\+/] if using to match the character +
,	[/\,/] if using to match the character ,
^	[/\\^/] if using to match the character ^
(	[/\\(/] if using to match the character (
)	[/\\)/] if using to match the character)
space	[/\ /] if using to match the character space

The SR OS does not support the combination of a partial string with a regular expression match operation.

For example, if the operator wants to display the SR-TE LSP names that begin with the string "RENO194_ATL", if part of the string is entered directly and the rest of the string is entered inside a regular expression, the command returns no match. The following example demonstrates the incorrect syntax:

```
*A:bkvm35# show router mpls sr-te-lsp RENO194_[/ATL/]
```

To obtain a match, the entire string must be inside the regular expression. The following example demonstrates the correct syntax for finding a match:

```
*A:bkvm35# show router mpls sr-te-lsp [/^RENO194_ATL/]
===============================================================================
MPLS SR-TE LSPs (Originating)
===============================================================================
LSP Name                        To              Tun      Protect     Adm    Opr
                                                Id       Path
-------------------------------------------------------------------------------
RENO194_ATL224_LSP1             38.120.48.224   4        N/A         Up     Dwn
-------------------------------------------------------------------------------
LSPs : 1
===============================================================================
```

2.8.7 Using the | match output modifier

The **| match** output modifier searches for a character string or pattern. When using the **| match** output modifier, the variables and attributes must be spelled correctly. The attributes follow the output modifier and must come before the expression or pattern. The following are examples of how to use the **| match** output modifier to complete different tasks:

- Task: Capture all the lines that include "echo" and redirect the output to a file on the compact flash:

  admin display-config | match "echo" > cf1:\test\echo_list.txt
- Task: Display all the lines that do not include "echo":

  admin display-config | match invert-match "echo"
- Task: Display the first match of "vpls" in the configuration file:

  admin display-config | match max-count 1 "vpls"
- Task: Display everything in the configuration after finding the first instance of "interface":

  admin display-config | match post-lines 999999 interface
- Task: Display a count of the total number of lines of output instead of displaying the output itself:

  admin display-config | match interface | count

Command syntax:

match *pattern* **context** {**parents** | **children** | **all**} [**ignore-case**] [**max-count** *lines-count*] [**expression**]

match *pattern* [**ignore-case**] [**invert-match**] [**pre-lines** *pre-lines*] [**post-lines** *lines-count*] [**max-count** *lines-count*] [**expression**]

where:

```
pattern         string or regular expression
context         keyword:  display context associated with the matching line
parents         keyword:  display parent context information
children        keyword:  display child context information
```

```
all             keyword:  display both parent and child context information
ignore-case     keyword
max-count       keyword:  display only a specific number of instances of matching
                          lines
lines-count     1 — 2147483647
expression      keyword:  pattern is interpreted as a regular expression
invert-match    keyword
pre-lines       keyword:  display some lines prior to the matching line
pre-lines       0 — 100
post-lines      keyword:  display some lines after the matching line
lines-count     1 — 2147483647
```

For example:

```
A:Dut-C# show log log-id 98 | match ignore-case "sdp bind"
"Status of SDP Bind 101:1002 in service 1001 (customer 1) changed to admin=up oper=u
p flags="
"Processing of a SDP state change event is finished and the status of all affected S
DP Bindings on SDP 101 has been updated."

A:Dut-C# show log log-id 98 | match max-count 1 "service 1001"
"Status of service 1001 (customer 1) changed to administrative state: up,
operational state: up"

A:Dut-C# admin display-config | match post-lines 5 max-
count 2 expression "OSPF.*Config"
echo "OSPFv2 Configuration"
#--------------------------------------------------
        ospf
            timers
                spf-wait 1000 1000 1000
            exit
echo "OSPFv2 (Inst: 1) Configuration"
#--------------------------------------------------
        ospf 1
            asbr
            router-id 10.0.0.1
            export "testall"
*A:Dut# admin display-config | match debug_mirror
            profile "debug_mirror"

*A:Dut# admin display-config | match context parent debug_mirror
#--------------------------------------------------
    system
        security
            profile "debug_mirror"

*A:Dut# admin display-config | match context all debug_mirror
#--------------------------------------------------
    system
        security
            profile "debug_mirror"
                default-action deny-all
                entry 10
                exit

*A:Dut# show log event-control | match ignore-case pre-lines 10 SyncStatus
L  2016 tmnxLogOnlyEventThrottled        MA  gen          0          0
MCPATH:
```

```

```

The following table describes regular expression symbols and their interpretation (similar to what is used for route policy regexp matching). Table 13: Character class expressions describes character class expressions.

Table 12: Regular expression symbols

String	Description
.	Matches any single character
[ ]	Matches a single character that is contained within the brackets [abc] matches "a", "b", or "c" [a-z] matches any lowercase letter [A-Z] matches any uppercase letter [0-9] matches any number
[^]	Matches a single character that is not contained within the brackets [^abc] matches any character other than "a", "b", or "c" [^a-z] matches any single character that is not a lowercase letter
^	Matches the start of the line (or any line, when applied in multiline mode)
$	Matches the end of the line (or any line, when applied in multiline mode)
()	Defines a "marked subexpression" Every matched instance will be available to the next command as a variable
*	A single character expression followed by "*" matches zero or more copies of the expression
{m,n}	Matches least *m* and at most *n* repetitions of the term
{m}	Matches exactly *m* repetitions of the term
{m,}	Matches *m* or more repetitions of the term
?	The preceding item is optional and matched at most once
+	The preceding item is matched one or more times

String	Description
-	Used between start and end of a range
\	An escape character to indicate that the following character is a match criteria and not a grouping delimiter

Table 13: Character class expressions

Character class	Characters matched[1]	Description
[:alnum:]	'ABCDEFGHIJKLMNOPQRSTUVWXYZ abcdefghijklmnopqrstuvwxyz 0123456789'	Alphanumeric characters
[:alpha:]	'ABCDEFGHIJKLMNOPQRSTUVWXYZ abcdefghijklmnopqrstuvwxyz'	Alphabetic characters
[:blank:]	' \t'	**Spacebar** and **Tab**
[:cntrl:]	'\007\b\t\n\v\f\r\1\2\3\4\5\6\16\17\20 \21\ 22\23\24\25\26\27\30 \31\32\33\34\35\ 36\37\177'	Control characters
[:digit:]	'0123456789'	Digits
[:graph:]	'ABCDEFGHIJKLMNOPQRSTUVWXYZ abcdefghijklmnopqrstuvwxyz 0123456789 !\"#$%&'()*+,-./:;<=>?@[\\ ]^_`{|}~'	Visible characters
[:lower:]	'abcdefghijklmnopqrstuvwxyz'	Lowercase letters
[:print:]	'ABCDEFGHIJKLMNOPQRSTUVWXYZ abcdefghijklmnopqrstuvwxyz 0123456789!\"#$%&'()*+,-./:;<=>?@[\\]^_ `{|}~ '	Visible characters and the Space character
[:punct:]	'!\"#$%&'()*+,-./:;<=>?@[\\]^_`{|}~'	Punctuation characters
[:space:]	'\t\n\v\f\r '	Whitespace (blank) characters
[:upper:]	'ABCDEFGHIJKLMNOPQRSTUVWXYZ'	Uppercase letters
[:xdigit:]	'0123456789ABCDEFabcdef'	Hexadecimal digits

Character class expressions must be enclosed within brackets. The expression [[:digit:]] is treated as a regular expression containing the character class "digit", while [:digit:] is treated as a regular expression matching ":", "d", "i", "g", or "t".

[1] Characters matching the character class are delimited by single quotation marks (').

2.8.8 Using the | count output modifier

The **| count** output modifier displays a count of the number of lines that would have otherwise been displayed. The **| count** output modifier is particularly useful when used in conjunction with the **| match** output modifier in order to count the number of output lines that match a specified pattern.

The following example shows usage of the **| count** output modifier.

Example: Using the | count output modifier

```
*A:dut-c# show service service-using vprn

===============================================================================
Services [vprn]
===============================================================================
ServiceId    Type      Adm  Opr  CustomerId Service Name
-------------------------------------------------------------------------------
1            VPRN      Down Down 1
44           VPRN      Up   Up   1
100          VPRN      Down Down 1
102          VPRN      Up   Up   1
235          VPRN      Down Down 1
1000         VPRN      Down Down 1000
-------------------------------------------------------------------------------
Matching Services : 6
-------------------------------------------------------------------------------
===============================================================================
*A:dut-c# show service service-using vprn | match Down | count
Count: 4 lines
*A:dut-c#
```

2.8.9 Using the | reverse-dns output modifier

The **| reverse-dns** output modifier performs a reverse DNS lookup on any IPv4 or IPv6 address in the input. The result of the lookup is inserted as the next line in the output on each line where an IP address is identified. If no match is found, no additional output is printed. If the output line is more than 80 characters, the line is truncated.

The following example shows usage of the **| reverse-dns** output modifier.

Example: Using the | reverse-dns output modifier

```
A:node-2# ping 10.184.216.34 | reverse-dns
PING 10.184.216.34 56 data bytes
(10.184.216.34) www.example.com
64 bytes from 10.184.216.34: icmp_seq=1 ttl=61 time=82.4ms.
64 bytes from 10.184.216.34: icmp_seq=2 ttl=61 time=82.5ms.
64 bytes from 10.184.216.34: icmp_seq=3 ttl=61 time=82.4ms.
64 bytes from 10.184.216.34: icmp_seq=4 ttl=61 time=82.3ms.
64 bytes from 10.184.216.34: icmp_seq=5 ttl=61 time=82.2ms.
---- 10.184.216.34 PING Statistics ----
(10.184.216.34) www.example.com
5 packets transmitted, 5 packets received, 0.00% packet loss
round-trip min = 82.2ms, avg = 82.4ms, max = 82.5ms, stddev = 0.122ms
```

2.8.10 Redirecting output to a file

SR OS supports output redirection (>), which allows the operator to store the output of a CLI command as a local or remote file.

For example:

```
‘ping <customer_ip> > cf3cf1:/ping/result.txt’
‘ping <customer_ip> > ftp://ron@ftp.nokia.com/ping/result.txt’
```

In some cases, only part of the output might be applicable. The **| match** and output redirection commands can be combined:

```
ping 10.0.0.1 | match expression “time.[[:digit:]]+” > cf3cf1:/ping/time.txt
```

This records only the RTT portion (including the word “time”).

2.9 Configuration rollback

The Configuration Rollback feature provides the ability to undo configurations and revert to previous router configuration states while minimizing impacts to services.

This feature gives the operator better control and visibility over the router configurations and reduces operational risk while increasing flexibility and providing powerful recovery options.

Configuration Rollback is useful in cases where configuration changes are made but the operator later decides not to keep the changes (for example, experimentation or when problems are identified in the configuration during actual network operation).

The advantages of this feature include the following.

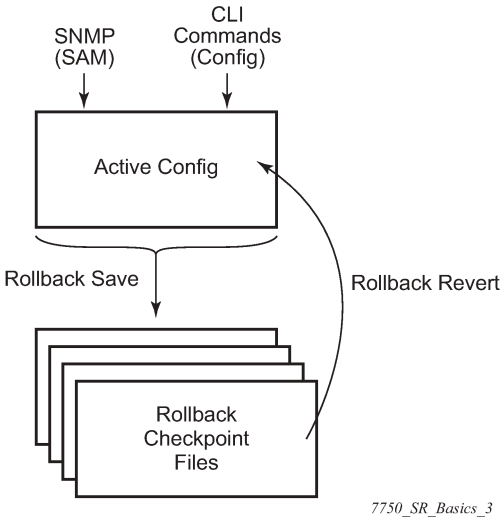
- Changes made to the router configuration are performed with minimal impact on services being provided by the SR because the router does not need to be rebooted.
- There is no impact in areas of the configuration that did not change.

With the rollback feature, the operator can smoothly revert to previous configurations.

Configuration parameters that are changed or items that the changed configuration have dependencies on are removed (revert to default) and the previous values are restored, which may briefly impact services in changed areas).

A history of changes is preserved using checkpoint IDs, which allow rollback to different points, as well as examination of changes made, as shown in the following figure.

Figure 5: Rollback operation



2.9.1 Feature behavior

The following list describes detailed behavior of the rollback feature, including the applicable CLI commands.

- The user can create a rollback checkpoint and later revert to this checkpoint with minimal impact to services.

  `admin>rollback# save [comment` *`comment-string`*`]`

  `comment-string: a comment associated with the checkpoint, maximum 255 characters`

- Rollback checkpoints include all current operationally active configurations:
  - changes from direct CLI commands in the configuration branch
  - SNMP sets
- Rollback checkpoints do not include BOF configurations. The BOF file and BOF configuration are not part of a rollback save or rollback. A rollback does not change the BOF configuration. The BOF contains basic information for the node and does not change frequently; changes are mostly made during initial commissioning of the node.
- A rollback save feature can be automatically executed (for example, scheduled monthly) using the CRON facility of SR OS.
- The latest rollback checkpoint file uses the suffix ".rb". The next latest rollback checkpoint file has the suffix ".rb.1", the next oldest has the suffix "rb.2", and so on.

  `file-url.rb` <--- latest rollback file

  `file-url.rb.1`

  …

  `file-url.rb.9 <--- oldest rollback file`

- When a **rollback save** is executed, the system shifts the file suffix of all the previous checkpoints by 1 (new ID = old ID + 1). If there are already as many checkpoint files as the maximum number supported, the last checkpoint file is deleted.
- The maximum number of rollback checkpoints is configurable and defaults to 10, which includes the latest file and files 1 through 9.
- The locations and names of the rollback checkpoint files are configurable to be local (on the compact flash) or remote. The *file-url* must contain a path/directory and filename with no suffix. The .rb suffix for rollback checkpoint files is automatically appended to the rollback checkpoint files.

  ```
  config>system>rollback# rollback-location file-url
  ```

- There is no default rollback location. If a rollback location is not specified, or it is cleared using **no rollback-location**, and a **rollback save** is attempted, the **rollback save** fails and returns an error message.
- The entire set of rollback checkpoint files can be copied from the active CPM CF to the standby CPM CF. This synchronization is done using the following command:

  ```
  admin>redundancy# rollback-sync
  ```

- The operator can enable an automatic synchronization of rollback checkpoint files between the active CPM and standby CPM. When this automatic synchronization is enabled, a **rollback save** causes the new checkpoint file to be saved to both the active and standby CPMs. The suffixes of the old checkpoint files on both active and standby CPMs are incremented.

  Automatic synchronization only causes the new checkpoint file to be copied to both CFs. The older checkpoint files are not automatically copied from active to standby but can be copied manually with **admin redundancy rollback-sync**.
- The **config**>**redundancy**>**synchronize** {**boot-env** | **config**} and **admin**>**redundancy**>**synchronize** {**boot-env** | **config**} commands do not apply to rollback checkpoint files. These commands do not manually or automatically synchronize rollback checkpoint files. The dedicated **rollback-sync** commands must be used to synchronize rollback checkpoint files.
- Rollback files can be deleted using a dedicated rollback checkpoint deletion command.

  ```
  admin>rollback# delete {latest-rb | checkpoint-id}
  ```

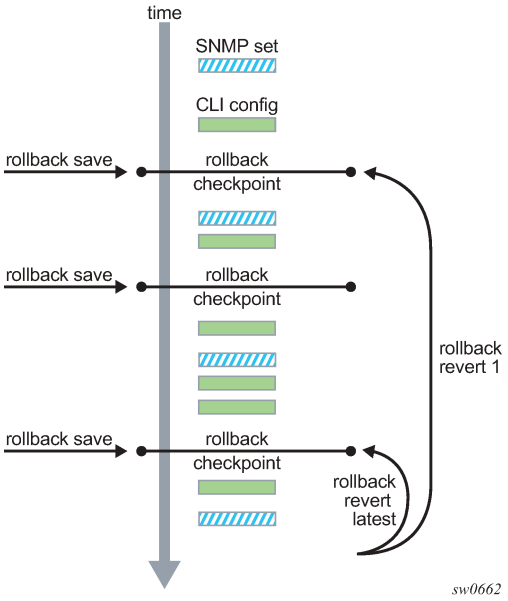
  – Deleting a rollback checkpoint causes the suffixes to be adjusted (decremented) for all checkpoints older that the one that was deleted in order to close the "hole” in the list of checkpoint files and create room to create another checkpoint.

  – If **config**>**redundancy**>**rollback-sync** is enabled, a **rollback delete** also deletes the equivalent checkpoint on the standby CF and shuffles the suffixes on the standby CF.

  – If an operator manually deletes a rollback checkpoint file using **file delete**, the suffixes of the checkpoint files are not shuffled, nor is the equivalent checkpoint file deleted from the standby CF. This manual deletion creates a "hole” in the checkpoint file list until enough new checkpoints have been created to roll the "hole” off the end of the list.
- The following figure shows how a configuration is rolled back to a previous configuration (a saved rollback checkpoint). The previous configuration is loaded and takes operational effect.

  ```
  admin>rollback# revert [latest-rb | checkpoint-id]
  ```

Figure 6: Configuration rollback



- A rollback revert does not affect the currently stored rollback checkpoint files; files are not deleted or renumbered. This means that if an operator issues the command **rollback revert 3** and then issues the **rollback save** command, the resulting rollback checkpoint files *file-url*.rb and *file-url*.rb.4 contain the same rollback state/configuration.
- The **boot-good-exec** or **boot-bad-exec** command is not automatically executed after a rollback.
- Impacts to the running services are minimized during a rollback.
  - There is no impact in areas of the configuration that did not change.
  - Configuration parameters that are changed or items that the changed configuration has dependencies on are removed (revert to default) and the previous values are restored, which may briefly impact services. The following are examples of service impact.
    - If the currently active configuration contains **configure port 5/1/1 dwdm tdcm dispersion -1000** and the rollback checkpoint contains **configure port 5/1/1 dwdm tdcm dispersion -1010**, the operational dispersion transitions from -1000 to 0 and then back to -1010 for port 5/1/1, which causes a traffic interruption.
    - If changing neighbor 1 of an MC-APS port, the port must be configured as **no neighbor** and then configured as neighbor 2. Moving through the **no neighbor** intermediate state requires the working and protection circuits to be torn down and rebuilt. This impacts the 7450 ESS and 7750 SR.
- A rollback undoes any SNMP sets or direct CLI configuration commands that occur after the creation of the last checkpoint.
- When a node is processing a **rollback revert**, both CLI commands from other users and SNMP commands continue to be processed. The only commands that are blocked during a **rollback revert** are other rollback commands, including **revert**, **save**, and **compare**. Only one **rollback** command can be executing at a time on a node.

- Commands are available to view and compare the various rollback checkpoints to current operating and candidate configurations.
- Rollback checkpoint files are not guaranteed to be in any particular format. They are not interchangeable with normal configuration files or executable scripts. A normal configuration file from an **admin save** cannot be renamed as a rollback checkpoint and then referenced for a **rollback revert** operation. Only rollback checkpoint files generated with **rollback save** can be used for rollback revert operations.
- If a hardware change is made after a **rollback save**, then:
  - a rollback can be executed as long as the hardware change was an addition of hardware to the node (for example, a new card or IOM was installed into a previously empty slot)
  - a rollback is not guaranteed to work if hardware was removed or changed (for example, an XCM/IOM was removed, or an XMA/MDA was swapped for a different XMA/MDA type)
- Rollback across a change to the following parameters is not supported:
  - **chassis-mode**
  - **configure isa application-assurance-group minimum-isa-generation**
- Rollback is supported even after an **admin reboot** is performed or the primary configuration in the BOF is changed and an **admin reboot** is performed. The **admin reboot** command does not "break the chain" for rollback.
- Lawful intercept configuration under the **config>li** branch is not affected by a rollback or rescue. LI configuration is not saved in the rollback checkpoint or rescue file, and a rollback revert does not affect any configuration under the **config>li** branch.
- Any configuration or state change performed under the debug branch of the CLI is not saved in the rollback checkpoint file or impacted by a rollback.
- Rollbacks to a checkpoint created in a more recent release are not supported (for example, a node running in 9.0r5 cannot roll back to a checkpoint created in 9.0r7).
- The following list captures some side effects and specific behaviors of a rollback revert. Some of these side effects are not related purely to configuration, that is, in the CLI configuration branch, and may have interactions with tools commands, RADIUS, and so on.
  - SAA jobs that are running when a rollback revert is initiated, and need configuration changes due to the rollback, are stopped. If the SAA job is a continuous type, then it is restarted as part of the rollback revert after the configuration changes have been applied (just as if the operator had typed **no shutdown** for the continuous SAA job). Non-continuous SAA jobs that were modified by the rollback would need to be manually restarted if they need to be run again.
  - If **max-nbr-mac-addr** is reduced as part of the revert and the number of MAC addresses in the forwarding database is greater than the **max-nbr-mac-addr**, the rollback is aborted before any actions are taken and an informative error message is provided. The operator must take actions to remove the MAC addresses if they wish to proceed with the rollback.
  - If active subscribers or subscriber hosts or DHCP lease states are present, some associated configuration changes may be blocked, just as those same changes would be blocked if an operator tried to make them using CLI.
  - When trying to delete an SLA profile being used by active subscriber hosts, or trying to change a NAT policy in a subscriber profile, if certain configuration changes associated with the hosts or lease states are required as part of the rollback but those changes are blocked, then for each blocked configuration item a warning is printed, that particular configuration item is not changed, and the rollback continues. This is supported on the 7450 ESS and 7750 SR.

- After a multi-chassis peer shutdown or if configuration changes have been made that affect the contents of the distributed database (for example, synchronization tag creation or deletion), further configuration changes related to that peer may be temporarily refused. The duration of the temporary configuration freeze depends on the size of the distributed database. A rollback attempting to make those refused configuration changes fails and an error message is provided to the CLI user.
- If a **force-switchover** command (for example, **tools perform service id 1 endpoint "x" force-switchover spoke-sdp-fec 1**) has been applied to a **spoke-sdp-fec** of a dynamic multi-segment pseudowire, and a rollback revert needs to change the admin state of the **spoke-sdp-fec** (for example, to modify **spoke-sdp-fec** parameters that may be dependent on the admin state), the rollback revert automatically removes the **force-switchover** and the node reverts to whatever is the best spoke SDP in the redundant set.
- Rollback impacts the configuration state of the router, and as with normal operator CLI or SNMP configuration changes, additional actions or steps may need to occur before certain configuration changes take operational effect.

  Configuration changes that require a manual **shutdown** and then **no shutdown** in order to take operational effect also need this manual **shutdown**/**no shutdown** in order to take operational effect after a rollback if the rollback changes those configuration items. Some examples include the following.

  - Changes to autonomous system or confederation values require a BGP **shutdown**/**no shutdown** command.
  - Changes to VPRN **max-routes** require a **shutdown**/**no shutdown** command on the VPRN service.
  - Changes to OSPF or IS-IS **export-limit** require a **shutdown**/**no shutdown** command on OSPF or IS-IS.
  - For configuration changes to an MSAP policy that normally require a **tools perform subscriber-mgmt eval-msap** command to take operational effect on subscribers that are already active, if a rollback changes the MSAP policy configuration, the operator must run the **eval-msap** tools command to have the changes applied to the active subscribers.
- Any uncommitted changes (for example, the **begin** command was entered and some changes were made, but the **commit** command was never entered) in the following areas are lost or cleared when a rollback revert is initiated:
  - **config>app-assure>group policy**
  - **config**>**router**>**policy-options**
  - **config**>**system**>**sync-if-timing**

- Some **card** and **mda** commands require a reboot, removal, or rebuild of an entire card or XMA/MDA. When these commands need to be executed as part of a rollback, the impacted cards and MDAs are listed in a warning and the operator is prompted with a single y/n prompt to proceed. This prompt will not occur for a rollback initiated via SNMP or if the operator uses the **now** keyword with the **rollback revert** command. Some examples of **card** and **mda** commands that may cause a prompt are:
  - **config**>**card**>**card-type**
  - **config**>**card**>**mda**
  - **config**>**card**>**mda**>**mda-type**

- Although the use of the **Ctrl-C** key combination is not recommended during a rollback revert, it is supported via CLI or SNMP. Interrupting a rollback revert may leave the router in a state that is not necessarily between the old active configuration and the rollback checkpoint, as the rollback processing may have been in the middle of tearing things down or rebuilding configurations. A strong warning is issued in this case to indicate that the operator must examine the configuration and potentially issue another rollback revert to return to a known and coherent configuration.
- An HA CPM switchover during a rollback revert causes the rollback operation to abort. The newly active CPM has an indeterminate configuration. When an HA switchover occurs during a rollback or within a few seconds of a rollback completing, the operator is advised to repeat the rollback revert operation to the same checkpoint.
- A rollback revert operation does not check authorization of each command that is applied during the revert. Permission to execute the revert operation, that is, authorization to execute the **admin rollback revert** command, should only be given to users who are allowed to initiate a rollback revert. It is generally recommended that only system administrators be allowed access to the file system where the rollback files are stored so that they cannot be manually edited.

2.9.2 Rollback and SNMP

The SR OS has SNMP support for rollback status and control. See the TIMETRA-SYSTEM-MIB for details (for example, items such as tmnxSysRollbackStarted).

When the router is doing a rollback revert, SNMP managers see a tmnxSysRollbackStarted trap, then a rapid set of "config change" traps, and then finally, the tmnxSysRollbackStatusChange trap.

During the period when a router is processing a rollback revert, both CLI commands from other users and SNMP commands continue to be processed.

2.9.3 Rescue configuration

A special rescue configuration checkpoint can be created that an operator can revert to at any time. The rescue configuration has its own keyword (**rescue**) and does not use the same rolling suffix indices as the normal rollback checkpoints. This allows the operator to easily return to the rescue configuration state without having to consider a checkpoint index, and ensures that the rescue checkpoint is always available and does not roll off the bottom of the list of checkpoints.

The operator should define a basic rescue configuration that is known to work and give appropriate management access to the node.

The location and filename of the rescue file are configurable. The SR OS appends the .rc suffix to the specified rescue filename.

2.9.4 Operational guidelines

The following points offer some operational guidance on the use of rollback.

- The **admin save** and **admin rollback save** commands should be performed periodically.
- The **admin save** command can be used to back up a complete configuration file that can be used during router reboot, with the following considerations:
  - used with a reboot as a last resort

  - performed after any major hardware changes or major service changes
  - performed after any software upgrade
- The **admin rollback save** command can be used to create a rollback checkpoint as follows:
  - to be used for intermediate checkpoints that can be recovered with minimal impact to services
  - to be performed each time a moderate number of configuration changes have been made
  - to be performed after any hardware changes
  - to be performed after any software upgrade
  - to be scheduled with CRON (for example, once every one or two weeks)
- A new **admin rollback save rescue** must be created when hardware is changed.
- Rollback checkpoint files are not editable, or compatible or interchangeable with configuration files generated with **admin save**.
- The repeated use of the **admin rollback save**, **admin rollback delete**, and **admin rollback revert** commands over the course of weeks or months is not recommended without also executing an occasional **admin save**. In a serious situation, use one of the saved configurations as the primary configuration for an **admin reboot**.
- For a software upgrade, it is recommended that a rollback checkpoint be created using **admin rollback save** in addition to saving the configuration with **admin save**, after an upgrade has been performed and the system is operating as expected. This ensures that a good checkpoint that is fully compatible with the new release is available at a point shortly after the upgrade.
- An operator can create a set of rollback checkpoints to support busy or quiet days or weekends or weekdays and use CRON to shift between them.
- It is beneficial to create a rollback checkpoint before a rollback revert is initiated, especially if significant configuration changes have been applied since the last checkpoint was created. If the rollback is especially significant, that is, there are a lot of major changes, it is also a good practice to perform an **admin save** in case a full reboot is required to recover from an issue.
- A rollback failure may occur in some limited cases where the node needs a long time to complete one of the resulting configuration changes. If a rollback (for example, **rollback revert 5**) fails during execution, it should be attempted again. The second attempt typically completes the remaining configuration changes required to fully revert to the desired checkpoint.
- When a new backup CPM is commissioned, the user executes the **admin redundancy rollback-sync** command to copy the entire set of rollback files from the active CPM CF to the new standby CPM CF. If the operator wants the system to automatically copy new rollback checkpoints to both CFs whenever a new checkpoint is created, the **configure redundancy rollback-sync** command should be enabled.
- An HA CPM switchover during a rollback revert causes the rollback operation to abort. The newly active CPM has an indeterminate configuration. A log event is created in this case to warn the operator. When an HA switchover occurs during a rollback or within a few seconds of a rollback completing, the operator is advised to repeat the rollback revert operation to the same checkpoint.
- A rollback checkpoint stores the rollback location and the **local-max-checkpoint** and **remote-max-checkpoint** values, and it is possible that a rollback revert operation may change those values. If an operator changes the **local-max-checkpoint** or **remote-max-checkpoint** values, it is recommended that all the existing checkpoints be deleted to prevent a subsequent rollback revert from changing the maximum values to any of the previous values.

- If a warning prompt (**y/n**) is displayed when a rollback revert is initiated, it is highly recommended that the operator respond **no** to the warning prompt the first time, save a rollback checkpoint before attempting this rollback revert, execute the revert again, and respond **yes**. If the rollback encounters problems, a revert to the saved checkpoint can be used to return to the initial configuration state.

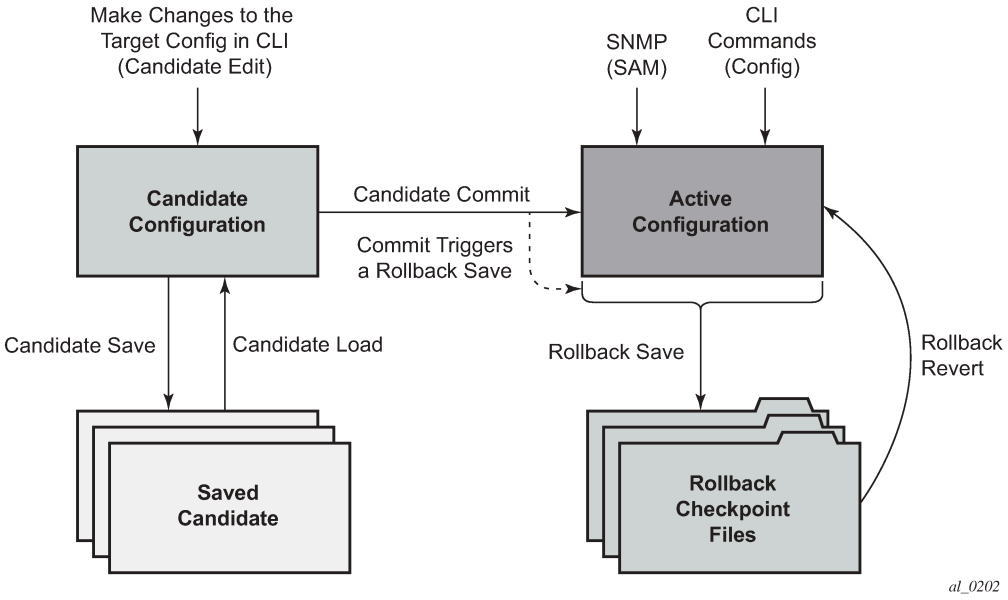
2.10 Transactional configuration

Transactional configuration allows an operator to edit a candidate configuration (a set of configuration changes) without causing operational changes in the router (the active or operational configuration). When the candidate configuration is complete, the operator can explicitly commit the changes to make the entire new configuration become active.

Transactional configuration gives the operator better control and visibility over their router configurations and reduces operational risk while increasing flexibility.

The transactional configuration and configuration rollback functions combine to provide the operational model depicted in the following figure.

Figure 7: Router configuration with rollback and transactions



2.10.1 Basic operation

In order to edit the candidate configuration, the operator must first enter the candidate edit mode (edit-cfg) with the **candidate>edit** command. The operator can enter and quit the configuration mode as many times as they wish before finally committing the candidate configuration.

In edit-cfg mode, the operator builds a set of candidate configuration changes using the same CLI tree as the standard line-by-line, non-transactional configuration. Tab completion and keyword syntax checking is available.

Just as there is a single operational active configuration that can be modified simultaneously by multiple users in the SR OS, there is also a single global candidate configuration instance. All users make changes in the same global candidate configuration, and a **commit** operation by any user commits the changes made by all users.

Users can exclusively create a candidate configuration by blocking other users and sessions of the same user from entering edit-cfg mode by specifying the **exclusive** parameter. The **config**>**system**>**management-interface**>**cli**>**classic-cli**>**allow-immediate** command can be used to enforce the use of candidate configuration, instead of allowing immediate line-by-line configuration changes.

If a **commit** operation is successful, all of the candidate changes take operational effect and the candidate is cleared. If there is an error in the processing of the commit, or a **commit confirmed** is not confirmed and an auto-revert occurs, the router returns to a configuration state with none of the candidate changes applied. The operator can then continue editing the candidate and try a commit later.

All commands in the candidate configuration must be in the correct order for a commit to be successful. Configuration that depends on other candidate objects must be placed after those objects in the candidate. A set of candidate editing commands (**copy**, **insert**, and so on) are available to correct and reorder the candidate configuration.

The edit-cfg mode is primarily intended for building a candidate configuration while navigating the **configure** branch of the CLI. Many CLI commands in branches other than **configure** are supported while in edit-cfg mode, but access to some CLI branches and commands are blocked, including:

- **exec** command
- **enable-admin** command
- **enable-dynamic-services-config** command
- **admin** branch
- **bof** branch
- **debug** branch
- **tools** branch

The candidate configuration can be saved to a file and subsequently loaded into a candidate configuration. A saved candidate is similar to, but not the same as, an SR OS configuration file generated with an **admin save** command. The saved candidate cannot be used in general as a configuration file and may not **exec** without failures.

There is no SNMP access to the candidate configuration and no SNMP management of candidates, although any configuration changes made using transactional configuration are reported via the standard SR OS SNMP change traps and basic candidate status information is available via SNMP.

A commit may fail for a number of reasons, including:

- misordering: the candidate configuration has changes that are not in the correct order, that is, an object is referred to before it is actually created
- invalid options and combinations: although many syntax errors are eliminated during the candidate editing process, the candidate configuration may contain combinations of configurations and options that are not valid and are rejected when the SR OS attempts to have them take operational effect
- out of resources: the application of the candidate may exhaust system resources, such as queue resources

Error messages are provided for commit failures to help the operator take the necessary actions to correct the candidate.

Standard line-by-line, non-transactional CLI and SNMP commands are not blocked during the creation or editing of a candidate or the processing of a commit. These commands take immediate operational effect when **Enter** is pressed.

2.10.2 Transactions and rollback

By default, the SR OS automatically creates a new rollback checkpoint after a **commit** operation. The rollback checkpoint includes the new configuration changes made by the commit. An optional **no-checkpoint** keyword can be used to prevent the auto-creation of a rollback checkpoint after a commit. If the commit fails, no new rollback checkpoint is created.

When the **commit confirmed** option is used, a rollback checkpoint is created after the processing of the commit and exists whether the commit is automatically reverted or not.

Transactional configuration relies on the rollback mechanism to operate. Any commands and configurations that are not supported in a rollback revert are also not supported in edit-cfg mode; for example, changes to **chassis-mode**.

2.10.3 Authorization

Authorization works transparently in edit-cfg mode and no unique or new local profile or TACACS+ permissions rules are required other than allowing access to the **candidate** branch. For example, if an operator has permission to access the **configure filter** context, they automatically also have access to the **configure filter** context when in edit-cfg mode.

If the operator’s profile allows access to the candidate **load** and **save** commands, the operations load and save only those items that the user is authorized to access.

The candidate view only displays the items that the user is authorized to access.

The candidate editing commands (such as adding lines, removing lines, and delete operations) only allow operations on items that the user is authorized to access.

The candidate **commit** and **discard** commands, along with **admin rollback revert**, operate on the entire candidate and impact all items; authorization does not apply.

3 Command Trees

3.1 admin Commands

```
- admin
    - application-assurance
        - group
        - group
            - url-list
        - upgrade
    - certificate
        - clear-ocsp-cache
        - cmpv2
            - cert-request
            - clear-request
            - initial-registration
            - key-update
            - poll
            - show-request
        - convert-file
        - crl-update
        - display
        - est
            - cacert
            - enroll

4 3 Commands

4.1 3gpp-charging-id

3gpp-charging-id

Syntax

3gpp-charging-id {**auto** | **esm-info** | **id**}

no 3gpp-charging-id

Context

[Tree] (config>subscr-mgmt>diam-appl-plcy>gy>avp 3gpp-charging-id)

Full Context

configure subscriber-mgmt diameter-application-policy gy include-avp 3gpp-charging-id

Description

This command includes the 3GPP-Charging-Id AVP in all Diameter DCCA CCR messages. The value can be configured to contain a unique 32-bit identifier or ESM information.

The **no** form of this command removes the 3GPP-Charging-Id AVP from the Diameter DCCA CCR messages.

Default

3gpp-charging-id auto

Parameters

auto

When the vendor support is 3GPP, this parameter specifies the AVP value for the *subscriber-id*, *sap-id*, and *sla-profile*. The default parameter value selected is **auto**.

esm-info

Specifies the AVP value to *subscriber-id*, *sap-id*, and *sla-profile*.

id

Specifies the AVP value as a unique 32-bit identifier per Diameter Gy session.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

4.2 3gpp-ggsn-address

3gpp-ggsn-address

Syntax

[**no**] **3gpp-ggsn-address**

Context

[Tree] (config>subscr-mgmt>diam-appl-plcy>gy>include-avp 3gpp-ggsn-address)

Full Context

configure subscriber-mgmt diameter-application-policy gy include-avp 3gpp-ggsn-address

Description

This command includes the 3GPP GGSN Address AVP in the Diameter Gy messages. The value is set to the source IPv4 address that is used for outgoing diameter messages.

The **no** form of this command disables the command.

Default

3gpp-ggsn-address

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

4.3 3gpp-ggsn-ipv6-address

3gpp-ggsn-ipv6-address

Syntax

3gpp-ggsn-ipv6-address

no 3gpp-ggsn-ipv6-address

Context

[Tree] (config>subscr-mgmt>diam-appl-plcy>gy>include-avp 3gpp-ggsn-ipv6-address)

Full Context

configure subscriber-mgmt diameter-application-policy gy include-avp 3gpp-ggsn-ipv6-address

Description

This command includes the 3GPP GGSN IPv6 Address AVP in the Diameter Gy messages. The value is set to the source IPv6 address that is used for outgoing diameter messages.

The **no** form of this command reverts to the default.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

4.4 3gpp-gprs-negotiated-qos-profile

3gpp-gprs-negotiated-qos-profile

Syntax

[**no**] **3gpp-gprs-negotiated-qos-profile**

Context

[Tree] (config subscr-mgmt diam-appl-plcy gy avp 3gpp-gprs-negotiated-qos-profile)

Full Context

configure subscriber-mgmt diameter-application-policy gy include-avp 3gpp-gprs-negotiated-qos-profile

Description

This command includes the 3GPP-GPRS-QoS-Negotiated-Profile AVP in all Diameter DCCA CCR messages. The value is the active SLA profile.

The **no** form of this command removes the 3GPP-GPRS-QoS-Negotiated-Profile AVP from the Diameter DCCA CCR messages.

Default

3gpp-gprs-negotiated-qos-profile

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

4.5 3gpp-imsi

3gpp-imsi

Syntax

3gpp-imsi {**circuit-id** | **imsi** | **subscriber-id**}

no 3gpp-imsi

Context

[Tree] (config>subscr-mgmt>diam-appl-plcy>gy>avp 3gpp-imsi)

Full Context

configure subscriber-mgmt diameter-application-policy gy include-avp 3gpp-imsi

Description

This command includes the 3GPP-IMSI AVP in all Diameter DCCA CCR messages.

The **no** form of this command removes the 3GPP-IMSI AVP from the Diameter DCCA CCR messages.

Default

3gpp-imsi subscriber-id

Parameters

circuit-id

Specifies the circuit-id as DCCA IMSI AVP value.

subscriber-id

Specifies the subscriber-id as DCCA IMSI AVP value.

imsi

Specifies the IMSI as DCCA IMSI AVP value.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

4.6 3gpp-nsapi

3gpp-nsapi

Syntax

[**no**] **3gpp-nsapi**

Context

[Tree] (config>subscr-mgmt>diam-appl-plcy>gy>avp 3gpp-nsapi)

Full Context

configure subscriber-mgmt diameter-application-policy gy include-avp 3gpp-nsapi

Description

This command includes the 3GPP-NSAPI AVP in all Diameter DCCA CCR messages. The **3gpp-nsapi** avp value is created from a semi-colon separated concatenation of the system name, service ID, and SAP ID of the subscriber host or session.

The **no** form of this command removes the 3GPP-NSAPI AVP from the Diameter DCCA CCR messages.

Default

3gpp-nsapi

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

4.7 3gpp-qos-mapping

3gpp-qos-mapping

Syntax

3gpp-qos-mapping

Context

[Tree] (config>subscr-mgmt>diam-appl-plcy>gx 3gpp-qos-mapping)

Full Context

configure subscriber-mgmt diameter-application-policy gx 3gpp-qos-mapping

Description

This command enables the configuration of mapping certain 3GPP-specific QoS attributes to SR OS objects.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

4.8 3gpp-rat-type

3gpp-rat-type

Syntax

3gpp-rat-type *value*

no 3gpp-rat-type

Context

[Tree] (config>subscr-mgmt>diam-appl-plcy>gy>avp 3gpp-rat-type)

Full Context

configure subscriber-mgmt diameter-application-policy gy include-avp 3gpp-rat-type

Description

This command includes the 3GPP-RAT-Type AVP with the specified value in all Diameter DCCA CCR messages.

The **no** form of this command removes the 3GPP-RAT-Type AVP from the Diameter DCCA CCR messages.

Parameters

value

Specifies the 3GPP-RAT-Type AVP value to be included in Diameter DCCA CCR messages.

Values 1 to 255

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

4.9 3gpp-selection-mode

3gpp-selection-mode

Syntax

[**no**] **3gpp-selection-mode**

Context

[Tree] (config>subscr-mgmt>diam-appl-plcy>gy>avp 3gpp-selection-mode)

Full Context

configure subscriber-mgmt diameter-application-policy gy include-avp 3gpp-selection-mode

Description

This command includes the 3GPP-Selection-Mode AVP in all Diameter DCCA CCR messages.

The **no** form of this command removes the 3GPP-Selection-Mode AVP from the Diameter DCCA CCR messages.

Default

3gpp-selection-mode

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

4.10 3gpp-session-stop-indicator

3gpp-session-stop-indicator

Syntax

[**no**] **3gpp-session-stop-indicator**

Context

[Tree] (config>subscr-mgmt>diam-appl-plcy>gy>avp 3gpp-session-stop-indicator)

Full Context

configure subscriber-mgmt diameter-application-policy gy include-avp 3gpp-session-stop-indicator

Description

This command includes the 3GPP-Session-Stop-Indicator AVP in all Diameter DCCA CCR-Terminate messages.

The **no** form of this command removes the 3GPP-Session-Stop-Indicator AVP from the Diameter DCCA CCR-Terminate messages.

Default

3gpp-session-stop-indicator

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

4.11 3gpp-user-location-info

3gpp-user-location-info

Syntax

[**no**] **3gpp-user-location-info**

Context

[Tree] (config>subscr-mgmt>diam-appl-plcy>gy>avp 3gpp-user-location-info)

Full Context

configure subscriber-mgmt diameter-application-policy gy include-avp 3gpp-user-location-info

Description

This command, in case of ESM over GTP access, includes the 3GPP-User-Location-Info attribute. If **ps-information** is also enabled this is grouped within the PS information AVP.

The **no** version of this command disables inclusion of the ULI AVP.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

5 a Commands

5.1 aa-admit-deny

aa-admit-deny

Syntax

aa-admit-deny

Context

[Tree] (config>app-assure>group>statistics aa-admit-deny)

Full Context

configure application-assurance group statistics aa-admit-deny

Description

Commands in this context configure admit-deny statistics generation.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.2 aa-interface

aa-interface

Syntax

aa-interface *aa-if-name* [**create**]

no aa-interface *aa-if-name*

Context

[Tree] (config>service>vprn aa-interface)

[Tree] (config>service>ies aa-interface)

Full Context

configure service vprn aa-interface

configure service ies aa-interface

Description

This commands creates a new AA interface within an IES or VPRN service. It is used by the aa-isa to send/receive IPv4 traffic. In the context of ICAP url-filtering this interface is used by the ISA to establish ICAP TCP connections to the ICAP servers.

This interface supports /31 subnet only, and uses by default .1q encapsulation.

The system will automatically configure the ISA IP address based on the address configured by the operator under the aa-interface object (which represents the ISA sap facing interface on the ISA).

Parameters

aa-if-name

specifies the name of the AA Interface.

create

Keyword that specifies to create the interface.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.3 aa-specific

aa-specific

Syntax

[**no**] **aa-specific**

Context

[Tree] (config>log>acct-policy>cr aa-specific)

Full Context

configure log accounting-policy custom-record aa-specific

Description

Commands in this context configure information for this custom record.

The **no** form of this command excludes aa-specific attributes in the AA subscriber's custom record.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.4 aa-sub

aa-sub

Syntax

aa-sub esm {**eq** | **neq**} *sub-ident-string*

aa-sub esm-mac {**eq** | **neq**} *esm-mac-name*

aa-sub sap {**eq** | **neq**} *sap-id*

aa-sub spoke-sdp {**eq** | **neq**} *sdp-id:vc-id*

aa-sub transit {**eq** | **neq**} *transit-aasub-name*

no aa-sub

Context

[Tree] (config>app-assure>group>policy>aqp>entry>match aa-sub)

Full Context

configure application-assurance group policy app-qos-policy entry match aa-sub

Description

This command specifies a Service Access Point (SAP) or an ESM subscriber as matching criteria.

The **no** form of this command removes the SAP or ESM matching criteria.

Parameters

eq

Specifies that the value configured and the value in the flow are equal.

neq

Specifies that the value configured differs from the value in the flow.

sub-ident-string

Specifies the name of an existing application assurance subscriber.

esm-mac-name

Specifies the name of an ESM-MAC subscriber.

sap-id

Specifies the SAP ID.

sap *sap-id*

Specifies the physical port identifier portion of the SAP definition.

sdp-id:vc-id

Specifies the spoke SDP ID and VC ID.

Values 1 to 32767

1 to 4294967295

transit-aasub-name

Specifies the name of a transit AA subscriber.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

aa-sub

Syntax

aa-sub

Context

[Tree] (config>app-assure>group>statistics aa-sub)

Full Context

configure application-assurance group statistics aa-sub

Description

Commands in this context configure accounting and statistics collection parameters per application assurance subscribers.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

aa-sub

Syntax

[**no**] **aa-sub {esm** *sub-ident-string* **| sap** *sap-id* **| spoke-sdp** *sdp-id:vc-id* **| transit** *transit-aasub-name* **| esm-mac** *esm-mac-name* **}**

Context

[Tree] (config>app-assure>group>statistics>aa-sub-study aa-sub)

Full Context

configure application-assurance group statistics aa-sub-study aa-sub

Description

This command adds an existing subscriber identification to a group of special study subscribers (for example, subscribers for which per subscriber statistics and accounting records can be collected for protocols and applications of application assurance).

The **no** form of this command removes the subscriber from the special study subscribers.

Up to 100 subscribers can be configured into the special study group for protocols and up to a 100 potentially different subscribers can be configured into the special study group for applications.

When adding a subscriber to the special study group, accounting records and statistics generation will commence immediately. When removing a subscriber from the group, special study statistics and accounting records for that subscriber in the current interval will be lost.

Parameters

sub-ident-string

Specifies the name of a subscriber ID. The subscriber does not need to be currently active. Any sub-ident-string will be accepted. When the subscriber becomes active, statistics generation will start automatically at that time.

sap-id

Specifies the physical port identifier portion of the SAP definition.

spoke-id sdp-id:vc-id

Specifies the spoke SDP ID and VC ID.

Values 1 to 32767

1 to 4294967295

transit-aasub-name

Specifies an existing transit subscriber name string, up to 32 characters in length.

esm-mac-name

Specifies an existing ESM-MAC subscriber name, up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

aa-sub

Syntax

aa-sub *transit-aasub-name*

no aa-sub

Context

[Tree] (config>app-assure>group>transit-prefix-policy>entry aa-sub)

Full Context

configure application-assurance group transit-prefix-policy entry aa-sub

Description

This command configures a transit prefix policy entry subscriber.

The **no** form of this command removes the transit subscriber name from the transit prefix policy configuration.

Parameters

transit-aasub-name

specifies the name of the transit prefix AA subscriber up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.5 aa-sub-attributes

aa-sub-attributes

Syntax

aa-sub-attributes [**all**]

no aa-sub-attributes

Context

[Tree] (config>log>acct-policy>cr>aa aa-sub-attributes)

Full Context

configure log accounting-policy custom-record aa-specific aa-sub-attributes

Description

Commands in this context configure aa-specific attributes such as aa-sub-attributes and counters that will be available in the AA subscriber's custom record.

The **no** form of this command excludes aa specific attributes from the AA subscriber's custom record.

Parameters

all

Specifies all counters.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.6 aa-sub-congestion-detection

aa-sub-congestion-detection

Syntax

aa-sub-congestion-detection

Context

[Tree] (config>app-assure>group aa-sub-congestion-detection)

Full Context

configure application-assurance group aa-sub-congestion-detection

Description

Commands in this context configure Non-Location Based DEM (NLB-DEM) parameters.

Note:
NLB-DEM and Access-Network Location (ANL) DEM mode are mutually exclusive, and cannot operate simultaneously.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.7 aa-sub-counters

aa-sub-counters

Syntax

aa-sub-counters [**all**]

no aa-sub-counters

Context

[Tree] (config>log>acct-policy>cr>aa aa-sub-counters)

Full Context

configure log accounting-policy custom-record aa-specific aa-sub-counters

Description

Commands in this context configure subscriber counter information. This command only applies to the 7750 SR.

The **no** form of this command excludes the aa-sub-counters attributes in the AA subscriber's custom record.

Parameters

all

Specifies all counters.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.8 aa-sub-ip

aa-sub-ip

Syntax

aa-sub-ip *ip-address*[*/mask*]

no aa-sub-ip

Context

[Tree] (config>app-assure>group>transit-prefix-policy>entry>match aa-sub-ip)

Full Context

configure application-assurance group transit-prefix-policy entry match aa-sub-ip

Description

This command configures a transit prefix subscriber ip address prefix. It is used when the site is on the local side, being the same side of the system as the parent SAP. The local aa-sub-ip addresses represent the src-IP in the from-SAP direction and dest-IP in the to-SAP direction.

The **no** form of this command deletes the aa-sub-ip address assigned from the entry configuration.

Default

no aa-sub-ip

Parameters

ip-address[/mask]

Specifies the address type of the subscriber address prefix associated with this transit prefix policy entry.

Values

ip-address[*/mask*] :	ipv4-address - a.b.c.d[/mask]
	mask - [1..32]
	ipv6-address - x:x:x:x:x:x:x:x/prefix-length
	x:x:x:x:x:x:d.d.d.d

x - [0..FFFF]H

d - [0..255]D

prefix-length [1..128]

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.9 aa-sub-remote

aa-sub-remote

Syntax

[**no**] **aa-sub-remote**

Context

[Tree] (config>app-assure>group aa-sub-remote)

Full Context

configure application-assurance group aa-sub-remote

Description

This command specifies whether or not the from subscriber and to subscriber traffic direction is reversed for this group-partition.

Default

no aa-sub-remote

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.10 aa-sub-study

aa-sub-study

Syntax

aa-sub-study *study-type*

Context

[Tree] (config>app-assure>group>statistics aa-sub-study)

Full Context

configure application-assurance group statistics aa-sub-study

Description

Commands in this context configure accounting and statistics collection parameters per application assurance special study subscribers.

Parameters

study-type

Specifies special study protocol subscriber stats.

Values application, protocol

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.11 aa-sub-suppressible

aa-sub-suppressible

Syntax

aa-sub-suppressible

no aa-sub-suppressible

Context

[Tree] (config>app-assure>group>policy>app-profile aa-sub-suppressible)

Full Context

configure application-assurance group policy app-profile aa-sub-suppressible

Description

This command configures an app-profile as "aa-sub-suppressible”, this function is used in the context of an SRRP group interface. If an SRRP group interface is configured as "suppress-aa-sub” then subscribers with an app-profile configured as "aa-sub-suppressible” will not be diverted to Application Assurance.

The **no** form of this command restores the default behavior.

Default

no aa-sub-suppressible

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.12 aa-sub-tethering-state

aa-sub-tethering-state

Syntax

aa-sub-tethering-state {**detected** | **not-detected**}

no aa-sub-tethering-state

Context

[Tree] (config>app-assure>group>policy>aqp>entry>match aa-sub-tethering-state)

Full Context

configure application-assurance group policy app-qos-policy entry match aa-sub-tethering-state

Description

This command specifies the tethering state of the subscriber where the AQP match entry will be applied.

The tethering state match condition is meaningful when configured in non-default subscriber policy AQP. Default subscriber policy consists of those AQPs that include match criteria based on the subscriber's configuration. Tethering state match condition is also applicable in those AQPs that include matching criteria that are derived from actual subscriber's traffic.

The **no** form of this command removes detection of sub-tethering state from the configuration.

Default

no aa-sub-tethering-state

Parameters

detected

Specifies that the subscriber is in the tethering state.

not-detected

Specifies that the subscriber is not in the tethering state.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

Context
[Tree] (config>service>epipe>sap aarp)

[Tree] (config>service>epipe>spoke-sdp aarp)

Full Context
configure service epipe sap aarp

configure service epipe spoke-sdp aarp

Description

This command associates an AARP instance with a multi-homed SAP or spoke SDP. This instance uses the same AARP ID in the same node to provide traffic flow and packet asymmetry removal for a multi-homed SAP or spoke SDP.

The type specifies the role of this service point in the AARP: either, primary (dual-homed) or secondary (dual-homed-secondary). The AA service attributes (app-profile and transit-policy) of the primary are inherited by the secondary endpoints. All endpoints within an AARP must be of the same type (SAP or spoke), and all endpoints with an AARP must be within the same service.

The no form of this command removes the association between an AARP instance and a multi-homed SAP or spoke SDP.

Default

no aarp

Parameters

aarpid

Specifies the AARP instance associated with this SAP. If not configured, no AARP instance is associated with this SAP.

Values 1 to 65535

type

Specifies the role of the SAP referenced by the AARP instance.

Values **dual-homed** — The primary dual-homed AA subscriber side service-point of an AARP instance; only supported for Epipe, IES, and VPRN SAP and spoke SDP.

dual-homed-secondary — One of the secondary dual-homed AA subscriber side service-points of an AARP instance; only supported for Epipe, IES, and VPRN SAP and spoke SDP.

Platforms

configure service ipipe spoke-sdp aarp

Description

This command associates an AARP instance to an Ipipe spoke SDP. This instance is paired with the same *aarp-id* in a peer node as part of a configuration to provide flow and packet asymmetry removal for traffic for a multi-homed SAP or spoke SDP. The **type** parameter specifies the role of this service point in the AARP instance.

The **no** form of this command removes the association.

Default

no aarp

Parameters

aarp-id

An integer that identifies an AARP instance.

Values 1 to 65535

subscriber-side-shunt

Specifies that the AARP type is an inter-chassis shunt service for subscriber-side traffic.

network-side-shunt

Specifies that the AARP type is an inter-chassis shunt service for network-side traffic.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

configure service ies interface spoke-sdp aarp

configure service ies interface sap aarp

Description

This command associates an AARP instance with a multi-homed SAP or spoke SDP. This instance uses the same AARP ID in the same node or in a peer node (pre-configured) to provide traffic flow and packet asymmetry removal for a multi-homed SAP or spoke SDP.

The type specifies the role of this service point in the AARP: either, primary (dual-homed) or secondary (dual-homed-secondary). The AA service attributes (app-profile and transit-policy) of the primary are inherited by the secondary endpoints. All endpoints within an AARP must be of the same type (SAP or spoke), and all endpoints with an AARP must be within the same service.

The **no** form of this command removes the association between an AARP instance and a multi-homed SAP or spoke SDP.

Default

no aarp

Parameters

aarpId

Specifies the AARP instance associated with this SAP. If not configured, no AARP instance is associated with this SAP.

Values 1 to 65535

type

Specifies the role of the SAP referenced by the AARP instance.

Values **dual-homed** — The primary dual-homed AA subscriber side service-point of an AARP instance; only supported for Epipe, IES, and VPRN SAP and spoke SDP.

dual-homed-secondary — One of the secondary dual-homed AA subscriber side service-points of an AARP instance; only supported for Epipe, IES, and VPRN SAP and spoke SDP.

above-offered-cap {**percent** *percent-of-admin-pir* | **rate** *rate-in-kilobits-per-second*}

no above-offered-cap

Context

[Tree] (config>qos>adv-config-policy>child-control>bandwidth-distribution above-offered-cap)

Full Context

configure qos adv-config-policy child-control bandwidth-distribution above-offered-cap

Description

This command is used to limit the operationally configured shaping or policing rate on the child associated with the policy. After the parent virtual scheduler or policer control policy determines the appropriate rate for a specific child, a separate operation decides the actual PIR that should be configured for that child. When the parent determines that the distributed rate is equal to or less than the child's offered rate, the configured operational PIR will be equal to that determined rate. But when the parent determines that the child's offered rate is less than the available bandwidth the child could consume, the operational PIR may be set to a value larger than the distributed bandwidth. This extra rate is not currently used by the child because the offered rate is less. The system provides this extra bandwidth in case the child's offered rate increases before the next sampling interval is complete, to mitigate the periodic nature of the child's operational PIR adjustments. The increase in the offered rate is not subtracted from the parent's remaining distribution bandwidth for lower priority children, only the determined rate is considered consumed by the parent virtual scheduler or policer control policy instance. The actual operationally configured PIR will never be greater than the child's administratively defined PIR.

This 'fair share' PIR configuration behavior may result in the sum of the children's PIRs exceeding the aggregate rate of the parent. If this behavior violates the downstream QoS requirements, the **above-offered-cap** command may be used to minimize or eliminate the increase in the child's configured PIR.

If the **above-offered-cap** command is used with a percent-based value, the increase is a function of the configured PIR value on the policer or queue. In this case, care should be taken that the child is either configured with an explicit PIR rate (other than max) or the child's administrative PIR is defined using the percent-rate command with the local parameter enabled if an explicit value is not needed. When a maximum PIR is in use on the child, the system attempts to interpret the maximum child forwarding rate. This rate could be very large if the child is associated with multiple ingress or egress ports.

If the child's administrative PIR is modified while a percent based above-offered-cap is in effect, the system automatically uses the new relative limit value the next time the child's operational PIR is distributed.

When this command is not specified or removed, the child's operational 'fair share' operational PIR may be configured up to the child's administrative PIR, based on the actual parental bandwidth available at the child's priority level.

The **no** form of this command is used to remove a fair share operational PIR rate increase limit from all child policers and queues associated with the policy.

Parameters

percent-of-admin-pir

When the percent qualifier is used, the following percent-of-admin-pir parameter specifies the percentage of the child's administrative PIR that is used as the fair share increase limit. The new operational PIR result is capped by the child's PIR. If a value of 0 or 0.00 is used, the system will disable the fair share increase function and only configure the actual distribution rate. If a value of 100 or 100.00 is used, the system will interpret this equivalent to executing the **no above-offered-cap** command and return the fair-share operation to the default behavior.

Values 0.00 to 100.00

rate-in-kilobits-per-second

When the rate qualifier is used, the rate-in-kilobits-per-second parameter specifies an explicit rate, in kb/s, that are used as the limit to the child's fair share increase to the operational PIR. The new operational PIR result is capped by the child's PIR. If a value of 0 is used, the system will disable the fair share increase function and only configure the actual distribution rate.

Values 0 to 100,000,000

configure test-oam link-measurement measurement-template sample-window threshold absolute

configure test-oam link-measurement measurement-template aggregate-sample-window threshold absolute

Description

This command specifies the delta, in microseconds, that a new delay measurement must differ from the previously reported measurement to be reported directly to the routing engine.

The **no** form of this command reverts to the default value.

Default

absolute 0

Parameters

microseconds

Specifies the difference, in microseconds.

A value of 0 (zero) indicates that the absolute threshold is not used for reporting.

Values 0 to 100000

5.22 ac-df-capability

ac-df-capability

Syntax

ac-df-capability {**include** | **exclude**}

Context

[Tree] (config>service>system>bgp-evpn>eth-seg ac-df-capability)

Full Context

configure service system bgp-evpn ethernet-segment ac-df-capability

Description

This command configures the inclusion or exclusion of the Attachment Circuit-influenced (AC-Influenced) designated forwarder (DF) election capability (AC-DF) capability into the DF Election for the Ethernet Segment.

The SR OS supports the AC-DF capability, in accordance with RFC8584. The **include** option is the default command setting. The AC-DF capability is enabled by default to support the EVPN auto-discovery per EVI/ES (AD per EVI/ES) routes for a specific PE, which ensures that the PE is included in the candidate DF election list.

Configuring the **exclude** option disables the AC-DF capability. When **ac-df-capability exclude** is configured on a specific Ethernet Segment (ES), the presence or absence of the AD per EVI/ES routes from the ES peers do not modify the candidate DF Election list for the ES. The **exclude** option is recommended in ESs that use an **oper-group** monitored by the access LAG to signal standby lacp or power-off.

All PE routers attached to the same ES must be configured consistently for the AC-DF capability.

Default

ac-df-capability include

Parameters

include

Specifies that AC-DF capability is enabled.

exclude

Specifies that AC-DF capability is disabled.

Full Context

configure service vprn bgp group link-bandwidth accept-from-ebgp

configure service vprn bgp group neighbor link-bandwidth accept-from-ebgp

Description

This command configures BGP to accept and use the link-bandwidth extended community attached to any route received from any EBGP peer in the scope of the command, as long as that route belongs to one of the listed address families.

The link-bandwidth extended community is encoded as a non-transitive type. This means that by default it should not be attached to any route advertised to an EBGP peer and it should be discarded when received in any route from an EBGP peer. This command overrides the standard behavior.

Up to three families may be configured.

The **no** form of this command restores the default behavior of discarding the link-bandwidth extended community in any route received from an EBGP peer.

Default

no accept-from-ebgp

Parameters

family

Specifies the address families for which receiving the link-bandwidth extended community from EBGP peers should be supported.

Values ipv4 — Adds a link-bandwidth extended community to unlabeled unicast IPv4 routes.

label-ipv4 — Adds a link-bandwidth extended community to labeled-unicast IPv4 routes.

ipv6 — Adds a link-bandwidth extended community to unlabeled unicast IPv6 routes.

access

Syntax

[**no**] **access**

Context

[Tree] (config>service>vprn>snmp access)

Full Context

configure service vprn snmp access

Description

This command enables SNMP access using VPRN interface addresses. This command allows SNMP messages destined to the VPRN interface IP addresses for this VPRN (including VPRN interfaces that are bound to R-VPLS services) to be processed by the SNMP agent on the router. SNMP messages that arrive on VPRN interfaces but are destined to IP addresses in the Base routing context that can be accessed in the VPRN (for example, the router system address via grt leaking) do not require **snmp access** to be enabled but do require **allow-local-management** to be enabled.

Using an SNMP community defined inside the VPRN context (**configure service vprn snmp community**) allows access to a subset of the full SNMP data model. This subset can be seen in the output of **show system security view "vprn-view"**.

Using an SNMP community defined in the system context (**configure system security snmp community**) allows access to the full SNMP data model (unless otherwise restricted used SNMP views).

Alternatively, grt leaking and a Base routing IP address can be used (along with an SNMP community defined at the system context) to get access to the entire SNMP data model (see the **allow-local-management** command).

The Nokia NSP cannot discover or fully manage an SR OS router using an SNMP community defined inside the VPRN context. Full SNMP access requires using one of the approaches described above.

Refer to the *7450 ESS, 7750 SR, 7950 XRS, and VSR System Management Guide* for detailed information about SNMP.

[Tree] (config>system>security>user access)

Full Context

configure system security user-template access

configure system security user access

Description

This command grants a user permission for FTP, SNMP, console, lawful intercept (LI), NETCONF, or gRPC access.

If a user requires access to more than one application, then multiple applications can be specified in a single command. Multiple commands are treated additively.

The **no** form of this command removes access for a specific application, and denies permission for all management access methods.

To deny a single access method, enter the **no** form of this command followed by the method to be denied, for example, **no access FTP** denies FTP access.

Default

no access

Parameters

ftp

Specifies FTP permission.

snmp

Specifies SNMP permission. This keyword is only configurable in the **config>system>security>user** context.

console

Specifies console access (serial port or Telnet) permission.

li

Specifies CLI command access in the lawful intercept (LI) context.

netconf

Specifies NETCONF session access for the user defined in the specified user context. Because of the Base-R13 SR OS YANG data models, **console** access is also necessary in both classic and mixed configuration modes. **console** access is not required for the Nokia SR OS YANG data models in model-driven mode.

grpc

Specifies gRPC access.

Context

[Tree] (config>system>security>snmp access)

Full Context

configure system security snmp access

Description

This command creates an association between a user group, a security model, and the views that the user group can access. Access parameters must be configured unless security is limited to the preconfigured access groups and views for SNMPv1 and SNMPv2. An access group is defined by a unique combination of the group name, security model and security level.

Access groups are used by the usm-community command.

Access must be configured unless security is limited to SNMPv1/SNMPv2c with community strings. See the **community** command.

Default access group configurations cannot be modified or deleted.

To remove the user group with associated, security model(s), and security level(s), use:

no access group *group-name*

To remove a security model and security level combination from a group, use:

no access group *group-name* **security-model** {**snmpv1** | **snmpv2c** | **usm**} **security-level** {**no-auth-no-privacy** | **auth-no-privacy** | **privacy**}

Parameters

group-name

Specify a unique group name up to 32 characters.

security-model {snmpv1 | snmpv2c | usm}

Specifies the security model required to access the views configured in this node. A group can have multiple security models. For example, one view may only require SNMPv1/ SNMPv2c access while another view may require USM (SNMPv3) access rights.

security-level {no-auth-no-priv | auth-no-priv | privacy}

Specifies the required authentication and privacy levels to access the views configured in this node.

security-level no-auth-no-privacy

Specifies that no authentication and no privacy (encryption) is required. When configuring the user's authentication, select the **none** option.

security-level auth-no-privacy

Specifies that authentication is required but privacy (encryption) is not required. When this option is configured, both the **group** and the **user** must be configured for authentication.

security-level privacy

Specifies that both authentication and privacy (encryption) is required. When this option is configured, both the **group** and the user must be configured for **authentication**. The user must also be configured for **privacy**.

context-name

Specifies a set of SNMP objects that are associated with the context-name.

The *context-name* is treated as either a full context-name string or a context name prefix depending on the keyword specified (**exact** or **prefix**).

prefix-match

Specifies the context name **prefix-match** keywords, **exact** or **prefix**. This parameter applies only to the 7750 SR.

The VPRN context names begin with a **vprn** prefix. The numerical value is associated with the service ID that the VPRN was created with and identifies the service in the service domain. For example, when a new VPRN service is created such as **config>service>vprn 2345 customer 1**, a VPRN with context name **vprn2345** is created.

The **exact** keyword specifies that an exact match between the context name and the prefix value is required. For example, when context **vprn2345 exact** is entered, matches for only **vprn2345** are considered.

The **prefix** keyword specifies that only a match between the prefix and the starting portion of context name is required. If only the **prefix** keyword is specified, simple wildcard processing is used. For example, when context **vprn prefix** is entered, all **vprn** contexts are matched.

Default **exact**

view-name-1

Specifies the SNMP view used to control which MIB objects can be accessed using a read (get) operation.

view-name-2

Specifies the SNMP view used to control which MIB objects can be accessed using a write (set) operation.

view-name-3

Specifies the SNMP view used to control which MIB objects can be accessed for notifications.

no access-algorithm

Context

[Tree] (config>service>vprn>aaa>remote-servers>radius access-algorithm)

Full Context

configure service vprn aaa remote-servers radius access-algorithm

Description

This command indicates the algorithm used to access the set of RADIUS servers.

Default

access-algorithm direct

Parameters

direct

The first server will be used as primary server for all requests, the second as secondary and so on.

round-robin

The first server will be used as primary server for the first request, the second server as primary for the second request, and so on. If the router gets to the end of the list, it starts again with the first server.

Platforms

All

access-algorithm

Syntax

access-algorithm {**direct** | **round-robin** | **hash-based** | **direct-priority**}

no access-algorithm

Context

[Tree] (config>aaa>isa-radius-plcy>servers access-algorithm)

Full Context

configure aaa isa-radius-policy servers access-algorithm

Description

This command defines the algorithm used to access the list of available RADIUS servers. A RADIUS server is considered available initially and marked as unavailable if no response packets are received in a period equal to the configured packet **timeout** multiplied by the **retry** *count* after sending a request. A server is always marked as available when any valid RADIUS packet is received from that server. Some access algorithms periodically probe unavailable servers by sending a single request. If the server responds to the request, it is immediately marked as available.

Default

access-algorithm direct

Parameters

direct

Specifies that the first server is used as primary server for all requests, the second as secondary and so on.

round-robin

Specifies that the first server is used as primary server for the first request, the second server as primary for the second request, and so on. If the router gets to the end of the list, it starts again with the first server.

hashed-based

Specifies that the selection is based on the hash-based procedures.

direct-priority

Specifies that the first server is used for all requests. If that server is not available, the second server is used, and so on. This method periodically probes and falls back to higher-priority servers.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

access-algorithm

Syntax

access-algorithm {**direct** | **round-robin**}

no access-algorithm

Context

[Tree] (config>system>security>radius access-algorithm)

Full Context

configure system security radius access-algorithm

Description

This command indicates the algorithm used to access the set of RADIUS servers.

Default

access-algorithm direct

Parameters

direct

Specifies that the first server is used as primary server for all requests, the second as secondary and so on.

round-robin

Specifies that the first server is used as primary server for the first request, the second server as primary for the second request, and so on. If the router gets to the end of the list, it starts again with the first server.

Full Context

configure subscriber-mgmt radius-accounting-policy include-radius-attribute access-loop-options

configure subscriber-mgmt authentication-policy include-radius-attribute access-loop-options

Description

This command enables inclusion of access loop information: Broadband Forum (BBF) access loop characteristics, DSL line state and DSL type. The BBF access loop characteristics are returned as BBF specific RADIUS attributes where DSL line state and DSL type are returned as Nokia-specific RADIUS VSAs.

Information obtained via the ANCP protocol has precedence over information received in PPPoE Vendor Specific BBF tags or DHCP Vendor Specific BBF Options.

If ANCP is utilized and interim accounting update is enabled, any Port Up event from GSMP will initiate in an interim update. Port Up messages can include information such as an update on the current subscriber actual-upstream-speed. The next interim accounting message is from port up triggering point.

The **no** form of this command reverts to the default.

Full Context

configure service vprn aaa remote-servers tacplus request-format access-operation-cmd

configure system security tacplus request-format access-operation-cmd

Description

This command sends an operation argument in authorization requests.

In model-driven interfaces, this command configures the system to send the operation in the cmd argument, and the path in the cmd-args argument, in TACACS+ authorization requests. This command does not apply to authorization requests in classic interfaces.

The **no** form of this command removes the operation from the configuration.

Default

no access-operation-cmd

Parameters

access-operation

Specifies that an operation in the authorization request is sent.

Values delete — Keyword that sends the operation "cmd=delete" and "cmd-args=path".

Platforms

All

5.40 accounting

accounting

Syntax

configure service vprn aaa remote-servers tacplus accounting

Description

This command configures the type of accounting record packet that is to be sent to the TACACS+ server. The **record-type** parameter indicates whether TACACS+ accounting start and stop packets be sent or just stop packets be sent.

Default

no accounting

Parameters

record-type start-stop

Specifies that a TACACS+ start packet is sent whenever the user executes a command and a TACACS+ stop packet when command execution is complete.

record-type stop-only

Specifies that only a TACACS+ stop packet is sent whenever the command execution is complete.

5.43 accounting-files-total-size

accounting-files-total-size

Syntax

accounting-files-total-size *megabytes*

Context

[Tree] (config>log>storage accounting-files-total-size)

Full Context

configure log file-storage-control accounting-files-total-size

Description

This command configures the limit for the total space that all accounting files can occupy on each storage device on the active CPM.

When this threshold is reached, new accounting files are no longer created in the `\act-collect` directory of the storage device until SR OS removes older accounting files from the `\act` directory and the occupancy is below the limit. Currently open, in-progress accounting files in the `\act-collect` directory are not affected by this limit and are completed.

When unconfigured, there is no specific limit for the total size of all accounting files.

Only accounting files in the `\act` directory with system generated names (including no file extension) are applicable toward the total size limit.

If a user manually adds or deletes accounting files from the `\act` directory, the size of the files is not taken into account for up to 1 hour.

The configured total size limit is not validated against the actual size of the installed storage devices. If the configured limit is larger than the installed compact flash (CF) device, the limit is never reached.

The **no** form of this command removes the total size limit for accounting files.

Default

no accounting-files-total-size

Parameters

megabytes

Specifies the total size limit for accounting files, in MB.

Values	50 to 4,194,304 MBytes (4 TBytes, 2^{22} MB)
Default	0

Platforms

All

configure service vpls sap accounting-policy

configure service ies interface sap accounting-policy

configure service vprn interface spoke-sdp accounting-policy

configure service vprn interface sap accounting-policy

configure service ies subscriber-interface group-interface sap accounting-policy

Description

This command creates the accounting policy context that can be applied to an interface SAP or interface SAP spoke SDP.

An accounting policy must be defined before it can be associated with a SAP or SDP.

If the *policy-id* does not exist, an error message is generated.

A maximum of one accounting policy can be associated with a SAP or SDP at one time. Accounting policies are configured in the **config>log** context.

The **no** form of this command removes the accounting policy association from the SAP or SDP, and the accounting policy reverts to the default.

Default

no accounting policy

Parameters

acct-policy-id

Specifies the accounting *policy-id* as configured in the **config>log>accounting-policy** context.

Values 1 to 99

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

[Tree] (config>card>fp>ingress>network>queue-group accounting-policy)

Full Context

configure card fp ingress access queue-group accounting-policy

configure card fp ingress network queue-group accounting-policy

Description

This command configures an accounting policy that can apply to a queue-group on the forwarding plane.

An accounting policy must be configured before it can be associated to an interface. If the accounting *policy-id* does not exist, an error is returned.

Accounting policies associated with service billing can only be applied to SAPs. The accounting policy can be associated with an interface at a time.

The **no** form of this command removes the accounting policy association from the queue-group.

Default

No accounting policies are specified by default. You must explicitly specify a policy. If configured, the accounting policy configured as the default is used.

Parameters

acct-policy-id

Specifies the name of the accounting policy to use for the queue-group.

Values 1 to 99

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, 7950 XRS, VSR

configure port tdm e1 channel-group network accounting-policy

configure port ethernet access egress queue-group accounting-policy

configure port sonet-sdh path network accounting-policy

Description

This command configures an accounting policy that can apply to an interface.

An accounting policy must be configured before it can be associated to an interface. If the accounting *policy-id* does not exist, an error is returned.

Accounting policies associated with service billing can only be applied to SAPs. Accounting policies associated with network ports can only be associated with interfaces. Only one accounting policy can be associated with an interface at a time.

The **no** form of this command removes the accounting policy association from the network interface, and the accounting policy reverts to the default.

Default

No accounting policies are specified by default. You must explicitly specify a policy. If configured, the accounting policy configured as the default is used.

Parameters

policy-id

The accounting *policy-id* of an existing policy. Accounting policies record either service (access) or network information. A network accounting policy can only be associated with the network port configurations. Accounting policies are configured in the **config>log>accounting-policy** context.

Values 1 to 99

Full Context

configure saa test accounting-policy

Description

This command associates an accounting policy to the SAA test. The accounting policy must already be defined before it can be associated otherwise an error message is generated.

A notification (trap) is issued whenever a test is completed or terminates.

The **no** form of this command removes the accounting policy association.

Parameters

acct-policy-id

Specifies the accounting *policy-id* as configured in the **config>log>accounting-policy** context.

Values 1 to 99

Platforms

All

accounting-policy

Syntax

accounting-policy *acct-policy-id*

no accounting-policy

Context

[Tree] (config>oam-pm>session>meas-interval accounting-policy)

Full Context

configure oam-pm session meas-interval accounting-policy

Description

This optional command allows the operator to assign an accounting policy and the policy-id (configured under the **config>log>accounting-policy**) with a record-type of complete-pm. This runs the data collection process for completed measurement intervals in memory, file storage, and maintenance functions moving data from memory to flash. A single accounting policy can be applied to a measurement interval.

The **no** form of this command removes the accounting policy.

Parameters

acct-policy-id

Specifies the accounting policy to be applied to the measurement interval.

Values 1 to 99

Platforms

All

accounting-policy

Syntax

accounting-policy *acct-policy-id*

no accounting-policy

Context

[Tree] (config>service>sdp accounting-policy)

[Tree] (config>service>pw-template accounting-policy)

Full Context

configure service sdp accounting-policy

configure service pw-template accounting-policy

Description

This command creates the accounting policy context that can be applied to an SDP. An accounting policy must be defined before it can be associated with a SDP. If the *acct-policy-id* does not exist, an error message is generated.

A maximum of one accounting policy can be associated with a SDP at one time. Accounting policies are configured in the **config>log** context.

The **no** form of this command removes the accounting policy association from the SDP, and the accounting policy reverts to the default.

Default

no accounting-policy

Parameters

acct-policy-id

Specifies the accounting *policy-id* as configured in the **config>log>accounting-policy** context.

Values 1 to 99

Platforms

All

accounting-policy

Syntax

accounting-policy *policy-id* [**interval** *minutes*]

no accounting-policy *policy-id*

Context

[Tree] (config>log accounting-policy)

Full Context

configure log accounting-policy

Description

This command creates an access or network accounting policy. An accounting policy defines the accounting records that are created.

Access accounting policies are policies that can be applied to one or more SAPs. Changes made to an existing policy, using any of the sub-commands, are applied immediately to all SAPs where this policy is applied.

If an accounting policy is not specified on a SAP, then accounting records are produced in accordance with the access policy designated as the **default**. If a default access policy is not specified, then no accounting records are collected other than the records for the accounting policies that are explicitly configured.

Only one policy can be regarded as the default access policy. If a policy is configured as the default policy, then a **no default** command must be used to allow the data that is currently being collected to be written before a new access default policy can be configured.

Network accounting policies are policies that can be applied to one or more network ports or SONET/SDH channels. Any changes made to an existing policy, using any of the sub-commands, will be applied immediately to all network ports or SONET/SDH channels where this policy is applied.

If no accounting policy is defined on a network port, accounting records will be produced in accordance with the default network policy as designated with the **default** command. If no network default policy is created, then no accounting records will be collected other than the records for the accounting policies explicitly configured. Default accounting policies cannot be explicitly applied. For example, for **accounting-policy 10**, if default is set, then that policy cannot be used:

```
A:node-2>config>service>vpls>spoke-sdp# accounting-policy 10
```

Only one policy can be regarded as the default network policy. If a policy is configured as the default policy, then a **no default** command must be used to allow the data that is currently being collected to be written before a new network default policy can be configured.

The **no** form of this command deletes the policy from the configuration. The accounting policy cannot be removed unless it is removed from all the SAPs, network ports or channels where the policy is applied.

Parameters

policy-id

Specifies the policy ID that uniquely identifies the accounting policy, expressed as a decimal integer.

Values 1 to 99

Platforms

All

accounting-policy

Syntax

accounting-policy *acct-policy-id*

no accounting-policy

Context

[Tree] (conf>router>segment-routing>sr-policies>egress-stats accounting-policy)

Full Context

configure router segment-routing sr-policies egress-statistics accounting-policy

Description

This command adds the accounting record type to the accounting policy that is forwarded to the configured accounting file. A record name can only be used in one accounting policy. To obtain a list of all record types that can be configured, use the show log accounting-records command.

To configure an accounting policy for access ports, select a service record. To change the record name to another service record, configure the new record name with this command.

When configuring an accounting policy for network ports, select a network record. To change the record name to another network record, configure the new record name with this command.

The **no** form of this command removes the accounting policy association from the egress statistics configuration.

Default

no accounting-policy

Parameters

acct-policy-id

Specifies the accounting *policy-id* as configured in the **config>log>accounting-policy** context.

Values 1 to 99

Platforms

All

5.45 accounting-port

accounting-port

Syntax

accounting-port *port*

no accounting-port

Context

[Tree] (config>service>vprn>aaa>remote-servers>radius accounting-port)

Full Context

configure service vprn aaa remote-servers radius accounting-port

Description

This command specifies a UDP port number on which to contact the RADIUS server for accounting requests.

Default

accounting-port 1813

Parameters

port

Specifies the UDP port number.

Values 1 to 65535

Default 1813

Platforms

All

accounting-port

Syntax

accounting-port *port*

no accounting-port

Context

[Tree] (config>system>security>radius accounting-port)

Full Context

configure aaa l2tp-accounting-policy accounting-type

Description

This command specifies the accounting type for the L2TP tunnel accounting policy.

The **no** form of this command reverts to the default.

Default

accounting-type session tunnel

Parameters

session

Enables tunnel level accounting, including:

Tunnel-Link-Start

Tunnel-Link-Stop

Tunnel-Link-Reject

tunnel

Enables link level accounting, including:

Tunnel-Start

Tunnel-Stop

Tunnel-Reject

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

5.47 accounting-update-interval

accounting-update-interval

Syntax

accounting-update-interval [*interval*]

no accounting-update-interval

Context

[Tree] (config>service>ies>sub-if>grp-if>wlan-gw>vlan-tag-ranges>range>xconnect accounting-update-interval)

[Tree] (config>service>vprn>sub-if>grp-if>wlan-gw>vlan-tag-ranges>range>xconnect accounting-update-interval)

5.50 acct-include-attributes

acct-include-attributes

Syntax

[**no**] **acct-include-attributes**

Context

[Tree] (config>aaa>isa-radius-plcy acct-include-attributes)

Full Context

configure aaa isa-radius-policy acct-include-attributes

Description

This command configures attributes to be included in RADIUS accounting messages.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.51 acct-interim

acct-interim

Syntax

acct-interim min *min-val* **max** *max-val* **lifetime** *lifetime*

no acct-interim

Context

[Tree] (config>aaa>radius-srv-plcy>servers>buffering acct-interim)

Full Context

configure aaa radius-server-policy servers buffering acct-interim

Description

This command enables RADIUS accounting interim update message buffering.

1. The message is stored in the buffer, a lifetime timer is started and the message is sent to the RADIUS server
2. If after retry*timeout seconds no RADIUS accounting response is received for the interim update then a new attempt to send the message is started after minimum[(min-val*2n), max-val] seconds.

3. Repeat step 2 until for one of the following:
   a. a RADIUS accounting response is received.
   b. the lifetime of the buffered message expires.
   c. a new RADIUS accounting interim-update or a RADIUS accounting stop for the same accounting session-id and radius-server-policy is stored in the buffer.
   d. the message is manually purged from the message buffer via a clear command.
4. The message is purged from the buffer.

The **no** form of this command disables RADIUS accounting interim update message buffering.

Parameters

min-val

Specifies the minimum interval in seconds between attempts to resend the RADIUS accounting interim update.

Values 1 to 3600

max-val

Specifies the maximum interval in seconds between attempts to resend the RADIUS accounting interim update.

Values 1 to 3600

lifetime

Specifies the lifetime in hours.

Values 1 to 25

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

5.52 acct-on-off

acct-on-off

Syntax

acct-on-off

acct-on-off monitor-group *group-name*

acct-on-off oper-state-change [**group** *group-name*]

Context

[Tree] (config>aaa>radius-srv-plcy acct-on-off)

Full Context

configure aaa radius-server-policy acct-on-off

Description

This command controls the sending of Accounting-On and Accounting-Off messages and the acct-on-off oper-state of the radius-server-policy:

acct-on-off: enables the sending of Accounting-On and Accounting-Off messages for this radius-server-policy. The acct-on-off oper-state is always not blocked.

acct-on-off oper-state-change [group *group-name*]: enables the sending of Accounting-On and Accounting-Off messages for this radius-server-policy. The acct-on-off oper-state is function of the Accounting-response received for the Accounting-On and Accounting-Off. Optionally, sets the acct-on-off oper-state of the acct-on-off-group.

acct-on-off monitor-group *group-name*: no Accounting-On and Accounting-Off messages are sent for this radius-server-policy. The acct-on-off oper-state is inherited from the acct-on-off-group.

The **no** form of this command disables the sending of Accounting-On and Accounting-Off messages.

Parameters

group-name

Specifies the name of an acct-on-off group up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

5.53 acct-on-off-group

acct-on-off-group

Syntax

acct-on-off-group *group-name* [**create**]

no acct-on-off-group *group-name*

Context

[Tree] (config>aaa acct-on-off-group)

Full Context

configure aaa acct-on-off-group

Description

This command creates an acct-on-off-group.

An acct-on-off-group can be referenced by:

- A single radius-server-policy as controller — The acct-on-off oper-state of the acct-on-off-group is set to the acct-on-off oper-state of the radius-server-policy.
- Multiple radius-server-policies as monitor — The acct-on-off oper-state of the radius-server-policy is inherited from the acct-on-off oper-state of the acct-on-off group.

The **no** form of this command deletes the acct-on-off-group.

Parameters

group-name

Specifies the name of an acct-on-off group up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

5.54 acct-policy

acct-policy

Syntax

acct-policy *acct-policy-name* [**duplicate** *acct-policy-name*]

no acct-policy

Context

[Tree] (config>subscr-mgmt>loc-user-db>ppp>host acct-policy)

[Tree] (config>subscr-mgmt>loc-user-db>ipoe>host acct-policy)

Full Context

configure subscriber-mgmt local-user-db ppp host acct-policy

configure subscriber-mgmt local-user-db ipoe host acct-policy

Description

This command specifies the accounting policy used for sending an Accounting Stop message to report RADIUS authentication failures of PPPoE sessions. A duplicate policy can be specified if a copy of the Accounting Stop message must be sent to another destination.

Reporting RADIUS authentication failures with an Accounting Stop message must be enabled in the RADIUS authentication policy ("send-acct-stop-on-fail").

A duplicate RADIUS accounting policy can be specified if the accounting stop resulting from a RADIUS authentication failure must also be sent to a second RADIUS destination.

The **no** form of this command reverts to the default.

Parameters

acct-policy-name

Specifies the name of a RADIUS accounting policy, up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

5.55 acct-port

acct-port

Syntax

acct-port *port*

no acct-port

Context

[Tree] (config>router>radius-server>server acct-port)

[Tree] (config>service>vprn>radius-server>server acct-port)

Full Context

configure router radius-server server acct-port

configure service vprn radius-server server acct-port

Description

This command specifies the UDP listening port for RADIUS accounting requests.

The **no** form of this command resets the UDP port to its default value (1813).

Default

acct-port 1813

Parameters

port

Specifies the UDP listening port for accounting requests of the external RADIUS server.

Values 1 to 65535

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

5.56 acct-request-script-policy

acct-request-script-policy

Syntax

acct-request-script-policy *policy-name*

no acct-request-script-policy

Context

[Tree] (config>subscr-mgmt>acct-plcy acct-request-script-policy)

Full Context

configure subscriber-mgmt radius-accounting-policy acct-request-script-policy

Description

This command configures the Python script policy to modify Accounting-Request messages.

The **no** form of this command removes the policy name from the configuration.

Parameters

policy-name

Specifies the Python script policy to modify Accounting-Request messages.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

acct-request-script-policy

Syntax

acct-request-script-policy *policy-name*

no acct-request-script-policy

Context

[Tree] (config>aaa>radius-srv-plcy acct-request-script-policy)

Full Context

configure aaa radius-server-policy acct-request-script-policy

Description

This command specifies the name of the RADIUS script policy used to change the RADIUS attributes of the Accounting-Request messages.

Parameters

policy-name

Specifies the name of the Python script to modify Accounting-Request messages, up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

5.57 acct-session-id

acct-session-id

Syntax

acct-session-id [*session-id-type*]

no acct-session-id

Context

[Tree] (config>subscr-mgmt>auth-plcy>include-radius-attribute acct-session-id)

Full Context

configure subscriber-mgmt authentication-policy include-radius-attribute acct-session-id

Description

The **acct-session-id** attribute for each subscriber host is generated at the very beginning of the session initiation. This command will enable or disable sending this attribute to the RADIUS server in the Access-Request messages regardless of whether the accounting is enabled or not. The **acct-session-id** attribute can be used to address the subscriber hosts from the RADIUS server in the CoA Request.

The **acct-session-id** attribute is unique per subscriber host network wide. It is a 22 byte field comprised of the system MAC address along with the creation time and a sequence number in a hex format.

The **no** form of this command reverts to the default.

Default

no acct-session-id

Parameters

session-id-type

Specifies the format for the **acct-session-id** attribute used in RADIUS accounting requests.

Values host, session

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

5.58 acct-stats

acct-stats

Syntax

[**no**] **acct-stats**

Context

[Tree] (config>ipsec>rad-acct-plcy>include acct-stats)

Full Context

configure ipsec radius-accounting-policy include-radius-attribute acct-stats

Description

This command enables the system to include accounting attributes in RADIUS acct-stop and interim-update packets.

The **no** form of this command disables the system from including accounting attributes in RADIUS acct-stop and interim-update packets.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.59 acct-stop

acct-stop

Syntax

acct-stop min *min-val* **max** *max-val* **lifetime** *lifetime*

no acct-stop

Context

[Tree] (config>aaa>radius-srv-plcy>servers>buffering acct-stop)

Full Context

configure aaa radius-server-policy servers buffering acct-stop

Description

This command enables RADIUS accounting stop message buffering.

1. The message is stored in the buffer, a lifetime timer is started and the message is sent to the RADIUS server
2. If after retry*timeout seconds no RADIUS accounting response is received for the accounting stop, then a new attempt to send the message is started after minimum[(min-val*2n), max-val] seconds.
3. Repeat step 2 until one of the following events occurs:
   a. A RADIUS accounting response is received.
   b. The lifetime of the buffered message expires.
   c. The message is manually purged from the message buffer via a clear command.
4. The message is purged from the buffer.

The **no** form of this command disables RADIUS accounting stop message buffering.

Parameters

min-val

Specifies the minimum interval in seconds between attempts to resend the RADIUS accounting stop.

Values 1 to 3600

max-val

Specifies the maximum interval in seconds between attempts to resend the RADIUS accounting stop.

Values 1 to 3600

lifetime

Specifies the lifetime in hours.

Values 1 – 25

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

5.60 acct-trigger-reason

acct-trigger-reason

Syntax

[**no**] **acct-trigger-reason**

Context

[Tree] (config>aaa>isa-radius-plcy>acct-include-attributes acct-trigger-reason)

Full Context

configure aaa isa-radius-policy acct-include-attributes acct-trigger-reason

Description

This command enables the acct-trigger-reason.

Default

no acct-trigger-reason

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.61 acct-tunnel-connection-fmt

acct-tunnel-connection-fmt

Syntax

acct-tunnel-connection-fmt *ascii-spec*

no acct-tunnel-connection-fmt

Context

[Tree] (config>aaa>l2tp-acct-plcy acct-tunnel-connection-fmt)

Full Context

configure aaa l2tp-accounting-policy acct-tunnel-connection-fmt

Description

This command configures the accounting tunnel connection ascii-specification.

Default

no acct-tunnel-connection-fmt

Parameters

ascii-spec

Specifies the ASCII specifications.

<*ascii-spec*>	<char-specification> <ascii-spec>
char-specification	<ascii-char> | <char-origin>

ascii-char	a printable ASCII character	
char-origin	%<origin>	
origin	n | s | S | t | T | c | C	
	n	Call Serial Number
	s | S	Local (s) or Remote (S) Session Id
	t | T	Local (t) or Remote (T) Tunnel Id
	c | C	Local (c) or Remote (C) Connection Id

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

acct-tunnel-connection-fmt

Syntax

acct-tunnel-connection-fmt *ascii-spec*

no acct-tunnel-connection-fmt

Context

[Tree] (config>subscr-mgmt>acct-plcy acct-tunnel-connection-fmt)

Full Context

configure subscriber-mgmt radius-accounting-policy acct-tunnel-connection-fmt

Description

This command specifies the string that is sent in the accounting message.

Default

no acct-tunnel-connection-fmt

Parameters

ascii-spec

Specifies the accounting tunnel connection ASCII specification.

Values

asci-spec	<*char-specification*> <*ascii-spec*>	
char-specification	<*ascii-char*> | <*char-origin*>	
ascii-char	A printable ASCII character	

char-origin	%<origin>	
origin	n | s | S | t | T | c | C	
	n	Call Serial Number
	s | S	Local (s) or Remote (S) Session Id
	t | T	Local (t) or Remote (T) Tunnel Id
	c | C	Local (c) or Remote (C) Connection Id

5.62 acct-update-triggers

acct-update-triggers

Syntax

acct-update-triggers

Context

[Tree] (config>aaa>isa-radius-plcy acct-update-triggers)

Full Context

configure aaa isa-radius-policy acct-update-triggers

Description

Commands in this context enable or disable the sending of triggered interim-updates, with the exception of the following:

- After an update interval change, an interim update is always sent to indicate the start of the new interval.
- Mobility-triggered updates are configured in the (**service vprn <svc-id> | router**) **wlan-gw mobility-triggered-acct** context.
- NAT port block allocation depends on the inclusion of NAT-related attributes (port-range, outside-service, outside-ip).

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.63 accu-stats-policy

accu-stats-policy

Syntax

accu-stats-policy *policy-name* [**create**]

no accu-stats-policy *policy-name*

Context

[Tree] (config>subscr-mgmt accu-stats-policy)

Full Context

configure subscriber-mgmt accu-stats-policy

Description

This command creates a storage policy for cumulative statistics for subscribers. The policy defines the specific direction for the policer or the queue to be stored and performs the following functions.

- The policy stores subscriber statistics even if the subscriber session has ended. The subscriber statistics can be viewed even if the subscriber is offline.
- When the subscriber session ends, the statistics are added to the past statistics stored in memory so that all previous session statistics are accumulated. The accumulated statistics are not persistent; they are only stored in memory and reset to zero when the chassis reboots.

The **no** form of this command deletes the policy only when it is no longer referenced by a subscriber profile.

Parameters

policy-name

Specifies the name for the policy, up to 32 characters.

create

Configures an entry for the policy.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

accu-stats-policy

Syntax

accu-stats-policy *policy-name*

no accu-stats-policy

Context

[Tree] (config>subscr-mgmt>sub-profile accu-stats-policy)

Full Context

configure subscriber-mgmt sub-profile accu-stats-policy

Description

This command associates an accumulated statistics policy with a subscriber profile.

The **no** form of this command removes the association of the accu-stats-policy from the subscriber profile. It is possible to remove the policy from the subscriber profile while the subscriber is still online, however, the statistics remain in memory and must be cleared manually, using the **clear subscriber-mgmt accu-stats active-subs no-accu-stats-policy** command.

Parameters

policy-name

Specifies the name of the accumulated statistics policy, up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

5.64 ack

ack

Syntax

ack [**detail**]

no ack

Context

[Tree] (debug>router>rsvp>packet ack)

Full Context

debug router rsvp packet ack

Description

This command debugs ack events.

The **no** form of the command disables the debugging.

Parameters

detail

Displays detailed information about ack events.

Platforms

All

5.65 ack-auth-retry-count

ack-auth-retry-count

Syntax

ack-auth-retry-count [*value*]

no ack-auth-retry-count

Context

[Tree] (config>service>vprn>wpp>portals>portal ack-auth-retry-count)

[Tree] (config>router>wpp>portals>portal ack-auth-retry-count)

Full Context

configure service vprn wpp portals portal ack-auth-retry-count

configure router wpp portals portal ack-auth-retry-count

Description

This command configures the number of retransmissions of an ACK_OUT message.

The **no** form of this command reverts to the default.

Default

ack-auth-retry-count 5

Parameters

value

Specifies the number of retransmissions of an ACK_OUT message.

Values 0 to 5

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

5.66 acknowledgment

acknowledgment

Syntax

[**no**] **acknowledgment**

Context

[Tree] (config>service>vpls>spoke-sdp>control-channel-status acknowledgment)

[Tree] (config>service>epipe>spoke-sdp>control-channel-status acknowledgment)

[Tree] (config>service>cpipe>spoke-sdp>control-channel-status acknowledgment)

Full Context

configure service vpls spoke-sdp control-channel-status acknowledgment

configure service epipe spoke-sdp control-channel-status acknowledgment

configure service cpipe spoke-sdp control-channel-status acknowledgment

Description

This command enables the acknowledgment of control channel status messages. By default, no acknowledgment packets are sent.

Platforms

All

- configure service vpls spoke-sdp control-channel-status acknowledgment
- configure service epipe spoke-sdp control-channel-status acknowledgment

5.67 action

action

Syntax

action bypass-host-creation

action drop

no action

Context

[Tree] (config>filter>dhcp-filter>entry action)

Full Context

configure filter dhcp-filter entry action

Description

This command specifies the action to take on DHCP host creation when the filter entry matches.

The **no** form of this command reverts to the default wherein the host creation proceeds as normal.

Parameters

bypass-host-creation

Specifies that the host creation is bypassed.

drop

Specifies that the DHCP message is dropped.

Platforms

All

action

Syntax

action bypass-host-creation [**na**] [**pd**]

action drop

no action

Context

Full Context

configure filter dhcp6-filter entry action

Description

This command specifies the action to take on DHCP6 host creation when the filter entry matches.

The **no** form of this command reverts to the default wherein the host creation proceeds as normal.

Parameters

bypass-host-creation

Specifies that the host creation is bypassed.

Values **na** — Bypasses the DHCP6 NA hosts creation.

pd — Bypasses the DHCP6 PD hosts creation.

drop

Specifies that the DHCP6 message is dropped.

Platforms

All

Syntax

action {**accept** | **next-entry** | **next-policy** | **drop** | **reject**}

no action

Context

[Tree] (config>router>policy-options>policy-statement>entry action)

Full Context

configure router policy-options policy-statement entry action

Description

This command creates the context to configure actions to take for routes matching a route policy statement entry.

This command is required and must be entered for the entry to be active.

Any route policy entry without the **action** command will be considered incomplete and will be inactive.

The **no** form of this command deletes the action context from the entry.

Default

no action

Parameters

accept

Specifies that routes matching the entry match criteria will be accepted and propagated.

next-entry

Specifies that the actions specified would be made to the route attributes and then policy evaluation would continue with next policy entry (if any others are specified).

next-policy

Specifies that the actions specified would be made to the route attributes and then policy evaluation would continue with next route policy (if any others are specified).

drop

Specifies that routes matching the entry match criteria should be rejected. This parameter provides a context for modifying route properties.

reject

Specifies that routes matching the entry match criteria should be rejected. This parameter does not provide a context for modifying route properties.

configure service ies subscriber-interface group-interface dhcp option action

configure subscriber-mgmt msap-policy vpls-only-sap-parameters dhcp option action

configure service vprn interface dhcp option action

configure service vpls sap dhcp option action

Description

This command configures the processing required when the SR-Series receives a DHCP request that already has a Relay Agent Information Option (Option 82) field in the packet.

The **no** form of this command returns the system to the default value.

Default

action keep — Per RFC 3046, *DHCP Relay Agent Information Option*, section 2.1.1, *Reforwarded DHCP requests*. The default is to keep the existing information intact. The exception to this is if the giaddr of the received packet is the same as the ingress address on the router. In that case the packet is dropped and an error is logged.

Parameters

replace

In the upstream direction (from the user), the existing Option 82 field is replaced with the Option 82 field from the router. In the downstream direction (towards the user) the Option 82 field is stripped (in accordance with RFC 3046).

drop

Specifies that the packet is dropped, and an error is logged.

keep

Specifies that the existing information is kept in the packet and the router does not add any additional information. In the downstream direction the Option 82 field is not stripped and is sent on towards the client.

The behavior is slightly different in case of Vendor Specific Options (VSOs). When the keep parameter is specified, the router inserts its own VSO into the Option 82 field. This is only done when the incoming message has already an Option 82 field.

If no Option 82 field is present, the router will not create the Option 82 field. In this in that case, no VSO is added to the message.

no action

Context

[Tree] (config>service>vprn>log>filter>entry action)

[Tree] (config>log>filter>entry action)

Full Context

configure service vprn log filter entry action

configure log filter entry action

Description

This command specifies a drop or forward action associated with the filter entry. If neither **drop** nor **forward** is specified, the default-action will be used for traffic that conforms to the match criteria. This could be considered a No-Op filter entry used to explicitly exit a set of filter entries without modifying previous actions.

Multiple action statements entered will overwrite previous actions.

The **no** form of this command removes the specified action statement.

Default

Action specified by the **default-action** command will apply.

Parameters

drop

Specifies packets matching the entry criteria will be dropped.

forward

Specifies packets matching the entry criteria will be forwarded.

Platforms

All

action

Syntax

action {**drop** | **forward**}

no action

Context

configure subscriber-mgmt category-map category exhausted-credit-service-level ingress-ip-filter-entries entry action

configure subscriber-mgmt category-map category exhausted-credit-service-level ingress-ipv6-filter-entries entry action

configure subscriber-mgmt category-map category exhausted-credit-service-level egress-ip-filter-entries entry action

configure subscriber-mgmt category-map category exhausted-credit-service-level egress-ipv6-filter-entries entry action

Description

This command configures the action for the filter entry.

The **no** form of this command reverts to the default.

Default

action drop

Parameters

drop

Specifies to drop the packets matching the IP filter entry.

forward

Specifies to forward the packets matching the IP filter entry.

http-redirect *url* [allow-override]

Specifies the HTTP web address, up to 255 characters, that is sent to the user's browser for redirection.

Note:
This action is not supported for IPv6 filter entries.

The specified URL can be overridden by a Diameter Credit Control Server when the following conditions are met:

- a Final-Unit-Indication AVP is present in the Multiple-Services-Credit-Control AVP of a CCA message
- the Final-Unit-Action AVP is set to REDIRECT (1)
- a Redirect-Server AVP is included with the following:
  - the Redirect-Address-Type AVP set to URL (2)
  - the Redirect-Server-Address AVP containing the URL to use for this rating group (**category-map**)
- the out of credit action for the corresponding rating group is set to **change-service-level** using one of the following commands:
  - **configure>subscriber-mgmt>credit-control-policy** *policy-name***>out-of-credit-action change-service-level**
  - **configure>subscriber-mgmt>category-map** *category-map-name* **category** *category-name***>out-of-credit-action-override change-service-level**
- an IPv4 HTTP redirect action with **allow-override** is specified in the exhausted credit service level context for the corresponding rating group using the command **configure>subscriber-mgmt>category-map** *category-map-name* **category** *category-*

name>**exhausted-credit-service-level>ingress-ip-filter-entries**> **entry** *entry-id*>**action http-redirect** *url* **allow-override**

In all other cases, the URL specified in the Redirect-Server-Address AVP is ignored and the configured URL is used. The URL received from the Credit Control Server is included in the output of **show>service>active-subscribers>credit-control**. The **allow-override** is ignored for RADIUS credit control.

The following variables can optionally be added in the configured URL (http-redirect url) and in the override URL from the Credit Control Server (Redirect-Server-Address AVP):

- $IP – Customer's IP address
- $MAC – Customer's MAC address
- $URL – Original requested URL
- $SAP – Customer's SAP
- $SUB – Customer's subscriber identification string
- $CID – string that represents the circuit-id or interface-id of the subscriber host (hexadecimal format)
- $RID – string that represents the remote-id of the subscriber host (hexadecimal format)

configure subscriber-mgmt isa-filter ipv6 entry action

configure subscriber-mgmt isa-filter entry action

Description

This command specifies what should happen to packets that do match this entry.

The **no** form of this command reverts to the default value.

Default

action none

Parameters

drop

Specifies to drop the packet.

forward

Specifies to forward the packet.

none

Specifies to ignore the entry and continue processing with subsequent entries.

rdr-url-string

Specifies the URL to which matching HTTP flows are redirected, up to 255 characters. The URL can be overridden by AAA. Non-HTTP packets are dropped. The URL supports the $URL, $MAC, and $IP variables. For other macro substitutions, the string is not modified.

Platforms

Full Context

configure subscriber-mgmt isa-policer action

Description

This command specifies what happens to packets that are in-profile and out-of-profile.

The **no** form of this command reverts to the default value.

Default

action permit-deny

Parameters

permit-deny

Drops all packets that are out of profile (they do not conform to the PIR).

priority-mark

Currently not supported. The policer will take no action.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

action

Syntax

action {**log-only** | **reset-mda** | **fail-mda**}

no action

Context

[Tree] (config>card>mda>event action)

Full Context

configure card mda event action

Description

This command defines the action to be taken when a specific hardware error event is raised against the target mda.

Only one action can be enabled at a time. Entering a new action will override a previously defined action.

The **no** form of this command sets the action to the default value.

Default

action log-only

Parameters

log-only

Specifies to pass the log event to log management. No other action is taken.

reset-mda

Specifies to reset the mda.

fail-mda

Specifies to set the operational state of the mda to Failed. This Failed state will persist until the clear mda command is issued (reset) or the mda is removed and re-inserted (re-seat).

Platforms

All

action

Syntax

[**no**] **action**

Context

[Tree] (configure>system>security>profile>netconf>base-op-authorization action)

Full Context

configure system security profile netconf base-op-authorization action

Description

This command enables the NETCONF action operation.

The **no** form of this command disables the operation.

Default

no action

Note:
The operation is enabled by default in the built-in system-generated administrative profile.

Platforms

All

action

Syntax

action {**priority-mark** | **permit-deny**}

Context

[Tree] (config>app-assure>group>policer action)

Full Context

configure application-assurance group policer action

Description

This command configures the action to be performed by single-bucket bandwidth policers for non-conformant traffic.

Dual bucket bandwidth policers cannot have their action configured and always mark traffic below CIR in profile, between CIR and PIR out of profile, and drop traffic above PIR. Flow policers always discard non-conformant traffic.

When multiple application assurance policers are configured against a single flow (including policers at both subscriber and system), the final action done to the flow/packet will be a logical OR of all policers actions. For example, if only of the policers requires the packet to be discarded, the packet will be dropped regardless of the action of the other policers.

Default

action permit-deny

Parameters

priority-mark

Non-conformant traffic will be marked out of profile and the conformant traffic will be marked in profile. The new marking will overwrite any previous IOM QoS marking done to a packet.

permit-deny

Non-conformant traffic will be dropped.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

action

Syntax

action

Context

[Tree] (config>app-assure>group>policy>aqp>entry action)

Context

[Tree] (config>app-assure>group>sess-fltr>entry action)

Full Context

configure application-assurance group session-filter entry action

Description

This command configures the action for this entry.

Parameters

deny

Packets matching the criteria are denied.

permit

Packets matching the criteria are permitted.

event-log-name

Specifies the event log name, up to 32 characters.

http-redirect-name

Specifies the HTTP redirect name, up to 32 characters.

tcp-optimizer

Specifies to use TCP Optimization (TCPO) on the matching flows.The TCPO policy referenced within this session filter entry is configured under the AA group. If the TCPO action is removed from a session-filter entry, the existing flows are not affected. However, no new TCP flows are optimized.

tcp-optimizer-name

Specifies the name of the TCPO policy, up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

action

Syntax

action {**permit** | **deny**}

action {**dnat** | **forward**} [**ip-address** *ip-address*]

no action

Context

[Tree] (config>service>nat>nat-classifier>entry action)

Full Context

configure service nat nat-classifier entry action

Description

This command specifies the action to take for packets that match this nat-classifier entry. The **no** form of the command removes the specified action statement. By default, the entry is ignored (skipped). Consequently, the action from another matching entry is applied. If there are no other matching entries found, the default-action is applied.

Default

no action.

Parameters

dnat

Performs the DNAT function. The destination IP address of the packet traversing the router in the direction from inside to outside is replaced by the configured IP address. Destination port is not translated. In the opposite direction (from outside to inside), the source address in the returning packet is restored to the original value.

forward

Specifies that the forward action ensures that the packet is transparently passed through the nat-classifier.

ip-address *ip-address*

Specifies that the destination IP address replaces the original IP address in the packet traveling from inside to outside.

[Tree] (config>filter>ip-filter>entry action)

Full Context

configure filter ipv6-filter entry action

configure filter mac-filter entry action

configure filter ip-filter entry action

Description

Commands in this context configure a primary (no option specified) or secondary (**secondary** option specified) action to be performed on packets matching this filter entry. An ACL filter entry remains inactive (is not programmed in hardware) until a specific action is configured for that entry.

A primary action supports any filter entry action, a secondary action is used for redundancy and defines a redundant Layer 3 PBR action for an Layer 3 PBR primary action or a redundant L2 PBF action for a Layer 2 PBF primary action.

The **no** form of this command removes the specific action configured in the context of the action command. The primary action cannot be removed if a secondary action exists.

Default

no action

Parameters

secondary

Specifies a secondary action to be performed on packets matching this filter entry. A secondary action can only be configured if a primary action is configured.

Platforms

All

action

Syntax

action [**fc** *fc-name*] [**priority** {**high** | **low**}] [**policer** *policer-id*]

Full Context

configure qos sap-ingress ip-criteria entry action

configure qos sap-ingress mac-criteria entry action

configure qos sap-ingress ipv6-criteria entry action

Description

This mandatory command associates the forwarding class or enqueuing priority with specific IP, IPv6, or MAC criteria entry ID. The action command supports setting the forwarding class parameter to a subclass. Packets that meet all match criteria within the entry have their forwarding class and enqueuing priority overridden based on the parameters included in the **action** parameters. When the forwarding class is not specified in the **action** command syntax, a matching packet preserves (or inherits) the existing forwarding class derived from earlier matches in the classification hierarchy. When the enqueuing priority is not specified in the action, a matching packet preserves (or inherits) the existing enqueuing priority derived from earlier matches in the classification hierarchy.

When a policer is specified in the action, a matching packet is directed to the configured policer instead of the policer/queue assigned to the forwarding class of the packet.

The **action** command must be executed for the match criteria to be added to the active list of entries. If the entry is designed to prevent more explicit (higher entry ID) entries from matching certain packets, the **fc** *fc-name* and **match** *protocol* fields should not be defined when executing action. This allows packets matching the entry to preserve the forwarding class and enqueuing priority derived from previous classification rules.

Each time action is executed on a specific entry ID, the previously entered values for **fc** *fc-name* and **priority** are overridden with the newly defined parameters or inherit previous matches when a parameter is omitted.

The **no** form of this command removes the entry from the active entry list. Removing an entry on a policy immediately removes the entry from all SAPs using the policy. All previous parameters for the action is lost.

If no action is specified, the action specified by the **default-fc** command will be used.

Parameters

fc *fc-name*

The value given for **fc** *fc-name* must be one of the predefined forwarding classes in the system. Specifying the **fc** *fc-name* is required. When a packet matches the rule, the forwarding class is only overridden when the **fc** *fc-name* parameter is defined on the rule. If the packet matches and the forwarding class is not explicitly defined in the rule, the forwarding class is inherited based on previous rule matches.

The *subclass-name* parameter is optional and used with the *fc-name* parameter to define a pre-existing subclass. The *fc-name* and *subclass-name* parameters must be separated by a period (.). If *subclass-name* does not exist in the context of *fc-name*, an error will occur. If *subclass-name* is removed using the **no fc** *fc-name.subclass-name* **force** command, the **default-fc** command will automatically drop the *subclass-name* and only use *fc-name* (the parent forwarding class for the subclass) as the forwarding class.

Values

fc: *class*[.*subclass*]

class: be, l2, af, l1, h2, ef, h1, nc

subclass: 29 characters max

Default Inherit (When **fc** *fc-name* is not defined, the rule preserves the previous forwarding class of the packet.)

priority

The **priority** parameter overrides the default enqueuing priority for all packets received on a SAP using this policy that match this rule. Specifying the priority (**high** or **low**) is optional. When a packet matches the rule, the enqueuing priority is only overridden when the priority parameter is defined on the rule. If the packet matches and priority is not explicitly defined in the rule, the enqueuing priority is inherited based on previous rule matches.

Default Inherit (When the **priority** (**high** or **low**) is not defined, the rule preserves the previous enqueuing priority of the packet)

high

The **high** parameter is used in conjunction with the **priority** parameter. Setting the **priority** enqueuing parameter to **high** for a packet increases the likelihood to enqueue the packet when the queue is congested. The enqueuing priority only affects ingress SAP queuing. When the packet is placed in a buffer on the queue, the significance of the enqueuing priority is lost.

low

The **low** parameter is used in conjunction with the **priority** parameter. Setting the **priority** enqueuing parameter to **low** for a packet decreases the likelihood to enqueue the packet when the queue is congested. The enqueuing priority only affects ingress SAP queuing. When the packet is placed in a buffer on the ingress queue, the significance of the enqueuing priority is lost.

Default Inherit

policer-id

A valid policer-id must be specified. The parameter policer-id references a policer-id that has already been created within the sap-ingress QoS policy.

Values 1 to 63

[Tree] (config>qos>sap-egress>ip-criteria>entry action)

Full Context

configure qos sap-egress ipv6-criteria entry action

configure qos sap-egress ip-criteria entry action

Description

This command defines the reclassification actions that should be performed on any packet matching the defined IP flow criteria within the entries match node. When defined under the **ip-criteria** context, the reclassification only applies to IPv4 packets. When defined under the **ipv6-criteria** context, the reclassification only applies to IPv6 packets.

If an egress packet on the SAP matches the specified IP flow entry, the forwarding class, or profile or egress queue accounting behavior may be overridden. By default, the forwarding class and profile of the packet is derived from ingress classification and profiling functions. Matching an IP flow reclassification entry will override all IP precedence- or DSCP-based reclassification rule actions when an explicit reclassification action is defined for the entry.

It is also possible to redirect the egress packet to a configured policer. The forwarding class or profile can also be optionally specified.

When an IP flow entry is first created, the entry will have no explicit behavior defined as the reclassification actions to be performed. In **show** and **info** commands, the entry will display no action as the specified reclassification action for the entry. When the entry is defined with no action, the entry will not be populated in the IP flow reclassification list used to evaluate packets egressing a SAP with the SAP egress policy defined. An IP flow reclassification entry is only added to the evaluation list when the action command for the entry is executed either with explicit reclassification entries or without any actions defined. Specifying action without any trailing reclassification actions allows packets matching the entry to exit the evaluation list without matching entries lower in the list. Executing no action on an entry removes the entry from the evaluation list and also removes any explicitly defined reclassification actions associated with the entry.

The **fc** keyword is optional. When specified, the egress classification rule will overwrite the forwarding class derived from ingress. The new forwarding class is used for egress remarking and queue mapping decisions.

The **profile** keyword is optional. When specified, the egress classification rule will overwrite the profile of the packet derived from ingress. The new profile value is used for egress remarking and queue congestion behavior.

The **policer** keyword is optional. When specified, the egress packet will be redirected to the configured policer. Optional parameters allow the user to control how the forwarded policed traffic exits the egress port. By default, the policed forwarded traffic will use a queue in the egress port's policer-output-queue queue group; alternatively, a queue in an instance of a user-configured queue group can be used or a local SAP egress queue.

The **no** form of this command removes all reclassification actions from the IP flow reclassification entry and also removes the entry from the evaluation list. An entry removed from the evaluation list will not be matched to any packets egress a SAP associated with the SAP egress QoS policy.

Parameters

fc *fc-name*

The fc reclassification action is optional. When specified, packets matching the IP flow reclassification entry will be explicitly reclassified to the forwarding class specified as fc-name regardless of the ingress classification decision. The fc-name defined must be one of the eight forwarding classes supported by the system. To remove the forwarding class reclassification action for the IP flow entry, the action command must be re-executed without the fc reclassification action defined.

Values

fc	class	
	class	be, l2, af, l1, h2, ef, h1, nc

profile {in | out | exceed | inplus}

The profile reclassification action is optional. When specified, packets matching the IP flow reclassification entry will be explicitly reclassified to the configured profile regardless of the ingress profiling decision. To remove the profile reclassification action for the IP flow reclassification entry, the action command must be re-executed without the profile reclassification action defined.

in

The **in** parameter is mutually exclusive to the **exceed**, **inplus**, and **out** parameters following the profile reclassification action keyword. **In, exceed**, **inplus**, or **out** must be specified when the profile keyword is present. When **in** is specified, any packets matching the reclassification rule will be treated as in-profile by the egress forwarding plane.

out

The **out** parameter is mutually exclusive to the **exceed**, **inplus**, and **in** parameters following the profile reclassification action keyword. **In, exceed**, **inplus**, or **out** must be specified when the profile keyword is present. When **out** is specified, any packets matching the reclassification rule will be treated as out-of-profile by the egress forwarding plane.

exceed

The **exceed** parameter is mutually exclusive to the **out**, **inplus**, and **in** parameters following the profile reclassification action keyword. **In, exceed**, **inplus**, or **out** must be specified when the profile keyword is present. When **exceed** is specified, any packets matching the reclassification rule will be treated as exceed-profile by the egress forwarding plane.

inplus

The **inplus** parameter is mutually exclusive to the **out**, **exceed**, and **in** parameters following the profile reclassification action keyword. **In, exceed**, **inplus**, or **out** must be specified when the profile keyword is present. When **inplus** is specified, any packets matching the reclassification rule will be treated as inplus-profile by the egress forwarding plane.

policer *policer-id*

When the action policer command is executed, a valid policer ID must be specified. The parameter policer ID references a policer ID that has already been created within the SAP egress QoS policy.

Values 1 to 63

port-redirect-group-queue queue *queue-id*

Used to override the forwarding class default egress queue destination to an egress port queue group. The specific egress queue group instance to use is specified at the time the QoS policy is applied to the SAP. Therefore, this parameter is only valid if SAP-based redirection is required. The queue parameter overrides the policer's default egress queue destination to a specified queue-id in the egress port queue group instance.

Values 1 to 8

queue *queue-id*

This parameter overrides the policer's default egress queue destination to a specified local SAP queue of that queue-id. A queue of ID queue-id must exist within the egress QoS policy.

Values 1 to 8

use-fc-mapped-queue

This parameter overrides the policer's default egress queue destination to the queue mapped by the traffic's forwarding class.

Platforms

All

action

Syntax

action [**fc** *fc-name* **profile** {**in** | **out** | **exceed** | **inplus**}] [**port-redirect-group** {**queue** *queue-id* | **policer** *policer-id* [**queue** *queue-id*]}]

Context

[Tree] (config>qos>network>egress>ipv6-criteria>entry action)

[Tree] (config>qos>network>egress>ip-criteria>entry action)

Full Context

configure qos network egress ipv6-criteria entry action

configure qos network egress ip-criteria entry action

Description

This command defines the reclassification actions that are performed on any packet matching the defined IP flow criteria within the entry's matched node. When defined under the **ip-criteria** context, the reclassification only applies to IPv4 packets. When defined under the **ipv6-criteria** context, the reclassification only applies to IPv6 packets.

If an egress packet matches the specified IP flow entry, the forwarding class and profile may be overridden. By default, the forwarding class and profile of the packet are derived from ingress classification and profiling functions. Matching an IP flow reclassification entry will override all IP precedence-based or DSCP-based reclassification rule actions when an explicit reclassification action is defined for the entry.

When an IP flow entry is first created, the entry will have no explicit behavior defined as the reclassification actions to be performed. When the entry is defined with no action, the entry will not be populated in the IP flow reclassification list used to evaluate egress packets. An IP flow reclassification entry is only added to the evaluation list when the action command for the entry is executed.

The **fc** and **profile** keywords are optional. When specified, the egress classification rule will overwrite the forwarding class and profile derived from ingress. The new forwarding class and profile are used for egress remarking, queue mapping decisions, and queue congestion behavior.

The **port-redirect-group** keyword is optional. When specified, the egress packet will be redirected to the configured queue or policer in the specified egress network queue group. By default, the policed forwarded traffic will use the regular network queue to which the packet's forwarding class is mapped. Alternatively, a queue in the network egress queue group instance can be used for post-policed traffic by specifying a queue after the **policer** parameter. The **port-redirect-group** keyword requires that the network egress queue group instance is specified when this network QoS policy is applied to a network interface. The **port-redirect-group** is not supported on a 7750 SR-a4/a8.

The **no** form of this command removes all reclassification actions from the IP flow reclassification entry and also removes the entry from the evaluation list. An entry removed from the evaluation list will not be matched to any egress packets.

Default

no action

Parameters

fc *fc-name*

The fc reclassification action is optional. When specified, packets matching the IP flow reclassification entry will be explicitly reclassified to the forwarding class specified as *fc-name* regardless of the ingress classification decision. The *fc-name* defined must be one of the eight forwarding classes supported by the system. The profile reclassification action is mandatory when an **fc** is specified. To remove the forwarding class reclassification action for the IP flow entry, the action command must be re-executed without the fc reclassification action defined.

Values be, l2, af, l1, h2, ef, h1, nc

profile {in | out | exceed | inplus}

The profile reclassification action is mandatory when an fc is specified, otherwise it is optional. When specified, packets matching the IP flow reclassification entry will be explicitly reclassified to the configured profile regardless of the ingress profiling decision. **In**, **exceed**, **inplus**, or **out** must be specified when the profile keyword is present. To remove the profile reclassification action for the IP flow reclassification entry, the action command must be re-executed without the profile reclassification action defined.

in

When specified, any packets matching the reclassification rule will be treated as in-profile by the egress forwarding plane.

out

When specified, any packets matching the reclassification rule will be treated as out-of-profile by the egress forwarding plane.

exceed

When specified, any packets matching the reclassification rule will be treated as exceed-profile by the egress forwarding plane.

inplus

When specified, any packets matching the reclassification rule will be treated as inplus-profile by the egress forwarding plane.

queue *queue-id*

Used to override the forwarding class default egress queue destination to the specified network egress queue group instance queue. The specific egress queue group instance to use is specified at the time the QoS policy is applied to the network interface.

Values 1 to 8

policer *policer-id*

Specifies a valid policer ID that has already been created within the network egress queue group instance.

Values 1 to 16

queue *queue-id*

The queue following the configured policer overrides the default policed traffic egress queue destination to a specified queue in the network egress queue group instance.

Values 1 to 8

[Tree] (config>qos>network>ingress>ipv6-criteria>entry action)

Full Context

configure qos network ingress ip-criteria entry action

configure qos network ingress ipv6-criteria entry action

Description

This command defines the reclassification actions that are performed on any packet matching the defined IP flow criteria within the entry's matched node. When defined under the **ip-criteria** context,

the reclassification only applies to IPv4 packets. When defined under the **ipv6-criteria** context, the reclassification only applies to IPv6 packets.

If an ingress packet matches the specified IP flow entry, the forwarding class and profile may be overridden. By default, the forwarding class and profile of the packet are derived from ingress classification and profiling functions. Matching an IP flow reclassification entry will override all non-criteria reclassification rule actions when an explicit reclassification action is defined for the entry.

When an IP flow entry is first created, the entry will have no explicit behavior defined as the reclassification actions to be performed. When the entry is defined with no action, the entry will not be populated in the IP flow reclassification list used to evaluate ingress packets. An IP flow reclassification entry is only added to the evaluation list when the action command for the entry is executed.

The **no** form of this command removes all reclassification actions from the IP flow reclassification entry and also removes the entry from the evaluation list. An entry removed from the evaluation list will not be matched to any ingress packets.

Default

no action

Parameters

fc *fc-name*

The fc reclassification action is optional. When specified, packets matching the IP flow reclassification entry will be explicitly reclassified to the forwarding class specified as *fc-name* regardless of the ingress classification decision. The *fc-name* defined must be one of the eight forwarding classes supported by the system. The profile reclassification action is mandatory when an **fc** is specified. To remove the forwarding class reclassification action for the IP flow entry, the action command must be re-executed without the fc reclassification action defined.

Values be, l2, af, l1, h2, ef, h1, nc

profile {in | out}

The profile reclassification action is mandatory. Packets matching the IP flow reclassification entry will be explicitly reclassified to the configured profile regardless of other ingress profiling decisions. **In** or **out** must be specified when the profile keyword is present. To remove the profile reclassification action for the IP flow reclassification entry, the action command must be re-executed without the profile reclassification action defined.

in

When specified, any packets matching the reclassification rule will be treated as in-profile by the ingress forwarding plane.

out

When specified, any packets matching the reclassification rule will be treated as out-of-profile by the ingress forwarding plane.

Platforms

All

action

Syntax

action {**replace** | **drop** | **keep**}

no action

Context

[Tree] (config>router>if>dhcp>option action)

Full Context

configure router interface dhcp option action

Description

This command configures the processing required when the SR-Series router receives a DHCP request that already has a Relay Agent Information Option (Option 82) field in the packet.

The **no** form of this command returns the system to the default value.

Default

Per RFC 3046, *DHCP Relay Agent Information Option*, section 2.1.1, *Reforwarded DHCP requests*, the default is to keep the existing information intact. The exception to this is if the GI address of the received packet is the same as the ingress address on the router. In that case the packet is dropped and an error is logged.

Parameters

replace

In the upstream direction (from the user), the existing Option 82 field is replaced with the Option 82 field from the router. In the downstream direction (toward the user) the Option 82 field is stripped (in accordance with RFC 3046).

drop

The packet is dropped, and an error is logged.

keep

The existing information is kept in the packet and the router does not add any additional information. In the downstream direction the Option 82 field is not stripped and is sent on toward the client.

The behavior is slightly different in case of Vendor Specific Options (VSOs). When the keep parameter is specified, the router will insert his own VSO into the Option 82 field. This will only be done when the incoming message has already an Option 82 field.

If no Option 82 field is present, the router will not create the Option 82 field. In this in that case, no VSO will be added to the message.

All

action

Syntax

action {*action*}

no action

Context

[Tree] (config>serv>mrp>mrp-policy>entry action)

Full Context

configure service mrp mrp-policy entry action

Description

This command specifies the action to be applied to the MMRP attributes (Group B-MACs) whose ISIDs match the specified ISID criteria in the related entry.

The *action* keyword must be entered for the entry to be active. Any filter entry without the action keyword will be considered incomplete and will be inactive. If neither keyword is specified (no action is used), this is considered a No-Op policy entry used to explicitly set an entry inactive without modifying match criteria or removing the entry itself. Multiple action statements entered will overwrite previous actions parameters when defined. To remove a parameter, use the **no** form of the action command with the specified parameter.

The **no** form of the command removes the specified action statement. The entry is considered incomplete and hence rendered inactive without the action keyword.

Default

no action

Parameters

action

Specifies the action for the MRP policy entry.

block

Specifies that the matching MMRP attributes will not be declared or registered on this SAP or SDP.

allow

Specifies that the matching MMRP attributes will be declared and registered on this SAP or SDP.

end-station

Specifies that an end-station emulation is present on this SAP or SDP for the MMRP attributes related with matching ISIDs. Equivalent action with the block keyword on that SAP or SDP. The attributes associated with the matching ISIDs are not declared or registered on the SAP or SDP. The matching attributes on the other hand are mapped as static MMRP entries on the SAP or SDP which implicitly instantiates in the data plane as a MFIB entry associated with that SAP or SDP for the related Group B-MAC. For the other SAPs/SDPs in the BVPLS with MRP enabled (no shutdown). This means that the

permanent declaration of the matching attributes, as in the case when the IVPLS instances associated with these ISIDs were locally configured.

If an MRP policy has end-station action in one entry, the only default action allowed in the policy is block. Also no other actions are allowed to be configured in other entry configured under the policy.

This policy will apply even if the MRP is shutdown on the local SAP or SDP or for the whole BVPLS to allow for manual creation of MMRP entries in the data plane. Specifically the following rules apply:

- If **service vpls mrp shutdown** is executed, and the MMRP on all SAP or SDPs is shutdown, then MRP PDUs pass-through transparently.
- If **service vpls mrp no shutdown**, and the **endstation** statement (even with no ISID values in the related match statement) is used in an MRP policy applied to SAP or SDP, then no declaration is sent on SAP or SDP. The provisioned ISIDs in the match statement are registered on that SAP or SDP and are propagated on all the other MRP enabled endpoints.

configure system security management-access-filter ipv6-filter entry action

configure system security management-access-filter mac-filter entry action

configure system security management-access-filter ip-filter entry action

Description

This command creates the action associated with the management access filter match criteria entry.

The **action** keyword is required. If no **action** is defined, the filter is ignored. If multiple action statements are configured, the last one overwrites previous configured actions.

If the packet does not meet any of the match criteria the configured **default action** is applied.

Parameters

permit

Specifies that packets matching the configured criteria will be permitted.

deny

Specifies that packets matching the configured selection criteria will be denied and that a ICMP host unreachable message will not be issued.

deny-host-unreachable

Specifies that packets matching the configured selection criteria will be denied and that a host unreachable message will not be issued.

The **deny-host-unreachable** parameter only applies to ip-filter and ipv6-filter.

5.70 activate

activate

Syntax

activate [*file-url*] [**now**]

Context

[Tree] (admin>system>license activate)

Full Context

admin system license activate

Description

This command performs an activation on the license file pointed to by the command line argument. The file is first validated as described in the **admin>system>license>validate** command and upon success, replaces the existing license attributes in the system with the information in the new license file.

The license attributes that are active on a system can be viewed with the **show>licensing>entitlements** command.

Note:
If the CLM tool is being used for license management, it shall perform the validation and activation and there is no need to enter these commands manually.

Parameters

file-url

Specifies the file URL location to read the license file.

Values local-url, remote-url

Note:
IPv6 addresses apply only to 7750 SR and 7950 XRS.

now

If the **now** keyword is not present, the operator is prompted to confirm the activation. With the **now** keyword the license file is activated without the additional prompt.

active-flow-timeout

Syntax

active-flow-timeout *seconds*

no active-flow-timeout

Context

[Tree] (config>cflowd active-flow-timeout)

Full Context

configure cflowd active-flow-timeout

Description

This command configures the maximum amount of time before an active flow is aged out of the active cache. If an individual flow is active for the specified amount of time, the flow is aged out and a new flow is created on the next packet sampled for that flow.

Existing flows do not inherit the new **active-flow-timeout** value if this parameter is changed while **cflowd** is active. The **active-flow-timeout** value for a flow is set when the flow is first created in the active cache table and does not change dynamically.

The **no** form of this command resets the timeout back to the default value.

Default

active-flow-timeout 1800

Parameters

seconds

Specifies the value, in seconds, before an active flow is exported.

Values 30 to 36000

Platforms

All

[Tree] (config>service>cpipe>endpoint active-hold-delay)

Full Context

configure service ipipe endpoint active-hold-delay

configure service epipe endpoint active-hold-delay

configure service cpipe endpoint active-hold-delay

Description

This command specifies that the node will delay sending the change in the T-LDP status bits for the VLL endpoint when the MC-LAG transitions the LAG subgroup which hosts the SAP for this VLL endpoint from **active** to **standby** or when any object in the endpoint. For example, SAP, ICB, or regular spoke SDP, transitions from up to down operational state.

By default, when the MC-LAG transitioned the LAG subgroup which hosts the SAP for this VLL endpoint from **active** to **standby**, the node sends immediately new T-LDP status bits indicating the new value of "standby" over the spoke SDPs which are on the mate-endpoint of the VLL. The same applies when any object in the endpoint changes an operational state from up to down.

There is no delay applied to the VLL endpoint status bit advertisement when the MC-LAG transitions the LAG subgroup which hosts the SAP from **standby** to **active** or when any object in the endpoint transitions to an operationally up state.

Default

active-hold-delay 0

Parameters

active-hold-delay

Specifies the active hold delay in 100s of milliseconds.

A value of zero means that when the MC-LAG transitioned the LAG subgroup which hosts the SAP for this VLL endpoint from **active** to **standby,** the node sends immediately new T-LDP status bits indicating the new value of **standby** over the spoke SDPs which are on the mate-endpoint of the VLL. The same applies when any object in the endpoint changes an operational state from up to down.

configure isa wlan-gw-group active-iom-limit

Description

This command specifies the number of WLAN-GW IOMs used as active IOMs from the total number of configured WLAN-GW IOMs. If there are more configured IOM than active-iom-limit, then the remaining number of IOMs is designated as backup(s).

The **no** form of this command removes the number from the configuration.

Parameters

number

Specifies the number of IOMs in this WLAN Gateway ISA group that are intended for active use.

Values 1 to 3

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.78 active-mda-limit

active-mda-limit

Syntax

active-mda-limit *number*

no active-mda-limit

Context

[Tree] (config>isa>wlan-gw-group active-mda-limit)

Full Context

configure isa wlan-gw-group active-mda-limit

Description

This command specifies how many ISAs may be in active use by the WLAN-GW group at the same time. If the maximum number of active ISAs is reached and more ISAs are added to the group, the new ISAs are considered to be in standby mode.

The **no** form of this command removes the limit on the maximum number of active ISAs.

Parameters

number

Specifies the number of WLAN-GW ISAs intended for active use.

Values 1 to 14

Platforms

7750 SR, 7750 SR-e, 7750 SR-s

active-mda-limit

Syntax

active-mda-limit *number*

no active-mda-limit

Context

[Tree] (config>isa>nat-group active-mda-limit)

Full Context

configure isa nat-group active-mda-limit

Description

This command configures the number of active ISAs in active-standby ISA redundancy model for NAT. The active ISAs are automatically selected by the system and any the remaining ISA beyond the number of active limit will automatically assume the standby role. An ISA in the standby mode is idle until the failure of an active ISA occurs. Standby ISA can accept traffic from exactly one failed active ISA. Multiple standby ISAs can be configured in the system to protect against multiple simultaneous failures.

Once the active ISA fails, the standby ISA will start forwarding traffic. NAT translations from the failed ISA will have to be re-initiated by the clients and consequently setup on the newly active ISA.

In order for this command to take effect, the intra-chassis redundancy mode must be set to active-standby (**config>isa>nat-group>redundancy active-standby**).

Default

no active-mda-limit

Parameters

number

Specifies the active MDA limit.

Values 1 to 14

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.79 active-mda-number

active-mda-number

Syntax

active-mda-number *number*

no active-mda-number

Context

[Tree] (config>isa>tunnel-grp active-mda-number)

Full Context

configure isa tunnel-group active-mda-number

Description

This command specifies the number of active MS-ISA within all configured MS-ISA in the tunnel-group with multi-active enabled. IPsec traffic will be load balanced across all active MS-ISAs. If the number of configured MS-ISA is greater than the active-mda-number then the delta number of MS-ISA will be backup.

Default

active-mda-number 1

Parameters

number

Specifies the number of active MDAs.

Values 1 to 16

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.80 active-outbound-sa

active-outbound-sa

Syntax

active-outbound-sa *spi*

no active-outbound-sa

Context

[Tree] (config>grp-encryp>encryp-keygrp active-outbound-sa)

Full Context

configure group-encryption encryption-keygroup active-outbound-sa

Description

This command specifies the Security Association, referenced by the Security Parameter Index (SPI), to use when performing encryption and authentication on NGE packets egressing the node for all services configured using this key group.

The **no** form of the command returns the parameter to its default value and is the same as removing this key group from all outbound direction key groups in all services configured with this key group (that is, all packets of services using this key group will egress the node in without being encrypted).

Parameters

spi

Specifies the SPI to use for packets of services using this key group when egressing the node.

Values 1 to 127

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

ad-per-es-route-target evi-rt

ad-per-es-route-target evi-rt-set route-distinguisher *ip-address* [**extended-evi-range**]

Context

[Tree] (config>service>system>bgp-evpn ad-per-es-route-target)

Full Context

configure service system bgp-evpn ad-per-es-route-target

Description

This command controls how Ethernet AD per-ES routes are generated.

The system can either send a separate Ethernet AD per-ES route per service, or an Ethernet AD per-ES route aggregating the route-targets for multiple services. While both alternatives can interoperate, RFC 7432 states that the EVPN Auto-Discovery per-ES route must be sent with a set of route-targets corresponding to all the EVIs defined on the Ethernet Segment. This command supports both options.

The default **ad-per-es-route-target evi-rt** option configures the system to send a separate AD per-ES route per service.

When enabled, the **evi-rt-set** option allows the aggregation of routes: a single AD per-ES route with the associated RD (ip-address:1) and a set of EVI route-targets are advertised (to a maximum of 128). When a significant number of EVIs are defined in the Ethernet Segment (hence the number of route-targets), the system sends more than one route. For example:

- AD per-ES route for evi-rt-set 1 will be sent with RD ip-address:1
- AD per-ES route for evi-rt-set 2 will be sent with RD ip-address:2

Default

ad-per-es-route-target evi-rt

Parameters

evi-rt

Specifies the option to advertise a separate AD per-ES route per service.

evi-rt-set

Specifies the option to advertise a set of AD per-ES routes aggregating the route-targets for all the services in the Ethernet Segment.

ip-address

Specifies the ip-address part of the route-distinguisher being used in the evi-rt-set option.

extended-evi-range

Specifies that the system reserves the RD *comm-val* 1 to 65535 out of the type 1 RD that is used for AD per-ES routes.

Platforms

All

5.87 ad-validation

ad-validation

Syntax

ad-validation {**fall-through** | **drop**}

no ad-validation

Context

[Tree] (config>system>dns>dnssec ad-validation)

Full Context

configure system dns dnssec ad-validation

Description

This command enables validation of the presence of the AD-bit in responses from the DNS servers, and reports a warning to the SECURITY log if DNSSEC validation was not possible.

This command requires either the fall-through or drop parameters be configured. When the fall-through parameter is supplied, the system will allow DNS responses that do not pass DNSSEC validation to be accepted and logged. When the drop parameter is specified, the system will reject and log DNS responses that do not pass DNSSEC validation and the resolution will appear to fail.

Default

no ad-validation

Parameters

fall-through

Specifies that the DNSSEC validator should allow non-DNSSEC responses to fall-through to permit resolution in case of validation failure.

drop

Specifies that the DNSSEC validator should drop non-DNSSEC responses in case of validation failure.

Platforms

All

5.88 adapt-qos

adapt-qos

Syntax

adapt-qos {**link** | **port-fair** | **distribute** [**include-egr-hash-cfg**]}

Context

[Tree] (config>lag>access adapt-qos)

Full Context

configure lag access adapt-qos

Description

This command specifies how the LAG SAP queue and virtual scheduler buffering and rate parameters are adapted over multiple active XMAs/MDAs. This command applies only to access LAGs.

Default

adapt-qos distribute

Parameters

link

Specifies that the LAG will create the SAP queues and virtual schedulers with the actual parameters on each LAG member port.

port-fair

Places the LAG instance into a mode that enforces QoS bandwidth constraints in the following manner:

- all egress QoS objects associated with the LAG instance are created on a per port basis
- bandwidth is distributed over these per port objects based on the proportion of the port's bandwidth relative to the total of all active ports bandwidth within the LAG
- the **include-egr-hash-cfg** behavior is automatically enabled allowing the system to detect objects that hash to a single egress link in the lag and enabling full bandwidth for that object on the appropriate port

distribute

Creates an additional internal virtual scheduler per IOM/XCM as parent of the configured SAP queues and virtual schedulers per LAG member port on that IOM/XCM. This internal virtual scheduler limits the total amount of egress bandwidth for all member ports on the IOM/XCM to the bandwidth specified in the egress qos policy.

include-egr-hash-cfg

Specifies whether explicitly configured hashing should factor into the egress buffering and rate distribution.

When this parameter is configured, all SAPs on this LAG which have explicit hashing configured, the egress HQoS and HPol (including queues, policers, schedulers and arbiters) will receive 100% of the configured bandwidth (essentially operating in adapt-qos link mode). For any Multi-Service-Sites assigned to such a LAG, bandwidth will continue to be divided according to adapt-qos distribute mode.

A LAG instance that is currently in adapt-qos link mode may be placed at any time in port-fair mode. Similarly, a LAG instance that is currently in adapt-qos port-fair mode may be placed at any time in link mode. However, a LAG instance in adapt-qos distribute mode may not be placed into port-fair (or link) mode while QoS objects are associated with the LAG instance. To move from distribute to port-fair mode it is necessary to remove all QoS objects from the LAG instance.

Platforms

All

adapt-qos

Syntax

adapt-qos {**distribute** | **link** | **port-fair**}

no adapt-qos

Context

[Tree] (config>eth-tunnel>lag-emulation>access adapt-qos)

Full Context

configure eth-tunnel lag-emulation access adapt-qos

Description

This command specifies how the emulated LAG queue and virtual scheduler buffering and rate parameters are adapted over multiple active MDAs.

The **no** form of the command reverts to the default.

Parameters

distribute

Creates an additional internal virtual scheduler per line card as parent of the configured SAP queues and virtual schedulers per member path on that line card. This internal virtual scheduler limits the total amount of egress bandwidth for all member paths on the line card to that line card's share of the bandwidth specified in the egress qos policy. This mode is not supported together with an egress port scheduler or the use of egress queue groups.

link

Specifies that the emulated LAG will create the SAP queues and virtual schedulers with the bandwidth specified in the egress QoS policy on each member path.

port-fair

Specifies that the emulated LAG will create the SAP queues and virtual schedulers on each member path based on the bandwidth specified in the egress QoS policy divided by the number of active paths.

Platforms

5.89 adaptation-rule

adaptation-rule

Syntax

adaptation-rule [**pir** *adaptation-rule*] [**cir** *adaptation-rule*]

no adaptation-rule

Context

[Tree] (config>qos>sap-egress>queue adaptation-rule)

Full Context

configure qos sap-egress queue adaptation-rule

Description

This command defines the method used by the system to derive the operational CIR and PIR settings when the queue is provisioned in hardware. For the CIR and PIR parameters individually, the system attempts to find the best operational rate depending on the defined constraint.

When a specific **adaptation-rule** is removed, the default constraints for **pir** and **cir** apply.

The **no** form of this command removes any explicitly defined constraints used to derive the operational CIR and PIR created by the application of the policy.

Default

adaptation-rule pir closest cir closest

Parameters

pir

Defines the constraints enforced when adapting the queue's PIR. The **pir** parameter requires a qualifier that defines the constraint used when deriving the operational PIR for the queue. When the **pir** parameter is not specified, the default constraint applies.

Values **max** — Specifies that the operational PIR for the queue will be equal to or less than the requested rate.

min — Specifies that the operational PIR for the queue will be equal to or greater than the requested rate.

closest — Specifies that the operational PIR for the queue will be the rate closest to the requested rate.

cir

Defines the constraints enforced when adapting the queue's CIR defined. The **cir** parameter requires a qualifier that defines the constraint used when deriving the operational CIR for the queue. When the **cir** parameter is not specified, the default constraint applies.

Values **max** — Specifies that the operational rate for the queue will be equal to or less than the requested rate.

min — Specifies that the operational rate for the queue will be equal to or greater than the requested rate.

closest — Specifies that the operational rate for the queue will be the rate closest to the requested rate.

configure service ies subscriber-interface group-interface sap egress queue-override queue adaptation-rule

configure service vpls sap egress queue-override queue adaptation-rule

Description

This command overrides specific attributes of the specified queue’s adaptation rule parameters. The adaptation rule controls the method used by the system to derive the operational CIR and PIR settings when the queue is provisioned in hardware. For the CIR and PIR parameters individually, the system attempts to find the best operational rate depending on the defined constraint.

This command is ignored for egress HSQ queue group queues which are attached to an HS WRR group within an associated HS attachment policy. In this case, the configuration of the adaptation rule is performed under the **hs-wrr-group** within the SAP egress QoS policy.

The **no** form of this command removes any explicitly defined constraints used to derive the operational CIR and PIR created by the application of the policy. When a specific **adaptation-rule** is removed, the default constraints for **rate** and **cir** apply.

Default

no adaptation-rule

Parameters

pir

Specifies the constraints enforced when adapting the PIR rate defined within the **queue** *queue-id* **rate** command. The **pir** parameter requires a qualifier that defines the constraint used when deriving the operational PIR for the queue. When the **rate** command is not specified, the default applies.

cir

Specifies the constraints enforced when adapting the CIR rate defined within the **queue** *queue-id* **rate** command. The **cir** parameter requires a qualifier that defines the constraint used when deriving the operational CIR for the queue. When the **cir** parameter is not specified, the default constraint applies.

adaptation-rule

Specifies the CIR and PIR adaptation rules.

Values max — The **max** (maximum) option is mutually exclusive with the **min** and **closest** options. When **max** is defined, the operational PIR for the queue is equal to or less than the administrative rate specified using the **rate** command.

min — The **min** (minimum) option is mutually exclusive with the **max** and **closest** options. When **min** is defined, the operational PIR for the queue is equal to or greater than the administrative rate specified using the **rate** command.

closest — The **closest** parameter is mutually exclusive with the **min** and **max** parameter. When **closest** is defined, the operational PIR for the queue is the rate closest to the rate specified using the **rate** command.

configure service ipipe sap egress queue-override queue adaptation-rule

configure service epipe sap egress queue-override queue adaptation-rule

configure service ipipe sap ingress queue-override queue adaptation-rule

configure service epipe sap ingress queue-override queue adaptation-rule

Description

This command can be used to override specific attributes of the specified queue's adaptation rule parameters. The adaptation rule controls the method used by the system to derive the operational CIR and PIR settings when the queue is provisioned in hardware. For the CIR and PIR parameters individually, the system attempts to find the best operational rate depending on the defined constraint.

This command is ignored for egress HSQ queue group queues which are attached to an HS WRR group within an associated HS attachment policy. In this case the configuration of the adaptation rule is performed under the hs-wrr-group within the SAP egress QoS policy.

The **no** form of this command removes any explicitly defined constraints used to derive the operational CIR and PIR created by the application of the policy. When a specific **adaptation-rule** is removed, the default constraints for **rate** and **cir** apply.

Default

no adaptation-rule

Parameters

pir

The **pir** parameter defines the constraints enforced when adapting the PIR rate defined within the **queue** *queue-id* **rate** command. The **pir** parameter requires a qualifier that defines the constraint used when deriving the operational PIR for the queue. When the **rate** command is not specified, the default applies.

cir

The **cir** parameter defines the constraints enforced when adapting the CIR rate defined within the **queue** *queue-id* **rate** command. The **cir** parameter requires a qualifier that defines the constraint used when deriving the operational CIR for the queue. When the **cir** parameter is not specified, the default constraint applies.

adaptation-rule

Specifies the criteria to use to compute the operational CIR and PIR values for this queue, while maintaining a minimum offset.

Values **max** — The **max** (maximum) keyword is mutually exclusive with the **min** and **closest** options. When **max** is defined, the operational PIR for the queue will be equal to or less than the administrative rate specified using the **rate** command.

min — The **min** (minimum) keyword is mutually exclusive with the **max** and **closest** options. When **min** is defined, the operational PIR for the queue will be equal to or greater than the administrative rate specified using the **rate** command.

closest — The **closest** parameter is mutually exclusive with the **min** and **max** parameter. When **closest** is defined, the operational PIR for the queue will be the rate closest to the rate specified using the **rate** command.

Description

This command can be used to override specific attributes of the specified queue's adaptation rule parameters. The adaptation rule controls the method used by the system to derive the operational CIR and PIR settings when the queue is provisioned in hardware. For the CIR and PIR parameters individually, the system attempts to find the best operational rate depending on the defined constraint.

This command is ignored for egress HSQ queue group queues which are attached to an HS WRR group within an associated HS attachment policy. In this case, the configuration of the adaptation rule is performed under the **hs-wrr-group** within the SAP egress QoS policy.

The **no** form of this command removes any explicitly defined constraints used to derive the operational CIR and PIR created by the application of the policy. When a specific **adaptation-rule** is removed, the default constraints for **rate** and **cir** apply.

Default

no adaptation-rule

Parameters

pir

The **pir** parameter defines the constraints enforced when adapting the PIR rate defined within the **queue** *queue-id* **rate** command. The **pir** parameter requires a qualifier that defines the constraint used when deriving the operational PIR for the queue. When the **rate** command is not specified, the default applies.

cir

The **cir** parameter defines the constraints enforced when adapting the CIR rate defined within the **queue** *queue-id* **rate** command. The **cir** parameter requires a qualifier that defines the constraint used when deriving the operational CIR for the queue. When the **cir** parameter is not specified, the default constraint applies.

adaptation-rule

Specifies the criteria to use to compute the operational CIR and PIR values for this queue, while maintaining a minimum offset.

Values **max** — The **max** (maximum) keyword is mutually exclusive with the **min** and **closest** options. When **max** is defined, the operational PIR for the queue will be equal to or less than the administrative rate specified using the **rate** command.

min — The **min** (minimum) keyword is mutually exclusive with the **max** and **closest** options. When **min** is defined, the operational PIR for the queue will be equal to or greater than the administrative rate specified using the **rate** command.

closest — The **closest** parameter is mutually exclusive with the **min** and **max** parameter. When **closest** is defined, the operational PIR for the queue will be the rate closest to the rate specified using the **rate** command.

Description

This command defines the method used by the system to derive the operational CIR and PIR settings when the queue is provisioned in hardware. For the CIR and PIR parameters individually, the system attempts to find the best operational rate depending on the defined option. To change the CIR adaptation rule only, the current PIR rule must be part of the command executed.

The **no** form of this command removes any explicitly defined constraints used to derive the operational CIR and PIR created by the application of the policy. When a specific adaptation-rule is removed, the default constraints for rate and cir apply.

Default

adaptation-rule pir closest cir closest

Parameters

max

The operational PIR or CIR for the queue will be equal to or less than the administrative rate specified using the **rate** command.

min

The operational PIR or CIR for the queue will be equal to or greater than the administrative rate specified using the **rate** command.

closest

The operational PIR or CIR for the queue will be the rate closest to the rate specified using the **rate** command.

[Tree] (config>qos>sap-ingress>policer adaptation-rule)

Full Context

configure qos sap-egress policer adaptation-rule

configure qos sap-ingress policer adaptation-rule

Description

This command is used to define how the policer's configuration parameters are translated into the underlying hardware capabilities used to implement each policer instance. For instance, the configured rates for the policer need to be mapped to the timers and decrement granularity used by the hardware's leaky bucket functions that actually perform the traffic metering. If a rate is defined that cannot be exactly matched by the hardware, the adaptation-rule setting provides guidance for which hardware rate should be used.

The hardware also needs to adapt the given mbs and cbs values into the PIR bucket violate threshold (discard) and the CIR bucket exceed threshold (out-of-profile). The hardware may not have an exact threshold match that it can use. The system treats the mbs and cbs values as minimum threshold values.

The **no** form of this command is used to return the policer's metering and profiling hardware adaptation rules to closest.

Parameters

pir *adaptation-rule*

When the optional **pir** parameter is specified, the **max**, **min,** or **closest** keyword qualifier must follow.

Values max — Specifies that the metering rate defined for the policer is the maximum allowed rate. The system will choose a hardware supported rate that is closest but not exceeding the specified rate.

min — Specifies that the metering rate defined for the policer is the minimum allowed rate. The system will choose a hardware supported rate that is closest but not lower than the specified rate.

closest — Specifies that the metering rate defined for the policer is the target rate. The system will choose a hardware supported rate that is closest to the specified rate.

Default closest

cir *adaptation-rule*

When the optional **cir** parameter is specified, the **max**, **min**, or **closest** keyword qualifier must follow.

Values max — Specifies that the profiling rate defined for the policer is the maximum allowed rate. The system will choose a hardware supported rate that is closest but not exceeding the specified rate.

min — Specifies that the profiling rate defined for the policer is the minimum allowed rate. The system will choose a hardware supported rate that is closest but not lower than the specified rate.

closest — Specifies that the profiling rate defined for the policer is the target rate. The system will choose a hardware supported rate that is closest to the specified rate.

configure qos sap-ingress queue adaptation-rule

Description

This command defines the method used by the system to derive the operational FIR, CIR and PIR settings when the queue is provisioned in hardware. For the FIR, CIR and PIR parameters individually, the system attempts to find the best operational rate depending on the defined constraint.

When a specific **adaptation-rule** is removed, the default constraints for **pir**, **cir** and **fir** apply.

The **no** form of this command removes any explicitly defined constraints used to derive the operational FIR, CIR and PIR created by the application of the policy.

Default

adaptation-rule pir closest cir closest fir closest

Parameters

pir *adaptation-rule*

Defines the constraints enforced when adapting the queue's PIR. The **pir** parameter requires a qualifier that defines the constraint used when deriving the operational PIR for the queue. When the **pir** parameter is not specified, the default applies.

cir *adaptation-rule*

Defines the constraints enforced when adapting the queue's CIR. The **cir** parameter requires a qualifier that defines the constraint used when deriving the operational CIR for the queue. When the **cir** parameter is not specified, the default constraint applies.

fir

Defines the constraints enforced when adapting the queue's FIR. The **fir** parameter requires a qualifier that defines the constraint used when deriving the operational CIR for the queue. When the **fir** parameter is not specified, the default constraint applies. FIR is only supported on FP4 hardware and is ignored when the related policy is applied to FP2- or FP3-based hardware.

max

Specifies that the operational rate for the queue will be equal to or less than the requested rate.

min

Specifies that the operational rate for the queue will be equal to or greater than the requested rate.

closest

Specifies that the operational rate for the queue will be the rate closest to the requested rate.

Description

This command specifies how the system should resolve differences between the specified scheduling limit derived from the WRR group's rate command and the actual operational rate obtainable in hardware. The **min**, **max**, and **closest** mutually exclusive keywords specify whether the next highest rate, next lowest rate, or closest rate should be selected by the system.

The **no** form of the command reverts to the default value.

Default

adaptation-rule pir closest

Parameters

adaptation-rule

Specifies the adaptation rule (**min**, **max**, or **closest**) to be used while computing the operational PIR value. The adaptation rule specifies the rules to compute the operational values while maintaining minimum offset. The **min**, **max**, and **closest** keywords are mutually exclusive.

Values min — When **min** is specified, the queue's rate parameter is treated as the minimum rate to shape the queue. The hardware chooses the appropriate timers and PIR leaky bucket behavior to ensure that the queues shaping rate is the closest possible value without going under the specified rate.

max — When **max** is specified, the queue's rate parameter is treated as the maximum rate to shape the queue. The hardware chooses the appropriate timers and PIR leaky bucket behavior to ensure that the queue's shaping rate is the closest possible value without going over the specified rate.

closest — When **closest** is specified, the queue's rate parameter is treated as the target rate to shape the queue. The hardware chooses the appropriate timers and PIR leaky bucket behavior to ensure that the queues shaping rate is the closest possible value and can be higher or lower than the specified rate.

Context

[Tree] (config>qos>adv-config-policy>child-control>offered-measurement add)

Full Context

configure qos adv-config-policy child-control offered-measurement add

Description

This command is used to increase the measured rate of the policer or queue associated with the policy. The offered rate (capped by the administrative PIR configured on the queue or policer) is usually used unaltered by the parent virtual scheduler. The add command allows this measured rate to be increased by the specified amount or by a percentage of the administrative PIR. The resulting rate will not exceed the administrative PIR.

The parent scheduler uses the modified measured rate as the available work load for the queue or policer in determining how much bandwidth the child should receive from the bandwidth distribution algorithm.

One example of when an increase in the measured offered rate may be desired is when a queue or policer is handling VoIP traffic. A characteristic of VoIP is the step nature in how traffic is used. Each call typically adds a certain maximum amount to the overall load. By using the add command, the bandwidth required for the next added call may be included in the current measured rate. This allows the virtual scheduler to allocate sufficient bandwidth to the queue or policer so that when the call is made the scheduling algorithm does not need to run to increase the bandwidth.

A side effect of increasing the measured offered rate is that if the extra bandwidth is allocated by the virtual scheduler, the available bandwidth to lower priority queues or policers is diminished even though the extra allocated bandwidth may not be in use. If this is the case, the effect will be seen as an underrun in the aggregate output of the virtual scheduler.

If the add command is used with a percent-based value, the increase is a function of the configured PIR value on the policer or queue. In this case, care should be taken that the child is either configured with an explicit PIR rate (other than max) or the child's administrative PIR is defined using the percent-rate command with the local parameter enabled if an explicit value is not desired. When a maximum PIR is in use on the child, the system attempts to interpret the maximum child forwarding rate. This rate could be very large if the child is associated with multiple ingress or egress ports.

Except for the overall cap on the offered input into the virtual scheduler, the child's administrative PIR has no effect on the calculated increase if an explicit rate is specified.

If the child's administrative PIR is modified while a percent based add is in effect, the system automatically uses the new relative increase value the next time the child's offered rate is determined.

When the add command is not specified or removed, the child's offered rate used by the child's virtual scheduler is not increased.

The **no** form of this command is used to remove an offered rate increase from all child policers and queues associated with the policy.

Parameters

percent-of-admin-pir

When the percent qualifier is used, this parameter specifies the percentage of the child's administrative PIR that should be added to the child's offered rate. The new offered rate result is capped by the child's PIR. If a value of 0 or 0.00 is used, the system interprets this equivalent to no add.

Values 1.00 to 100.00

rate-in-kilobits-per-second

When the rate qualifier is used, this parameter specifies an explicit rate, in kb/s, that should be added to the child's offered rate. The new offered rate result is capped by the child's PIR. If a rate increase of 0 is specified, the system interprets this equivalent to no add.

Values 0 to 100,000,000

min-only

This optional parameter is used to reinterpret the increase as a minimum offered rate. When this option is enabled, the system uses the specified increase as a minimum offered rate even for inactive queues or policers associated with the policy.

active-min-only

When this optional parameter is specified, the respective rate or percentage is treated as the minimum offered rate for a queue only when the queue has an actual non-zero offered rate. This is intended to limit the artificial increase in offered rate to queues that are currently active. When a queue's measured offered rate drops to zero, the system stops enforcing the minimum value.

5.93 add-paths

add-paths

Syntax

[**no**] **add-paths**

Context

[Tree] (config>router>bgp>group>neighbor add-paths)

[Tree] (config>router>bgp add-paths)

[Tree] (config>router>bgp>group add-paths)

Full Context

configure router bgp group neighbor add-paths

configure router bgp add-paths

configure router bgp group add-paths

Description

This command allows the add-paths node to be the configured for one or more families of the BGP instance, a group or a neighbor. The BGP add-paths capability allows the router to send and/or receive multiple paths per prefix to/from a peer. The add-paths command without additional parameters is equivalent to removing Add-Paths support for all address families, which causes sessions that previously negotiated the add-paths capability for one or more address families to go down and come back up without the add-paths capability.

The no form of this command (no add-paths) removes add-paths from the configuration of BGP, the group or the neighbor, causing sessions established using add-paths to go down and come back up without the add-paths capability.

Default

no add-paths

Platforms

All

5.94 add-paths-send-limit

add-paths-send-limit

Syntax

add-paths-send-limit *send-limit*

no add-paths-send-limit

Context

[Tree] (config>router>policy-options>policy-statement>entry add-paths-send-limit)

[Tree] (config>router>policy-options>policy-statement>default-action add-paths-send-limit)

Full Context

configure router policy-options policy-statement entry add-paths-send-limit

configure router policy-options policy-statement default-action add-paths-send-limit

Description

This command sets the *send-limit* to a specific value for all routes matched by the policy entry or default action. Add-paths allows a BGP router to send multiple paths for the same NLRI/prefix to a peer advertising the add-paths receive capability. The *send-limit* dictates the maximum number of paths that can be advertised.

The default *send-limit* is controlled by the instance, group or neighbor level configuration and applies to all prefixes in a particular address family. Using route policies allows the default send-limit to be overridden to use a larger or smaller maximum value on a per-prefix basis. For example, if, for most prefixes advertised to a peer, at most 1 path should be advertised but for a few exceptional prefixes up to 4 paths should be advertised, then the neighbor-level *send-limit* can be set to a value of 1 and the **add-paths-send-limit** in the policy entry that matches the exceptional routes can be set to a value of 4.

Default

no add-paths-send-limit

Parameters

send-limit

Specifies the maximum number of paths to advertise for matched routes to an Add-Paths peer. If the value is **multipaths**, then BGP advertises all of the used BGP multipaths for each matched route that is the best path for its prefix (NLRI). Add paths can be advertised only if the peer has signaled support for receiving multiple add paths.

Values 1 to 16, none, multipaths

5.95 add-srv6-tlvs

add-srv6-tlvs

Syntax

add-srv6-tlvs locator *locator-name*

add-srv6-tlvs micro-segment-locator *ms-locator-name*

no add-srv6-tlvs

Context

[Tree] (config>router>bgp>srv6>family add-srv6-tlvs)

Full Context

configure router bgp segment-routing-v6 family add-srv6-tlvs

Description

This command adds a prefix SID attribute containing an SRv6 TLV to routes belonging to the family that are redistributed from another protocol into BGP. This command also adds a prefix SID attribute with SRv6 TLV to BGP routes received from other peers without the SRv6 TLV and that are propagated to other peers with **next-hop-self** applied.

The **no** form of this command reverts to the default value which does not append the SRv6 TLV.

Default

no add-srv6-tlvs

Parameters

locator-name

Specifies an existing locator name, up to 64 characters.

ms-locator-name

Specifies a micro-segment locator name, up to 64 characters.

Full Context

configure service vprn bgp group neighbor link-bandwidth add-to-received-ebgp

configure service vprn bgp group link-bandwidth add-to-received-ebgp

Description

This command configures BGP to automatically add a link-bandwidth extended community to every route received from a directly connected (single-hop) EBGP peer within the scope of the command, as long as that route belongs to one of the listed address families.

The link-bandwidth extended community added by this command encodes the local-AS number of receiving BGP instance and the bandwidth of the interface to the directly connected EBGP peer.

Up to three families may be configured.

The **no** form of this command removes the link-bandwidth extended community added to received BGP routes.

Default

no add-to-received-ebgp

Parameters

family

Specifies the address families for which receiving the link-bandwidth extended community from EBGP peers should be supported.

Values ipv4 — Adds a link-bandwidth extended community to unlabeled unicast IPv4 routes.

label-ipv4 — Adds a link-bandwidth extended community to labeled-unicast IPv4 routes.

ipv6 — Adds a link-bandwidth extended community to unlabeled unicast IPv6 routes.

5.98 add-tunnel

add-tunnel

Syntax

add-tunnel never

add-tunnel on *reason* [*reason*]

no add-tunnel

Context

[Tree] (config>router>l2tp>tunnel-selection-blacklist add-tunnel)

[Tree] (config>service>vprn>l2tp>tunnel-selection-blacklist add-tunnel)

Full Context

configure router l2tp tunnel-selection-blacklist add-tunnel

configure service vprn l2tp tunnel-selection-blacklist add-tunnel

Description

This command will force the tunnel to the denylist and render it unavailable for new sessions for the duration of preconfigured time. Peers are always forced to the denylist in case they time out (failure to receive response to control packets). In addition to time outs, certain events can be used to trigger placement of the tunnel on the denylist.

Default

add-tunnel never

Parameters

never

When specified, no tunnels will be placed on the denylist under any circumstance. This parameter will available to preserve backward compatibility.

reason

Specifies the return codes or events that determine which tunnels are added to the denylist. A maximum of eight reasons can be specified in a single statement.

Table 14: Return codes

Return code	Tunnels added to denylist
cdn-err-code	A tunnel is forced to the denylist if that CDN message with the Result Code 2 (Call disconnected for the reasons indicated in error code) is received.
cdn-inv-dest	A tunnel is forced to the denylist if that CDN message with the Result Codes 6 (Invalid destination) is received.
cdn-tmp-no-facilities	A tunnel is forced to the denylist if that CDN message with the Result Code 4 is received (Call failed due to lack of appropriate facilities being available - temporary condition) is received.
cdn-perm-no-facilities	A tunnel is forced to the denylist if that CDN message with the Result Codes 5 (Call failed due to lack of appropriate facilities being available - permanent condition) is received.
tx-cdn-not-established-in-time	A tunnel is forced to the denylist if that CDN message with the Result Code 10 (Call was not established within time allotted by LAC) is sent from the LAC to the LNS.
stop-ccn-err-code	A tunnel is forced to the denylist if that StopCCN message with the Result Code 2 (General error – Error Code indicates the problem) is sent or received.
stop-ccn-other	A tunnel is forced to the denylist if that StopCCN message with the following Result Codes is received: (1) General request to clear control connection (4) Requester is not authorized to establish a control channel (5) Protocol version not supported (6) Requester is being shutdown Or in the case that the StopCCN with the following result codes is transmitted: (4) Requester is not authorized to establish a control channel. (5) Protocol version not supported The receipt of the following Result Codes will never denylist a tunnel: (0) Reserved (3) Control channel already exist (7) Finite state machine error (8) Undefined

Return code	Tunnels added to denylist
	Transmission of the following Result Codes will never denylist a tunnel: (1) General request to clear control connection (3) Control channel already exist (6) Requester is being shutdown (7) Finite state machine error
addr-change-timeout	A timed-out tunnel for which the peer IP address has changed mid-session (from the one that is provided initially during configuration) is forced to the denylist. In absence of this configuration option, only the configured peer for the tunnel is, but not the tunnel itself which now has a different peer address than the one initially configured.

Context

[Tree] (config>subscr-mgmt>loc-user-db>ipoe>host address)

[Tree] (config>subscr-mgmt>loc-user-db>ppp>host address)

Full Context

configure subscriber-mgmt local-user-db ipoe host address

configure subscriber-mgmt local-user-db ppp host address

Description

This command configures how the IP address is defined for this host.

When the user database is used from a local DHCP server, then this command defines how to define the IP address the server offers to the DHCP-client.

When the user-db is used for PPPoE authentication, the **gi-address** parameter cannot be used. A fixed IP address causes PPPoE to use this IP address. If no IP address is specified, the PPPoE looks for IP address by other means (DHCP). If a pool name is given, this pool is sent in the DHCP request so it can be used in by the DHCP server to determine which address to give to the host.

The **no** form of this command causes no IP address to be assigned to this host. In a user database referred to from a local DHCP server, creating a host without address information causes the matching client never to get an IP address.

The **no** form of this command reverts to the default.

Parameters

gi-address

When specified, the gi-address of the DHCP message is taken to look for a subnet in the local DHCP server. The first available free address of the subnet is taken and "offered" to the host. When **local-user-db** is used for PPPoE authentication, this has the same result as **no address**.

ip-address

Specifies the fixed IP address to use for this host.

Values a.b.c.d

pool-name/sec-pool-name

Specifies the primary (and secondary) pool (in the local DHCP server), up to 32 characters, to look for an available address. The first available IP address from any subnet in the pool is used. When the local user database is used for PPPoE authentication, this causes the specified pool name to be sent to the DHCP server in a vendor-specific sub-option under Option 82.

use-pool-from-client

Use the pool-name in the Option 82 vendor-specific sub-option.

delimiter

Specifies a single ASCII character specifies the delimiter of separating primary and secondary pool names in option82 VSO.

address

Syntax

address *ipv6-address/prefix-length* [**eui-64**] [**track-srrp** *srrp-instance*] [**modifier** *cga-modifier*] [**dad-disable**] [**primary-preference** *primary-preference*]

no address *ipv6-address/prefix-length*

Context

[Tree] (config>service>ies>if>ipv6 address)

[Tree] (config>service>vprn>if>ipv6 address)

Full Context

configure service ies interface ipv6 address

configure service vprn interface ipv6 address

Description

This command assigns an IPv6 address/subnet to the interface.

Up to 16 total primary and secondary IPv4 and IPv6 addresses can be assigned to network interfaces, and up to 256 to access interfaces.

Caution:
Configurations must not exceed 16 secondary IP addresses when IPsec, GRE, L2TPv3, or IP in IP protocols are active on an access interface.

The **no** form of this command removes the IPv6 address from the interface.

Parameters

ipv6-address/prefix-length

Specifies the IPv6 address on the interface.

Values	ipv6-address/prefix:	ipv6-address	x:x:x:x:x:x:x:x (eight 16-bit pieces)
			x:x:x:x:x:x:d.d.d.d
			x [0 to FFFF]H
			d [0 to 255]D
	prefix-length		1 to 128

eui-64

When the **eui-64** keyword is specified, a complete IPv6 address from the supplied prefix and 64-bit interface identifier is formed. The 64-bit interface identifier is derived from MAC address on Ethernet interfaces. For interfaces without a MAC address, for example ATM interfaces, the Base MAC address of the chassis is used.

srrp-instance

Specifies the SRRP instance ID that this interface route needs to track.

Values 1 to 4294967295

cga-modifier

Specifies the modifier in 32 hexadecimal nibbles.

Values 0x0–0xFFFFFFFF

dad-disable

Disables Duplicate Address Detection (DAD) and sets the address to preferred, even if there is a duplicated address.

primary-preference

Specifies a *primary-preference* index to an IPv6 address of the interface to enforce the order in which the address is used by control plane protocols and applications which require a fixed address of the interface. These include LDP and Segment Routing.

When originating packets from this interface, the source IPv6 address follows the selection rules in RFC 6724 except for the specific cases where a fixed address is required. In the latter case, the IPv6 address with the lowest primary-preference index is selected. If the selected address is removed, the system selects the IPv6 address with the next lowest *primary-preference* index.

The system assigns the next available index value to any IPv6 address of the interface when configured without the *primary-preference* index value specified. The address index space is unique across all addresses of a given interface.

Values 1 to 4294967295

Platforms

[Tree] (config>service>ies>sub-if>ipv6 address)

Full Context

configure service vprn subscriber-interface ipv6 address

configure service ies subscriber-interface ipv6 address

Description

This command assigns an IPv6 address/subnet to the subscriber interface.

SRRP and an IPv6 Global Unicast Address on a subscriber interface are mutual exclusive:

- **track-srrp** cannot be enabled on a subscriber interface ipv6 address
- when an ipv6 address is configured on a subscriber interface, SRRP cannot be enabled on its group interfaces

The **no** form of this command removes the IPv6 address from the interface.

Parameters

ipv6-address

Specifies the 128-bit IPv6 address.

Values 128-bit hexadecimal IPv6 address in compressed form

prefix-length

Specifies the length of any associated aggregate prefix.

Values 32 to 127

pd

Specifies that this aggregate is used by IPv6 ESM hosts for DHCPv6 prefix-delegation.

wan-host

Specifies that this aggregate is used by IPv6 ESM hosts for local addressing or by a routing gateway's WAN interface.

srrp-instance

Specifies the SRRP instance number.

Values 1 to 4294967295

milli-seconds

Specifies the time to wait, in milli-seconds, for the route before it accepts the new state attribute. This timer is used to prevent fluctuations in route advertisement caused by short lived SRRP instabilities, in the case that such condition arises.

Values 100 to 5000

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

configure router gtp s11 peer-profile-map address

configure router gtp uplink peer-profile-map address

configure service vprn gtp uplink peer-profile-map address

configure service vprn gtp s11 peer-profile-map address

Description

This command configures a mapping of an IP address or subnet to a peer profile. If one peer profile is used for the entire router, it is possible to map the entire IPv4 subnet using 0.0.0.0/0.

If no match is found, the default or default S11 peer profile is used.

The **no** form of this command removes the peer profile mapping, affecting only the setup of new peers.

Parameters

ip-prefix/ip-prefix-length

Specifies the IP prefix and prefix length of the subnet.

Values		
	ipv4-prefix	a.b.c.d (host bits must be 0)
	ipv4-prefix-length	[0 to 32]
	ipv6-prefix	x:x:x:x:x:x:x:x (eight 16-bit pieces)
		x:x:x:x:x:x:d.d.d.d
		x - [0 to FFFF]H
		d - [0 to 255]D
	ipv6-prefix-le	[0 to 128]

profile-name

Specifies the GTP peer profile associated with the address prefix, up to 32 characters.

[Tree] (config>service>ies>if address)

Full Context

configure service vprn network-interface address

configure service vprn interface address

configure service ies interface address

Description

This command assigns an IP address, IP subnet, and broadcast address format to an IES IP router interface. Only one IP address can be associated with an IP interface. Use the **secondary** command to assign multiple addresses.

An IP address must be assigned to each IES or VPRN IP interface. An IP address and a mask are used together to create a local IP prefix. The defined IP prefix must be unique within the context of the routing instance. It cannot overlap with other existing IP prefixes defined as local subnets on other IP interfaces in the same routing context within the router.

The IP address for the interface can be entered in either CIDR (Classless Inter-Domain Routing) or traditional dotted decimal notation. The show commands display CIDR notation and is stored in configuration files.

By default, no IP address or subnet association exists on an IP interface until it is explicitly created.

Table 15: Address Admin and Operational States

Address	Admin State	Oper State
No address	up	down
No address	down	down
1.1.1.1	up	up
1.1.1.1	down	down

The operational state is a read-only variable and the only controlling variables are the address and admin states. The address and admin states are independent and can be set independently. If an interface is in an administratively up state and an address is assigned, it becomes operationally up and the protocol interfaces and the MPLS LSPs associated with that IP interface are reinitialized.

The **no** form of this command removes the IP address assignment from the IP interface. When the **no address** command is entered, the interface becomes operationally down.

Parameters

ip-address

Specifies the IP address of the IP interface. The *ip-address* portion of the **address** command specifies the IP host address that is used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).

/

The forward slash is a parameter delimiter and separates the *ip-address* portion of the IP address from the mask that defines the scope of the local subnet. No spaces are allowed between the *ip-address*, the "*/*" and the *mask-length* parameter. If a forward slash is not immediately following the *ip-address*, a dotted decimal mask must follow the prefix.

mask-length

Specifies the subnet mask length when the IP prefix is specified in CIDR notation. When the IP prefix is specified in CIDR notation, a forward slash (/) separates the *ip-address* from the *mask-length* parameter. The mask length parameter indicates the number of bits used for the network portion of the IP address; the remainder of the IP address is used to determine the host portion of the IP address.

Note:
A mask length of 32 is reserved for loopback addresses (includes system addresses).

Default 0 to 31

mask

The subnet mask in dotted decimal notation. When the IP prefix is not specified in CIDR notation, a space separates the *ip-address* from a traditional dotted decimal mask. The *mask* parameter indicates the complete mask that is used in a logical 'AND' function to derive the local subnet of the IP address. Allowed values are dotted decimal addresses in the range 128.0.0.0 – 255.255.255.254.

Note:
A mask of 255.255.255.255 is reserved for system IP addresses.

broadcast

Overrides the default broadcast address used by the IP interface when sourcing IP broadcasts on the IP interface. If no broadcast format is specified for the IP address, the default value is **host-ones** which indicates a subnet broadcast address. Use this parameter to change the broadcast address to **all-ones** or revert back to a broadcast address of **host-ones**.

The broadcast format on an IP interface can be specified when the IP address is assigned or changed.

This parameter does not affect the type of broadcasts that can be received by the IP interface. A host sending either the local broadcast (**all-ones**) or the valid subnet broadcast address (**host-ones**) is received by the IP interface.

Default host-ones

all-ones

Specifies the broadcast address used by the IP interface for this IP address is 255.255.255.255, also known as the local broadcast.

host-ones

Specifies that the broadcast address used by the IP interface for this IP address is the subnet broadcast address. This is an IP address that corresponds to the local subnet described by the *ip-address* and the *mask-length* or *mask* with all the host bits set to binary one. This is the default broadcast address used by an IP interface.

The **broadcast** parameter within the **address** command does not have a negate feature, which is usually used to revert a parameter to the default value. To change the **broadcast** type to **host-ones** after being changed to **all-ones**, the **address** command must be executed with the **broadcast** parameter defined.

srrp-instance

Tracks the specified SRRP instance state on the IPv6 address.

configure service vprn subscriber-interface address

configure service ies subscriber-interface address

Description

This command configures the subscriber interface address along with additional parameters related to multi-chassis redundancy.

The **no** form of this command reverts to the default.

Parameters

ip-address

The IP address of the IP interface. The *ip-address* portion of the **address** command specifies the IP host address that is used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).

/

The forward slash is a parameter delimiter and separates the *ip-address* portion of the IP address from the mask that defines the scope of the local subnet. No spaces are allowed between the *ip-address*, the "*/*" and the *mask-length* parameter. If a forward slash is not immediately following the *ip-address*, a dotted decimal mask must follow the prefix.

mask

The subnet mask in dotted decimal notation. When the IP prefix is not specified in CIDR notation, a space separates the *ip-address* from a traditional dotted decimal mask. The *mask* parameter indicates the complete mask that is used in a logical AND function to derive the local subnet of the IP address. Allowed values are dotted decimal addresses in the range 128.0.0.0 – 255.255.255.254.

Note:
A mask of 255.255.255.255 is reserved for system IP addresses.

netmask

The subnet mask in dotted decimal notation.

Values 0.0.0.0 - 255.255.255.255

gw-ip-address

Specifies a separate IP address within the subnet for SRRP routing purposes. This parameter must be followed by a valid IP interface that exists within the subscriber subnet created by the address command. The defined gateway IP address cannot currently exist as a subscriber host (static or dynamic). If the defined ip-address already exists as a subscriber host address, the address command will fail. The specified ip-address must be unique within the system.

The *gw-ip-address* parameter may be specified at any time. If the subscriber subnet was created previously, executing the **address** command with a *gw-ip-address* parameter will simply add the SRRP gateway IP address to the existing subnet.

If the **address** command is executed without the *gw-ip-address* parameter when the subscriber subnet is associated with an active SRRP instance, the address will fail. If the SRRP instance is inactive or removed, executing the **address** command without the *gw-ip-address* parameter removes the SRRP gateway IP address from the specified subscriber subnet.

If the **address** command is executed with a new GW address, all SRRP instances associated with the specified subscriber subnet is updated with the new SRRP gateway IP address.

populate-host-routes

Specifies to populate subscriber-host routes in local FDB. Storing them in FDB benefits topologies only where the external router advertises more specific routes than the one corresponding to locally configured subscriber-interface subnets.

milli-seconds

Specifies the time to wait, in milli-seconds, for the route before it accepts the new state attribute. This timer is used to prevent fluctuations in route advertisement caused by short lived SRRP instabilities, in the case that such condition arises.

Values 100 to 5000

srrp-inst

Enables the subscriber interface route to track the SRRP state of the specified SRRP instance. The route updates its state attribute to reflect the *state* of SRRP instance:

- Master = srrp-master
- Any other = srrp-non-master

Routing policy can be applied towards the state attribute in order to customize the advertisement of the route. Only one SRRP instance can be tracked per subscriber interface route. Tracked SRRP instance can be part of the Fate Sharing Group. This command can be enabled at any time.

Values 1 to 4294967295

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

configure service vprn subscriber-interface group-interface wlan-gw address

Description

This command configures an IPv4 or IPv6 address of a WLAN Gateway.

The **no** form of this command removes the IPv4 or IPv6 address from the configuration.

Parameters

ip-address

Specifies up to four IPv4 addresses.

Values a.b.c.d

ipv6-address

Specifies up to six gateway IPv6 endpoint addresses.

Values

ipv6-address:	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x - [0 to FFFF]H
	d - [0 to 255]D

ipv6-address

Specifies up to six IPv6 addresses.

Platforms

address

Syntax

address *ip-address* [/*mask*] [*netmask*]

no address

Context

[Tree] (config>service>vpls>interface address)

Full Context

configure service vpls interface address

Description

This command assigns an IP address, IP subnet, and broadcast address format to an IES IP router interface. Only one IP address can be associated with an IP interface.

An IP address must be assigned to each IES IP interface. An IP address and a mask are used together to create a local IP prefix. The defined IP prefix must be unique within the context of the routing instance. It cannot overlap with other existing IP prefixes defined as local subnets on other IP interfaces in the same routing context within the router.

The IP address for the interface can be entered in either CIDR (Classless Inter-Domain Routing) or traditional dotted decimal notation. The show commands display CIDR notation and is stored in configuration files.

By default, no IP address or subnet association exists on an IP interface until it is explicitly created.

Use the **no** form of this command to remove the IP address assignment from the IP interface. When the **no address** command is entered, the interface becomes operationally down.

Address	Admin State	Oper State
No address	up	down
No address	down	down
1.1.1.1	up	up
1.1.1.1	down	down

The operational state is a read-only variable and the only controlling variables are the address and admin states. The address and admin states are independent and can be set independently. If an interface is in an administratively up state and an address is assigned, it becomes operationally up and the protocol interfaces and the MPLS LSPs associated with that IP interface will be reinitialized.

Parameters

ip-address

The IP address of the IP interface. The *ip-address* portion of the **address** command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP netmask

The subnet mask in dotted decimal notation. When the IP prefix is not specified in CIDR notation, a space separates the *ip-address* from a traditional dotted decimal mask. The *mask* parameter indicates the complete mask that will be used in a logical 'AND' function to derive the local subnet of the IP address. Allowed values are dotted decimal addresses in the range 128.0.0.0 to 255.255.255.254. A mask of 255.255.255.255 is reserved for system IP addresses.

configure service ies redundant-interface address

Description

This command assigns an IP address mask or netmask and a remote IP address to the interface.

Parameters

ip-address/mask

Assigns an IP address/IP subnet format to the interface.

ip-address netmask

Specifies a string of 0s and 1s that mask or screen out the network part of an IP address so that only the host computer part of the address remains.

Assigns an IP address netmask to the interface.

remote-ip *ip-address*

Assigns a remote IP to the interface.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

address

Syntax

address *ip-address*

no address

Context

[Tree] (config>service>vprn>log>syslog address)

Full Context

configure service vprn log syslog address

Description

This command adds the syslog target host IP address to/from a syslog ID.

The *ip-address* parameter is mandatory. If no **address** is configured, syslog data cannot be forwarded to the syslog target host.

Only one address can be associated with a *syslog-id*. If multiple addresses are entered, the last address entered overwrites the previous address.

The same syslog target host can be used by multiple log IDs.

The **no** form of this command removes the syslog target host IP address.

Default

no address

Parameters

ip-address

Specifies the IP address of the syslog target host in dotted decimal notation.

Values		
	ipv4-address	a.b.c.d
	ipv6-address	x:x:x:x:x:x:x:x[-interface]
		x:x:x:x:x:x:d.d.d.d[-interface]
		x: [0 to FFFF]H
		d: [0 to 255]D
		interface: 32 characters maximum, mandatory for link local addresses

The ipv6-address applies to the 7750 SR.

Platforms

All

address

Syntax

configure router radius-proxy server wlan-gw address

Description

This command configures the IPv4 address of the distributed RADIUS proxy server for use by the access points.

The **no** form of this command removes the address from the configuration.

Parameters

ip-address

Specifies the destination IPv4 address of the RADIUS proxy server.

Values ipv4-address a.b.c.d

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

address

Syntax

[**no**] **address** *ip-address/mask*

Context

[Tree] (config>service>vprn>nat>inside>l2-aware address)

Full Context

configure service vprn nat inside l2-aware address

Description

This command configures a Layer 2-aware NAT address. This address will act as a local address of the system. Hosts connected to the inside service will be able to ARP for this address. To verify connectivity, a host can also ping the address. This address is typically used as next hop of the default route of a Layer 2-aware host. The given mask defines a Layer 2-aware subnet. The (inside) IP address used by a Layer 2-aware host must match one of the subnets defined here or it will be rejected.

Parameters

ip-address

Specifies the IP address in a.b.c.d format.

mask

Specifies the mask.

Values 16 to 32

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

Context

[Tree] (config>router>if address)

Full Context

configure router interface address

Description

This command assigns an IP address, IP subnet, and broadcast address format to an IP interface. Only one IP address can be associated with an IP interface. Use the **secondary** command to assign additional addresses.

An IP address must be assigned to each IP interface. An IP address and a mask combine to create a local IP prefix. The defined IP prefix must be unique within the context of the routing instance. It cannot overlap with other existing IP prefixes defined as local subnets on other IP interfaces in the same routing context within the router.

From Release 19.10, The overlap restriction is not applicable for host-addresses configured on loopback interfaces. For example, a loopback interface addresses configured with mask of 32 or netmask of 255.255.255.255 can overlap with other prefixes on other IP interfaces in the same routing context within the router.

The IP address for the interface can be entered in either CIDR (Classless Inter-Domain Routing) or traditional dotted decimal notation. **Show** commands display CIDR notation and are stored in configuration files.

By default, no IP address or subnet association exists on an IP interface until it is explicitly created.

The **no** form of this command removes the IP address assignment from the IP interface. Interface specific configurations for MPLS are also removed. This will operationally stop any MPLS LSPs that explicitly reference that IP address. When a new IP address is configured, interface specific configurations for MPLS need to be added. IEEE 1588 port based timestamping configured with **ptp-hw-assist** is also disabled.

Default

no address

Parameters

ip-address

Specifies the IP address of the IP interface. The *ip-address* portion of the **address** command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation.

Values 1.0.0.0 to 223.255.255.255

/

The forward slash is a parameter delimiter that separates the *ip-address* portion of the IP address from the mask that defines the scope of the local subnet. No spaces are allowed between the *ip-address*, the "*/*" and the *mask* parameter. If a forward slash does not immediately follow the *ip-address*, a dotted decimal mask must follow the prefix.

mask

Specifies the subnet mask length when the IP prefix is specified in CIDR notation. When the IP prefix is specified in CIDR notation, a forward slash (/) separates the *ip-address* from the *mask* parameter. The *mask* parameter indicates the number of bits used for the network portion of the IP address; the remainder of the IP address is used to determine the host portion of the IP address. Allowed values are integers in the range 1— 32. A mask length of 32 is reserved for system IP addresses.

Values 1 to 32

netmask

Specifies the subnet mask in dotted decimal notation.

Values 0.0.0.0 to 255.255.255.255 (network bits all 1 and host bits all 0)

broadcast

The optional **broadcast** parameter overrides the default broadcast address used by the IP interface when sourcing IP broadcasts on the IP interface. If no broadcast format is specified for the IP address, the default value is **host-ones,** which indicates a subnet broadcast address. Use this parameter to change the broadcast address to **all-ones** or revert back to a broadcast address of **host-ones**.

The **broadcast** parameter within the **address** command does not have a negate feature, which is usually used to revert a parameter to the default value. To change the **broadcast** type to **host-ones** after being changed to **all-ones**, the **address** command must be executed with the **broadcast** parameter defined.

The broadcast format on an IP interface can be specified when the IP address is assigned or changed.

This parameter does not affect the type of broadcasts that can be received by the IP interface. A host sending either the local broadcast (**all-ones**) or the valid subnet broadcast address (**host-ones**) will be received by the IP interface.

Default host-ones

Values all-ones, host-ones

all-ones

The **all-ones** keyword following the **broadcast** parameter specifies that the broadcast address used by the IP interface for this IP address will be 255.255.255.255, also known as the local broadcast.

host-ones

Specifies that the broadcast address used by the IP interface for this IP address will be the subnet broadcast address. This is an IP address that corresponds to the local subnet described by the *ip-address* and the *netmask* with all the host bits set to binary 1. This is the default broadcast address used by an IP interface.

srrp-instance

Specifies the SRRP instance ID that this interface route needs to track.

Values 1 to 4294967295

gre-termination

The optional **gre-termination** keyword allows GRE SDP tunnel packets to terminate on the router interface using the /31 value of the configured IP address. Refer to the *7450 ESS, 7750 SR, 7950 XRS, and VSR Services Overview Guide* for information about using **gre-termination**.

Platforms

address

Syntax

address *ipv6-address/prefix-length* [**eui-64**] [**track-srrp** *srrp-instance*] [**modifier** *cga-modifier*] [**dad-disable**] [**primary-preference** *primary-preference*]

no address *ipv6-address/prefix-length*

Context

[Tree] (config>router>if>ipv6 address)

Full Context

configure router interface ipv6 address

Description

This command assigns an IPv6 address to the interface. Up to 16 total primary and secondary IPv4 and IPv6 addresses can be assigned to network interfaces, and up to 256 to access interfaces.

Caution:
Configurations must not exceed 16 IPv6 addresses when IPsec, GRE, L2TPv3, or IP in IP protocols are active on an access interface.

A global IPv6 address together with the *prefix-length* create a locally configured interface IPv6 prefix and subnet. The defined global IP prefix must be unique within the context of a routing instance. It cannot overlap with any other existing global IP prefix defined on another IP interface within the same routing context in the router.

This overlap restriction is not applicable for IPv6 host addresses configured on loopback interfaces. For example, an IPv6 loopback host address configured upon a loopback interface may overlap with another prefix subnet configured on another IP interface within the same routing context.

Parameters

ipv6-address/prefix-length

Specifies the IPv6 address on the interface.

Values

ipv6-address/prefix-length:	ipv6-address	x:x:x:x:x:x:x:x (eight 16-bit pieces)
		x:x:x:x:x:x:d.d.d.d
		x [0 to FFFF]H
		d [0 to 255]D
	prefix-length	1 to 128

eui-64

When the **eui-64** keyword is specified, a complete IPv6 address from the supplied prefix and 64-bit interface identifier is formed. The 64-bit interface identifier is derived from MAC address on Ethernet interfaces. For interfaces without a MAC address, for example POS interfaces, the Base MAC address of the chassis should be used.

srrp-instance

Indicates the unique identifier of the tracked SRRP instance.

Values 1 to 4294967295

cga-modifier

Sets the modifier for cryptographically-assigned addresses.

Values 0x0..0xFFFFFFFF...(32 hex nibbles)

dad-disable

Disables Duplicate Address Detection (DAD) and sets the address to preferred, even if there is a duplicated address.

primary-preference

Specifies a *primary-preference* index to an IPv6 address of the interface to enforce the order in which the address is used by control plane protocols and applications which require a fixed address of the interface. These include LDP and Segment Routing.

When originating packets from this interface, the source IPv6 address follows the selection rules in RFC 6724 except for the specific cases where a fixed address is required. In the latter case, the IPv6 address with the lowest primary-preference index is selected. If the selected address is removed, the system selects the IPv6 address with the next lowest *primary-preference* index.

The system assigns the next available index value to any IPv6 address of the interface when configured without the *primary-preference* index value specified. The address index space is unique across all addresses of a given interface.

Values 1 to 4294967295

srrp

Tracks the specified SRRP instance state on the IPv6 address.

Values 1 to 4294967295

Platforms

All

address

Syntax

[**no**] **address** *ip-prefix/ip-prefix-length* [**active** | **standby** | **standby/A** | **standby/B** | **standby/C** | **standby/D**]

Context

[Tree] (bof address)

Full Context

bof address

Description

This command assigns an IP address to the management Ethernet port on a CPM. The IP addresses are applied by the boot loader and the running image. The active and standby IP addresses must be on the same subnet.

On all systems except the 7950 XRS-40, an address must be assigned with the **active** keyword and for systems with a redundant CPM an additional address may be assigned with the **standby** keyword. The active address is used by the active CPM whether its CPM A or CPM B and the standby address, if specified, is used by the standby CPM whether its CPM B or CPM A.

For the 7950 XRS-40, if the extension chassis shall boot from local compact flash then an active and standby address should be defined for use by the master chassis as defined above.

For the 7950 XRS-40, if the extension chassis shall boot from remote URL, then it is required to assign addresses to the management Ethernet ports for CPM C and CPM D. In this case, the BOF should be updated to have addresses defined using the **standby/A**, **standby/B**, **standby/C**, and **standby/D** keywords in addition to an address using the **active** keyword. With these keywords, CPM A shall always use the address defined using the **standby/A** address when CPM A is running as the standby CPM. Similarly, CPM B shall always use the address defined using the **standby/B** address when CPM B is running as the standby CPM. The active CPM of CPM A and CPM B shall use the address defined using the **active** keyword.

Deleting a BOF address entry is not allowed from a remote session.

Note that changing the active and standby addresses without reboot standby CPM may cause a boot-env sync to fail.

The **no** form of this command deletes the IP address from the CPM Ethernet port.

Parameters

ip-prefix/ip-prefix-length

Specifies the destination address of the aggregate route in dotted decimal notation.

Values

ipv4-prefix	*a.b.c.d* (host bits must be 0)	
ipv4-prefix-length	0 to 32	
ipv6-prefix	*x:x:x:x:x:x:x:x* (eight 16-bit pieces)	
	x:x:x:x:x:x:d.d.d.d	
	x:	[0 to FFFF]H
	d:	[0 to 255]D
ipv6-prefix-length	0 to 128	

active | standby | standby/A | standby/B | standby/C | standby/D

address

Syntax
address {**01:1b:19:00:00:00**| **01:80:c2:00:00:0e**}

Context
[Tree] (config>system>ptp>port address)

Full Context
configure system ptp port address

Description
This command allows for the specification of the mac-address to be used for the destination MAC address of the transmitted ptp messages.

IEEE Std 1588-2008 Annex F defines two reserved addresses for 1588 messages. These are:

- **01-1B-19-00-00-00** — all except the peer delay mechanism messages
- **01-80-C2-00-00-0E** — peer delay mechanism messages

Both addresses are supported for reception independent of the address configured by this command.

The **no** form of this command sets the address to the default address.

Default
address 01-1B-19-00-00-00

Platforms

address

Syntax

address *ip-address*

no address

Context

[Tree] (config>log>syslog address)

Full Context

configure log syslog address

Description

This command adds the syslog target host IP address to/from a syslog ID.

This parameter is mandatory. If no **address** is configured, syslog data cannot be forwarded to the syslog target host.

Only one address can be associated with a *syslog-id*. If multiple addresses are entered, the last address entered overwrites the previous address.

The same syslog target host can be used by multiple log IDs.

The **no** form of this command removes the syslog target host IP address.

Default

no address

Parameters

ip-address

Specifies the IP address of the syslog target host in dotted decimal notation. An IPv6-address applies only to the 7750 SR.

Values

ipv4-address	a.b.c.d
ipv6-address	x:x:x:x:x:x:x:x[-interface]
	x:x:x:x:x:x:d.d.d.d[-interface]
	x: [0..FFFF]H
	d: [0..255]D
	interface: 32 characters maximum, mandatory for link local
	addressesipv6-address x:x:x:x:x:x:x:x[-interface]

x:x:x:x:x:x:d.d.d.d[-interface]

x: [0..FFFF]H

d: [0..255]D

Context

[Tree] (config>system>security>ldap>server address)

Full Context

configure system security ldap server address

Description

This command configures the IPv4 or IPv6 address for the LDAP server.

The **no** version of this command removes the server address.

Parameters

ip-address

The IP address of the LDAP server.

Values		
	ipv4-address	a.b.c.d (host bits must be 0)
	ipv6-address	x:x:x:x:x:x:x:x (eight 16-bit pieces)
		x:x:x:x:x:x:d.d.d.d
		x: [0..FFFF]H
		d: [0..255]D

port

Specifies the port ID. The port is the LDAP server listening port; by default it is 389 but if the listening port on LDAP server is changed, this command needs to be configured accordingly.

Values	1 to 65535
Default	389

Context

[Tree] (config>router>static-route-entry>next-hop>backup-next-hop address)

[Tree] (config>service>vprn>static-route-entry>next-hop>backup-next-hop address)

Full Context

configure router static-route-entry next-hop backup-next-hop address

configure service vprn static-route-entry next-hop backup-next-hop address

Description

This command specifies the backup IP forwarding address that is used for static route Fast ReRoute (FRR). The configured address, if reachable, acts as pre-installed backup forwarding information that can be used when the primary IP next-hop suddenly fails.

The configured backup next-hop IP address can be directly or indirectly connected (using an IGP or tunnel) to the node. The backup next-hop forwarding information or the Next-hop Label Forwarding Entry (NHLFE) tunnel forwarding information from the IP Routing Table Manager (RTM) is used to preconfigure an IP fast-reroute backup path.

One backup next-hop address can protect a single primary static route entry next-hop address without ECMP and it is only activated when the primary next-hop has no active ECMP.

The configured IP address can be either on the network or the access side.

By default, there is no backup next-hop address configured.

The **no** form of this command deletes the backup next-hop address entry.

Parameters

ip-address

Specifies the backup IP forwarding address.

Values	ipv4-address	a.b.c.d
	ipv6-address	x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x: [0..FFFF]H

d: [0..255]D

Context

[Tree] (config>subscr-mgmt>diam-appl-plcy>gy>avp address-avp)

Full Context

configure subscriber-mgmt diameter-application-policy gy include-avp address-avp

Description

This command includes the following subscriber host/session address/prefix AVPs in all Diameter DCCA CCR messages:

- [8] Framed-IP-Address
- [97] Framed-IPv6-Prefix
- [123] Delegated-IPv6-Prefix
- [6527-99] Alc-IPv6-Address

Note: Only the address/prefix of the subscriber host that triggered the creation of the Diameter Gy session is included.

The **no** form of this command removes the address AVPs from the Diameter DCCA CCR messages.

Default

address-avp

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

5.101 address-pooling

address-pooling

Syntax

[no] address-pooling {paired | arbitrary}

Context

[Tree] (config>router>nat>outside>pool address-pooling)

Full Context

configure router nat outside pool address-pooling

Description

This command configures address pooling to allocate outside ports for a NAT subscriber in relation to the outside IP address.

The behavior in NAT, as defined in RFC 7857, §4, allows the subscriber to be mapped to a single outside IP address and allows for outside ports always to be allocated from that same outside IP address. If this outside IP address becomes exhausted of ports, no new ports for the subscriber can be allocated. This behavior is called paired address pooling.

The alternative behavior is arbitrary address pooling, where a NAT subscriber is mapped to an alternate IP address when the current outside IP address runs out of ports. This way, the subscriber becomes associated with multiple outside IP addresses. While this results in better resource utilization in NAT, it may negatively affect the behavior of some applications.

Default

address-pooling paired

Parameters

paired

Specifies that the subscriber can allocate ports from a single outside IP address. When this IP address runs out of the ports, the subscriber is denied allocation of new ports.

arbitrary

Specifies that the subscriber can allocate ports from multiple outside IP addresses.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.102 address-pref

address-pref

Syntax

address-pref {**ipv4-only** | **ipv6-first**}

no address-pref

Context

[Tree] (config>system>dns address-pref)

Full Context

configure system dns address-pref

Description

This command configures the DNS address resolving order preference. By default, DNS names are queried for A-records only (address-preference is IPv4-only).

If the address-preference is set to IPv6-first, the DNS server will be queried for AAAA-records (IPv6) first and if a successful replied is not received, then the DNS server is queried for A-records. IPv6 applies only to the 7750 SR and 7950 XRS.

Default

address-pref ipv4-only

[Tree] (config>router>dhcp>server>pool>subnet address-range)

Full Context

configure service vprn dhcp server pool address-range

configure router dhcp local-dhcp-server pool subnet address-range

Description

This command configures a range of IP addresses to be served from the pool. All IP addresses between the start and end IP addresses are included (other than specific excluded addresses).

The **no** form of this command removes the address-range parameters from the configuration.

Parameters

start-ip-address

Specifies the start address of this range to include. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).

Values a.b.c.d

end-ip-address

Specifies the end address of this range to include. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).

Values a.b.c.d

local

Specifies that the local DHCP server has the ownership of this dress range in a redundant setup under normal operation.

remote

Specifies that the remote DHCP server has the ownership of this address range in a redundant setup under normal operation.

access-driven

Specifies that the DHCP server failover system is in control by the access protection mechanisms (SRRP or MC-LAG).

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

configure service vprn interface sap ipsec-gw local-address-assignment ipv6 address-source

configure service vprn interface sap ipsec-gw local-address-assignment ipv4 address-source

configure service ies interface sap ipsec-gw local-address-assignment ipv4 address-source

Description

This command specifies the IPv4 or IPv6 source of the local address assignment for the IPsec gateway, which is a pool of a local DHCPv4 or DHCPv6 server. The system will assign an internal address to an IKEv2 remote-access client from the specified pool.

Beside the IP address, netmask and DNS server can also be returned. For IPv4, the netmask and DNS server address can be returned from the specified pool, as well as the IP address. The netmask returned to the IPsec client is derived from the subnet length from the **subnet** *x.x.x.x/m* **create** configuration, not the **subnet-mask** configuration in the subnet context. For IPv6, the DNS server address can be returned from the specified pool, as well as the IP address.

For IPv4, a secondary pool can be optionally specified. The secondary pool is used if the system is unable to assign addresses from the primary pool.

Default

no address-source

Parameters

router-instance

Specifies the router instance ID where the local DHCPv4 or DHCPv6 server is defined, up to 32 characters.

This variant of this command is only supported in 'classic' configuration-mode (**configure system management-interface configuration-mode classic**). The **address-source service-name** *service-name* variant can be used in all configuration modes.

service-name

Specifies the name of the service where the local DHCPv4 or DHCPv6 server is defined, up to 64 characters.

local-dhcp4-svr-name

Specifies the name of the local DHCPv4 server, up to 32 characters.

local-dhcp6-svr-name

Specifies the name of the local DHCv6 server, up to 32 characters.

dhcp4-server-pool

The name of the pool defined in the specified DHCPv4 server, up to 32 characters.

dhcp6-server-pool

The name of the pool defined in the specified DHCPv6 server, up to 32 characters.

secondary-pool-name

The name of the secondary pool defined in the specified server, up to 32 characters.

Context

[Tree] (config>router>isis>segm-rtng adj-sid-hold)

Full Context

configure router isis segment-routing adj-sid-hold

Description

This command configures a timer to hold the ILM or LTN of an adjacency SID following a failure of the adjacency.

When an adjacency to a neighbor fails, the following procedures are followed for both the LFA protected SID and the LFA unprotected SID of this adjacency in SR-MPLS. An adjacency can have both types of SIDs assigned by configuration. An LFA protected adjacency SID is eligible for LFA protection, but the following procedures apply even if a LFA backup was not programmed at the time of the failure. An LFA unprotected adjacency SID is not eligible for LFA protection.

- IGP withdraws the advertisement of the link TLV as well as its adjacency SID sub-TLV.
- The adjacency SID hold timer starts.
- The LTN and ILM records of the adjacency are kept in the datapath for as long as the adjacency SID hold time is running. This allows packets to flow over the LFA backup path, when the adjacency is protected, and allows the ingress LER or PCE time to compute a new path of the SR-TE LSP after IGP converges.
- If the adjacency is restored while the adjacency SID hold timer is running, the timer is aborted, and the adjacency SID remains programmed in the datapath with the retained SID values. However, the backup NHLFE may change if a new LFA SPF runs while the adjacency SID hold timer running. An update to the backup NHLFE is performed immediately following the LFA SPF. In all cases, the adjacency keeps its assigned SID label value.
- If the adjacency SID hold timer expires before the adjacency is restored, the SID is deprogrammed from the datapath and the label returned into the common pool where it was drawn from. Users of the adjacency (for example, SR policy and SR-TE LSP) are also informed.

  When the adjacency is subsequently restored, it gets assigned its allocated static-label value or a new dynamic-label value.
- A new PG-ID is assigned each time an adjacency comes back up. This PG-ID is used by the ILM and LTN of the adjacency SID and of all downstream node SIDs that resolve to a next hop over this adjacency.

The **no** form of this command reverts to the default value.

Default

adj-sid-hold 15

Parameters

seconds

Specifies the adjacency SID hold time, in seconds.

Values 1 to 1800

Platforms

All

adj-sid-hold

Syntax

adj-sid-hold *seconds*

no adj-sid-hold

Context

[Tree] (config>router>isis>srv6 adj-sid-hold)

Full Context

configure router isis segment-routing-v6 adj-sid-hold

Description

This command specifies the length of time the system holds the SRv6 adjacency route and tunnel entries programmed in datapath while the adjacency is down.

When an adjacency to a neighbor fails, the following procedures are followed for both the LFA protected SID and the LFA unprotected SID of this adjacency in SRv6. An adjacency can have both types of SIDs assigned by configuration. An LFA protected adjacency SID is eligible for LFA protection, but the following procedures apply even if a LFA backup was not programmed at the time of the failure. An LFA unprotected adjacency SID is not eligible for LFA protection.

- IGP withdraws the advertisement of the link TLV as well as its SRv6 End.X SID sub-TLV.
- The adjacency SID hold timer starts.
- The route table, FIB, and tunnel table entries are kept for as long as the adjacency SID hold timer is running. This allows packets to flow over the LFA backup path, when the adjacency is protected, and to allow the ingress LER or PCE time to compute a new path of a SRv6 policy after IGP converges.
- If the adjacency is restored while the adjacency SID hold timer is running, the timer is aborted, and the adjacency SID remains programmed in the datapath with the retained SID values. However, the backup NHLFE may change if a new LFA SPF runs while the adjacency SID hold timer is running. An update to the backup NHLFE is performed immediately following the LFA SPF. In all cases, the adjacency keeps its assigned SID value.

- If the adjacency SID hold timer expires before the adjacency is restored, the SID is deprogrammed from the datapath and the SID value returned into the locator subnet where it was drawn from. Users of the adjacency (for example, SRv6 policy) are also informed.

  When the adjacency is subsequently restored, it gets assigned its allocated static SID value or a new dynamic SID value.
- A new PG-ID is assigned each time an adjacency comes back up. This PG-ID is used by tunnel of the local adjacency SID and of all remote locator routes that resolve to a next hop over this adjacency.

Note:
Each IS-IS instance runs a single timer per adjacency that IPv4 SR-MPLS, IPv6 SR-MPLS, and SRv6 adjacency SIDs share. When you enable both SR-MPLS and SRv6 in the IS-IS instance via the following commands, the system programs the higher of the two timer values for all SIDs on the adjacency.

```
configure router isis segment-routing
configure router isis segment-routing-v6
```

The **no** form of this command reverts to the default value.

Description

This command configures a timer to hold the ILM or LTN of an adjacency SID following a failure of the adjacency.

When an adjacency to a neighbor fails, the following procedures are followed for both the LFA protected SID and the LFA unprotected SID of this adjacency in SR-MPLS. An adjacency can have both types of SIDs assigned by configuration. An LFA protected adjacency SID is eligible for LFA protection, but the following procedures apply even if a LFA backup was not programmed at the time of the failure. An LFA unprotected adjacency SID is not eligible for LFA protection.

- IGP withdraws the advertisement of the link TLV as well as its adjacency SID sub-TLV.
- The adjacency SID hold timer starts.
- The LTN and ILM records of the adjacency are kept in the datapath for as long as the adjacency SID hold time is running. This allows packets to flow over the LFA backup path, when the adjacency is protected, and allows the ingress LER or PCE time to compute a new path of the SR-TE LSP after IGP converges.
- If the adjacency is restored while the adjacency SID hold timer is running, the timer is aborted, and the adjacency SID remains programmed in the datapath with the retained SID values. However, the backup NHLFE may change when a new LFA SPF is run while the adjacency SID hold timer running. An update to the backup NHLFE is performed immediately following the LFA SPF. In all cases, the adjacency keeps its assigned SID label value.
- If the adjacency SID hold timer expires before the adjacency is restored, the SID is deprogrammed from the datapath and the label returned into the common pool where it was drawn from. Users of the adjacency (for example, SR policy and SR-TE LSP) are also informed.

  When the adjacency is subsequently restored, it gets assigned its allocated static label value or a new dynamic label value.
- A new PG-ID is assigned each time an adjacency comes back up. This PG-ID is used by the ILM and LTN of the adjacency SID and of all downstream node SIDs that resolve to a next hop over this adjacency.

The **no** form of this command reverts to the default value.

debug router isis adjacency

Description

This command enables debugging for IS-IS adjacency.

The **no** form of the command disables debugging.

Parameters

ip-address

When specified, only adjacencies with the specified interface address are debugged.

Values ipv4-address:

- a.b.c.d (host bits must be 0)

ipv6-address:

- x:x:x:x:x:x:x:x (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d
- x: [0 to FFFF]H
- d: [0 to 255]D

ip-int-name

When specified, only adjacencies with the specified interface name are debugged.

nbr-system-id

When specified, only the adjacency with the specified ID is debugged.

[Tree] (config>mcast-mgmt>mcast-info-plcy>bundle>channel admin-bw)

Full Context

configure mcast-management multicast-info-policy bundle admin-bw

configure mcast-management multicast-info-policy bundle channel source-override admin-bw

configure mcast-management multicast-info-policy bundle channel admin-bw

Description

This command specifies an administrative bandwidth for multicast channels. The specified bandwidth rate can be used by the multicast ingress path manger, multicast CAC manager or multicast ECMP manager.

The *kbps* value is closely tied to the **bw-activity** command. When the bw-activity command is set to use-admin-bw, the multicast ingress path manager uses the configured administrative bandwidth value as the managed ingress bandwidth. The **admin-bw** value must be defined for the **bw-activity use-admin-bw** command to succeed. Once the bw-activity command is set to use the admin-bw value, the value cannot be set to 0 and the no admin-bw command fails. Setting the bw-activity command to dynamic (the default setting), breaks the association between the commands.

The **no** form of this command restores the default value for admin-bw. If the command is executed in the **channel** context, the channels administrative bandwidth value is set to null. If the command is executed in the **source-override** context, the source override administrative bandwidth value is set to null.

Parameters

kbps

Specifies the administrative bandwidth for multicast channels.

Values 1 to 40000000 kb/s

Bundle default: 0

Channel default:	Null (undefined)
Source-override default:	Null (undefined)

Override sequence — The channel setting overrides the bundle setting. The source-override setting overrides the channel and bundle settings.

Platforms

5.118 admin-bw-threshold

admin-bw-threshold

Syntax

admin-bw-threshold *kilo-bits-per-second*

no admin-bw-threshold

Context

[Tree] (config>mcast-mgmt>bw-plcy admin-bw-threshold)

Full Context

configure mcast-management bandwidth-policy admin-bw-threshold

Description

This command defines at which bandwidth rate a multicast channel configured to use an administrative rate starts and stop using that rate as the in-use ingress bandwidth when managing ingress multicast paths. This parameter only applies to channels that are configured to use the admin-bw rate with the **bw-activity use-admin-bw** command (both are configured in the multicast-info-policy associated with the channel context).

To be effective, the **admin-bw-threshold** value must be less than the channels configured admin-bw. If the administrative bandwidth configured on the channel is less than the administrative bandwidth threshold defined in the bandwidth policy, the admin-bw value is ignored for ingress multicast path management and the system continually uses the dynamic ingress bandwidth associated with the channel. Since the value is defined in the bandwidth-policy and the channel admin-bw value is defined in the **multicast-info-policy**, it is not possible to pre-determine that a given administrative bandwidth value is less than an administrative bandwidth threshold. Since a typical administrative bandwidth threshold is set significantly lower than any administrative bandwidth values, this corner case is not expected to be prevalent. However, if the case does arise in a production environment, no ill behavior is expected as the threshold is simply a tuning parameter used to detect when the bandwidth associated with a channel has risen above any OAM or background type traffic.

While a channel that is configured to the **use-admin-bw** parameter (in the **bw-activity** command) current bandwidth is less than the admin-bw-threshold, the system treats the channel as a dynamic type channel.

Once the threshold is crossed, the system immediately allocates the full admin-bw value to the channel and manages the ingress multicast path accordingly. If the bandwidth monitored on the channel rises above the admin-bw value, the system reverts to dynamic bandwidth management operation. If the bandwidth drops below the admin-bw value, but is above the **admin-bw-threshold**, the system uses the admin-bw value. If the bandwidth drops below the admin-bw-threshold, the system goes back to dynamic bandwidth management operation.

This command has no effect on multicast ECMP or egress CAC management operations.

The **no** form of this command reverts to the default, which is 10 kb/s.

Parameters

kilobits-per-second

Specifies the defines the rate at which channels configured to use administrative bandwidths change from dynamic bandwidth management to using the channels configured administrative bandwidth. The parameter is expressed as an integer value and represents multiples of 1,000 bits per second. A value of 3000 indicates 3,000,000 bits per second.

Values 1 to 40,000,000

Platforms

7450 ESS, 7750 SR-1x-48D, 7750 SR-1x-92S, 7750 SR-7/12/12e, 7750 SR-s, 7950 XRS, VSR

Full Context

configure router mpls interface admin-group

configure service vprn interface if-attribute admin-group

configure router interface if-attribute admin-group

configure service ies interface if-attribute admin-group

Description

This command configures the admin group membership of an interface. The user can apply admin groups to an IES, VPRN, network IP, or MPLS interface.

Each single operation of the **admin-group** command allows a maximum of five (5) groups to be specified at a time. However, a maximum of 32 groups can be added to a given interface through multiple operations. Once an admin group is bound to one or more interface, its value cannot be changed until all bindings are removed.

The configured **admin-group** membership will be applied in all levels or areas the interface is participating in. The same interface cannot have different memberships in different levels or areas.

Only the admin groups bound to an MPLS interface are advertised in TE link TLVs and sub-TLVs when the **traffic-engineering** option is enabled in IS-IS or OSPF. IES and VPRN interfaces do not have their attributes advertised in TE TLVs.

The **no** form of this command deletes one or more of the admin-group memberships of an interface. The user can also delete all memberships of an interface by not specifying a group name.

Default

no admin-group

Parameters

group-name

Specifies up to five groups, each up to 32 characters. The association of group name and value should be unique within an IP/MPLS domain. Each single operation of the **admin-group** command allows a maximum of 5 groups to be specified. However, a maximum of 32 groups can be added to a given interface through multiple operations.

Platforms

All

admin-group

Syntax

admin-group *group-name* **value** *group-value*

no admin-group *group-name*

Context

[Tree] (config>router>if-attribute admin-group)

Full Context

configure router if-attribute admin-group

Description

This command defines an Administrative Group (AG) that can be associated with an IP or MPLS interface.

AGs, also known as affinity, are used to tag IP and MPLS interfaces that share a specific characteristic with the same identifier. For example, an AG identifier can represent:

- all links that connect to core routers
- all links that have a bandwidth higher than 10 Gb
- all links that are dedicated to a specific service

First configure locally on each router the name and identifier of each AG. A maximum of 32 AGs can be configured per system.

After configuring the router name and identifier, configure the AG membership of an interface. You can apply AGs to a IES, VPRN, network IP, or MPLS interface.

When applied to MPLS interfaces, the interfaces can be included or excluded in the LSP path definition by inferring the AG name. CSPF computes a path that satisfies the AG include and exclude constraints.

When applied to IES, VPRN, or network IP interfaces, the interfaces can be included or excluded in the route next-hop selection by inferring the AG name in a route next-hop policy template applied to an interface or a set of prefixes.

The following provisioning rules apply to the AG configuration. The system rejects the creation of an AG:

- if the name of the AG is the same as that of an existing group, even if the new AG group value is different from the existing group value
- if the AG reuses the same group value but with a different name from an existing group

Only the AGs bound to an MPLS interface are advertised area wide in TE link TLVs and sub-TLVs when the **traffic-engineering** option is enabled in IS-IS or OSPF. IES and VPRN interfaces do not have their attributes advertised in TE TLVs.

Parameters

group-name

Specifies the name of the group, up to 32 characters. The association of group name and value should be unique within an IP/MPLS domain

group-value

Specifies the integer value associated with the group. The association of group name and value should be unique within an IP or MPLS domain.

Values 0 to 31 – Specifies the value range to use with link LFA next-hop policies or is used as a link color (AG or EAG) with Segment Routing Flex-Algorithms.

32 to 255 – Specifies the value range to use when the EAG is used as a link color with Segment Routing Flex-Algorithms. This higher range fails if used for other applications, such as LFA next-hop policies.

configure router flexible-algorithm-definitions flex-algo include-any admin-group

Description

This command configures an administrative group link that will be included in the topology graph of the configured FAD. If multiple administrative groups are configured, at least one of the administrative groups must be present in a link before the link is included into the flexible algorithm topology graph.

The **no** form of this command removes the *admin-group* from being included in the topology graph.

Default

no admin-group

Parameters

admin-group

Configures an administrative group to include in the topology graph of the configured FAD.

Platforms

All

5.120 admin-group-frr

admin-group-frr

Syntax

[**no**] **admin-group-frr**

Context

[Tree] (config>router>mpls admin-group-frr)

Full Context

configure router mpls admin-group-frr

Description

This command enables the use of the admin-group constraints in the association of a manual or dynamic bypass LSP with the primary LSP path at a Point-of-Local Repair (PLR) node.

When this command is enabled, each PLR node reads the admin-group constraints in the FAST_REROUTE object in the Path message of the LSP primary path. If the FAST_REROUTE object is not included in the Path message, then the PLR will read the admin-group constraints from the Session Attribute object in the Path message.

If the PLR is also the ingress LER for the LSP primary path, then it just uses the admin-group constraint from the LSP and/or path level configurations.

The PLR node then uses the admin-group constraints along with other constraints, such as hop-limit and SRLG, to select a manual or dynamic bypass among those that are already in use.

If none of the manual or dynamic bypass LSP satisfies the admin-group constraints, and/or the other constraints, the PLR node will request CSPF for a path that merges the closest to the protected link or node and that includes or excludes the specified admin-group IDs.

If the user changes the configuration of the above command, it will not have any effect on existing bypass associations. The change will only apply to new attempts to find a valid bypass.

The **no** form of this command disables the use of administrative group constraints on a FRR backup LSP at a PLR node.

Default

no frr-admin-group

Platforms

All

5.121 admin-password

admin-password

Syntax

admin-password *password* [**hash** | **hash2**]

no admin-password

Context

[Tree] (config>system>security>password admin-password)

Full Context

configure system security password admin-password

Description

This command allows a user (with admin permissions) to configure a password that enables a user to become an administrator.

This password is valid only for one session. When enabled, no authorization to TACACS+ or RADIUS is performed and the user is locally regarded as an admin user.

This functionality can be enabled in two contexts:

config>system>security>password>admin-password

<global> enable-admin

If the admin-password is configured in the **config>system>security>password** context, then any user can enter the special mode by entering the **enable-admin** command.

enable-admin is in the default profile. By default, all users are given access to this command.

After the **enable-admin** command is entered, the user is prompted for a password. If the password matches, user is given unrestricted access to all the commands.

The minimum length of the password is determined by the **minimum-length** command. The complexity requirements for the password are determined by the **complexity** command.

Note:
The *password* argument of this command is not sent to the servers. This is consistent with other commands that configure secrets.

The usernames and passwords in the FTP and TFTP URLs will not be sent to the authorization or accounting servers when the **file>copy** *source-url dest-url* command is executed.

For example:

file copy ftp://test:secret@10.20.31.79/test/srcfile cf1:\destfile

In this example, the username 'test' and password 'secret' will not be sent to the AAA servers (or to any logs). They will be replaced with "****".

The **no** form of this command removes the admin password from the configuration.

Note:
This command applies to a local user, in addition to users on RADIUS, TACACS, and LDAP.

Default

no admin-password

Parameters

password

Configures the password that enables a user to become a system administrator. The maximum length can be up to 56 characters if unhashed, 60 characters if hashed with bcrypt, from 87 to 92 characters if hashed with sha2-pbkdf2, 32 characters if the hash keyword is specified, or 54 characters if the hash2 keyword is specified. The unhashed cleartext password form should meet all the requirements that are defined by the **complexity** command.

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form or hashed with bcrypt or PBKDF2. For security, all keys are stored in the configuration file in hashed form (using bcrypt or PBKDF2, depending on the hashing configuration parameter) or, for backward compatibility, can be stored in encrypted form with the **hash** or **hash2** parameter specified.

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form or hashed with bcrypt or PBKDF2. For security, all keys are stored in the configuration file in hashed form (using bcrypt or PBKDF2, depending on the hashing configuration parameter) or, for backward compatibility, can be stored in encrypted form with the **hash** or **hash2** parameter specified.

5.122 admin-state

admin-state

Syntax

admin-state {**up** | **down**}

no admin-state

Context

[Tree] (config>router>l2tp>group>tunnel>mlppp admin-state)

[Tree] (config>service>vprn>l2tp>group>tunnel>mlppp admin-state)

Full Context

configure router l2tp group tunnel mlppp admin-state

configure service vprn l2tp group tunnel mlppp admin-state

Description

This command enables MLPPP for this tunnel group and is applicable only to LNS.

The tunnel can be explicitly activated (if the parent group is in a **no shutdown** state) or deactivated by the **up** and **down** keywords.

If there the admin state is not configured, the tunnel inherits its administrative state from its parent (group).

The **no** form of this command causes the tunnel administrative state to be inherited from the group.

Parameters

up

Specifies that the tunnel is to be administratively up.

down

Specifies that the tunnel is to be administratively down.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s

5.123 admin-status

admin-status

Syntax

admin-status {**rx** | **tx** | **tx-rx** | **disabled**}

Context

[Tree] (config>port>ethernet>lldp>dstmac admin-status)

Full Context

configure port ethernet lldp dest-mac admin-status

Description

This command configures LLDP transmission/reception frame handling.

Default

admin-status disabled

Parameters

rx

Specifies the LLDP agent will receive, but will not transmit LLDP frames on this port.

tx

Specifies that the LLDP agent will transmit LLDP frames on this port and will not store any information about the remote systems connected.

tx-rx

Specifies that the LLDP agent transmits and receives LLDP frames on this port.

disabled

Specifies that the LLDP agent does not transmit or receive LLDP frames on this port. If there is remote systems information which is received on this port and stored in other tables, before the port's admin status becomes disabled, then the information will naturally age out.

5.124 admin-tag

admin-tag

Syntax

[**no**] **admin-tag** *tag-value*

Context

[Tree] (config>router>mpls>lsp-template admin-tag)

[Tree] (config>router>mpls>lsp admin-tag)

Full Context

configure router mpls lsp-template admin-tag

configure router mpls lsp admin-tag

Description

This assigns an administrative tag to an LSP. The administrative tag can be used to enable routes with certain administrative tags to resolve using LSPs of matching administrative tags.

Up to four tags can be assigned to an LSP.

The administrative tag must exist under **config>router>admin-tags**.

The **no** form of this command removes the administrative tag.

Parameters

tag-value

The value of the admin-tag, up to 32 characters.

Platforms

All

admin-tag

Syntax

[**no**] **admin-tag** *tag*

Context

[Tree] (config>router>admin-tags admin-tag)

Full Context

configure router admin-tags admin-tag

Description

This command configures an admin tag value in the nodal LSP administrative tag database.

Up to 256 admin tags can be configured.

The **no** form of this command removes the admin tag.

Parameters

tag

The value of the administrative tag, up to 32 characters.

Platforms

All

5.125 admin-tag-policy

admin-tag-policy

Syntax

configure router admin-tags

Description

Commands in this context configure admin tags and router admin tag policy templates used for route resolution to LSPs.

Platforms

All

5.127 adspec

adspec

Syntax

[**no**] **adspec**

Context

[Tree] (config>router>mpls>lsp adspec)

[Tree] (config>router>mpls>lsp-template adspec)

Full Context

configure router mpls lsp adspec

configure router mpls lsp-template adspec

Description

When enabled, the ADSPEC object will be included in RSVP messages for this LSP. The ADSPEC object is used by the ingress LER to discover the minimum value of the MTU for links in the path of the LSP. By default, the ingress LER derives the LSP MTU from that of the outgoing interface of the LSP path.

A bypass LSP always signals the ADSPEC object since it protects both primary paths which signal the ADSPEC object and primary paths which do not. This means that MTU of LSP at ingress LER may change to a different value from that derived from the outgoing interface even if the primary path has ADSPEC disabled.

Default

no adspec — No ADSPEC objects are included in RSVP messages.

Platforms

5.128 adv-adj-addr-only

adv-adj-addr-only

Syntax

[**no**] **adv-adj-addr-only**

Context

[Tree] (config>router>ldp>session-params>peer adv-adj-addr-only)

Full Context

configure router ldp session-parameters peer adv-adj-addr-only

Description

This command provides a means for an LDP router to advertise only the local IPv4 or IPv6 interfaces it uses to establish hello adjacencies with an LDP peer. By default, when a router establishes an LDP session with a peer, it advertises in an LDP Address message the addresses of all local interfaces to allow the peer to resolve LDP FECs distributed by this router. Similarly, a router sends a Withdraw Address message to of all its peers to withdraw a local address if the corresponding interface went down or was deleted.

This new option reduces CPU processing when a large number of LDP neighbors come up or go down. The new CLI option is strongly recommended in mobile backhaul networks where the number of LDP peers can be very large.

The **no** form of this command reverts LDP to the default behavior of advertising all local interfaces.

Platforms

All

5.129 adv-config-policy

adv-config-policy

Syntax

adv-config-policy *policy-name* [**create**]

no adv-config-policy *policy-name*

Context

[Tree] (config>qos adv-config-policy)

Full Context

configure qos adv-config-policy

Description

Commands in this context configure an advanced QoS policy. This command contains only queue and policer child control parameters within a child-control node.

The parameters within the **child-control** node are intended to allow more precise control of the method that hierarchical virtual scheduling employs to emulate the effect of a scheduling context upon a member child queue or policer.

When a policy is created, it may be applied to a queue or policer defined within a **sap-egress** or **sap-ingress** QoS policy. It may also be applied to a queue or policer defined within an ingress or **egress queue-group** template. When a policy is currently associated with a QoS policy or template, the policy may be modified but not deleted (even in the event that the QoS policy or template is not in use).

While the system maintains default values for the advanced configuration parameters, no default **adv-config-policy** exists.

The **no** form of this command removes the specified advanced policy.

Parameters

policy-name

The name of the advanced QoS policy. A policy-name must be specified and conform to the policy naming guidelines. If the specified name does not exist, the optional **create** keyword requirements are met and the total number of policies per system will not be exceeded, an **adv-config-policy** of that name will be created. If the specified name does exist, the system will switch context to that **adv-config-policy** for the purpose of modification of the policy's contents.

Values Valid names consist of any string up to 32 characters, composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

Full Context

configure qos sap-egress queue adv-config-policy

configure qos sap-ingress queue adv-config-policy

configure qos sap-egress policer adv-config-policy

configure qos sap-ingress policer adv-config-policy

Description

This command specifies the advanced QoS policy. The advanced QoS policy contains only queue and policer child control parameters within a child-control node.

When a policy is created, it may be applied to a queue or policer defined within a **sap-egress** or **sap-ingress** QoS policy. It may also be applied to a queue or policer defined within an **ingress** or **egress queue-group** template. When a policy is currently associated with a QoS policy or template, the policy may be modified but not deleted (even in the event that the QoS policy or template is not in use).

The **no** form of this command removes the specified advanced policy.

Default

no adv-config-policy

Parameters

policy-name

The name of the advanced QoS policy.

Values Valid names consist of any string up to 63 characters, composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

adv-config-policy

Syntax

adv-config-policy *src-name dst-name* [**overwrite**]

Context

[Tree] (config>qos>copy adv-config-policy)

Full Context

configure qos copy adv-config-policy

Description

This command copies existing QoS policy entries for a QoS policy-id to another QoS policy-id.

The **copy** command is a configuration-level maintenance tool used to create new policies using existing policies. It also allows bulk modifications to an existing policy with the use of the **overwrite** keyword.

Parameters

adv-config-policy

Indicates that the source policy ID and the destination policy ID are advanced policy IDs. Specify the source advanced policy ID that the copy command will attempt to copy from and specify the destination advanced policy ID to which the command will copy a duplicate of the policy.

overwrite

Specifies that this policy is to replace the existing destination advanced policy. Everything in the existing destination policy will be overwritten with the contents of the source advanced policy. If **overwrite** is not specified, an error will occur if the destination policy ID exists, as shown here:

Example:

```
– ALA-7>config>qos# copy adv-config-policy default sp1
– MINOR: CLI Destination "sp1" exists - use {overwrite}
– ALA-7>config>qos#overwrite
```

Platforms

All

5.130 adv-local-lsr-id

adv-local-lsr-id

Syntax

[**no**] **adv-local-lsr-id**

Context

[Tree] (config>router>ldp>targeted-session>peer-template adv-local-lsr-id)

[Tree] (config>router>ldp>session-params>peer adv-local-lsr-id)

Full Context

configure router ldp targeted-session peer-template adv-local-lsr-id

configure router ldp session-parameters peer adv-local-lsr-id

Description

This command advertises a local LSR ID over a specified LDP session.

Advertisement of a local LSR ID over a given LDP session is configured using the **adv-local-lsr-id** command in the peer session-parameters. If a user disables the **adv-local-lsr-id** command, then the system will withdraw the FEC for the local LSR ID.

The SR OS router uses the following rules when advertising a local LSR ID:

- If the session parameters have the default configuration and the targeted peer template has the default configuration, the local LSR ID is not advertised.
- If the session parameters have the default configuration but the targeted peer template has an explicit configuration for advertisement of the local LSR ID, the targeted peer template configuration is used.
- If the session parameters have an explicit configuration for advertisement of the local LSR ID but the targeted peer template has the default configuration, the session parameter configuration is used.
- If both the session parameters and the targeted peer template have an explicit configuration for advertisement of the local LSR ID, then the session parameter configuration is used.

The **no** form of this command withdraws the FEC for the local LSR ID.

Default

no adv-local-lsr-id

Platforms

All

5.131 adv-mtu-override

adv-mtu-override

Syntax

[**no**] **adv-mtu-override**

Context

[Tree] (config>service>sdp adv-mtu-override)

Full Context

configure service sdp adv-mtu-override

Description

This command overrides the advertised VC-type MTU of all spoke-sdps of L2 services using this SDP-ID. When enabled, the router signals a VC MTU equal to the service MTU, which includes the Layer 2 header. It also allows this router to accept an MTU advertised by the far-end PE which value matches either its advertised MTU or its advertised MTU minus the L2 headers.

By default, the router advertises a VC-MTU equal to the L2 service MTU minus the Layer 2 header and always matches its advertised MTU to that signaled by the far-end PE router, otherwise the spoke-sdp goes operationally down.

When this command is enabled on the SDP, it has no effect on a spoke-sdp of an IES/VPRN spoke interface using this SDP-ID. The router continues to signal a VC MTU equal to the net IP interface MTU, which is min{ip-mtu, sdp operational path mtu - L2 headers}. The router also continues to make sure that the advertised MTU values of both PE routers match or the spoke-sdp goes operationally down.

The **no** form of the command disables the VC-type MTU override and returns to the default behavior.

Default

no adv-mtu-override

Context

[Tree] (config>system>dhcp6 adv-noaddrs-global)

Full Context

configure system dhcp6 adv-noaddrs-global

Description

This command configures the different DHCPv6 applications to send the NoAddrsAvail Status-Code in DHCPv6 Advertise messages at the global DHCP message level.

By default, all applications send the NoAddrsAvail Status-Code in DHCPv6 Advertise messages at the IA_NA Option level.

Different applications for which NoAddrsAvail Status-Code in DHCPv6 Advertise messages can be configured at the global DHCP message level.

The only valid combination in current SR OS is **adv-noaddrs-global esm-relay server**.

The **no** form of this command reverts to the default.

Default

no adv-noaddrs-global. All applications send the NoAddrsAvail Status-Code in DHCPv6 Advertise messages at the IA_NA Option level.

Parameters

esm-proxy

Specifies the DHCPv6 proxy server on subscriber group-interfaces. Not supported in current SR OS.

esm-relay

Specifies the DHCPv6 relay on subscriber group-interfaces. Must be enabled together with the DHCPv6 server (server) application.

relay

Specifies the DHCPv6 relay on regular IES or VPRN interfaces. Not supported in current SR OS.

server

Specifies the DHCPv6 server. Must be enabled together with the DHCPv6 relay on subscriber interfaces (esm-relay) application.

Syntax

adv-service-mtu *octets*

no adv-service-mtu

Context

[Tree] (config>service>epipe>spoke-sdp adv-service-mtu)

Full Context

configure service epipe spoke-sdp adv-service-mtu

Description

This command configures the MTU value signaled in targeted LDP for the spoke-SDP and the value used to validate the value signaled by the far-end PE. If configured, this value is used instead of the service MTU. However, the configuration does not affect the locally enforced value, which is still based on the service MTU. This command for the MTU cannot be configured on a spoke-SDP that is bound to an SDP with the **adv-mtu-override** command.

When unconfigured, an adjusted service MTU is used. See the **service-mtu** command for more information.

The **no** form of this command removes the configuration.

Default

no adv-service-mtu

Parameters

octets

The size of the MTU in octets, expressed as a decimal integer.

Values 0 to 9782

Platforms

configure service ies interface vpls evpn nd advertise

configure service vprn interface vpls evpn arp advertise

configure service vprn interface vpls evpn nd advertise

configure service ies interface vpls evpn arp advertise

Description

This command enables the advertisement of static and dynamic ARP and ND entries that are installed in the ARP and ND cache into EVPN MAC/IP routes. This command must be used along with **no learn-dynamic**.

Default

no advertise

Parameters

static

Enables ARP/ND host routes to be created in the route table from EVPN ARP/ND entries

dynamic

Enables ARP/ND host routes to be created in the route table out of dynamic ARP/ND entries (learned from ARP/ND messages received from the hosts).

route-tag

Specifies the route tag that is added in the route table for ARP/ND host routes of type **dynamic**, or **static**. This tag can be matched on BGP VRF export and BGP peer export policies.

[Tree] (config>router>isis>flex-algos>flex-algo advertise)

[Tree] (config>router>ospf>flex-algos>flex-algo advertise)

Full Context

configure router isis flexible-algorithms flex-algo advertise

configure router ospf flexible-algorithms flex-algo advertise

Description

This command enables the advertisement of a locally configured Flexible Algorithm Definition (FAD).

A locally defined FAD is only advertised if it is administratively enabled. A router can advertise only a single locally defined FAD by using the *fad-name* as reference anchor.

The winning FAD used by a router must be consistent with the winning FAD on all other routers. This avoids routing loops and traffic blackholing. The winning FAD is selected using a tie-breaker algorithm that first selects the highest advertised FAD priority and next the highest system Id.

The **no** form of this command removes the advertisement of a flexible algorithm definition.

Default

no advertise

Parameters

fad-name

Configures the FAD name, up to 32 characters. By default, no locally configured FAD is advertised.

Platforms

All

advertise

Syntax

advertise {**mvpn-pim** | **mvpn-only**| **pim-only**}

configure service vprn bgp-evpn segment-routing-v6 evpn-link-bandwidth advertise

configure service vprn bgp-evpn mpls evpn-link-bandwidth advertise

Description

This command enables the advertisement of the EVPN link bandwidth extended community along with the IP Prefix routes.

The **no** form of this command disables the advertisement of the EVPN link bandwidth extended community.

Default

no advertise

Parameters

weight

Specifies the weight advertised in the EVPN link bandwidth extended community for the advertised EVPN IP prefix routes for the service.

Values 1 to 128

weight dynamic

Keyword to specify that the weight is dynamically set based on the number of BGP PE-CE paths for the IP-Prefix that is advertised in an EVPN IP-Prefix route.

max-dynamic-weight

Specifies the maximum weight advertised in the EVPN link bandwidth extended community for the advertised EVPN IP-Prefix routes for the service. If **weight dynamic** is configured, the actual advertised weight is the minimum of the number of BGP PE-CE paths for the prefix and the configured maximum weight.

configure router bgp group neighbor bfd-strict-mode advertise

configure service vprn bgp bfd-strict-mode advertise

configure router bgp bfd-strict-mode advertise

configure service vprn bgp group bfd-strict-mode advertise

Description

This command configures BGP to advertise the Strict-BFD capability to peers that are within scope of this command and meet the following requirements:

- The **bfd-enable** command that applies to the peer is enabled (through either configuration or inheritance).
- The interface associated with the peer has a valid BFD configuration.

When the preceding conditions are satisfied and two peers attempting to form a session both advertise the Strict-BFD capability, the BGP finite state machine in each router transitions the session state to established after the BFD session with the peer enters the up state.

The **no** form of this command prevents BGP from advertising the Strict-BFD capability to peers.

Default

no advertise

Parameters

seconds

Specifies the maximum time (in seconds) BGP waits for the BFD session to come up, provided that the Strict-BFD procedures apply to a session, and the negotiated BGP hold time is zero (no keepalives). If the negotiated BGP hold time is greater than zero, the **holdtime** parameter is not considered.

[Tree] (config>router>ospf>flex-algos advertise-admin-group)

Full Context

configure router isis flexible-algorithms advertise-admin-group

configure router ospf flexible-algorithms advertise-admin-group

Description

This command configures the type of Aministrative Group (AG) or Extended Administrative Group (EAG) TLVs the router advertises as the Interior Gateway Protocol (IGP) link attribute. This command is configured for this IGP instance.

The **no** form of this command removes the configuration.

Default

prefer-ag

Parameters

prefer-ag

Keyword to specify that the router advertises the Administrative Group (AG) TLV as the IGP link attribute if the affinity bits in the **configure router if-attribute admin-group** *value* command are configured between 0 to 31. If no EAG (32 to 255) affinity bits are configured, only the AG TLV is advertised as the IGP link attribute.

If the affinity bits are configured in both the AG (0 to 31) and EAG (32 to 255) range, the router advertises both the AG and the EAG TLVs as the IGP link attributes.

eag-only

Keyword to specify that the router advertises only the EAG TLV as the IGP link attribute. No AG TLV is advertised if this keyword is configured.

ag-eag

Keyword to specify that the router can advertise both the AG and the EAG TLVs as the IGP link attributes, even without the affinity bit in the EAG range configured in the **configure router if-attribute admin-group** *value* command. If no affinity bit is configured in the AG range (0 to 31), the router prunes the AG TLV. Configuring this keyword allows for backward compatibility for vendor implementations that support only AG, while still supporting EAG.

configure service pw-routing local-prefix advertise-bgp

Description

This command enables a given prefix to be advertised in MP-BGP for dynamic MS-PW routing.

The **no** form of this command will explicitly withdraw a route if it has been previously advertised.

Default

no advertise-bgp

Parameters

rd

Specifies an 8-octet route distinguisher associated with the prefix. Up to 4 unique route distinguishers can be configured and advertised for a given prefix though multiple instances of the advertise-bgp command. This parameter is mandatory.

Values (6 bytes, other 2 Bytes of type will be automatically generated) asn:number1 (RD Type 0): 2bytes ASN and 4 bytes locally administered number ip-address:number2 (RD Type 1): 4bytes IPv4 and 2 bytes locally administered number;

community

An optional BGP communities attribute associated with the advertisement. To delete a previously advertised community, advertise-bgp route-distinguisher must be run again with the same value for the RD but excluding the community attribute.

[Tree] (config>port>ethernet>efm-oam>discovery advertise-capabilities)

Full Context

configure port ethernet efm-oam discovery advertise-capabilities

Description

This is the top level of the hierarchy which allows for the overriding of default advertising of capabilities to a remote peer.

Platforms

All

5.138 advertise-delay

advertise-delay

Syntax

[**no**] **advertise-delay**

Context

[Tree] (config>router>ospf>te-opts advertise-delay)

Full Context

configure router ospf traffic-engineering-options advertise-delay

Description

This command configures the advertisement of link delay in the IGP LSDB within the OSPF-TE TLV attribute or when the Application Specific Link Attribute (ASLA) is enabled within the SR-TE ASLA.

When the router is configured with the **configure router ospf traffic-engineering-options sr-te application-specific-link-attributes** command to generate SR-TE ASLA attributes, link delay is advertised as a legacy RFC 3630 TE TLV when RSVP-TE is enabled and as an ASLA RFC 8920 TLV for SR-TE when MPLS is enabled for an interface.

SR OS accepts and handles both legacy RSVP-TE TLVs and ASLAs for the RSVP application. However, SR OS only advertises RFC 3630 legacy RSVP-TE TLVs (as recommended by RFC 8920) to avoid compatibility issues.

The **no** form of this command disables link delay advertisement.

Default

no advertise-delay

Platforms

All

advertise-delay

Syntax

[**no**] **advertise-delay**

Context

[Tree] (config>router>isis>te advertise-delay)

Full Context

configure router isis traffic-engineering-options advertise-delay

Description

This command enables the advertisement of link delay in the IGP LSDB within legacy Traffic Engineering (TE) attributes in IS-IS or within the Application Specific Link Attribute (ASLA) when ASLA is enabled for SR-TE or RSVP-TE applications.

When **application-link-attributes legacy** command is configured for SR-TE or RSVP-TE, link delay is advertised as a legacy TE TLV with the ASLA legacy bit set.

The **no** form of this command disables link delay advertisement.

Default

no advertise-delay

5.139 advertise-external

advertise-external

Syntax

[**no**] **advertise-external** [**ipv4**] [**ipv6**] [**label-ipv4**] [**label-ipv6**]

Context

[Tree] (config>router>bgp advertise-external)

Full Context

configure router bgp advertise-external

Description

This command allows BGP to advertise its best external route to a destination even when its best overall route is an internal route. Entering the command (or its **no** form) with no address family parameters is equivalent to specifying all supported address families.

The **no** form of this command disables Advertise Best External for the BGP family.

Default

no advertise-external

Parameters

ipv4

Enables the best-external advertisement for unlabeled unicast IPv4 routes.

ipv6

Enables the best-external advertisement for unlabeled unicast IPv6 routes.

label-ipv4

Enables the best-external advertisement for labeled-unicast IPv4 routes.

label-ipv6

Enables the best-external advertisement for labeled-unicast IPv6 routes.

Full Context

configure service vprn bgp group neighbor advertise-inactive

configure service vprn bgp group advertise-inactive

configure service vprn bgp advertise-inactive

Description

This command enables or disables the advertising of inactive BGP routers to other BGP peers.

By default, BGP only advertises BGP routes to other BGP peers if a given BGP route is chosen by the route table manager as the most preferred route within the system and is active in the forwarding plane. This command allows system administrators to advertise a BGP route even though it is not the most preferred route within the system for a given destination.

When the BGP **advertise-inactive** command is configured so that it applies to a BGP session it has the following effect on the IPv4, IPv6, mcast-ipv4, mcast-ipv6, label-IPv4 and label-IPv6 routes advertised to that peer:

- If the active route for the IP prefix is a BGP route then that route is advertised.

- If the active route for the IP prefix is a non-BGP route and there is at least one valid but inactive BGP route for the same destination then the best of the inactive and valid BGP routes is advertised unless the non-BGP active route is matched and accepted by an export policy applied to the session.
- If the active route for the IP prefix is a non-BGP route and there are no (valid) BGP routes for the same destination then no route is advertised for the prefix unless the non-BGP active route is matched and accepted by an export policy applied to the session.

Default

no advertise-inactive

Full Context

configure service vprn bgp group neighbor advertise-ipv6-next-hops

configure service vprn bgp advertise-ipv6-next-hops

configure service vprn bgp group advertise-ipv6-next-hops

Description

When this command is configured, with the IPv4 option, so that it applies to a BGP session established on top of IPv6 transport, IPv4 BGP routes can be advertised with a true IPv6 address when originated or when **next-hop-self** (configured or automatic) is applied.

If an IPv4 route must originate or be advertised with a **next-hop-self** and the corresponding **advertise-ipv6-next-hops** command option does not apply to the session or if an appropriate **extended-nh-encoding** capability was not received from the remote peer, then the route is advertised with the IPv4 system address as the BGP next-hop.

If an IPv4 route is matched by a BGP export policy entry that tries to change the next hop to an IPv6 address and the corresponding **advertise-ipv6-next-hops** command option does not apply to the session or if an appropriate **extended-nh-encoding** capability was not received from the remote peer, then the route is handled as though it was rejected by the policy entry.

This command has no effect on sessions established over IPv4 transport.

The **no** form of this command reverts to the default.

Default

no advertise-ipv6-next-hops

Parameters

ipv4

Allows IPv4 unicast routes to be advertised to IPv6-transport peers with an IPv6 address as the BGP next-hop in cases of route origination or **next-hop-self** (configured or automatic). It also allows export policies to change the BGP next-hop of an IPv4 route to an IPv6 address. All of these cases require the remote peer to advertise the necessary extended NH encoding capability. It may be necessary to configure the **forward-ipv4-packets** command under the appropriate **interface>ipv6** contexts in order to enable datapath support for these control plane exchanges.

Full Context

configure router bgp group advertise-ipv6-next-hops

configure router bgp advertise-ipv6-next-hops

configure router bgp group neighbor advertise-ipv6-next-hops

Description

This command applies to a BGP session established on top of IPv6 transport; BGP routes belonging to the specified families can be advertised with a true IPv6 address when originated or when **next-hop-self** (configured or automatic) is applied.

This command has no effect on routes advertised to IPv4 peers.

When this command is not enabled, the following considerations apply:

- If a VPN IPv6 or label IPv6 route needs to be originated or advertised with **next-hop-self** to an IPv6 transport peer the route is advertised with the IPv4 system address as BGP next-hop (encoded as an IPv4-mapped IPv6 address).
- If a VPN-IPv4 or label IPv4 route needs to be originated or advertised with **next-hop-self** or if an appropriate **extended-nh-encoding** capability was not received from the remote peer, the route is advertised with the IPv4 system address as the BGP next-hop.
- If a VPN IPv4 or label IPv4 route is matched by a BGP export policy entry that tries to change the next-hop to an IPv6 address and an appropriate **extended-nh-encoding** capability was not received from the remote peer, the route is handled as though it was rejected by the policy entry.

The **no** form of this command disables the setting of next hops to a global IPv6 address for the family.

Default

no advertise-ipv6-next-hops

Parameters

vpn-ipv6

Allows VPN IPv6 routes to be advertised to IPv6 transport peers with an IPv6 address as the BGP next-hop in cases of route origination or **next-hop-self** (configured or automatic).

label-ipv6

Allows label IPv6 routes to be advertised to IPv6 transport peers with an IPv6 address as the BGP next-hop in cases of route origination or **next-hop-self** (configured or automatic).

vpn-ipv4

Allows VPN IPv4 routes to be advertised to IPv6 transport peers with an IPv6 address as the BGP next-hop in cases of route origination or **next-hop-self** (configured or automatic). It also allows export policies to change the BGP next-hop of a VPN IPv4 route to an IPv6 address. All of these cases require the remote peer to advertise the necessary extended NH encoding capability.

label-ipv4

Allows label IPv4 routes to be advertised to IPv6 transport peers with an IPv6 address as the BGP next-hop in cases of route origination or **next-hop-self** (configured or automatic). It also allows export policies to change the BGP next-hop of a label IPv4 route to an IPv6 address. All of these cases require the remote peer to advertise the necessary extended NH encoding capability.

ipv4

Instructs BGP to advertise an extended NH encoding capability for NLRI AFI=1, NLRI SAFI=1 and next-hop AFI=2.

evpn

Allows EVPN routes to be advertised to IPv6 transport peers.

Platforms

All

5.143 advertise-label

advertise-label

Syntax

advertise-label {**per-prefix** | **pop** | **pop-and-forward**}

no advertise-label

Context

[Tree] (config>router>policy-options>policy-statement>entry>action advertise-label)

[Tree] (config>router>policy-options>policy-statement>default-action advertise-label)

Full Context

configure router policy-options policy-statement entry action advertise-label

configure router policy-options policy-statement default-action advertise-label

Description

This command configures the label allocation method for advertised routes. The effect of the **advertise-label** command depends on the context where the associated policy is applied.

Use the **per-prefix** option and configure the command in the default action or entry-specific action of a VRF export policy to advertise every qualifying matched route with a per-prefix label in the resulting VPN-IP routes. In this situation, non-qualifying routes include local interface routes and BGP-VPN routes. The command overrides, for specific routes, the configured label-mode of the exporting VPRN service.

Use the per-prefix option and configure the command in the default action or entry-specific action of a BGP import policy to assign a per-prefix label to qualifying label-IPv4 and label-IPv6 routes when:

- these routes are the best path for their prefix in the respective RIB
- there is a BGP next-hop change

A label-IPv4 or label-IPv6 route advertised with a pre-prefix label supports ECMP forwarding across multiple BGP next-hops.

The **pop** option is applicable in route-table-import policies. The advertised BGP label is programmed for a pop operation when:

- a /32 IPv4 static, OSPF, or IS-IS route is matched and accepted by a label-IPv4 or label-IPv6 RIB route-table-import policy entry or default-action with this command
- the route is a candidate to be advertised as a label-IPv4 or label-IPv6 route (due to a BGP export policy)

When the label-IPv4 RIB imports a /32 static, OSPF, or IS-IS route and then exports the route as a BGP route, the default behavior is to program a swap operation in the datapath, which swaps the BGP label with the tunnel label that takes traffic to the destination of the /32 route.

The **pop-and-forward** option is applicable in route-table-import policies, when these policies match an unlabeled BGP route and apply this policy action.

Use the **pop-and-forward** option to program the label that is advertised in the BGP-LU route to forward the packet according to the resolution of the unlabeled route that triggered the origination of the BGP-LU route. The forwarding is done without an IP FIB lookup, which can be useful in situations where the IP FIB at the exit of the MPLS tunnel is not synchronized with the FIB at the head-end of the MPLS tunnel. The advertisement of a pop-and-forward label overrides the configuration to advertise label-ipv6 routes with an explicit null label and the configuration to advertise BGP-LU with a prefix SID attribute. Those features are not available when using the pop-and-forward label.

Default

no advertise-label

Parameters

per-prefix

Sets the per-prefix label allocation for matched routes. This takes effect only in VRF export policies and BGP import policies, and only for certain types of routes.

pop

Sets the pop label allocation for matched routes. This takes effect only in label-IPv4 route-table-import policies and only applies to /32 IPv4 routes that were learned through static configuration, OSPF, or IS-IS.

pop-and-forward

Sets the pop-and-forward label allocation for matched routes. This takes effect only when an unlabeled BGP IPv4 or IPv6 route is matched by a label-IPv4 or label-IPv6 route-table-import policy.

advertise-local

Syntax

[**no**] **advertise-local**

Context

[Tree] (config>service>vpls>isid-policy>entry advertise-local)

Full Context

configure service vpls isid-policy entry advertise-local

Description

The **no advertise-local** option prevents the advertisement of any locally defined I-VPLS ISIDs or static-isids in the range in a B-VPLS. For I-VPLS services or static-isids that are primarily unicast traffic, the use-def-mcast and no advertise-local options allows the forwarding of ISID based multicast frames locally using the default multicast. The **no advertise-local** option also suppresses this range of ISIDs from being advertised in ISIS. When using the **use-def-mcast** and **no advertise-local** policies, the ISIDs configured under this **static-isid** declarations SPBM treats the ISIDs as belonging to the default tree.

configure service vprn bgp group graceful-restart long-lived advertise-stale-to-all-neighbors

configure service vprn bgp graceful-restart long-lived advertise-stale-to-all-neighbors

Description

This command allows BGP routes marked as LLGR stale to be advertised to BGP peers that did not advertise the LLGR capability when the session was opened. The **no** version of this command causes advertisement behavior to follow the rule that stale routes cannot be advertised to a peer that does not understand or implement the LLGR capability. Stale routes are withdrawn towards such peers.

When this command is configured with the **without-no-export** option, LLGR stales routes can be advertised to any peer (EBGP or IBGP) that did not signal the LLGR capability. Towards IBGP and confederation-EBGP peers that did not advertise the LLGR capability, the LOCAL_PREFERENCE attribute in the advertised stale routes is automatically set to zero.

When this command is configured without the **without-no-export** option, LLGR stale routes are not advertised to any EBGP peer that did not signal the LLGR capability. Towards IBGP and confederation-EBGP peers that did not advertise the LLGR capability the LOCAL_PREFERENCE attribute in the advertised stale routes is automatically set to zero and a NO_EXPORT standard community is automatically added to the routes.

Default

no advertise-stale-to-all-neighbors

Parameters

without-no-export

Allows LLGR stale routes to be advertised to all peers, such that they can exit the local AS.

Platforms

Description

This command allows BGP routes marked as LLGR stale to be advertised to BGP peers that did not advertise the LLGR capability when the session was opened.

When this command is configured with the **without-no-export** option, LLGR stale routes can be advertised to any peer (EBGP or IBGP) that did not signal the LLGR capability. Towards IBGP and confederation-EBGP peers that did not advertise the LLGR capability, the LOCAL_PREFERENCE attribute in the advertised stale routes is automatically set to zero.

When this command is configured without the **without-no-export** option, LLGR stale routes are not advertised to any EBGP peer that did not signal the LLGR capability. Towards IBGP and confederation-EBGP peers that did not advertise the LLGR capability the LOCAL_PREFERENCE attribute in the advertised stale routes is automatically set to zero and a NO_EXPORT standard community is automatically added to the routes.

The **no** version of this command causes advertisement behavior to follow the rule that stale routes cannot be advertised to a peer that does not understand or implement the LLGR capability. Stale routes are withdrawn towards such peers.

Default

no advertise-stale-to-all-neighbors

Parameters

without-no-export

Allows LLGR stale routes to be advertised to all peers, such that they can exit the local AS.

Context

[Tree] (config>router>isis advertise-tunnel-link)

[Tree] (config>router>ospf advertise-tunnel-link)

Full Context

configure router isis advertise-tunnel-link

configure router ospf advertise-tunnel-link

Description

This command enables the forwarding adjacency feature. With this feature, IS-IS or OSPF advertises an RSVP LSP as a link so that other routers in the network can include it in their SPF computations. The RSVP LSP is advertised as an unnumbered point-to-point link and the link LSP or LSA has no Traffic Engineering opaque sub-TLVs, as per RFC 3906. An SR-TE LSP is not supported with forwarding adjacency.

The forwarding adjacency feature can be enabled independently from the IGP shortcut feature in CLI. If both **igp-shortcut** and **advertise-tunnel-link** options are enabled for a given IGP instance, then the **advertise-tunnel-link** takes precedence.

When the forwarding adjacency feature is enabled, each node advertises a p2p unnumbered link for each best metric tunnel to the router ID of any endpoint node. The node does not include the tunnels as IGP shortcuts in SPF computation directly. Instead, when the LSA or LSP that advertises the corresponding

P2P unnumbered link is installed in the local routing database, the node performs an SPF using it like any other link LSA or LSP. The bidirectional check of the link requires that a link, regular or tunnel, exists in the reverse direction for the tunnel to be used in SPF.

The **igp-shortcut** option under the LSP name governs the use of the LSP with both the **igp-shortcut** and the **advertise-tunnel-link** options in IGP. In other words, the user can exclude a specific RSVP LSP from being used as a forwarding adjacency by entering the command **config>router>mpls>lsp>no igp-shortcut**.

Support is provided for resolving and forwarding IPv4 and IPv6 prefixes over IPv4 forwarding adjacency RSVP-TE LSP. Specifically, the forwarding adjacency feature supports family IPv4 in OSPFv2, family IPv6 in OSPFv3, families IPv4 and IPv6 in ISIS MT=0, and family IPv6 in ISIS MT=2.

In addition, both IPv4 and IPv6 SR-ISIS tunnels can be resolved and further tunneled over one or more RSVP-TE LSPs used as forwarding adjacencies. This is enabled by configuring both segment routing and forwarding adjacency features within an IS-IS instance in a multi-topology MT=0.

IS-IS forwarding adjacency using the **advertise-tunnel-link** command is not supported in combination with the IS-IS link bundling and the IS-IS metric link quality adjustment features.

The **no** form of this command disables forwarding adjacency and disables the advertisement of RSVP LSP into IGP.

Default

no advertise-tunnel-link

no agg-rate-limit

Context

[Tree] (config>subscr-mgmt>sub-prof>egress agg-rate-limit)

Full Context

configure subscriber-mgmt sub-profile egress agg-rate-limit

Description

This command defines a subscriber aggregate limit when the subscriber profile is directly associated with an egress port based scheduler instead of a scheduler policy. The optional queue-frame-based-accounting keyword allows the subscriber queues to operate in the frame based accounting mode.

Once egress frame based accounting is enabled on the subscriber profile, all queues associated with the subscriber (created through the sla-profile associated with each subscriber host) will have their rate and CIR values interpreted as frame based values. When shaping, the queues will include the 12-byte Inter-Frame Gap (IFG) and 8-byte preamble for each packet scheduled out the queue. The profiling CIR

threshold will also include the 20-byte frame encapsulation overhead. Statistics associated with the queue do not include the frame encapsulation overhead. Packet byte offset settings are not included in the applied rate when queue frame based accounting is configured, however the offsets are applied to the statistics.

The **queue-frame-based-accounting** keyword does not change the behavior of the egress-agg-rate-limit rate value. Since the egress-agg-rate-limit is always associated with egress port based scheduling and egress port based scheduling is dependent on frame based operation, the egress-agg-rate-limit rate is always interpreted as a frame based value.

Enabling queue-frame-based-accounting will not cause statistics for queues associated with the subscriber to be cleared.

The **no** form of this command removes both an egress aggregate rate limit and egress frame based accounting for all subscribers associated with the sub-profile. If a subscriber's accounting mode is changed, the subscriber's queue statistics are cleared.

Parameters

agg-rate

Specifies the egress aggregate rate.

Values 1 to 800000000, **max**

min-rate

Specifies the minimum rate of the minimum reserved bandwidth for unicast data traffic. Since minimum rate can oversubscribe subscriber bandwidth to guarantee a minimum bandwidth for unicast traffic, care must be taken in QoS provisioning to prioritize packets accordingly (downstream network elements such as the access node or aggregation nodes) when congestion occurs.

Values 0 to 800000000

queue-frame-based-accounting

Specifies whether to use frame-based accounting when evaluating the aggregation rate limit for the egress queues for this SAP.

no aggregate *ip-prefix/ip-prefix-length*

Context

[Tree] (config>service>vprn aggregate)

Full Context

configure service vprn aggregate

Description

This command creates an aggregate route. Use this command to automatically install an aggregate route in the routing table when there are one or more component routes. A component route is any route used for forwarding that is a more specific match of the aggregate.

The use of aggregate routes can reduce the number of routes that need to be advertised to neighbor routers, leading to smaller routing table sizes.

Overlapping aggregate routes may be configured; in this case a route becomes a component of only the one aggregate route with the longest prefix match. For example if one aggregate is configured as 10.0.0.0/16 and another as 10.0.0.0/24, then route 10.0.128/17 would be aggregated into 10.0.0.0/16, and route 10.0.0.128/25 would be aggregated into 10.0.0.0/24. If multiple entries are made with the same prefix and the same mask the previous entry is overwritten.

A list of up to 12 BGP communities (any mix of standard, extended, and large communities) may be associated with an aggregate route. These communities can be matched in route policies and are automatically added to BGP routes that are created from the aggregate route.

By default, aggregate routes are not installed in the forwarding table, however there are configuration options that allow an aggregate route to be installed with a black-hole next hop or with an indirect IP address as next hop.

Aggregate routes can be advertised via MP-BGP to other PEs within the network. Aggregate routes advertised using MP-BGP do not include aggregated BGP path attributes from the component routes which were used to activate the aggregate route. The aggregate route will be advertised with the minimal set of path attributes as if the aggregate was originated by the advertising routes. Export route policies should be used to control and modify the advertisement and path attributes of the aggregate routes.

The **no** form of this command removes the aggregate.

Default

no aggregate

Parameters

ip-prefix

The destination address of the aggregate route in dotted decimal notation.

Values

ipv4-prefix	a.b.c.d (host bits must be 0)
ipv4-prefix-length	0 to 32
ipv6-prefix	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x: [0 to FFFF]H
	d: [0 to 255]D
ipv6-prefix-length	0 to 128

the ipv6-prefix and ipv6-prefix-length apply only to the 7750 SR and 7950 XRS

the mask associated with the network address expressed as a mask length

Values: 0 to 32

summary-only

This optional parameter suppresses advertisement of more specific component routes for the aggregate.

To remove the **summary-only** option, enter the same aggregate command without the **summary-only** parameter.

as-set

This optional parameter is only applicable to BGP and creates an aggregate where the path advertised for this route will be an AS_SET consisting of all elements contained in all paths that are being summarized. Use this feature carefully as it can increase the amount of route churn due to best path changes.

aggregator *as-number*:*ip-address*

This optional parameter specifies the BGP aggregator path attribute to the aggregate route. When configuring the aggregator, a two-octet AS number used to form the aggregate route must be entered, followed by the IP address of the BGP system that created the aggregate route.

discard-component-communities

This optional keyword causes the aggregate to be advertised with only the configured BGP community set, none of the communities from the component routes activating the aggregate are included. (Component attributes are never included in aggregate routes advertised to other PE routers via MP-BGP).

black-hole

This optional parameter installs the aggregate route, when activated, in the FIB with a black-hole next-hop, where packets matching this route are discarded.

generate-icmp

This optional parameter keyword generates an ICMP.

community

This configuration option associates a BGP community with the aggregate route. The community can be matched in route policies and is automatically added to BGP routes exported from the aggregate route.

comm-id

Specifies a BGP community value, up to 72 characters.

Values [*as-num:comm-val* | *well-known-comm* | *ext-comm* | *large-comm*]

where:

- *as-num* — 0 to 65535
- *comm-val* — 0 to 65535
- *well-known-comm* — **null** | **no-export** | **no-export-subconfed** | **no-advertise** | **llgr-stale** | **no-llgr** | **blackhole**
- *ext-comm* — the extended community, defined as one of the following:
  - {*target* | *origin*}:*ip-address*:*comm-val*
  - {*target* | *origin*}:*asnum*:*ext-comm-val*
  - {*target* | *origin*}:*ext-asnum*:*comm-val*
  - **bandwidth**:*asnum*:*val-in-mbps*

– **ext:4300**:*ovstate*
– **ext**:*value1*:*value2*
– color:co-bits:*color-value*

where:

– *target* — route target
– *origin* — route origin
– *ip-address* — a.b.c.d
– *ext-comm-val* — 0 to 4294967295
– *ext-asnum* — 0 to 4294967295
– *val-in-mbps* — 0 to 16777215
– *ovstate* — 0, 1, or 2 (0 for valid, 1 for not found, 2 for invalid)
– *value1* — 0000 to FFFF
– *value2* — 0 to FFFFFFFFFFFF
– *co-bits* — 00, 01, 10 or 11
– *color-value* — 0 to 4294967295

- *large-comm — asn-or-ex:val-or-ex:val-or-ex*

description

Specifies a text description stored in the configuration file for a configuration context.

local-preference

Specifies a BGP local-preference value with the aggregate route. The local-preference overrides the default local preference value of a BGP route originated by exporting the aggregate route.

Values 0 to 4294967295

indirect *ip-address*

This configuration option specifies that the aggregate route should be installed in the FIB with a next-hop taken from the route used to forward packets to ip-address.

Values

ipv4-prefix	a.b.c.d
ipv6-prefix	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x: [0 to FFFF]H
	d: [0 to 255]D

The ipv6-prefix applies only to the 7750 SR and 7950 XRS.

tunnel-group-id

Specifies that the MC-IPsec state of the specific tunnel-group is added to the aggregate route.

Values 1 to 16

Context

[Tree] (config>router aggregate)

Full Context

configure router aggregate

Description

This command creates an aggregate route.

Use this command to automatically install an aggregate route in the routing table when there are one or more component routes. A component route is any route used for forwarding that is a more-specific match of the aggregate.

The use of aggregate routes can reduce the number of routes that need to be advertised to neighbor routers, leading to smaller routing table sizes.

Overlapping aggregate routes may be configured; in this case a route becomes a component of only the one aggregate route with the longest prefix match. For example if one aggregate is configured as 10.0.0.0/16 and another as 10.0.0.0/24, then route 10.0.128/17 would be aggregated into 10.0.0.0/16, and route 10.0.0.128/25 would be aggregated into 10.0.0.0/24. If multiple entries are made with the same prefix and the same mask the previous entry is overwritten.

A standard 4-byte BGP community may be associated with an aggregate route in order to facilitate route policy matching.

By default aggregate routes are not installed in the forwarding table, however there are configuration options that allow an aggregate route to be installed with a black-hole next hop or with an indirect IP address as next hop.

The **no** form of this command removes the aggregate.

Default

no aggregate

Parameters

ip-prefix

Specifies the destination address of the aggregate route in dotted decimal notation.

Values The following values apply to the 7750 SR and 7950 XRS:

ipv4-prefix	a.b.c.d (host bits must be 0)	
ipv4-prefix-length	0 to 32	
ipv6-prefix	x:x:x:x:x:x:x:x (eight 16-bit pieces)	
	x:x:x:x:x:x:d.d.d.d	
	x:	[0 to FFFF]H
	d:	[0 to 255]D
ipv6-prefix-length	0 to 128	

Values The following values apply to the 7450 ESS:

ipv4-prefix	a.b.c.d (host bits must be 0)
ipv4-prefix-length	0 to 32

ip-prefix-length

Specifies the mask associated with the network address expressed as a mask length.

Values 0 to 32

summary-only

Suppresses advertisement of more specific component routes for the aggregate.

To remove the **summary-only** option, enter the same aggregate command without the **summary-only** parameter.

as-set

This optional parameter is only applicable to BGP and creates an aggregate where the path advertised for this route will be an AS_SET consisting of all elements contained in all paths that are being summarized. Use this feature carefully as it can increase the amount of route churn due to best path changes.

as-number:ip-address

Specifies the BGP aggregator path attribute to the aggregate route. When configuring the aggregator, a two-octet AS number used to form the aggregate route must be entered, followed by the IP address of the BGP system that created the aggregate route.

discard-component-communities

Causes the aggregate to be advertised with only the configured BGP community set, none of the communities from the component routes activating the aggregate are included.

black-hole

Installs the aggregate route, when activated, in the FIB with a black-hole next-hop, where packets matching this route are discarded.

generate-icmp

Mandatory keyword to generate an ICMP.

community

Associates a BGP community with the aggregate route. The community can be matched in route policies and is automatically added to BGP routes exported from the aggregate route.

comm-id

Specifies a BGP community value, up to 72 characters. A maximum of twelve community IDs can be specified in a single statement.

Values [*as-num:comm-val* | *well-known-comm* | *ext-comm* | *large-comm*]

where:

- *as-num* — 0 to 65535
- *comm-val* — 0 to 65535
- *well-known-comm* — **null** | **no-export** | **no-export-subconfed** | **no-advertise** | **llgr-stale** | **no-llgr** | **blackhole**
- *ext-comm* — the extended community, defined as one of the following:
  - {*target* | *origin*}:*ip-address*:*comm-val*
  - {*target* | *origin*}:*asnum*:*ext-comm-val*
  - {*target* | *origin*}:*ext-asnum*:*comm-val*
  - **bandwidth**:*asnum*:*val-in-mbps*
  - **ext:4300**:*ovstate*
  - **ext**:*value1*:*value2*
  - color:co-bits:*color-value*

  where:
  - *target* — route target
  - *origin* — route origin
  - *ip-address* — a.b.c.d
  - *ext-comm-val* — 0 to 4294967295
  - *ext-asnum* — 0 to 4294967295
  - *val-in-mbps* — 0 to 16777215
  - *ovstate* — 0, 1, or 2 (0 for valid, 1 for not found, 2 for invalid)
  - *value1* — 0000 to FFFF
  - *value2* — 0 to FFFFFFFFFFFF

- *co-bits* — 00, 01, 10 or 11
- *color-value* — 0 to 4294967295

- *large-comm — asn-or-ex:val-or-ex:val-or-ex*

indirect *ip-address*

Specifies that the aggregate route should be installed in the FIB with a next-hop taken from the route used to forward packets to ip-address.

Values The following values apply to the 7750 SR and 7950 XRS:

ipv4-prefix	a.b.c.d
ipv6-prefix	x:x:x:x:x:x:x:x
	x:x:x:x:x:x:d.d.d.d
	x: [0 to FFFF]H
	d: [0 to 255]D

Values The following values apply to the 7450 ESS:

ipv4-prefix: a.b.c.d

description

Specifies a text description stored in the configuration file for a configuration context, up to 80 characters.

local-preference

Specifies a BGP local-preference value with the aggregate route. The local-preference overrides the default local preference value of a BGP route originated by exporting the aggregate route.

Values 0 to 4294967295

policy-name

Specifies the route policy, up to 64 characters.

aggregate-contributor

Syntax

[**no**] **aggregate-contributor**

Context

[Tree] (config>router>policy-options>policy-statement>entry>from>aggregate-contributor aggregate-contributor)

Full Context

configure router policy-options policy-statement entry from aggregate-contributor aggregate-contributor

Description

This command matches all routes (BGP and non-BGP) that contributed to an active aggregate route. If the prefix tree above a particular route includes no active aggregate routes, or the most specific active aggregate route in the prefix tree above this route has a policy that rejects the route, then it is not considered as an aggregate-contributor.

This match condition is only supported when used in a BGP export policy. If it is used in an entry of a BGP import policy, VRF export policy or VRF import policy, no routes are matched by that entry.

The **no** form of this command disables matching of routes (BGP and non-BGP) that contributed to an active aggregate route.

Platforms

aggregate-prefix-match

Syntax

[**no**] **aggregate-prefix-match**

Context

[Tree] (config>router>ldp aggregate-prefix-match)

Full Context

configure router ldp aggregate-prefix-match

Description

The command enables the use by LDP of the aggregate prefix match procedures.

When this option is enabled, LDP performs the following procedures for all prefixes. When an LSR receives a FEC-label binding from an LDP neighbor for a given specific FEC1 element, it will install the binding in the LDP FIB if:

- It is able to perform a successful longest IP match of the FEC prefix with an entry in the routing table, and
- The advertising LDP neighbor is the next-hop to reach the FEC prefix.

When such a FEC-label binding has been installed in the LDP FIB, then LDP programs an NHLFE entry in the egress data path to forward packets to FEC1. It also advertises a new FEC-label binding for FEC1 to all its LDP neighbors.

When a new prefix appears in the routing table, LDP inspects the LDP FIB to determine if this prefix is a better match (a more specific match) for any of the installed FEC elements. For any FEC for which this is true, LDP may have to update the NHLFE entry for this FEC.

When a prefix is removed from the routing table, LDP inspects the LDP FIB for all FEC elements which matched this prefix to determine if another match exists in the routing table. If so, it updates the NHLFE entry accordingly. If not, it sends a label withdraw message to its LDP neighbors to remove the binding.

When the next hop for a routing prefix changes, LDP updates the LDP FIB entry for the FEC elements which matched this prefix. It also updates the NHLFE entry for these FEC elements accordingly.

The **no** form of this command disables the use by LDP of the aggregate prefix procedures and deletes the configuration. LDP resumes performing exact prefix match for FEC elements.

Full Context

configure service vprn bgp group link-bandwidth aggregate-used-paths

configure service vprn bgp group neighbor link-bandwidth aggregate-used-paths

Description

This command configures BGP to aggregate the bandwidth values from the link-bandwidth extended communities of the used multipaths towards an IP prefix when it is re-advertising a route with next-hop-self towards peers within the scope of the command, as long as the route belongs to one of the listed address families.

Aggregation is not supported unless all of the used multipaths (up to the configured ECMP limit) correspond to received BGP routes with a link-bandwidth extended community. If add-path is also enabled toward the peer, then all of the add-paths advertised to the peer encode the aggregated bandwidth in a link-bandwidth extended community.

Up to three families may be configured.

The **no** form of this command disables aggregation in a next-hop-self scenario and the link-bandwidth extended community in the advertised route is a copy of the link-bandwidth extended community in the

received route (which may have been added by import policy or by the effect of the **add-to-received-ebgp** command).

Default

no aggregate-used-paths

Parameters

family

Specifies the address families for which receiving the link-bandwidth extended community from EBGP peers should be supported.

Values ipv4 — Adds a link-bandwidth extended community to unlabeled unicast IPv4 routes.

label-ipv4 — Adds a link-bandwidth extended community to labeled-unicast IPv4 routes.

ipv6 — Adds a link-bandwidth extended community to unlabeled unicast IPv6 routes.

aging

Syntax

aging *days*

no aging

Context

[Tree] (config>system>security>password aging)

Full Context

configure system security password aging

Description

This command configures the number of days a user password is valid before the user must change their password. This parameter can be used to force the user to change the password at the configured interval. Note the aging starts after the last password configuration or update. This timer is persistence (per user) over a node reboot or activity switch between CPMs. When the user changes the password, the timer is reset to the maximum age. When the password for a user ages out, the user is prompted at login to change the password. Console/SSH/Telnet supports password change prompt.

The **no** form of this command reverts to the default value.

Parameters

days

Specifies the maximum number of days the password is valid.

Values 1 to 500

Note:
This command applies to local users.

Full Context

configure router policy-options policy-statement entry action aigp-metric

configure router policy-options policy-statement default-action aigp-metric

Description

This command assigns a BGP AIGP metric to routes matching the entry. The effect of this command on a route matched and accepted by a route policy entry depends on how the policy is applied (BGP import policy vs. BGP export policy), the type of route and the specific form of this command.

In a BGP import policy this command is used to:

- Associate an AIGP metric with an IBGP route received with an empty AS path and no AIGP attribute.
- Associate an AIGP metric with an EBGP route received without an AIGP attribute that has an AS path containing only AS numbers belonging to the local AIGP administrative domain.
- Modify the received AIGP metric value prior to BGP path selection.

In a BGP export policy this command is used to:

- Add the AIGP attribute and set the AIGP metric value in a BGP route originated by exporting a direct, static or IGP route from the routing table.
- Remove the AIGP attribute from a route advertisement to a particular peer.
- Modify the AIGP metric value in a route advertisement to a particular peer.

Default

no aigp-metric

Parameters

metric

Administratively defined metric.

Values	0 to 4294967295
Default	name — The AIGP metric parameter variable name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes. Policy parameters must start and end with at-signs (@); for example, "@variable@”.

add

Adds the AIGP attribute.

igp

Sets the AIGP metric to the IGP metric.

ais-enable

Syntax

[**no**] **ais-enable**

Context

[Tree] (config>router>mpls>if>mpls-tp-mep ais-enable)

Full Context

configure router mpls interface mpls-tp-mep ais-enable

Description

This command enables MPLS-TP AIS insertion for the forward and reverse directions of all MPLS-TP transit paths using the MPLS interface. This causes the generation of AIS packets in the forward or reverse directions of a path if a fault is detected on the applicable underlying interface for the ingress of the path direction.

The **no** form of this command disables AIS insertion.

Default

no ais-enable

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

5.174 alarm

alarm

Syntax

alarm *rmon-alarm-id* **variable-oid** *oid-string* **interval** *seconds* [*sample-type*] [**startup-alarm** *alarm-type*] [**rising-event** *rmon-event-id* **rising-threshold** *threshold*] [**falling-event** *rmon-event-id* **falling-threshold** *threshold*] [**owner** *owner-string*]

no alarm *rmon-alarm-id*

Context

[Tree] (config>system>thresholds>rmon alarm)

Full Context

configure system thresholds rmon alarm

Description

The alarm command configures an entry in the RMON-MIB alarmTable. The alarm command controls the monitoring and triggering of threshold crossing events. In order for notification or logging of a threshold crossing event to occur there must be at least one associated rmon>event configured.

The agent periodically takes statistical sample values from the MIB variable specified for monitoring and compares them to thresholds that have been configured with the alarm command. The alarm command configures the MIB variable to be monitored, the polling period (interval), sampling type (absolute or delta value), and rising and falling threshold parameters. If a sample has crossed a threshold value, the associated event is generated.

Use the **no** form of this command to remove an rmon-alarm-id from the configuration.

Parameters

rmon-alarm-id

Specifies a numerical identifier for the alarm being configured. The number of alarms that can be created is limited to 1200. Alarm ID values above 65400 are used for dynamic system threshold commands and should be avoided.

Values 1 to 65535

oid-string

Specifies the SNMP object identifier of the particular variable to be sampled. Only SNMP variables that resolve to an ASN.1 primitive type of integer (integer, Integer32, Counter32, Counter64, Gauge, or TimeTicks) may be sampled. The oid-string, up to 255 characters, may be expressed using either the dotted string notation or as object name plus dotted instance identifier. For example, "1.3.6.1.2.1.2.2.1.10.184582144" or "ifInOctets.184582144".

seconds

Specifies the polling period over which the data is sampled and compared with the rising and falling thresholds. When setting this interval value, care should be taken in the case of ’delta’ type sampling - the interval should be set short enough that the sampled variable is very unlikely to increase or decrease by more than 2147483647 - 1 during a single sampling interval. Care should also be taken not to set the interval value too low to avoid creating unnecessary processing overhead.

Values 1 to 2147483647

sample-type

Specifies the method of sampling the selected variable and calculating the value to be compared against the thresholds.

Values absolute — Specifies that the value of the selected variable will be compared directly with the thresholds at the end of the sampling interval.

delta — Specifies that the value of the selected variable at the last sample will be subtracted from the current value, and the difference compared with the thresholds.

Default absolute

alarm-type

Specifies the alarm that may be sent when this alarm is first created.

If the first sample is greater than or equal to the rising threshold value and **startup-alarm** is equal to **rising** or **either**, then a single rising threshold crossing event is generated.

If the first sample is less than or equal to the falling threshold value and **startup-alarm** is equal to **falling** or **either**, a single falling threshold crossing event is generated.

Values rising, falling, either

Default either

rising-event *rmon-event-id*

Specifies the identifier of the **rmon>event** that specifies the action to be taken when a rising threshold crossing event occurs.

If there is no corresponding event configured for the specified rmon-event-id, then no association exists and no action is taken.

If the **rising-event** *rmon-event-id* has a value of zero (0), no associated event exists.

If a **rising-event** *rmon-event-id* is configured, the CLI requires a **rising-threshold** to also be configured.

Values 0 to 65535

Default 0

rising-threshold *threshold*

Specifies a threshold for the sampled statistic. When the current sampled value is greater than or equal to this threshold, and the value at the last sampling interval was less than this threshold, a single threshold crossing event will be generated. A single threshold crossing event will also be generated if the first sample taken is greater than or equal to this threshold and the associated startup-alarm is equal to **rising** or **either**.

After a rising threshold crossing event is generated, another such event will not be generated until the sampled value falls below this threshold and reaches less than or equal the **falling-threshold** value.

Values -2147483648 to 2147483647

Default 0

falling-event *rmon-event-id*

Specifies the identifier of the **rmon>event** that specifies the action to be taken when a falling threshold crossing event occurs. If there is no corresponding event configured for the specified rmon-event-id, then no association exists and no action is taken. If the **falling-event** has a value of zero (0), no associated event exists.

If a **falling-event** is configured, the CLI requires a **falling-threshold** to also be configured.

Values 0 to 65535

Default 0

falling-threshold *threshold*

Specifies a threshold for the sampled statistic. When the current sampled value is less than or equal to this threshold, and the value at the last sampling interval was greater than this threshold, a single threshold crossing event will be generated. A single threshold crossing event will also be generated if the first sample taken is less than or equal to this threshold and the associated **startup-alarm** is equal to **falling** or **either**.

After a falling threshold crossing event is generated, another such event will not be generated until the sampled value rises above this threshold and reaches greater than or equal the rising-threshold value.

Values -2147483648 to 2147483647

Default 0

owner-string

Specifies the owner string; the owner identifies the creator of this alarm. It defaults to "TiMOS CLI". This parameter is defined primarily to allow entries that have been created in the RMON-MIB alarmTable by remote SNMP managers to be saved and reloaded in a CLI configuration file. The owner will not normally be configured by CLI users and can be a maximum of 80 characters long.

Default TiMOS CLI

Configuration example

```
alarm 3 variable-oid ifInOctets.184582144 interval 20 sample-type delta
start-alarm either rising-event 5 rising-threshold 10000 falling-event 5
falling-threshold 9000 owner "TiMOS CLI"
```

Platforms

All

alarm

Syntax

[**no**] **alarm**

Context

[Tree] (config>sys>security>cpu-protection>policy alarm)

Full Context

configure system security cpu-protection policy alarm

Description

This command enables the generation of an event when a rate is exceed. The event includes information about the offending source. Only one event is generated per monitor period.

The **no** form of this command disables the notifications.

Default

no alarm

Platforms

7450 ESS, 7750 SR-7/12/12e, 7750 SR-7s, 7750 SR-14s, 7950 XRS

5.175 alarm-contact-in-power

alarm-contact-in-power

Syntax

alarm-contact-in-power {**on** | **off**}

Context

[Tree] (config>system alarm-contact-in-power)

Full Context

configure system alarm-contact-in-power

Description

This command allows the user to enable a supply of +24V output power on the +24VDC pin of the Alarm Interface Port of the CPM. When enabled, the power supplied through the +24VDC output pin can be used as a source voltage for the alarm contact input pins. The +24VDC output can be used to supply power for monitoring external sensor devices such as cabinet door sensors instead of using an external power source. If users want to use a separate external power source, they should disable the supply of power to the +24VDC output pin by using this CLI command.

Default

alarm-contact-in-power off

Parameters

on

Specifies to turn on power to the +24VDC output pin of the Alarm Interface Port of the CPM.

off

Specifies to turn off power to the +24VDC output pin of the Alarm Interface Port of the CPM.

Platforms

7750 SR-a

algorithm

Syntax

algorithm *flex-algo-id*

no algorithm

Context

[Tree] (config>router>segment-routing>srv6>locator algorithm)

[Tree] (conf>router>segment-routing>srv6>micro-segment-locator algorithm)

Full Context

configure router segment-routing segment-routing-v6 locator algorithm

configure router segment-routing segment-routing-v6 micro-segment-locator algorithm

Description

This command configures an IGP flexible algorithm identifier for an SRv6 or micro-segment locator.

A locator can only be part of a single algorithm but it can be used in multiple IGP instances.

The **no** form of this command returns the locator to the base IGP algorithm 0.

Default

no algorithm

Parameters

flex-algo-id

Specifies the flexible algorithm ID.

Values 128 to 255

Platforms

7450 ESS, 7750 SR, 7750 SR-s, 7950 XRS, VSR

5.183 alias

alias

Syntax

alias *alias-name alias-command-name*

no alias *alias-name*

Context

[Tree] (environment alias)

Full Context

environment alias

Description

This command enables the substitution of a command line (or part of a command line) by an alias. Use this command to create alternative or easier to remember or understand names for an entity or command string. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed

within double quotes. The special characters forward slash (/) and backslash (\) cannot be used as the first character inside an alias string. An alias can contain a double quote character by preceding the quote with a backslash (\) character (for example, **alias my-alias "| match \"***string***\""**). Only a single command can be present in the command string (the command can be long with many parameters but there is no support for aliases that include multiple CLI commands or lines). This command can be entered in any context but must be created in the **root environment** context.

For example, to create an alias named **soi** to display OSPF interfaces, enter the following command:

alias soi "show router ospf interface”

Complex aliases can be created to have shortcuts for customized show routine output.

environment alias my-summary "| match expression \"----|Description|Interface|Admin State|Oper State|Transceiver Type|Optical Compliance|Link Length\" | match invert-match expression \"Ethernet Interface|OTU Interface\" | match invert-match expression \"----\" post-lines 1"

and then used like this:

show port detail my-summary

Parameters

alias-name

Specifies the alias name, up to 80 characters. Do not use a valid command string for the name of the alias. If the alias specified is an actual command, this causes the command to be replaced by the alias.

alias-command-name

Specifies the command name to be associated, up to 320 characters.

Platforms

configure service vprn isis all-l1isis

Description

This command specifies the MAC address to use for the VPRN instance of the Layer 1 IS-IS routers. The MAC address should be a multicast address.

The **no** form of this command reverts to the default value.

Default

all-l1isis 01:80:c2:00:00:14

Parameters

ieee-address

Specifies the destination MAC address for all Layer 1 I-IS neighbors on the link for this ISIS instance.

Platforms

All

all-l1isis

Syntax

all-l1isis *ieee-address*

no all-l1isis

Context

Full Context

configure router ospf3 segment-routing adjacency-sid allocate-dual-sids

configure router isis segment-routing adjacency-sid allocate-dual-sids

configure router ospf segment-routing adjacency-sid allocate-dual-sids

Description

This command enables the support of two SR-MPLS adjacency SIDs per interface. A protected and unprotected adjacency SID is instantiated and advertised. If an SR-MPLS adjacency SID already exists, an additional complementary (protected or unprotected) adjacency SID is created on the interface.

The **no** form of this command disables the support of two SR-MPLS adjacency SIDs per interface.

Default

no allocate-dual-sids

Platforms

All

5.193 allocation

allocation

Syntax

allocation explicit-percent *percent-of-parent-pool*

allocation port-bw-weight *pool-weight*

no allocation

Context

[Tree] (config>qos>hs-port-pool-policy>alt-port-class-pools>class-pool allocation)

[Tree] (config>qos>hs-port-pool-policy>std-port-class-pools>class-pool allocation)

Full Context

configure qos hs-port-pool-policy alt-port-class-pools class-pool allocation

configure qos hs-port-pool-policy std-port-class-pools class-pool allocation

Description

This command sizes the associated class-pool based on either the specified **explicit-percent** *percent-of-parent-pool* or based on the dynamic port bandwidth portioning mechanism. Setting an explicit percentage prevents the port-class pool from participating in the dynamic port level bandwidth-based distribution of the mid-pool's size as the port bandwidth weight of the port-class pool becomes zero (0). Setting a port bandwidth weight causes the explicit percent value to become zero (0) disabling explicit sizing of the port-class pool.

The **no** form of the command sets the *percent-of-parent-pool* value to zero (0) and the *pool-weight* parameter to 1 for the port-class pool, restoring the default settings.

Default

allocation 1

Parameters

percent-of-parent-pool

Specifies the percentage of parent pool being allocated. This parameter must be configured when specifying the **explicit-percent**. The *percent-of-parent-pool* value is expressed as a percentage with two decimal places (100th of a percent) that indicates that the port-class pool should be sized by applying the value to the parent mid-pool size. Specifying **explicit-percent** forces the **port-bw-weight** to a zero (0) value (disabled).

Values 0.01 to 100.00

pool-weight

Specifies port bandwidth weight being allocated. The **port-bw-weight** and **explicit-percent** commands are mutually exclusive. The *pool-weight* parameter is required when specifying the port bandwidth weight and defines both that the port-class pool should be sized in the port bandwidth distribution of the mid-pool's size and what the distribution weight should be for the port-class pool compared to other port-class pools associated with the same mid-pool when competing for the port's distribution portion.

Values 1 to 100

allocation-percent

Syntax

allocation-percent *percent-of-parent-pool*

no allocation-percent

Context

[Tree] (config>qos>hs-pool-policy>mid-tier>mid-pool allocation-percent)

Full Context

configure qos hs-pool-policy mid-tier mid-pool allocation-percent

Description

This command sizes the associated mid-pool based on the specified percent of the parent pool. The size is obtained by applying the specified percentage value to the current root-pool size acting as the mid-pool's parent. Whenever the parent root-pool is changed to a new root-pool or the size of the current parent root-pool is modified, the mid-pool's size is updated.

The **no** form of the command reverts to the default.

Default

allocation-percent 1.00

Parameters

percent-of-parent-pool

Specifies the percent of the parent pool. This parameter is required when the **allocation-percent** command is executed. This parameter defines the percentage of the root pool's size to derive the size of the mid-pool. The value is specified as a percentage with two decimal places (100th of a percent).

Values 0.01 to 100.00

Platforms

7750 SR-7/12/12e

5.195 allocation-weight

allocation-weight

Syntax

allocation-weight *pool-weight*

no allocation-weight

Context

[Tree] (config>qos>hs-pool-policy>root-tier>root-pool allocation-weight)

Full Context

configure qos hs-pool-policy root-tier root-pool allocation-weight

Description

This command specifies the weight that is applied to the root pool and is divided by the sum of all root pool weights to derive the pool's buffer allocation factor. The amount of buffers remaining after the system-reserve percentage is applied is multiplied by the buffer allocation factor to derive the pool size.

Root pools function as an oversubscription control mechanism. A root pool acts as the root of a hierarchy of buffer pools and queues with respect to buffer allocation. Because the sum of the root pool sizes does not exceed the total number of buffers available, the number of buffers indicated by the root pools size is always be available to the queues within the root pools hierarchy, queues from one hierarchy can never steal buffers from another.

A root pool hierarchy is based on the dynamic parenting of one or more mid-tier pools to a root pool. A mid-tier pool represents the buffering allowed for all port-class pools mapped to the mid-tier pool. Each mid-tier pool is sized as a percentage of the root pool to which it is parented. The sum of the mid-tier pools percentages for a root pool may be greater than 100 percent, which allows the root pool to be oversubscribed. This can be beneficial when large fluctuations in mid-tier buffer utilization are expected and a given mid-tier pool should be allowed to exceed its fair share of buffering.

Through the mapping hierarchy presented above, each queue is mapped to a port-class pool, mid-tier pool, and root pool.

A root pool with an **allocation-weight** set to "0" is considered inactive and is not allocated buffers. Mid-tier pools cannot be parented to a root pool with a weight set to "0". After a mid-tier pool is associated with a root pool, the root pool's weight cannot be set to "0".

As port classes are mapped to mid-tier pools in a different policy than mid-tier pools are mapped to root pools, a port-class pool can be mapped to a mid-tier pool that is not parented to a root pool. A queue mapped indirectly to a non-parented mid-tier pool has its operational MBS value set to zero and drops all incoming packets.

When a root pool's allocation weight is modified, all root pools, mid-tier pools, and port class pool sizes are reevaluated and modified when necessary.

The **no** form of the command restores the default **allocation-weight** value to the associated root pool. Root pool 1 has a different default weight than root pools 2 through 8. The **no allocation-weight** command fails for root pools 2 through 8 if the root pool is currently parented to a class pool.

Default

root-pool 1: allocation-weight 100

root-pool 2 to 16: allocation-weight 0

Parameters

pool-weight

Defines the weight of the associated **root-pool** *root-pool-id* and is used by the system to calculate the size of the root buffer pool. This parameter is required when executing the **allocation-weight** command. Setting the *pool-weight* to 0 disables the pool and prevents the root pool from being a parent to any class pools. Root pool 1 cannot be set with an allocation weight of 0.

Values root-pool 1: 1 to 100

root-pool 2 to 16: 0 to 100

Full Context

configure router interface allow-directed-broadcasts

configure service ies interface allow-directed-broadcasts

configure service vprn interface allow-directed-broadcasts

configure service vprn network-interface allow-directed-broadcasts

Description

This command enables the forwarding of directed broadcasts out of the IP interface.

A directed broadcast is a packet received on a local router interface destined for the subnet broadcast address on another IP interface. The **allow-directed-broadcasts** command on an IP interface enables or disables the transmission of packets destined to the subnet broadcast address of the egress IP interface.

When enabled, a frame destined to the local subnet on this IP interface is sent as a subnet broadcast out this interface. Care should be exercised when allowing directed broadcasts as it is a well-known mechanism used for denial-of-service attacks.

When disabled, directed broadcast packets discarded at this egress IP interface are counted in the normal discard counters for the egress SAP.

Note:
Allowing directed broadcasts is a well-known mechanism used for denial-of-service attacks.

By default, directed broadcasts are not allowed and are discarded at this egress IP interface.

The **no** form of this command disables the forwarding of directed broadcasts out of the IP interface. All broadcasts are dropped.

Default

no allow-directed-broadcasts — Directed broadcasts are dropped.

Platforms

5.199 allow-dot1q-msaps

allow-dot1q-msaps

Syntax

[**no**] **allow-dot1q-msaps**

Context

[Tree] (config>service>vpls>sap allow-dot1q-msaps)

Full Context

configure service vpls sap allow-dot1q-msaps

Description

This command enables support for single tagged traffic triggering managed SAP creation on a qinq encapsulated capture SAP.

With this command enabled, a single tagged trigger packet received on a qinq encapsulated capture SAP (x/y/z:*.* or x/y/z:tag.*) can trigger the creation of an x/y/z:tag.0 managed SAP (MSAP).

The **config>system>ethernet>new-qinq-untagged-sap** command should be configured:

- as a prerequisite for an x/y/z:tag.* capture-sap
- where x/y/z:tag1.0 and x/y/z:tag1.tag2 MSAPs for an x/y/z:*.* capture-sap should co-exist

Note that enabling new-qinq-untagged-sap affects the behavior of existing <port-id>:tag.0 SAPs.

With the allow-dot1q-msaps command disabled (default), a single tagged trigger packet received on a qinq encapsulated capture SAP (x/y/z:*.* or x/y/z:tag.*) is dropped as "Invalid QTag”.

This command cannot be enabled on:

- a dot1q encapsulated **capture-sap**
- an inverse capture sap (x/y/z:*.tag)

The **no** form of this command reverts to the default.

5.201 allow-export-bgp-vpn

allow-export-bgp-vpn

Syntax

[**no**] **allow-export-bgp-vpn**

Context

[Tree] (config>service>vprn allow-export-bgp-vpn)

Full Context

configure service vprn allow-export-bgp-vpn

Description

This command allows routes leaked from another local VPRN service to be re-exported by this VPRN in the form of new VPN-IP routes. The service label, route targets, and BGP next-hop of the re-advertised routes are based on the configuration and default values of the re-exporting VPRN.

When re-exporting leaked routes, the following restrictions apply.

- The **allow-export-bgp-vpn** command is not configurable in combination with any of the following commands: **carrier-carrier-vpn** (CSC), **label-mode next-hop** (LPN), **type** {**hub** | **spoke** | **subscriber-split-horizon**}, **redundant-interface**, and **export-inactive-bgp**.
- Re-exported routes always have the per-VRF label of the exporting VPRN; label-per-prefix advertisement is not supported.
- The best-external (inactive BGP) routes leaked by another VPRN cannot be re-exported by a VPRN configured with **allow-export-bgp-vpn**.

Caution:
When a VPRN configured with **allow-export-bgp-vpn** advertises a leaked route, the **split-horizon** context is lost. A re-exported route can be easily advertised back to the sending peer unless this is blocked by BGP export policies. This can cause route flaps or other similar instability.

If the **no** form of this command is configured, leaked routes cannot be re-advertised as VPN-IP routes; they can only be re-advertised to PE-CE BGP peers of the VPRN.

Default

no allow-export-bgp-vpn

configure router bgp next-hop-resolution shortcut-tunnel family allow-flex-algo-fallback

configure service vprn bgp-evpn mpls auto-bind-tunnel allow-flex-algo-fallback

Description

This command configures a router to relax the strictly enforced Flex-Algorithm aware autobind, which is enabled through an import policy configured with the **action flex-algo** command.

If the **allow-flex-algo-fallback** command is enabled, the BGP router can autobind to a fallback algorithm 0 tunnel if no target Flex-Algorithm tunnel is available. If the **allow-flex-algo-fallback** command is disabled, the BGP autobind is strictly enforced to an intended Flex-Algorithm tunnel, which may cause traffic loss if no corresponding Flex-Algorithm tunnel exists.

The **no** form of this command removes the **allow-flex-algo-fallback** command from the configuration.

5.209 allow-ip-int-bind

allow-ip-int-bind

Syntax

[**no**] **allow-ip-int-bind**

Context

[Tree] (config>service>vpls allow-ip-int-bind)

Full Context

configure service vpls allow-ip-int-bind

Description

The allow-ip-int-bind command that sets a flag on the VPLS or I-VPLS service that enables the ability to attach an IES or VPRN IP interface to the VPLS service in order to make the VPLS service routable. When the allow-ip-int-bind command is not enabled, the VPLS service cannot be attached to an IP interface.

VPLS Configuration Constraints for Enabling allow-ip-int-bind

When attempting to set the allow-ip-int-bind VPLS flag, the system first checks to see if the correct configuration constraints exist for the VPLS service and the network ports. The following VPLS features must be disabled or not configured for the allow-ip-int-bind flag to set:

- SAP ingress QoS policies applied to the VPLS SAPs cannot have MAC match criteria defined
- The VPLS service type cannot be B-VPLS or M-VPLS
- MVR from Routed VPLS and to another SAP is not supported
- Enhanced and Basic Subscriber Management (ESM and BSM) features
- Network domain on SDP bindings

Once the VPLS allow-ip-int-bind flag is set on a VPLS service, the above features cannot be enabled on the VPLS service.

Network Port Hardware Constraints

The system also checks to ensure that all ports configured in network mode are associated with FlexPath2 forwarding planes. If a port is currently in network mode and the port is associated with a FlexPath1 forwarding plane, the allow-ip-int-bind command will fail. Once the allow-ip-int-bind flag is set on any VPLS service, attempting to enable network mode on a port associated with a FlexPath1 forwarding plane will fail.

VPLS SAP Hardware Constraints

Besides VPLS configuration and network port hardware association, the system also checks to that all SAPs within the VPLS are created on Ethernet ports and the ports are associated with FlexPath2 forwarding planes. Certain Ethernet ports and virtual Ethernet ports are not supported which include CCAG virtual ports (VSM based). If a SAP in the VPLS exists on an unsupported port type or is associated with a FlexPath1 forwarding plane, the allow-ip-int-bind command will fail. Once the allow-ip-int-bind flag is set on the VPLS service, attempting to create a VPLS SAP on the wrong port type or associated with a FlexPath1 forwarding plane will fail.

VPLS Service Name Bound to IP Interface without allow-ip-int-bind flag Set

If a service name is applied to a VPLS service and that service name is also bound to an IP interface but the allow-ip-int-bind flag has not been set on the VPLS service context, the system attempt to resolve the service name between the VPLS service and the IP interface will fail. After the allow-ip-int-bind flag is successfully set on the VPLS service, either the service name on the VPLS service must be removed and reapplied or the IP interface must be re-initialized using the **shutdown** / **no shutdown** commands. This will cause the system to reattempt the name resolution process between the IP interface and the VPLS service.

The **no** form of this command resets the allow-ip-int-bind flag on the VPLS service. If the VPLS service currently has an IP interface from an IES or VPRN service attached, the no allow-ip-int-bind command will fail. Once the allow-ip-int-bind flag is reset on the VPLS service, the configuration and hardware restrictions associated with setting the flag are removed. The port network mode hardware restrictions are also removed.

Platforms

configure test-oam link-measurement measurement-template twamp-light allow-ipv6-udp-checksum-zero

configure router twamp-light reflector allow-ipv6-udp-checksum-zero

Description

This command configures the acceptance of IPv6 packets with UDP checksums of 0.This optional configuration allows the router to process arriving IPv6 TWAMP Test packets that contain IPv6 UDP checksum of 0x0000. The UDP port specific to this TWAMP Light test bypasses the default discard IPv6 UDP checksum 0x0000. If this optional command is not configured, IPv6 UDP checksum 0x000 arriving packets are discarded.

The **no** form of this command reverts to the default value, discarding packets that arrive with an IPv6 UDP checksum of 0x0000.

Default

no allow-ipv6-udp-checksum-zero

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

Full Context

configure application-assurance group url-filter local-filtering allow-list

Description

This command adds an allow-list URL list to the local filtering URL filter policy.

The **no** form of this command removes the URL list object.

Default

no allow-list

Parameters

allow-list-name

Specifies the URL list name.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.213 allow-local-management

allow-local-management

Syntax

[**no**] **allow-local-management**

Context

[Tree] (config>service>vprn>grt>enable-grt allow-local-management)

Full Context

configure service vprn grt-lookup enable-grt allow-local-management

Description

This command enables the support of specific management protocols over VPRN interfaces that terminate on Base routing context IPv4 and IPv6 interface addresses, including Base loopback and system addresses. Global Routing Table (GRT) leaking is used to enable the visibility and access of the Base interface addresses in the VPRN. The supported protocols are Telnet, FTP, SNMP, TACACS+, RADIUS (IPv4 only, not IPv6), SSH (including applications that ride over the standard SSH TCP port 22 such as SCP and SFTP) and NETCONF (configured on port 22 or 830).

Ping and traceroute responses from the Base router interfaces are supported but are not configurable.

The **allow-local-management** command does not control the support for management protocols terminating on VPRN interfaces directly. See "Node Management using VPRN" in the 7450 ESS, 7750 SR, 7950 XRS, and VSR Layer 3 Services Guide: IES and VPRN for more information. Also, see the **access** command in the **config>service>vprn>snmp** context, and the commands in the **config>service>vprn>management** context.

[Tree] (config>service>vprn>management allow-netconf)

Full Context

configure service vprn management allow-netconf

Description

This commands allows access to the NETCONF server from VPRN.

The **no** form of this command removes NETCONF access for this VPRN.

Platforms

All

5.216 allow-qinq-network-interface

allow-qinq-network-interface

Syntax

[**no**] **allow-qinq-network-interface**

Context

[Tree] (config>system>ip allow-qinq-network-interface)

Full Context

configure system ip allow-qinq-network-interface

Description

This command is a system-wide option that allows the creation of network interfaces on a QinQ encapsulated VLAN.

When enabled, the maximum number of allowed MPLS labels is reduced by 1 to allow for the additional VLAN tag at egress processing.

The **no** form of this command reverts the option to the default value, which is to not allow network interfaces on QinQ encapsulated VLANs.

Default

no allow-qinq-network-interface

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

5.217 allow-reverse-route-override

allow-reverse-route-override

Syntax

allow-reverse-route-override [*type*]

no allow-reverse-route-override

Context

[Tree] (config>service>vprn>ipsec allow-reverse-route-override)

Full Context

configure service vprn ipsec allow-reverse-route-override

Description

This command allows a new dynamic LAN-to-LAN tunnel that terminates in the private VPRN service to be created with an overlapping reverse route.

The **no** form of this command reverts to the default value.

Default

no allow-reverse-route-override

Parameters

type

Specifies the action to take when the system accepts a new reverse route.

Values same-idi — Specifies that the system accepts a new reverse route and removes the existing route only if the IDi of the new tunnel is the same as existing route.

any-idi — Specifies that the system accepts a new reverse route and removes the existing route regardless of the IDi.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.218 allow-sr-over-srte

allow-sr-over-srte

Syntax

[**no**] **allow-sr-over-srte**

Context

[Tree] (config>router>ospf>igp-sc allow-sr-over-srte)

[Tree] (config>router>isis>igp-sc allow-sr-over-srte)

Full Context

configure router ospf igp-shortcut allow-sr-over-srte

configure router isis igp-shortcut allow-sr-over-srte

Description

This command enables the SR-TE LSPs as eligible SRv4 or SRv6 IGP shortcuts.

For SR-MPLS SRv4 and SRv6, IGP shortcuts can only use SR-TE LSPs with **allow-sr-over-srte** explicitly enabled that have an adjacency SID as top SID in the SR-TE LSP. IPv4 and IPv6 addresses can use all available SR-TE LSPs as shortcuts regardless of the explicit **allow-sr-over-srte** configuration.

Under ECMP, when IGP **allow-sr-over-srte** is configured, preference is given to the SR-TE LSPs with **allow-sr-over-srte** explicitly configured over the LSPs that do not have **allow-sr-over-srte** configured.

The **no** form of this command disables the eligibility.

Default

no allow-sr-over-srte

Platforms

All

The **no** form of this command disallows SSH parameters from being configured.

Default

allow-ssh

Platforms

All

5.220 allow-static

allow-static

Syntax

allow-static

no allow-static

Context

[Tree] (config>router>bgp>next-hop-res>labeled-routes allow-static)

Full Context

configure router bgp next-hop-resolution labeled-routes allow-static

Description

This command allows the BGP next-hop of label-IPv4, label-IPv6, VPN-IPv4, and VPN-IPv6 routes received from any EBGP or IBGP peer to be resolved using static routes, except for static default routes (0/0 and ::/0).

A static route is less preferred than a local or interface route for resolving the BGP next-hop of labeled route, but more preferred than other IGP routes or tunnels.

Note:
A label-IPv4 or label-IPv6 route can be resolved by a static blackhole route, even when the **allow-static** command is not configured, but only if the static blackhole route is the longest prefix match (LPM) static route for the BGP next-hop address.

Default

no allow-static

Platforms

allowed-peer-as

Syntax

[**no**] **allowed-peer-as** *min-as-number* [**max** *max-as-number*]

Context

[Tree] (config>service>vprn>bgp>group>dynamic-neighbor>match>prefix allowed-peer-as)

Full Context

configure service vprn bgp group dynamic-neighbor match prefix allowed-peer-as

Description

This command configures a single peer AS value or a contiguous range of peer AS values to associate with a prefix from which dynamic BGP sessions can be accepted.

If an incoming dynamic BGP session is associated with the prefix then the peer's AS, as reported in the OPEN message, is checked against the list of allowed-peer-as values. If the peer AS is not contained in one of the **allowed-peer-as** commands, then the connection is rejected with a Bad_Peer_AS error. If there is no **allowed-peer-as** configuration in the matched prefix, then the ASN in the peer's OPEN message, is checked against the group level peer-as.

The **no** form of this command removes an allowed-peer-as entry.

Default

no allowed-peer-as

Parameters

min-as-number

Specifies an allowed peer AS value as well as the start of an allowed range if the *max-as-number* value is also configured.

Values 1 to 4294967295

max-as-number

Specifies the end of an allowed range.

Description

Commands in this context configure alternate port class pools parameters. Within this context, the corresponding port-class pools can be associated with a mid-pool, explicitly sized as a percentage of the mid-pool size, dynamically sized based on relative port bandwidth, or have a slope policy applied.

Platforms

7750 SR-7/12/12e

5.233 alternate-profile

alternate-profile

Syntax

alternate-profile *alternate-profile-name* [**create**]

no alternate-profile *alternate-profile-name*

Context

[Tree] (config system ptp alternate-profile)

Full Context

configure system ptp alternate-profile

Description

This command creates an alternate profile configuration for use in PTP messaging.

The alternate profile can be used at the edge of a network to provide PTP time or frequency distribution outward to external PTP clocks.

The alternate profile cannot be deleted if it is configured as the profile under a PTP port.

The **no** form of this command removes the alternate profile configuration.

Parameters

alternate-profile-name

Configures the alternate profile name, up to 64 characters. The string "profile" in any uppercase or lowercase form cannot be used for the alternate profile name.

create

Keyword used to create the alternate profile.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

alternate-profile

Syntax

alternate-profile *alternate-profile-name*

no alternate-profile *alternate-profile-name*

Context

[Tree] (config system ptp port alternate-profile)

Full Context

configure system ptp port alternate-profile

Description

This command assigns the alternate profile configuration that is used for PTP messaging on the port.

If no alternate profile is specified, the primary profile is used.

If an *alternate-profile-name* is specified, that alternate profile must already exist in the configuration.

The **no** form of this command removes the profile assignment.

Parameters

alternate-profile-name

Assigns the alternate profile name, up to 64 characters. The string "profile" in any uppercase or lowercase form cannot be used for the alternate profile name.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

5.234 always-compare-med

always-compare-med

Syntax

always-compare-med {**zero** | **infinity**}

no always-compare-med strict-as {**zero** | **infinity**}

no always-compare-med

Context

[Tree] (config>service>vprn>bgp>path-selection always-compare-med)

[Tree] (config>router>bgp>best-path-selection always-compare-med)

Full Context

configure service vprn bgp best-path-selection always-compare-med

configure router bgp best-path-selection always-compare-med

Description

This command configures the comparison of BGP routes based on the MED attribute. The default behavior of SR OS (equivalent to the **no** form of this command) is to only compare two routes on the basis of MED if they have the same neighbor AS (the first non-confed AS in the received AS_PATH attribute). Also by default, a route without a MED attribute is handled the same as though it had a MED attribute with the value 0. The **always-compare-med** command without the **strict-as** keyword allows MED to be compared even if the paths have a different neighbor AS; in this case, if neither **zero** nor **infinity** is specified, the **zero**

option is inferred, meaning a route without a MED is handled the same as though it had a MED attribute with the value 0. When the **strict-as** keyword is present, MED is only compared between paths from the same neighbor AS, and in this case, **zero** or **infinity** is mandatory and tells BGP how to interpret paths without a MED attribute.

Default

no always-compare-med

Parameters

zero

Specifies that for routes learned without a MED attribute that a zero (0) value is used in the MED comparison. The routes with the lowest metric are the most preferred.

infinity

Specifies for routes learned without a MED attribute that a value of infinity (2^32-1) is used in the MED comparison. This in effect makes these routes the least desirable.

strict-as

Specifies that the BGP MED values are only compared if the route comes from the same neighbor AS.

Platforms

All

5.235 always-set-sender-for-ir

always-set-sender-for-ir

Syntax

[**no**] **always-set-sender-for-ir**

Context

[Tree] (config>system>security>pki>ca-profile>cmpv2 always-set-sender-for-ir)

Full Context

configure system security pki ca-profile cmpv2 always-set-sender-for-ir

Description

This command specifies to always set the sender field in CMPv2 header of all Initial Registration (IR) messages with the subject name. By default, the sender field is only set if an optional certificate is specified in the CMPv2 request.

Default

no always-set-sender-for-ir

[Tree] (config>port>access>ingress>pool amber-alarm-threshold)

Full Context

configure port network egress pool amber-alarm-threshold

configure port access egress pool amber-alarm-threshold

configure port access ingress pool amber-alarm-threshold

Description

This command configures the threshold for the amber alarm on the over-subscription allowed.

Users can selectively enable amber or red alarm thresholds. But if both are enabled (non-zero), the amber alarm threshold cannot be more than the red alarm threshold.

The **no** form of this command reverts to the default value.

Default

no amber-alarm-threshold

Parameters

percentage

Specifies the amber alarm threshold.

Values 1 to 1000

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

amber-alarm-threshold

Syntax

amber-alarm-threshold *percentage*

no amber-alarm-threshold

Context

[Tree] (config>card>fp>ingress>network>pool amber-alarm-threshold)

Full Context

configure card fp ingress network pool amber-alarm-threshold

Description

This command configures the threshold for the amber alarm on the over-subscription allowed.

Users can selectively enable amber or red alarm thresholds. But if both are enabled (non-zero) then the red alarm threshold must be greater than the amber alarm threshold.

The **no** form of this command reverts to the default value.

Default

no amber-alarm-threshold

Parameters

percentage

Specifies the amber alarm threshold.

Values 1 to 1000

Platforms

5.237 ambr

ambr

Syntax

ambr down-link *down-link-kbps* **up-link** *up-link-kbps*

no ambr

Context

[Tree] (config>subscr-mgmt>gtp>peer-profile>pgw>qos ambr)

[Tree] (config>subscr-mgmt>gtp>peer-profile>ggsn>qos ambr)

[Tree] (config>subscr-mgmt>gtp>peer-profile>mme>qos ambr)

Full Context

configure subscriber-mgmt gtp peer-profile pgw qos ambr

configure subscriber-mgmt gtp peer-profile ggsn qos ambr

configure subscriber-mgmt gtp peer-profile mme qos ambr

Description

This command configures the Aggregated Maximum Bit Rate (AMBR) to be sent in the APN AMBR IE. The contents of this IE can be overridden by RADIUS or report-rate mechanisms. If those mechanisms specify a partial value, such as only specifying the **down-link** parameter, the other value is picked up from the **ambr** configuration.

For GTPv1, the **no** form of this command implies that the IE will not be sent. If a partial value is received from another source, the missing value will use the following defaults:

- 10000 kb/s up-link
- 20000 kb/s down-link

For GTPv2, the **no** form of this command reverts to the default of 10000 kb/s up-link and 20000 kb/s down-link.

Default

no ambr - for ggsn

ambr down-link 20000 up-link 10000 - for mme and pgw

Parameters

down-link-kbps

Specifies the downlink AMBR.

Values 0 to 10000000

up-link-kbps

Specifies the uplink AMBR.

Values 0 to 10000000

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.238 ambr-qos-mapping

ambr-qos-mapping

Syntax

ambr-qos-mapping

Context

[Tree] (config>subscr-mgmt>gtp>apn-policy>apn ambr-qos-mapping)

Full Context

configure subscriber-mgmt gtp apn-policy apn ambr-qos-mapping

Description

Mapping of an incoming APN-AMBR to SR OS QoS overrides.

Platforms

5.239 an-gw-address

an-gw-address

Syntax

[**no**] **an-gw-address**

Context

[Tree] (config>subscr-mgmt>diam-appl-plcy>gx>include-avp an-gw-address)

Full Context

configure subscriber-mgmt diameter-application-policy gx include-avp an-gw-address

Description

This command configures the IPv4 address of the node.

The **no** form of this command reverts to the default.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

5.240 analyze-gre-payload

analyze-gre-payload

Syntax

[**no**] **analyze-gre-payload**

Context

[Tree] (config>cflowd analyze-gre-payload)

Full Context

configure cflowd analyze-gre-payload

Description

This command enables cflowd analysis of the inner IP packet in a sampled GRE packet that is transiting the local router.

If the GRE packet terminates on the local node, the inner IP payload is analyzed and reported using existing IPv4 or IPv6 flow templates. This behavior is not affected by this command.

If this parameter is enabled and a GRE packet is transiting the local node, the inner payload is reported using the GRE Flow Template. (Template ID 308 or 309)

This behavior is only supported with V10 (IPFIX) collectors.

The **no** form of this command disables cflowd analysis of the inner IP packet in a sampled GRE packet.

Platforms

All

5.241 analyze-l2tp-traffic

analyze-l2tp-traffic

Syntax

[**no**] **analyze-l2tp-traffic**

Context

[Tree] (config>cflowd analyze-l2tp-traffic)

Full Context

configure cflowd analyze-l2tp-traffic

Description

This command causes cflowd to look for and analyze the inner IP header of an L2TPv2 frame.

L2TPv2 traffic is identified by either the source or destination UDP port numbering that is set to 1701.

The **no** form of this command disables this function.

Default

no analyze-l2tp-traffic

Platforms

All

5.242 analyze-v4overv6-traffic

analyze-v4overv6-traffic

Syntax

Commands in this context configure ANCP parameters for this GSMP group.

The **no** form of this command disables the ANCP parameters configured in this context.

Platforms

All

ancp

Syntax

ancp ancp-string *ancp-string* **loopback** [**count** *send-count*] [**timeout** *timeout*] [**alarm**]

ancp subscriber *sub-ident-string* **loopback** [**count** *send-count*] [**timeout** *timeout*] [**alarm**]

Context

[Tree] (oam ancp)

Full Context

oam ancp

Description

This command sends an OAM request to the access node. ANCP can be used to send OAM messages to the access node. The access node must be able to accept these messages and signals such support by the capability negotiations. If the operator attempts to send an OAM command to an access node that does not support, the operation results in an error.

Parameters

ancp-string

Specifies an existing ANCP string, up to 63 characters.

loopback

Sends an OAM loopback test request to the access node.

send-count

Specifies the number of messages the access node uses to test the circuit. If omitted, the number is determined by the access node via local policy.

Values 1 to 32

timeout

Specifies the length of time, in seconds, that the controlling node waits for a result.

Values 1 to 255

alarm

Specifies that the CLI the result is returned to the CLI and a trap is issued to indicate the test has finished. If the flag is used through SNMP the results are available in the results MIB and after the node sends the trap to indicate the results are ready.

sub-ident-string

Specifies an existing subscriber-id, up to 32 characters. The node uses the *ancp-string* value associated with the provided subscriber-id to identify the circuit.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

ancp

Syntax

ancp

Context

[Tree] (config>system>persistence ancp)

configure system persistence ancp

Description

This command configures ANCP persistence parameters.

Platforms

All

5.245 ancp-policy

ancp-policy

Syntax

ancp-policy *policy-name* [**create**]

no ancp-policy *policy-name*

Context

[Tree] (config>subscr-mgmt>ancp ancp-policy)

Full Context

configure subscriber-mgmt ancp ancp-policy

Description

This command creates an Access Node Control Protocol (ANCP) policy. The policy is associated with either the ANCP string (static case) or subscriber-profile (dynamic case) and defines the behavior of the hosts belonging to these profiles.

ANCP policies control rates and subscribers based on port-up/port-down messages from the access node. When configured, the 7450 ESS or 7750 SR should stop SHCV to a host that is part of a port defined to be down (by port-down message). When the node receives a port-up message for a port that was in port-down state, the node will initiate the SHCV process immediately to verify connectivity.

When ANCP is used with Enhanced Subscriber Management, the ANCP string last associated with the subscriber is used. All hosts of a subscriber is updated with the new ANCP string.

The **no** form of this command removes the policy name from the ANCP configuration.

Parameters

policy-name

Configures the ANCP policy name, up to 32 characters.

create

Keyword used to create the ANCP policy. The **create** keyword requirement can be enabled or disabled in the **environment>create** context.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

ancp-policy

Syntax

ancp-policy *name*

Context

[Tree] (config>subscr-mgmt>sub-prof>ancp ancp-policy)

Full Context

configure subscriber-mgmt sub-profile ancp ancp-policy

Description

This command specifies an existing Access Node Control Protocol (ANCP) policy to associate with the subscriber profile. The policy is associated with either the ANCP string (static case) or subscriber-profile (dynamic case) and defines the behavior of the hosts belonging to these profiles.

The **no** form of this command removes the policy name from the ANCP configuration.

Parameters

name

Specifies an existing ANCP policy name, up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

5.246 ancp-static-map

ancp-static-map

Syntax

ancp-static-map

Context

[Tree] (config>subscr-mgmt>ancp ancp-static-map)

Full Context

configure subscriber-mgmt ancp ancp-static-map

Description

Commands in this context configure a static ANCP name map.

Default

ancp-static-map

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

Description

This command specifies the ANCP string associated to this SAP host.

The **no** form of this command reverts to the default.

Parameters

ancp-string

Specifies the ANCP string up to 63 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

5.248 anno-rx-timeout

anno-rx-timeout

Syntax

anno-rx-timeout *count*

no anno-rx-timeout

Context

[Tree] (config>system>ptp anno-rx-timeout)

Full Context

configure system ptp anno-rx-timeout

Description

This command configures the announceReceiptTimeout value for all peer associations. This defines the number of Announce message intervals that must expire with no received Announce messages before declaring an ANNOUNCE_RECIPT_TIMEOUT event.

The **announce-rx-timeout** cannot be changed unless PTP is shut down.

Default

anno-rx-timeout 3

Parameters

count

Specifies the announce packet interval, in log form.

Values 2 to 10

Default 3

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

configure service ies subscriber-interface group-interface pppoe anti-spoof

configure service ies subscriber-interface group-interface sap anti-spoof

configure service vprn subscriber-interface group-interface pppoe anti-spoof

Description

This command enables anti-spoof filtering and optionally changes the anti-spoof matching type for the SAP.

The type of anti-spoof filtering defines what information in the incoming packet is used to generate the criteria to lookup an entry in the anti-spoof filter table. The type parameter (**ip**, **mac**, **ip-mac**) defines the anti-spoof filter type enforced by the SAP when anti-spoof filtering is enabled.

Enabling anti-spoof filtering on a subscriber-facing SAP causes the anti-spoof table to be populated with all static and dynamic host information available on the SAP. Enabling anti-spoof filtering on the SAP will fail if any static hosts are defined without the proper addresses specified for the selected anti-spoof filter type.

When enabled, forwarding IP packets that ingress the SAP is dependent on a successful anti-spoof table match with an entry in the table. DHCP and non-IP packets (including ARP) are not subject to anti-spoof filtering. If an entry does not match the ingress packet, the packet is silently discarded while incrementing the SAP discard counter.

Anti-spoof filtering is only allowed on VPLS SAPs, IES SAP-based IP interfaces, and VPRN SAP-based IP interfaces. Anti-spoof filtering is not available on IES or VPRN SDP bound IP interfaces. Anti-spoof filtering is not supported on Epipe and other VLL type services. Support for anti-spoofing is dependent on SAP based service interfaces. Note VPRN and VLL are supported on the 7750 SR only.

Note:
Anti-spoofing filters, with type **ip-mac**, must be enabled to perform Enhanced Subscriber Management (as described in the Triple Play Enhanced Subscriber Management section).

The **no** form of this command disables anti-spoof filtering on the SAP.

Default

no anti-spoof

Parameters

type

Specifies the anti-spoof filtering type for this SAP.

Values ip — Specifies to use only the source IP address in its lookup. If a static host exists on the SAP without an IP address specified, the **anti-spoof ip** command fails.

ip-mac — Specifies to use both the source IP address and the source MAC address in its lookup.

mac — Specifies to use only the source MAC address in its lookup. If a static host exists on the SAP without a specified MAC address, the **anti-spoof mac** command fails.

anti-spoof

Syntax

anti-spoof *type*

no anti-spoof

Context

[Tree] (config>service>ies>if>sap anti-spoof)

[Tree] (config>service>vprn>if>sap anti-spoof)

[Tree] (config>service>vpls>sap anti-spoof)

Full Context

configure service ies interface sap anti-spoof

configure service vprn interface sap anti-spoof

configure service vpls sap anti-spoof

Description

This command enables anti-spoof filtering and optionally changes the anti-spoof matching type for the SAP.

The type of anti-spoof filtering defines what information in the incoming packet is used to generate the criteria to lookup an entry in the anti-spoof filter table. The type parameter (**ip**, **mac**, **ip-mac**) defines the anti-spoof filter type enforced by the SAP when anti-spoof filtering is enabled.

The **no** form of the command disables anti-spoof filtering on the SAP.

Default

no anti-spoof

Parameters

type

Specifies the anti-spoof filtering type for this SAP.

Values ip — Configures SAP anti-spoof filtering to use only the source IP address in its lookup. If a static host exists on the SAP without an IP address specified, the anti-spoof type **ip** command fails.

ip-mac — Configures SAP anti-spoof filtering to use both the source IP address and the source MAC address in its lookup. If a static host exists on the SAP without both the IP address and MAC address specified, the anti-spoof type **ip-mac** command fails. This is also true if the default anti-spoof filter type of the SAP is **ip-mac** and the default is not overridden. The anti-spoof type **ip-mac** command will also fail if the SAP does not support Ethernet encapsulation.

mac — Configures SAP anti-spoof filtering to use only the source MAC address in its lookup. Setting the anti-spoof filter type to **mac** is not allowed on non-Ethernet encapsulated SAPs. If a static host exists on the SAP without a specified MAC address, the anti-spoof type **mac** command fails. The anti-spoof type **mac** command will also fail if the SAP does not support Ethernet encapsulation.

Platforms

anti-spoof

Syntax

anti-spoof {**ip** | **ip-mac** | **nh-mac**}

no anti-spoof

Context

[Tree] (config>service>vprn>sub-if>grp-if>sap anti-spoof)

[Tree] (config>service>ies>sub-if>grp-if>sap anti-spoof)

Full Context

configure service vprn subscriber-interface group-interface sap anti-spoof

configure service ies subscriber-interface group-interface sap anti-spoof

Description

This command configures the anti-spoof type of the MSAP.

The type of anti-spoof filtering defines what information in the incoming packet is used to generate the criteria to lookup an entry in the anti-spoof filter table. The type parameter (**ip**, **ip-mac**) defines the anti-spoof filter type enforced by the SAP when anti-spoof filtering is enabled.

The **no** form of this command reverts to the default.

Note:
For IES and VPRN subscriber group interfaces, setting no anti-spoof sets the default anti-spoofing type which is **ip-mac**.

Parameters

ip

Configures SAP anti-spoof filtering to use only the source IP address in its lookup. If a static host exists on the SAP without an IP address specified, the anti-spoof type **ip** command fails.

Note:
This parameter is not applicable in the **config>subscr-mgmt>msap-policy** context.

ip-mac

Configures SAP anti-spoof filtering to use both the source IP address and the source MAC address in its lookup. The anti-spoof type **ip-mac** command fails if the default anti-spoof filter type of the SAP is **ip-mac** and the default is not overridden, or if the SAP does not support Ethernet encapsulation.

nh-mac

Indicates that the ingress anti-spoof is based on the source MAC and egress anti-spoof is based on the nh-ip-address .

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

anti-spoof

Syntax

anti-spoof *pppoe-anti-spoofing-type*

no anti-spoof

Context

Full Context

configure service ies subscriber-interface group-interface pppoe anti-spoof

configure service vprn subscriber-interface group-interface pppoe anti-spoof

Description

This command specifies the type of PPPoE anti-spoof filtering to use.

The **no** form of this command reverts to the default.

Default

anti-spoof mac-sid

Parameters

pppoe-anti-spoofing-type

Specifies the PPPoE anti-spoof filtering.

Values mac-sid, mac-sid-ip

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

anti-spoof

Syntax

anti-spoof {**ip** | **mac** | **ip-mac** | **nh-mac**}

no anti-spoof-type

Context

[Tree] (config>service>vprn>if>sap anti-spoof)

Full Context

configure service vprn interface sap anti-spoof

Description

This command enables anti-spoof filtering and optionally changes the anti-spoof matching type for the interface.

The type of anti-spoof filtering defines what information in the incoming packet is used to generate the criteria to lookup an entry in the anti-spoof filter table. The type parameter (**ip**, **mac**, **ip-mac, nh-mac**) defines the anti-spoof filter type enforced by the SAP when anti-spoof filtering is enabled.

The **no** form of this command reverts to the default.

Default

Filter type default types:

- anti-spoof ip (Non-Ethernet encapsulated SAP)
- anti-spoof ip-mac (Ethernet encapsulated SAP)
- no anti-spoof-type (other SAPs)

Parameters

ip

Configures SAP anti-spoof filtering to use only the source IP address in its lookup. If a static host exists on the SAP without an IP address specified, the anti-spoof type **ip** command fails.

mac

Configures SAP anti-spoof filtering to use only the source MAC address in its lookup. Setting the anti-spoof filter type to **mac** is not allowed on non-Ethernet encapsulated SAPs. If a static host exists on the SAP without a specified MAC address, the anti-spoof type **mac** command fails. The anti-spoof type **mac** command will also fail if the SAP does not support Ethernet encapsulation.

ip-mac

Configures SAP anti-spoof filtering to use both the source IP address and the source MAC address in its lookup. If a static host exists on the SAP without both the IP address and MAC address specified, the anti-spoof type **ip-mac** command fails. This is also true if the default anti-spoof filter type of the SAP is **ip-mac** and the default is not overridden. The anti-spoof type **ip-mac** command will also fail if the SAP does not support Ethernet encapsulation.

nh-mac

Indicates that the ingress anti-spoof is based on the source MAC address and the egress anti-spoof is based on the nh-ip-address.

5.252 anycast

anycast

Syntax

[**no**] **anycast** *rp-ip-address*

Context

[Tree] (config>service>vprn>pim>rp anycast)

Full Context

configure service vprn pim rp anycast

Description

This command configures a PIM anycast protocol instance for the RP being configured. Anycast enables fast convergence when a PIM RP router fails by allowing receivers and sources to rendezvous at the closest RP.

The **no** form of this command removes the anycast instance from the configuration.

Parameters

rp-ip-address

Configure the loopback IP address shared by all routes that form the RP set for this anycast instance. Only a single address can be configured. If another anycast command is entered with an address then the old address will be replaced with the new address. If no ip-address is entered then the command is simply used to enter the anycast CLI level.

Values Any valid loopback address configured on the node.

Platforms

All

anycast

Syntax

anycast *ipv6-address*

no anycast *ipv6-address*

Context

[Tree] (config>service>vprn>pim>rp>ipv6 anycast)

Full Context

configure service vprn pim rp ipv6 anycast

Description

This command configures an IPv6 PIM anycast protocol instance for the RP being configured. Anycast enables fast convergence when a PIM RP router fails by allowing receivers and sources to rendezvous at the closest RP.

The **no** form of this command removes the anycast instance from the configuration.

Parameters

ipv6-address

Configures the loopback IP address shared by all routes that form the RP set for this anycast instance. Only a single address can be configured. If another anycast command is entered with an address then the old address will be replaced with the new address. If no address is entered then the command is simply used to enter the anycast CLI context.

Values

ipv6-address	: x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x [0 to FFFF]H
	d [0 to 255]D

Platforms

All

anycast

Syntax

[**no**] **anycast** *rp-ip-address*

Context

[Tree] (config>router>pim>rp anycast)

Full Context

configure router pim rp anycast

Description

This command configures a PIM anycast protocol instance for the RP being configured. Anycast enables fast convergence when a PIM RP router fails by allowing receivers and sources to rendezvous at the closest RP.

The **no** form of this command removes the anycast instance from the configuration.

Parameters

rp-ip-address

Specifies the loopback IP address shared by all routes that form the RP set for this anycast instance. Only a single address can be configured. If another anycast command is entered with an address then the old address will be replaced with the new address. If no ip-address is entered then the command is simply used to enter the anycast CLI level.

Values Any valid loopback address configured on the node.

Platforms

All

anycast

Syntax

5.253 ap-mac-learn-failed

ap-mac-learn-failed

Syntax

ap-mac-learn-failed {**true** | **false** | **not-specified**}

Context

[Tree] (config>subscr-mgmt>wlan-gw>tunnel-query ap-mac-learn-failed)

Full Context

configure subscriber-mgmt wlan-gw tunnel-query ap-mac-learn-failed

Description

This command specifies the matching criteria of tunnels based on whether or not learning the associated AP-MAC address last failed.

Default

ap-mac-learn-failed not-specified

Parameters

true

Specifies matching of tunnels status where learning of the AP-MAC address succeeded.

false

Specifies matching of tunnels status where learning of the AP-MAC address failed.

not-specified

Specifies no matching on the AP-MAC address learning status.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.254 apn

apn

Syntax

apn *apn*

no apn

Context

[Tree] (config>service>vprn>gtp>uplink apn)

[Tree] (config>router>gtp>uplink apn)

Full Context

configure service vprn gtp uplink apn

configure router gtp uplink apn

Description

This command configures the Network Identifier part of the APN.

The **no** form of this command removes the string from the configuration.

Default

no apn

Parameters

apn

Specifies the APN used for this IMSI to connect to this Mobile Gateway, up to 80 characters.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

apn

Syntax

apn {*apn-name* | **unknown**} [**create**]

no apn {*apn-name* | **unknown**}

Context

[Tree] (config>subscr-mgmt>gtp>apn-policy apn)

Full Context

configure subscriber-mgmt gtp apn-policy apn

Description

This command configures the parameters that should be applied to incoming connections with the APN specified. Multiple APN nodes can be defined per APN policy.

For each APN-policy, one **unknown** APN entry can be created. This APN is used by all connections not matching another APN.

The **no** form of this command removes the APN from the policy. Only new sessions are affected by the removal.

Parameters

apn-name

Specifies the APN name as it appears in GTP messaging, up to 80 characters.

create

Creates an *apn-name* instance. The **create** keyword requirement can be enabled or disabled in the **environment>create** context.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

apn

Syntax

[**no**] **apn**

Context

[Tree] (config>subscr-mgmt>acct-plcy>include-radius-attribute apn)

[Tree] (config>subscr-mgmt>auth-plcy>include-radius-attribute apn)

Full Context

configure subscriber-mgmt radius-accounting-policy include-radius-attribute apn

configure subscriber-mgmt authentication-policy include-radius-attribute apn

Description

This command enables the inclusion of the APN n AAA protocols as signaled in the incoming GTP setup message.

The **no** form of this command disables the inclusion of the attribute.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

apn

Syntax

apn *apn-string*

no apn

Context

[Tree] (config>app-assure>group>gtp>gtp-fltr>imsi-apn-fltr>entry apn)

Full Context

configure application-assurance group gtp gtp-filter imsi-apn-filter entry apn

Description

This command configures a matching condition for an APN configured as a GTP filter.

Parameters

apn-string

Specifies the match string, which can include 1 to 32 characters.

If no APN is specified, the entry will not check for the APN IE in GTP-C packets.

Values *string*: The extracted APN must match *string* exactly.

^*string*: The extracted APN must start with *string*.

*string***$**: The extracted APN must end with *string*.

WILDCARD_APN: Special string that indicates that the extracted APN must be "*" (that is, a length octet with value one, followed by the ASCII code for the asterisk)

EMPTY_APN: Special string that indicates that the extracted APN must be empty (that is, "")

ANY_APN: Special string that indicates that the extracted APN IE must be present and can have any value in order for the filter entry to match

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.255 apn-ambr

apn-ambr

Syntax

[**no**] **apn-ambr**

Context

[Tree] (config>subscr-mgmt>diam-appl-plcy>gx>include-avp apn-ambr)

Full Context

configure subscriber-mgmt diameter-application-policy gx include-avp apn-ambr

Description

This command enables the inclusion of the APN-Aggregate-Max-Bitrate-DL and APN-Aggregate-Max-Bitrate-UL AVPs inside the QoS-Information AVP, as signaled in the incoming GTP message.

The **no** form of this command disables the inclusion of the AVPs.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.256 apn-ambr-dl

apn-ambr-dl

Syntax

apn-ambr-dl agg-rate

apn-ambr-dl arbiter *arbiter-name*

apn-ambr-dl hs-sla-agg-rate

apn-ambr-dl policer *policer-id*

apn-ambr-dl queue *queue-id*

apn-ambr-dl scheduler *scheduler-name*

no apn-ambr-dl

Context

[Tree] (config>subscr-mgmt>diam-appl-plcy>gx>3gpp-qos-mapping apn-ambr-dl)

Full Context

configure subscriber-mgmt diameter-application-policy gx 3gpp-qos-mapping apn-ambr-dl

Description

This command configures the APN-Aggregate-Max-Bitrate-DL AVP. When enabled, the AVP is interpreted as a rate override for the specified egress QoS object. For queues and policers, the PIR is overridden.

This override uses the same QoS override mechanism as the native Gx and RADIUS-based QoS overrides. Therefore, a subsequent Gx/RADIUS-based override removes this override and an APN-AMBR based override removes any preceding Gx/RADIUS-based override.

The **no** form of this command disables the override mechanism based on APN-AMBR.

Parameters

agg-rate

Specifies to map to an aggregate rate.

arbiter-name

Specifies the name of the arbiter to be overridden.

hs-sla-agg-rate

Specifies to map to an HS SLA aggregate rate.

policer-id

Specifies the ID of the policer to be overridden.

queue-id

Specifies the ID of the queue to be overridden.

scheduler-name

Specifies the name of the scheduler to be overridden.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.257 apn-ambr-ul

apn-ambr-ul

Syntax

apn-ambr-ul arbiter *arbiter-name*

apn-ambr-ul policer *policer-id*

apn-ambr-ul queue *queue-id*

apn-ambr-ul scheduler *scheduler-name*

no apn-ambr-ul

Context

[Tree] (config>subscr-mgmt>diam-appl-plcy>gx>3gpp-qos-mapping apn-ambr-ul)

Full Context

configure subscriber-mgmt diameter-application-policy gx 3gpp-qos-mapping apn-ambr-ul

Description

This command configures the APN-Aggregate-Max-Bitrate-UL AVP. When enabled, the AVP is interpreted as a rate override for the specified egress QoS object. For queues and policers, the PIR is overridden.

This override uses the same QoS override mechanism as the native Gx and RADIUS-based QoS overrides. Therefore, a subsequent Gx/RADIUS-based override removes this override and an APN-AMBR based override removes any preceding Gx/RADIUS-based override.

The **no** form of this command disables the override mechanism based on APN-AMBR.

Parameters

arbiter-name

Specifies the name of the arbiter to be overridden.

policer-id

Specifies the ID of the policer to be overridden.

queue-id

Specifies the ID of the queue to be overridden.

scheduler-name

Specifies the name of the scheduler to be overridden.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

configure router gtp s11 interface apn-policy

configure service vprn gtp s11 interface apn-policy

Description

This command configures an Access Point Name (APN) policy for the S11 interface.

The **no** form of this command removes the APN policy.

Parameters

apn-policy-name

Specifies the name of the policy, up to 32 characters.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

apn-policy

Syntax

apn-policy *policy-name* [**create**]

no apn-policy *policy-name*

Context

[Tree] (config>subscr-mgmt>gtp apn-policy)

Full Context

configure subscriber-mgmt gtp apn-policy

Description

This command configures an APN policy that defines parameters to be used when setting up a new incoming GTP connection. Each APN can be mapped to its own set of parameters.

The **no** form of this command removes the policy from the system. A policy can only be removed if it is not in use.

Parameters

policy-name

Specifies the name of the policy, up to 32 characters.

create

Creates an entry.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

Full Context

configure application-assurance group cflowd rtp-performance app-group

configure application-assurance group cflowd tcp-performance app-group

configure application-assurance group cflowd comprehensive app-group

Description

This command configures application groups to export performance records with cflowd.

The **no** form of this command removes the parameters from the configuration.

Parameters

app-group-name

Specifies the application group name.

rate

Specifies which sampling flow rate to use; flow-rate or flow-rate2.

Values flow-rate, flow-rate2

Default flow-rate

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

app-group

Syntax

app-group *application-group-name* [**create**]

no app-group *application-group-name*

Context

[Tree] (config>app-assure>group>policy app-group)

Full Context

configure application-assurance group policy app-group

Description

This command creates an application group for an application assurance policy.

The **no** form of this command deletes the application group from the configuration. All associations must be removed in order to delete a group.

Default

no app-group

Parameters

application-group-name

A string of up to 32 characters uniquely identifying this application group in the system.

create

Mandatory keyword used when creating an application group. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

app-group

Syntax

app-group *app-group-name*

Context

[Tree] (config>app-assure>group>policy>application app-group)

Full Context

configure application-assurance group policy application app-group

Description

This command associates an application with an application group of an application assurance policy.

Parameters

app-group-name

A string of up to 32 characters uniquely identifying an existing application in the system.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

app-group

Syntax

app-group {**eq** | **neq**} *application-group-name*

no app-group

Context

configure application-assurance group policy app-qos-policy entry match app-group

configure application-assurance group policy charging-filter entry match app-group

Description

This command adds app-group to match criteria used by this entry.

The **no** form of this command removes the app-group from match criteria for this entry.

Default

no app-group

Parameters

eq

Specifies that the value configured and the value in the flow must be equal.

neq

Specifies that the value configured and the value in the flow must differ.

application-group-name

Specifies the name of the existing application group entry, up to 32 characters

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

app-group

Syntax

app-group *app-group-name* **export-using** *export-method* [*export-method* **...**(up to 2 max)]

app-group *app-group-name* **no-export**

no app-group *app-group-name*

Context

[Tree] (config>app-assure>group>statistics>aa-sub app-group)

Full Context

configure application-assurance group statistics aa-sub app-group

Description

Commands in this context configure accounting and statistics collection parameters per system for application groups of application assurance for a given AA ISA group/partition.

The **no** form of this command removes the application group name.

Parameters

app-group-name

Specifies an existing application group name, up to 32 characters.

export-method

Specifies the method of statistics export to be used.

Values accounting-policy, radius-accounting-policy

no-export

Allows the operator to enable the referred to application group to be selected (via Diameter) for Gx-usage monitoring. Gx usage monitoring is enabled automatically (and this command is not shown) if the **export-using** parameter is selected for the respective application group.

Usage monitoring must be enabled at the group:partition level (**config>app-assure>group>statistics>aa-sub>usage-monitoring**) as well in order to allow any application/application group/charging group usage monitoring.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

app-group

Syntax

app-group {eq | neq} *application-group-name*

no app-group

Context

[Tree] (config>app-assure>group>policy>chrg-fltr>entry>match app-group)

Full Context

configure application-assurance group policy charging-filter entry match app-group

Description

This command configures the addition of an application group to the match criteria used by this charging filter entry.

The **no** form of this command removes the application group match criteria.

Default

no app-group

Parameters

eq

Specifies that the value configured and the value in the flow must be equal.

neq

Specifies that the value configured and the value in the flow must differ.

application-group-name

Specifies the name of the existing application group entry, up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

configure service epipe sap app-profile

configure service ipipe spoke-sdp app-profile

Description

This command configures the application profile name.

Parameters

app-profile-name

Specifies an existing application profile name configured in the **config>app-assure>group>policy** context.

Platforms

All

- configure service ipipe spoke-sdp app-profile
- configure service ipipe sap app-profile

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

- configure service epipe spoke-sdp app-profile
- configure service epipe sap app-profile

app-profile

Syntax

app-profile *app-profile-name* [**create**]

no app-profile *app-profile-name*

Context

[Tree] (config app-assure group policy app-profile)

Full Context

configure application-assurance group policy app-profile

Description

This command creates an application profile and commands in this context configure the profile parameters.

The **no** form of this command removes the application profile from the configuration.

Parameters

app-profile-name

Specifies the name of the application profile up to 32 characters.

create

Mandatory keyword used when creating an application profile. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

app-profile

Syntax

[**no**] **app-profile**

Context

[Tree] (config log acct-policy cr aa aa-sub-attributes app-profile)

Full Context

configure log accounting-policy custom-record aa-specific aa-sub-attributes app-profile

Description

This command enables the subscriber app-profile attribute information to be exported in the AA subscriber's custom record.

The **no** form of this command excludes the subscriber app-profile attribute from the AA subscriber's custom record.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.262 app-profile-map

app-profile-map

Syntax

app-profile-map

Context

[Tree] (config>subscr-mgmt>sub-ident-pol app-profile-map)

Full Context

configure subscriber-mgmt sub-ident-policy app-profile-map

Description

Commands in this context configure an application profile mapping.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.263 app-profile-string

app-profile-string

Syntax

app-profile-string *app-profile-string*

no app-profile-string

Context

[Tree] (config>subscr-mgmt>loc-user-db>ipoe>host>ident-strings app-profile-string)

[Tree] (config>subscr-mgmt>loc-user-db>ppp>host>ident-strings app-profile-string)

Full Context

configure subscriber-mgmt local-user-db ipoe host identification-strings app-profile-string

configure subscriber-mgmt local-user-db ppp host identification-strings app-profile-string

Description

This command specifies the application profile string which is encoded in the identification strings.

The **no** form of this command returns to the default.

Parameters

app-profile-string

Specifies the application profile string, up to 16 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.264 app-qos-policy

app-qos-policy

Syntax

app-qos-policy

Context

[Tree] (config>app-assure>group>policy app-qos-policy)

Full Context

configure application-assurance group policy app-qos-policy

Description

Commands in this context configure an application QoS policy.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.265 app-route-notifications

app-route-notifications

Syntax

app-route-notifications

Context

[Tree] (config>log app-route-notifications)

Full Context

configure log app-route-notifications

Description

Specific system applications in SR OS can take action based on a route to certain IP destinations being available. This CLI branch contains configuration related to these route availability notifications. A delay can be configured between the time that a route is determined as available in the CPM, and the time that the application is notified of the available route. For example, this delay may be used to increase the chances that other system modules (such as IOMs/XCMs/MDAs/XMAs) are fully programmed with the new route before the application takes action. Currently, the only application that acts upon these *route available* or *route changed* notifications with their configurable delays is the SNMP replay feature, which receives notifications of route availability to the SNMP trap receiver destination IP address.

Platforms

All

5.266 app-service-options

app-service-options

Syntax

app-service-options

Context

[Tree] (config>app-assure>group>policy app-service-options)

Full Context

configure application-assurance group policy app-service-options

Description

Commands in this context configure application service option characteristics.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

app-service-options

Syntax

[**no**] **app-service-options**

Context

[Tree] (config>log>acct-policy>cr>aa>aa-sub-attributes app-service-options)

Full Context

configure log accounting-policy custom-record aa-specific aa-sub-attributes app-service-options

Description

This command enables the subscriber application service option attributes to be exported in the AA subscriber's custom record.

The **no** form of this command excludes the subscriber application service option attributes from the AA subscriber's custom record.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.267 applicant-sm

applicant-sm

Syntax

[**no**] **applicant-sm**

Context

[Tree] (debug>service>id>mrp applicant-sm)

Full Context

debug service id mrp applicant-sm

Description

This command enables debugging of the applicant state machine.

The **no** form of this command disables debugging of the applicant state machine.

Platforms

All

5.268 application

application

Syntax

application {**gx** | **gy** | **nasreq**}

no application

Context

[Tree] (config>subscr-mgmt>diam-appl-plcy application)

Full Context

configure subscriber-mgmt diameter-application-policy application

Description

This command specifies the Diameter application for which this policy contains the configuration details, such as AVPs to include and their format.

Applications are mutually exclusive.

The **no** form of this command reverts to the default.

Parameters

gx

Specifies that Gx is the supported application of this DIAMETER policy.

gy

Specifies that Gy is the supported application of this DIAMETER policy.

nasreq

Specifies that NASREQ is the supported application of this DIAMETER policy.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

application

Syntax

application

Context

[Tree] (debug>diam application)

Full Context

debug diameter application

Description

This command debugs application processing for the Diameter node. This level is session aware (the session state is maintained at this level). Connection level messages are not reported on this level.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

application

Syntax

application *dscp-app-name* **dscp** {*dscp-value* | *dscp-name*}

application *dot1p-app-name* **dot1p** *dot1p-priority*

no application {*dscp-app-name* | *dot1p-app-name*}

Context

[Tree] (config>service>vprn>sgt-qos application)

[Tree] (config>router>sgt-qos application)

Full Context

configure service vprn sgt-qos application

configure router sgt-qos application

Description

This command configures DSCP/dot1p remarking for self-generated application traffic. When an application is configured using this command, the specified DSCP name is used for all packets generated by this application within the router instance it is configured. The instances can be base router, vprn, or management.

Using the value configured in this command:

- sets the DSCP bits in the IP packet
- maps to the FC. This value will be signaled from the CPM to the egress forwarding complex.
- based on this signaled FC, the egress forwarding complex QoS policy sets the Ethernet 802.1p and MPLS EXP bits. This includes ARP, PPPoE, and IS-IS packets that do not carry DSCP bits.
- configure the DSCP value in the egress IP header. The egress QoS policy does not overwrite this value.

Only one DSCP name can be configured per application, if multiple entries are configured, the subsequent entry overrides the previous configured entry.

The **no** form of this command reverts back to the default value.

Parameters

dscp-app-name

Specifies the DSCP application name.

Values Some of the following values may only apply to specific products. Refer to the *SR OS R23.x.Rx Software Release Notes* for details about application support for different SR OS products:

bfd, bgp, bmp, call-trace, cflowd, dhcp, diameter, dns, ftp, grpc, gtp, http, icmp, igmp, igmp-reporter, l2tp, ldp, mld, mpls-udp-return, msdp, mtrace2, ndis, ntp, ospf, pcep, pim, ptp, radius, rip, rsvp, sflow, snmp, snmp-notification, srrp, ssh, syslog, tacplus, telnet, tftp, traceroute, vrrp

dscp-value

Specifies a value when this packet egresses; the respective egress policy should provide the mapping for the DSCP value to either LSP-EXP bits or IEEE 802.1p (dot1p) bits as appropriate. Otherwise, the default mapping applies.

Values 0 to 63

dscp-name

Specifies the DSCP name.

Values none, be, ef, cp1, cp2, cp3, cp4, cp5, cp6, cp7, cp9, cs1, cs2, cs3, cs4, cs5, nc1, nc2, af11, af12, af13, af21, af22, af23, af31, af32, af33, af41, af42, af43, cp11, cp13, cp15, cp17, cp19, cp21, cp23, cp25, cp27, cp29, cp31, cp33, cp35, cp37, cp39, cp41, cp42, cp43, cp44, cp45, cp47, cp49, cp50, cp51, cp52, cp53, cp54, cp55, cp57, cp58, cp59, cp60, cp61, cp62, cp63

dot1p-priority

Specifies the dot1p priority.

Values none, 0 to 7

dot1p-app-name

Specifies the dot1p application name.

Values Some of the following values may only apply to specific products. Refer to the *SR OS R23.x.Rx Software Release Notes* for details about application support for different SR OS products:

arp, isis, pppoe

Platforms

All

application

Syntax

application *app* [*ip-int-name* | *ip-address*]

no application *app*

Context

[Tree] (config>service>vprn>source-address application)

Full Context

configure service vprn source-address application

Description

This command specifies the source address and application name.

The **no** form of this command removes the interface name or IP address from the command.

Parameters

app

Specifies the application name.

Values cflowd, ntp, ping, ptp, snmptrap, ssh, telnet, traceroute, icmp-error

ip-int-name

Specifies the name of the IP interface, up to 32 characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed between double quotes.

ip-address

Specifies the source IP address.

Values

ipv4-address: a.b.c.d

Platforms

All

application

Syntax

application {**eq** | **neq**} *application-id*

no application

Context

[Tree] (config>service>vprn>log>filter>entry>match application)

Full Context

configure service vprn log filter entry match application

Description

This command adds an OS application as an event filter match criterion.

An OS application is the software entity that reports the event. Applications include IP, MPLS, OSPF, CLI, SERVICES and so on Only one application can be specified. The latest **application** command overwrites the previous command.

The **no** form of this command removes the application as a match criterion.

Default

no application — no application match criterion is specified

Parameters

eq | neq

The operator specifying the type of match.

Values

eq	equal to
neq	not equal to

application-id

The application name string.

Values port, ppp, rip, route, policy, rsvp, security, snmp, stp, svcmgr, system, user, vrrp, vrtr

Platforms

All

Full Context

configure application-assurance group cflowd comprehensive application

configure application-assurance group cflowd rtp-performance application

configure application-assurance group cflowd tcp-performance application

Description

This command configures applications to export performance records with cflowd.

The **no** form of this command removes the parameters from the configuration.

Parameters

application-name

Specifies the name defined for the application.

rate

Specifies which sampling flow rate to use; flow-rate or flow-rate2.

Values flow-rate, flow-rate2

Default flow-rate

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

application

Syntax

no application *application-name*

Context

[Tree] (config>app-assure>group>policy application)

Full Context

configure application-assurance group policy application

Description

This command creates an application of an application assurance policy.

The **no** form of this command deletes the application. To delete an application, all associations to the application must be removed.

Parameters

application-name

Specifies a string of up to 32 characters uniquely identifying this application in the system.

create

Mandatory keyword used when creating an application. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

application

Syntax

application *application-name*

Context

[Tree] (config>app-assure>group>policy>app-filter>entry application)

Full Context

configure application-assurance group policy app-filter entry application

Description

This command assigns this application filter entry to an existing application. Assigning the entry to **Unknown** application restores the default configuration.

Parameters

application-name

Specifies an existing application name.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

application

Syntax

application {**eq** | **neq**} *application-name*

no application

configure application-assurance group policy app-qos-policy entry match application

configure application-assurance group policy charging-filter entry match application

Description

This command adds an application to match criteria used by this entry.

The **no** form of this command removes the application from match criteria for this entry.

Default

no application

Parameters

eq

Specifies that the value configured and the value in the flow must be equal.

neq

Specifies that the value configured and the value in the flow must differ.

application-name

Specifies the name of name existing application name, up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

application

Syntax

application *application-name* **export-using** *export-method* [*export-method*...(up to 2 max)]

application *application-name* **no-export**

no application *application-name*

Context

[Tree] (config>app-assure>group>statistics>aa-sub application)

Full Context

configure application-assurance group statistics aa-sub application

Description

This command configures aa-sub accounting statistics for export of applications of a given AA ISA group/partition.

The no form of this command removes the application name.

Parameters

application-name

Specifies an existing application name, up to 32 characters.

export-method

Specifies the method of statistics export to be used.

Values accounting-policy, radius-accounting-policy

no-export

Allows the operator to enable the referred application group to be selected (via Diameter) for Gx-usage monitoring. Gx usage monitoring is enabled automatically (and this command is not shown) if the **export-using** parameter is selected for the respective application group.

Usage monitoring must be enabled at the group:partition level (**config>app-assure>group>statistics>aa-sub>usage-monitoring**) as well in order to allow any application/application group/charging group usage monitoring.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

[Tree] (debug>app-assure>group>traffic-capture>match application)

Full Context

debug application-assurance group traffic-capture match application

Description

This command configures debugging on an application.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

application

Syntax

[**no**] **application** *application-name*

Context

[Tree] (debug>app-assure>group>port-recorder application)

Full Context

debug application-assurance group port-recorder application

Description

This commands specifies the applications used as input by the port-recorder. Applications responsible for unknown or unidentified traffic are meant to be used by this tool.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

Output

The following output is an example of configuration records TCP and UDP port numbers for the application "Unidentified TCP”.

Output Example

```
7750# show debug
debug
    application-assurance
        group 1:1
            port-recorder
                application "Unidentified TCP"
                rate 100
                no shutdown
            exit
        exit
    exit
```

```
exit
```

application

Syntax

application {**eq** | **neq**} *application-id*

no application

Context

[Tree] (config>log>filter>entry>match application)

Full Context

configure log filter entry match application

Description

This command adds an OS application as an event filter match criterion.

An OS application is the software entity that reports the event. Applications include IP, MPLS, OSPF, CLI, SERVICES and so on. Only one application can be specified. The latest **application** command overwrites the previous command.

The **no** form of this command removes the application as a match criterion.

Parameters

eq | neq

Specifies the operator match type. Valid operators are listed in Table 16: Valid Operators.

Table 16: Valid Operators

Operator	Notes
eq	equal to
neq	not equal to

application-id

The application name string.

Values application_assurance, aps, bgp, cflowd, chassis, debug, dhcp, dhcps, diameter, dynsvc, efm_oam, elmi, ering, eth_cfm, etun, fiter, gsmp, igh, igmp, igmp_snooping, ip, ipsec, isis, l2tp, lag, ldp, li, lldp, logger, mcpath, mc_redundancy, mirror, mld, mld_snooping, mpls, mpls_tp, msdp, nat, ntp, oam, open_flow, ospf, pim, pim_snooping, port, ppp, pppoe, ptp, radius, rip, rip_ng, route_policy, rsvp, security, snmp, stp, svcmgr, system, user, video, vrrp, vrtr, wlan_gw, wpp

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

application-assurance

Syntax
application-assurance *app-profile-name*

Context
[Tree] (config>subscr-mgmt>http-rdr-plcy application-assurance)

Full Context
configure subscriber-mgmt http-redirect-policy application-assurance

Description
This command specifies the AA application profile used for HTTP redirect portal authentication. This forwards all UDP/TCP traffic to AA for packet filtering. Any forwarding entries under the HTTP redirect policy are not taken into account because only UDP/TCP can be configured. Outbound ICMP and ICMPv6 traffic is always dropped.

Parameters

app-profile-name

Specifies an AA application profile name, up to 32 characters, that is configured in the **config**>**app-assur**>**group**>**policy**>**app-prof** context.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.270 application-assurance-group

application-assurance-group

Syntax

application-assurance-group *application-assurance-group-index* [**create**] [**aa-sub-scale** *sub-scale*]

no application-assurance-group *application-assurance-group-index*

Context

[Tree] (config>isa application-assurance-group)

Full Context

configure isa application-assurance-group

Description

Commands in this context create an application assurance group with the specified system-unique index and configure that group's parameters.

The **no** form of this command deletes the specified application assurance group from the system. The group must be shutdown first.

Parameters

application-assurance-group-index

Specifies an integer to identify the AA group

Values 1 to 255

create

Mandatory keyword used when creating an application assurance group in the ISA context. The **create** keyword requirement can be enabled or disabled in the **environment>create** context.

sub-scale

Specifies the set of scaling limits that are supported with regards to the maximum number of AA subscribers per ISA, the max flow scale, and the corresponding policy scale that can be specified.

Values	residential	Scaling limits for ISA2 residential operation (on VSR, it has the same scale as residential-8k)
	residential-8k	Scaling limits for VSR or ESA-vm residential 8k sub operation
	residential-16k	Scaling limits for VSR or ESA-vm residential 16k sub operation
	residential-32k	Scaling limits for VSR or ESA-vm residential 32k sub operation
	residential-64k	Scaling limits for VSR or ESA-vm residential 64k sub operation
	vpn	Scaling limits for SR AA VPN operation
	vpn-1k	Scaling limits for VSR or ESA-vm AA VPN 1k sub operation
	vpn-2k	Scaling limits for VSR or ESA-vm AA VPN 2k sub operation
	vpn-4k	Scaling limits for VSR or ESA-vm AA VPN 4k sub operation
	vpn-8k	Scaling limits for VSR or ESA-vm AA VPN 8k sub operation
	lightweight-internet	Scaling limits for ISA2 or VSR operation as a wireless LAN gateway using DSM subscribers
	lightweight-internet-512k	Scaling limits for VSR or ESA-vm 512k sub operation as a wireless LAN gateway using DSM subscribers
Default	residential

5.271 application-link-attributes

application-link-attributes

Syntax

[**no**] **application-link-attributes**

Context

[Tree] (config>router>isis>traffic-engineering-options application-link-attributes)

Full Context

configure router isis traffic-engineering-options application-link-attributes

Description

Commands in this context configure the advertisement of the TE attributes of each link on a per-application basis. Two applications are supported in SR OS: RSVP-TE and SR-TE.

The legacy mode of advertising TE attributes that is used in RSVP-TE is still supported but it can be disabled by using the **no legacy** command, which also enables per-application TE attribute advertisement for RSVP-TE.

The **no** form of this command deletes the context.

Default

no application-link-attributes

Platforms

All

5.272 application-policy

application-policy

Syntax

[**no**] **application-policy** *name*

Context

[Tree] (config>app-assure>group>transit-ip>diameter application-policy)

Full Context

configure application-assurance group transit-ip-policy diameter application-policy

Description

This command specifies the Diameter application to be used by seen IP transit subs. The application policy is defined using the **config**>**subscr-mgmt**>**diameter-application-policy** command.

The **no** form of this command removes the policy.

Default

no application-policy

Parameters

name

Specifies the name of the application policy configured using the **diameter-application-policy** command up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.273 application6

application6

Syntax

application6 *app ipv6-address*

no application6 *app*

Context

[Tree] (config>service>vprn>source-address application6)

Full Context

configure service vprn source-address application6

Description

This command specifies the IPv6 source address and application.

The **no** form of this command removes the application and IPv6 address from the configuration.

Parameters

app

Specifies the application name.

Values cflowd, ntp, ping, ptp, snmptrap, ssh, telnet, traceroute, icmp6-error

ipv6-address

Specifies the IPv6 address.

Values

ipv6-address: x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x - [0 to FFFF]H

d - [0 to 255]D

configure system security source-address application6

Description

This command configures the application to use the source IPv6 address specified by the **source-address** command.

The **no** form of this command removes the application and IPv6 address from the configuration.

Parameters

app

Specifies the application name.

Values cflowd, dns, ftp, ldap, ntp, ping, ptp, radius, sflow, snmptrap, ssh, syslog, tacplus, telnet, traceroute, icmp6-error

ipv6-address

Specifies the IPv6 address.

Values

ipv6-address: x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x - [0 to FFFF]H

d - [0 to 255]D

Context

[Tree] (config>call-trace>trace-profile applications)

Full Context

configure call-trace trace-profile applications

Description

This command enables tracing of messages and events for the specified applications.

Default

applications all

Parameters

all

Enables tracing of all packets and events, with the exception of PPP events.

connectivity-management

Enables tracing for connectivity protocols, such as DHCP, ARP, and DHCPv6, and events related to connectivity management; for example, migrant or data-triggered host creation, idling, or session timeout.

gx

Enables tracing of Diameter Gx messages.

gy

Enables tracing of Diameter Gy messages.

nasreq

Enables tracing of Diameter NASREQ messages.

radius-auth

Enables tracing of messages and events related to RADIUS authentication, including CoA and Disconnect.

radius-acct

Enables tracing of messages and events related to RADIUS-based accounting.

python

Enables tracing of python script execution.

ludb

Enables tracing of local user database lookups.

msap

Enables tracing of MSAP creation events.

ppp-event

Enables tracing of all events related to the PPP state machine. This can result in a large amount of event messages.

Syntax

[**no**] **apply-bgp-nh-override**

Context

[Tree] (config>service>vprn>pim apply-bgp-nh-override)

Full Context

configure service vprn pim apply-bgp-nh-override

Description

This command forces the RPF check to be performed via IPv4 VPN AF next-hop and not via IPv4 VPN AF VRF import extended community.

Default

no apply-bgp-nh-override

Platforms

All

5.276 apply-function-specific-behavior

apply-function-specific-behavior

Syntax

[no] apply-function-specific-behavior

Context

[Tree] (config>app-assure>group>url-filter apply-function-specific-behavior)

Full Context

configure application-assurance group url-filter apply-function-specific-behavior

Description

If this command is enabled, the **default-action**, **default-http-redirect**, and **http-redirect** commands at the **url-filter** function level (ICAP, local filtering and web service) will apply.

The **no** form of this command indicates that the configuration at the **url-filter** level will apply to all of the configured **url-filter** functions.

Default

no apply-function-specific-behavior

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.277 apply-path

apply-path

Syntax

[**no**] **apply-path**

Context

[Tree] (config>filter>match-list>ipv6-prefix-list apply-path)

[Tree] (config>filter>match-list>ip-prefix-list apply-path)

Full Context

configure filter match-list ipv6-prefix-list apply-path

configure filter match-list ip-prefix-list apply-path

Description

Commands in this context configure the auto-generation of address prefixes for IPv4 or IPv6 address prefix match lists. The context in which the command is executed governs whether IPv4 or IPv6 prefixes will be auto-generated.

The **no** form of this command removes all auto-generation configuration under the **apply-path** context.

Default

no apply path

Platforms

All

5.278 apply-to

apply-to

Syntax

apply-to {**all** | **none**}

Context

[Tree] (config>service>vprn>pim apply-to)

Full Context

configure service vprn pim apply-to

Description

This command creates a PIM interface with default parameters.

If a manually created interface or modified interface is deleted, the interface will be recreated when the **apply-to** command is executed. If PIM is not required on a specific interface, then execute a **shutdown** command.

The **apply-to** command is saved first in the PIM configuration structure, all subsequent commands either create new structures or modify the defaults as created by the **apply-to** command.

Default

apply-to none

Parameters

all

Specifies that all VPRN and non-VPRN interfaces are automatically applied in PIM.

none

No interfaces are automatically applied in PIM. PIM interfaces must be manually configured.

Platforms

All

apply-to

Syntax

apply-to {**ies** | **non-ies** | **all** | **none**}

Context

[Tree] (config>router>pim apply-to)

Full Context

configure router pim apply-to

Description

This command creates a PIM interface with default parameters.

If a manually created or a modified interface is deleted, the interface is recreated when (re)processing the **apply-to** command and if PIM is not required on a specific interface a shutdown should be executed.

The **apply-to** command is first saved in the PIM configuration structure. Then, all subsequent commands either create new structures or modify the defaults as created by the apply-to command.

Default

apply-to none

Parameters

ies

Specifies to apply all IES interfaces in PIM.

non-ies

Specifies to apply non-IES interfaces created in PIM.

all

Specifies to apply all IES and non-IES interfaces created in PIM.

none

Removes all interfaces that are not manually created or modified. It also removes explicit no interface commands if present.

Platforms

All

5.279 aps

aps

Syntax

aps

Context

[Tree] (config>port aps)

Full Context

configure port aps

Description

This command configures APS (Automatic Protection Switching). APS is used by SONET/SDH add/drop multiplexers (ADMs) or other SONET/SDH-capable equipment to protect against circuit or equipment failure.

An APS group contains a working and a protect circuit and can span a single node (SC-APS) or two nodes (MC-APS).

The working and protection configurations on the 7750 SRs must match the circuit configurations on the peer. This means that the working circuit on the 7750 SR must be connected to the peer's working circuit and the protect circuit must be connected to the peer's protection circuit.

The **aps** command is only available for APS groups and not physical ports.

Platforms

7450 ESS, 7750 SR-7/12/12e, 7750 SR-a, 7750 SR-e

5.280 aqp-initial-lookup

aqp-initial-lookup

Syntax

aqp-initial-lookup

no aqp-initial-lookup

Context

[Tree] (config>app-assure>group aqp-initial-lookup)

Full Context

configure application-assurance group aqp-initial-lookup

Description

This command allows AA to perform AQP lookups on flows prior to complete application identification. As usual, AQP will be looked up again on identification complete. Without this, AA executes AQPs that are part of what so called "sub-default policy". Sub-default policy is formed by regular AQPs that contain ASOs, subID and/or flow direction as matching conditions.

This behavior is required, for example, in order to be able apply GTP and SCTP filtering on the first packet of a new GTP/SCTP flow (AQP matching conditions in this case contains protocol id).

The **no** form of this command forces complete AQP look up on identification finish stage only.

Default

no aqp-initial-lookup

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

5.281 arbiter

arbiter

Syntax

arbiter *arbiter-name* [**create**]

no arbiter *arbiter-name*

Context

[Tree] (config>qos>plcr-ctrl-plcy>tier arbiter)

Full Context

configure qos policer-control-policy tier arbiter

Description

This command is used to create an arbiter within the context of **tier 1** or **tier 2**. An arbiter is a child policer bandwidth control object that manages the throughput of a set of child policers. An arbiter allows child policers or other arbiters to parent to one of eight strict levels. Each arbiter is itself parented to either another tiered arbiter or to the **root** arbiter.

The root arbiter starts with its defined maximum rate and distributes the bandwidth to its directly attached child policers and arbiters beginning with priority 8. As the children at each priority level are distributed bandwidth according to their needs and limits, the root proceeds to the next lower priority until either all children's needs are met or it runs out of bandwidth. The bandwidth given to a tiered arbiter is then divided between that arbiter's children (child policers or a tier 2 arbiter) in the same fashion. A tiered arbiter may also have a rate limit defined that limits the amount of bandwidth it may receive from its parent.

An arbiter that is currently parented by another arbiter cannot be deleted.

Each time the **policer-control-policy** is applied to either a SAP, or a subscriber (through association with a sub-profile that has the policy applied), or a multiservice site, an instance of the parent policer and the arbiters is created.

Any child policer that uses the arbiter's name in its parenting command will be associated with the arbiter instance. The child policer will also become associated with any arbiter to which its parent arbiter is parented (grandparent). Having child policers parented to an arbiter does not prevent that arbiter from being removed from the **policer-control-policy**. When removed, the child policers become orphaned.

You can create up to 31 tiered arbiters within the **policer-control-policy** on either tier 1 or tier 2 (in addition to the arbiter).

The **no** form of this command is used to remove an arbiter from tier 1 or tier 2. If the specified arbiter does not exist, the command returns without an error. If the specified arbiter is currently specified as the parent for another arbiter, the command will fail. When an arbiter is removed from a **policer-control-policy**, all instances of the arbiter will also be removed. Any child policers currently parented to the arbiter instance will become orphans and will not be bandwidth managed by the policer control policy instances parent policer.

Parameters

arbiter-name

Any unique name within the policy. Up to 31 arbiters may be created.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, 7950 XRS, VSR

5.282 area

area

Syntax

[**no**] **area** *area-id*

Context

[Tree] (config>service>vprn>ospf area)

[Tree] (config>service>vprn>ospf3 area)

Full Context

configure service vprn ospf area

configure service vprn ospf3 area

Description

This command creates the context to configure an OSPF area. An area is a collection of network segments within an AS that have been administratively grouped together. The area ID can be specified in dotted decimal notation or as a 32-bit decimal integer.

The **no** form of this command deletes the specified area from the configuration. Deleting the area also removes the OSPF configuration of all the interfaces, virtual-links, sham-links, address-ranges and so on, that are currently assigned to this area.

Default

no area — No OSPF areas are defined.

Parameters

area-id

The OSPF area ID expressed in dotted decimal notation or as a 32-bit decimal integer.

Values 0.0.0.0 to 255.255.255.255 (dotted decimal)
0 to 4294967295 (decimal integer)

area-id

Syntax

[**no**] **area-id** *area-address*

Context

[Tree] (config>service>vprn>isis area-id)

Full Context

configure service vprn isis area-id

Description

This command configures the area ID portion of NSAP addresses for the VPRN instance. This identifies a point of connection to the network, such as a router interface, and is called a Network Service Access Point (NSAP). Addresses in the IS-IS protocol are based on the ISO NSAP addresses and Network Entity Titles (NETs), not IP addresses.

A maximum of 3 **area addresses** can be configured for the VPRN instance.

NSAP addresses are divided into three parts. Only the area ID portion is configurable.

- Area ID — A variable length field between 1 and 13 bytes long. This includes the Authority and Format Identifier (AFI) as the most significant byte and the area ID.
- System ID — A six-byte system identification. This value is not configurable. The system ID is derived from the system or router ID.
- Selector ID — A one-byte selector identification that must contain zeros when configuring a NET. This value is not configurable. The selector ID is always 00.

The NET is constructed like an NSAP but the selector byte contains a 00 value. NET addresses are exchanged in hello and LSP PDUs. All net addresses configured on the node are advertised to its neighbors.

For Level 1 interfaces, neighbors can have different area IDs, but, they must have at least one area ID (AFI + area) in common. Sharing a common area ID, they become neighbors and area merging between the potentially different areas can occur.

For Level 2 (only) interfaces, neighbors can have different area IDs. However, if they have no area IDs in common, they become only Level 2 neighbors and Level 2 LSPs are exchanged.

For Level 1 and Level 2 interfaces, neighbors can have different area IDs. If they have at least one area ID (AFI + area) in common, they become neighbors. In addition to exchanging Level 2 LSPs, area merging between potentially different areas can occur.

If multiple **area-id** commands are entered, the system ID of all subsequent entries must match the first **area** address.

The **no** form of this command removes the area address.

Platforms

[Tree] (config>router>isis area-id)

Full Context

configure router isis area-id

Description

This command was previously named the **net** *network-entity-title* command. The **area-id** command allows you to configure the area ID portion of NSAP addresses which identifies a point of connection to the network, such as a router interface, and is called a Network Service Access Point (NSAP). Addresses in the IS-IS protocol are based on the ISO NSAP addresses and Network Entity Titles (NETs), not IP addresses.

A maximum of three **area addresses** can be configured.

NSAP addresses are divided into three parts. Only the area ID portion is configurable.

- Area ID — A variable length field between 1 and 13 bytes long. This includes the Authority and Format Identifier (AFI) as the most significant byte and the area ID.
- System ID — A six-byte system identification. This value is not configurable. The system ID is derived from the system or router ID.
- Selector ID — A one-byte selector identification that must contain zeros when configuring a NET. This value is not configurable. The selector ID is always 00.

The NET is constructed like an NSAP but the selector byte contains a 00 value. NET addresses are exchanged in hello and LSP PDUs. All net addresses configured on the node are advertised to its neighbors.

For Level 1 interfaces, neighbors can have different area IDs, but, they must have at least one area ID (AFI + area) in common. Sharing a common area ID, they become neighbors and area merging between the potentially different areas can occur.

For Level 2 (only) interfaces, neighbors can have different area IDs. However, if they have no area IDs in common, they become only Level 2 neighbors and Level 2 LSPs are exchanged.

For Level 1 and Level 2 interfaces, neighbors can have different area IDs. If they have at least one area ID (AFI + area) in common, they become neighbors. In addition to exchanging Level 2 LSPs, area merging between potentially different areas can occur.

If multiple **area-id** commands are entered, the system ID of all subsequent entries must match the first **area** address.

The **no** form of this command removes the area address.

Parameters

area-address

Specifies a 1 — 13-byte address. Of the total 20 bytes comprising the NET, only the first 13 bytes can be manually configured. As few as one byte can be entered or, at most, 13 bytes. If less than 13 bytes are entered, the rest is padded with zeros.

configure service vprn ospf3 area area-range

configure service vprn ospf area area-range

configure service vprn ospf area nssa area-range

Description

This command creates ranges of addresses on an Area Border Router (ABR) for the purpose of route summarization or suppression. When a range is created, it is configured to be advertised or not advertised into other areas. Multiple range commands are used to summarize or hide different ranges. In the case of overlapping ranges, the most specific range command applies.

ABRs send summary link advertisements to describe routes to other areas. To minimize the number of advertisements that are flooded, you can summarize a range of IP addresses and send reachability information about these addresses in an LSA.

The **no** form of this command deletes the range (non) advertisement.

Default

no area-range

Parameters

ipv6-prefix/prefix-length

The IP prefix in dotted decimal notation for the range used by the ABR to advertise that summarizes the area into another area.

Values

ipv6-prefix	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x: [0 to FFFF]H

	d: [0 to 255]D
ipv6-prefix-length	0 to 128

mask

The subnet mask for the range expressed as a decimal integer mask length or in dotted decimal notation.

Values 0 to 32 (mask length), 0.0.0.0 to 255.255.255.255 (dotted decimal)

advertise | not-advertise

Specifies whether or not to advertise the summarized range of addresses into other areas. The **advertise** keyword indicates the range will be advertised, and the keyword **not-advertise** indicates the range will not be advertised.

The default is **advertise**.

Description

This command allows the ARP application to learn new entries based on any received ARP message (GARP, ARP-Request, or ARP-Reply, such as any frame with ethertype 0x0806).

The **no** form of this command disables the above behavior and causes ARP entries to only be learned when needed, that is, when the router receives an ARP-reply after an ARP-request triggered by received traffic.

Platforms

All

5.289 arp-limit

arp-limit

Syntax

arp-limit *limit* [**log-only**] [**threshold** *percent*]

no arp-limit

Context

[Tree] (config>service>ies>interface arp-limit)

Full Context

configure service ies interface arp-limit

Description

This command configures the maximum amount of dynamic IPv4 ARP entries that can be learned on an IP interface.

When the number of dynamic ARP entries reaches the configured percentage of this limit, a log event is raised. When the limit is exceeded, no new entries are learned until an entry expires and traffic to these destinations will be dropped. Entries that have already been learned will be refreshed.

The **no** form of this command removes the **arp-limit**.

Default

no arp-limit

Parameters

log-only

Enables the warning message to be sent at the specified threshold percentage, and also when the limit is exceeded. However, entries above the limit will be learned.

percent

The threshold value (as a percentage) that triggers a warning message to be sent.

Values 0 to 100

Default 90

limit

The number of entries that can be learned on an IP interface expressed as a decimal integer. If the limit is set to 0, dynamic ARP learning is disabled and no dynamic ARP entries are learned.

Values 0 to 524288

Platforms

configure service vprn subscriber-interface group-interface arp-populate

configure service ies subscriber-interface group-interface arp-populate

configure service vprn interface arp-populate

configure service ies interface arp-populate

Description

This command, when enabled, disables dynamic learning of ARP entries. Instead, the ARP table is populated with static and dynamic entries from the DHCP Lease State Table (enabled with **lease-populate**), and optionally with static entries entered with the **static-host** command.

The host's IP address and MAC address are placed in the system ARP cache as a managed entry. Static hosts must be defined on the interface using the **static-host** command. Dynamic hosts are enabled on the system through enabling lease-populate in the IP interface DHCP context.

In the event that both a static host and a dynamic host share the same IP and MAC address, the system's ARP cache retains the host information until both the static and dynamic information are removed.

Both static and dynamic hosts override static ARP entries. Static ARP entries are marked as inactive when they conflict with static or dynamic hosts and will be repopulated once all static and dynamic host information for the IP address are removed. Since static ARP entries are not possible when static subscriber hosts are defined or when DHCP lease state table population is enabled, conflict between static ARP entries and the arp-populate function is not an issue.

Enabling the **arp-populate** command removes any dynamic ARP entries learned on this interface from the ARP cache.

The **arp-populate** command fails if an existing static ARP entry exists for this interface.

When **arp-populate** is enabled, the system does not send out ARP requests for hosts that are not in the ARP cache. Only statically configured and DHCP learned hosts are reachable through an IP interface with **arp-populate** enabled. The **arp-populate** command can only be enabled on IES and VPRN interfaces supporting Ethernet encapsulation.

The **no** form of this command disables ARP cache population functions for static and dynamic hosts on the interface. All static and dynamic host information for this interface is removed from the system's ARP cache. Any existing static ARP entries previously inactive due to static or dynamic hosts will be populated in the system ARP cache.

Default

no arp-populate

5.292 arp-populate-host-route

arp-populate-host-route

Syntax

[**no**] **arp-populate-host-route**

Context

[Tree] (config>service>ies>if arp-populate-host-route)

Full Context

configure service ies interface arp-populate-host-route

Description

This command enables the addition or deletion of host routes in the route table derived from ARP entries in the ARP cache. To enable this command, the interface must be shut down. The command triggers the population of host routes in the route table out of their corresponding static, dynamic, or EVPN types in the ARP table. ARP entries installed by subscriber management, local interfaces, and others, do not create host routes.

The **no** form of this command disables the creation of host routes from the ARP cache.

5.294 arp-reply-agent

arp-reply-agent

Syntax

arp-reply-agent [**sub-ident**]

no arp-reply-agent

Context

[Tree] (config>service>vpls>sap arp-reply-agent)

Full Context

configure service vpls sap arp-reply-agent

Description

This command enables a special ARP response mechanism in the system for ARP requests destined to static or dynamic hosts associated with the SAP. The system responds to each ARP request using the host's MAC address as the both the source MAC address in the Ethernet header and the target hardware address in the ARP header.

ARP replies and requests received on a SAP with **arp-reply-agent** enabled is evaluated by the system against the anti-spoof filter entries associated with the ingress SAP (if the SAP has anti-spoof filtering enabled). ARPs from unknown hosts on the SAP is discarded when anti-spoof filtering is enabled.

The ARP reply agent only responds if the ARP request enters an interface (SAP, spoke SDP or mesh SDP) associated with the VPLS instance of the SAP.

A received ARP request that is not in the ARP reply agent table is flooded to all forwarding interfaces of the VPLS capable of broadcast except the ingress interface while honoring split-horizon constraints.

Static hosts can be defined on the SAP using the **host** command. Dynamic hosts are enabled on the system by enabling the **lease-populate** command in the SAP's **dhcp** context. If both a static host and a dynamic host share the same IP and MAC address, the VPLS ARP reply agent will retain the host information until both the static and dynamic information are removed. If both a static and dynamic host share the same IP address, but different MAC addresses, the VPLS ARP reply agent is populated with the static host information.

The **arp-reply-agent** command fails if an existing static host on the SAP does not have both MAC and IP addresses specified. Once the ARP reply agent is enabled, creating a static host on the SAP without both an IP address and MAC address will fail.

The apr-reply-agent can only be enabled on SAPs supporting Ethernet encapsulation.

The **no** form of the command disables arp-reply-agent functions for static and dynamic hosts on the SAP.

Default

no arp-reply-agent

Parameters

sub-ident

Configures the arp-reply-agent to discard ARP requests received on the SAP that are targeted for a known host on the same SAP with the same subscriber identification.

Hosts are identified by their subscriber information. For DHCP subscriber hosts, the subscriber hosts, the subscriber information is configured using the optional subscriber parameter string.

When arp-reply-agent is enabled with **sub-ident**:

- If the subscriber information for the destination host exactly matches the subscriber information for the originating host and the destination host is known on the same SAP as the source, the ARP request is silently discarded.
- If the subscriber information for the destination host or originating host is unknown or undefined, the source and destination hosts are not considered to be the same subscriber. The ARP request is forwarded outside the SAP's Split Horizon Group.
- When **sub-ident** is not configured, the arp-reply-agent does not attempt to identify the subscriber information for the destination or originating host and will not discard an ARP request based on subscriber information.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

arp-reply-agent

Context

[Tree] (config>subscr-mgmt>msap-policy>vpls-only arp-reply-agent)

Full Context

configure subscriber-mgmt msap-policy vpls-only-sap-parameters arp-reply-agent

Description

This command enables a special ARP response mechanism in the system for ARP requests destined to static or dynamic hosts associated with the SAP. The system responds to each ARP request using the hosts MAC address as the both the source MAC address in the Ethernet header and the target hardware address in the ARP header.

ARP replies and requests received on an MSAP with **arp-reply-agent** enabled is evaluated by the system against the anti-spoof filter entries associated with the ingress SAP (if the SAP has anti-spoof filtering enabled). ARPs from unknown hosts on the SAP is discarded when anti-spoof filtering is enabled.

The ARP reply agent only responds if the ARP request enters an interface (SAP, spoke-SDP or mesh-SDP) associated with the VPLS instance of the MSAP.

A received ARP request that is not in the ARP reply agent table is flooded to all forwarding interfaces of the VPLS capable of broadcast except the ingress interface while honoring split-horizon constraints.

Static hosts can be defined using the **host** command. Dynamic hosts are enabled on the system by enabling the **lease-populate** command in the **dhcp** context. In the event that both a static host and a dynamic host share the same IP and MAC address, the VPLS ARP reply agent will retain the host information until both the static and dynamic information are removed. In the event that both a static and dynamic host share the same IP address, but different MAC addresses, the VPLS ARP reply agent is populated with the static host information.

The **arp-reply-agent** command will fail if an existing static host does not have both MAC and IP addresses specified. Once the ARP reply agent is enabled, creating a static host on the MSAP without both an IP address and MAC address will fail.

The ARP-reply-agent may only be enabled on SAPs supporting Ethernet encapsulation.

The **no** form of this command disables ARP-reply-agent functions for static and dynamic hosts on the MSAP.

Parameters

sub-ident

Configures the arp-reply-agent to discard ARP requests received on the MSAP that are targeted for a known host on the same MSAP with the same subscriber identification.

Hosts are identified by their subscriber information. For DHCP subscriber hosts, the subscriber hosts, the subscriber information is configured using the optional subscriber parameter string.

When arp-reply-agent is enabled with **sub-ident**:

- If the subscriber information for the destination host exactly matches the subscriber information for the originating host and the destination host is known on the same MSAP as the source, the ARP request is silently discarded.
- If the subscriber information for the destination host or originating host is unknown or undefined, the source and destination hosts are not considered to be the same subscriber. The ARP request is forwarded outside the MSAP's Split Horizon Group.
- When **sub-ident** is not configured, the arp-reply-agent does not attempt to identify the subscriber information for the destination or originating host and will not discard an ARP request based on subscriber information.

Full Context

configure service vprn interface arp-timeout

configure service ies interface arp-timeout

configure service ies subscriber-interface group-interface arp-timeout

configure service vprn subscriber-interface group-interface arp-timeout

Description

This command configures the minimum time in seconds an ARP entry learned on the IP interface is stored in the ARP table. ARP entries are automatically refreshed when an ARP request or gratuitous ARP is seen from an IP host, otherwise, the ARP entry is aged from the ARP table. If **arp-timeout** is set to a value of zero seconds, ARP aging is disabled.

When the **arp-populate** and **lease-populate** commands are enabled on an interface, the ARP table entries will no longer be dynamically learned, but instead by snooping DHCP ACK message from a DHCP server. In this case the configured **arp-timeout** value has no effect.

The default value for **arp-timeout** is 14400 seconds (4 hours).

The **no** form of this command reverts to the default value.

Default

arp-timeout 14400

Parameters

seconds

Specifies the minimum number of seconds a learned ARP entry is stored in the ARP table, expressed as a decimal integer. A value of zero specifies that the timer is inoperative and learned ARP entries will not be aged.

Values 0 to 65535

Platforms

All

- configure service ies interface arp-timeout

Parameters

name

Specifies the AS path regular expression name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes. Policy parameters must be enclosed by at-signs (@) and may be midstring; for example, "@variable@," "start@variable@end", " @variable@end", or "start@variable@".

no as-path-ignore

Context

[Tree] (config>service>vprn>bgp>path-selection as-path-ignore)

Full Context

configure service vprn bgp best-path-selection as-path-ignore

Description

This command configures whether AS path length is considered in the selection of the best BGP route for a prefix.

If an address family is listed in this command, the length of AS paths is not a factor in the route selection process for routes of that address family.

The **no** form of this command removes the parameter from the configuration.

Default

no as-path-ignore

Parameters

ipv4

Specifies that the AS path length is ignored for all unlabeled unicast IPv4 routes.

ipv6

Specifies that the AS path length is ignored for all unlabeled unicast IPv6 routes.

label-ipv4

Specifies that the AS path length is ignored for all labeled unicast IPv4 routes.

label-ipv6

Specifies that the AS path length is ignored for all labeled unicast IPv6 routes.

Context

[Tree] (config>router>bgp>best-path-selection as-path-ignore)

Full Context

configure router bgp best-path-selection as-path-ignore

Description

This command configures whether AS path length is considered in the selection of the best BGP route for a prefix.

If an address family is listed in this command, then the length of AS paths is not a factor in the route selection process for routes of that address family.

The **no** form of this command removes the parameter from the configuration.

Default

no as-path-ignore

Parameters

ipv4

Specifies that the AS-path length will be ignored for all unlabeled unicast IPv4 routes.

label-ipv4

Specifies that the AS-path length will be ignored for all labeled-unicast IPv4 routes.

vpn-ipv4

Specifies that the length AS-path will be ignored for all VPN IPv4 (SAFI 128) routes.

ipv6
Specifies that the AS-path length will be ignored for all unlabeled unicast IPv6 routes.

label-ipv6
Specifies that the AS-path length will be ignored for all labeled-unicast IPv6 routes.

vpn-ipv6
Specifies that the AS-path length will be ignored for all VPN IPv6 (SAFI 128) routes.

mcast-ipv4
Specifies that the AS-path length will be ignored for all IPv4 multicast routes.

mcast-ipv6
Specifies that the AS-path length will be ignored for all IPv6 multicast routes.

mvpn-ipv4
Specifies that the AS-path length will be ignored for all IPv4 MVPN routes.

mvpn-ipv6
Specifies that the AS-path length will be ignored for all IPv6 MVPN routes.

l2-vpn
Specifies that the AS-path length will be ignored for all L2-VPN NLRIs.

5.302 as-path-length

as-path-length

Syntax
as-path-length *length* [**equal** | **or-higher** | **or-lower**] [**unique**]

no as-path-length

Context
[Tree] (config>router>policy-options>policy-statement>entry>from as-path-length)

Full Context
configure router policy-options policy-statement entry from as-path-length

Description
This command matches BGP routes based on their AS path length (the number of AS numbers in the AS_PATH).

If no comparison qualifiers are present (**equal**, **or-higher**, **or-lower**), then **equal** is the implied default.

Confederation member AS numbers in the AS_PATH do not count towards the total. An AS_SET element is considered to have a length of 1.

The **unique** option counts.

A non-BGP route does not match a policy entry if it contains the **as-path-length** command.

Default

no as-path-length

Parameters

length

Specifies the length of the AS path.

Values 0 to 255, or a parameter name delimited by starting and ending at-sign (@) characters

equal

Specifies that matched routes should have the same number of AS path elements as the value specified.

or-higher

Specifies that matched routes should have the same or a greater number of AS path elements as the value specified.

or-lower

Specifies that matched routes should have the same or a lower number of AS path elements as the value specified.

unique

Specifies that only the unique AS numbers should be counted (that is, multiple occurrences of the same AS number in the sequence count as one).

Full Context

configure router policy-options policy-statement entry action as-path-prepend

configure router policy-options policy-statement default-action as-path-prepend

Description

The command prepends a BGP AS number once or numerous times to the AS path attribute of routes matching the route policy statement entry.

If an AS number is not configured, the AS path is not changed.

If the optional *number* is specified, then the AS number is prepended as many times as indicated by the number.

The **no** form of this command disables the AS path prepend action from the route policy entry.

Default

no as-path-prepend

Parameters

as-path

Specifies the AS number to prepend expressed as a decimal integer.

Values 1 to 4294967295

param-name — Specifies the AS path parameter variable name. Allowed values are any string up to 32 characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes. Policy parameters must start and end with at-signs (@); for example, "@variable@”.

repeat

Specifies the number of times to prepend the specified AS number expressed as a decimal integer.

Values 1 to 50

param-name — Specifies the AS path parameter variable name. Allowed values are any string up to 32 characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes. Policy parameters must start and end with at-signs (@); for example, "@variable@”.

most-recent

Specifies that the most recent AS number must be prepended to the AS-Path attribute of the route.

[**no**] **asbr**

Context

[Tree] (config>router>ospf asbr)

[Tree] (config>router>ospf3 asbr)

Full Context

configure router ospf asbr

configure router ospf3 asbr

Description

This command configures the router as an Autonomous System Boundary Router (ASBR) if the router is to be used to export routes from the Routing Table Manager (RTM) into this instance of OSPF. After a router is configured as an ASBR, the export policies into this OSPF domain take effect. If no policies are configured, no external routes are redistributed into the OSPF domain.

The **no** form of this command removes the ASBR status and withdraws the routes redistributed from the Routing Table Manager into this instance of OSPF from the link state database.

When configuring multiple instances of OSPF, there is a risk of loops because networks are advertised by multiple domains configured with multiple interconnections to one another. To prevent this from happening, all routers in a domain should be configured with the same domain ID. Each domain (OSPF-instance) should be assigned a specific bit value in the 32-bit tag mask.

When an external route is originated by an ASBR using an internal OSPF route in a given domain, the corresponding bit is set in the AS-external LSA. As the route gets redistributed from one domain to another, more bits are set in the tag mask, each corresponding to the OSPF domain the route visited. Route redistribution looping is prevented by checking the corresponding bit as part of the export policy; if the bit corresponding to the announcing OSPF process is already set, the route is not exported there.

Domain IDs are incompatible with any other use of normal tags. The domain ID should be configured with a value between 1 and 31 by each router in a given OSPF domain (OSPF Instance).

When an external route is originated by an ASBR using an internal OSPF route in a given domain, the corresponding (1-31) bit is set in the AS-external LSA.

As the route gets redistributed from one domain to another, more bits are set in the tag mask, each corresponding to the OSPF domain the route visited. Route redistribution looping is prevented by checking the corresponding bit as part of the export policy; if the bit corresponding to the announcing OSPF process is already set, the route is not exported there.

Default

no asbr

Parameters

domain-id

Specifies the domain ID.

Values 1 to 31

Default 0

5.307 assignment

assignment

Syntax

assignment {**port** *port-id* | **card** *slot-number*}

no assignment

Context

[Tree] (config>service>cust>multi-service-site assignment)

Full Context

configure service customer multi-service-site assignment

Description

This command assigns a multi-service customer site to a specific chassis slot, port, or channel. This allows the system to allocate the resources necessary to create the virtual schedulers defined in the ingress and egress scheduler policies as they are specified. This also verifies that each SAP assigned to the site exists within the context of the proper customer ID and that the SAP was configured on the proper slot, port, or channel. The assignment must be given prior to any SAP associations with the site.

The **no** form of this command removes the port, channel, or slot assignment. If the customer site has not yet been assigned, the command has no effect and returns without any warnings or messages.

Default

no assignment

Parameters

port-id

Assigns the multi-service customer site to the port-id or port-id.channel-id given. When the multi-service customer site is assigned to a specific port or channel, all SAPs associated with this customer site must be on a service owned by the customer and created on the defined port or channel. The defined port or channel must already have been pre-provisioned on the system but need not be installed when the customer site assignment is made.

Syntax: *port-id*[:encap-val]

Values For the 7950 XRS:

slot/mda/port [.channel]

eth-tunnel-id - eth-tunnel-<id>

	eth-tunnel	keyword
	id	[1..1024]
lag-id	lag-id	
	lag	keyword
	id	1 to 800
	id	[1..1024]
eth-sat-id	esat-id/slot/port	
	esat	keyword
	id: 1 to 20	
	u	keyword
pxc-id	pxc-<id>.<sub-port>	

	pxc	keyword
	id: 1 to 64	
	sub-port	a, b
lag		keyword
id	1 to 800	1 to 800
pw-id	pw-<id>	
	pw	keyword
	id	1 to 32767

For the 7750 SR and the 7450 ESS:

port-id	slot/mda/port[.channel]		
	aps-id	aps-group-id[.channel]	
		aps keyword	
		group-id	1 to 128
	eth-tunnel-id	eth-tunnel-<id>	
		eth-tunnel	keyword
		id	1 to 1024
	lag-id	lag-id	
		lag	keyword
		id	1 to 800
		id	1 to 1024
	eth-sat-id	esat-<id>/<slot>/[u]<port>	
		esat	keyword
		id	1 to 20
		u	keyword for up-link port
	tdm-sat-id	tsat-<id>/<slot>/[<u>]<port>.<channel>	
		tsat	keyword
		id	1 to 20
		u	keyword for up-link port
	pxc-id	psc-id.sub-port	

			pxc psc-id.sub-port	
			pxc	keyword
			id: 1 to 64	
			sub-port: a, b	
		pw-id	pw-<id>	
			pw	keyword
			id	1 to 32767
	slot-number	1 to 10		
	fpe-id	1 to 64		

slot-number

Assigns the multi-service customer site to the slot-number given. When the multi-service customer site is assigned to a specific slot in the chassis, all SAPs associated with this customer site must be on a service owned by the customer and created on the defined chassis slot. The defined slot must already be pre-provisioned on the system but need not be installed when the customer site assignment is made.

Values Any pre-provisioned slot number for the chassis type that allows SAP creation.

1 to 20

fpe-id

Specifies the multi-service-site (MSS) assignment to an FPE object for the purpose of controlling aggregated bandwidth across a set of PW SAPs.

Values 1 to 64

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

5.309 assisted-replication

assisted-replication

Syntax

assisted-replication {**replicator** | **leaf**} [**replicator-activation-time** *seconds*]

no assisted-replication

Context

[Tree] (config>service>vpls>vxlan assisted-replication)

Full Context

configure service vpls vxlan assisted-replication

Description

This command enables the Assisted Replication (AR) function for VXLAN tunnels in the service. The execution of this command triggers the BGP EVPN to send an update containing the inclusive multicast route for the service and the AR type=AR Replicator (AR-R) or AR Leaf (AR-L).

The Replicators switch the VXLAN traffic back to VXLAN destinations when the IP destination address matches their own AR-IP address. Leaf nodes select a Replicator node and send all the Broadcast or Multicast frames to it so that the Replicator can replicate the traffic on their behalf.

Enabling or disabling the AR function, or changing the role between the replicator and leaf requires the BGP EVPN MPLS to be shutdown.

If the **leaf** parameter is configured, the system creates a Broadcast or Multicast (BM) destination to the selected AR-R and Unknown Unicast (U) destinations to the rest of the VTEPs. If no replicator exists, the leaf creates BUM bindings to all the VTEPs.

If the **replicator** parameter is configured, the system will create BUM destinations to the remote leafs, Regular Network Virtualization Edge routers (RNVE), and other AR-Rs. The system will perform

assisted replication for traffic from known VTEPs only (that is, where the routes have been received and programmed toward a VTEP).

The **no** version of this command removes the AR function from the service.

Default

no assisted-replication

Parameters

replicator-activation-time *seconds*

Optional parameter that can be added to the leaf parameter. It specifies the wait time before the leaf can begin sending traffic to a new replicator and is used to allow some time for the replicator to learn about the leaf.

Values 1 to 255

Default 0 seconds (indicates **no replicator-activation-time** and no delay in sending packets to the AR-R)

replicator | leaf

Selects the AR role of the router for the service.

Platforms

All

5.310 assisted-replication-ip

Syntax

assisted-replication-ip *ip-address*

no assisted-replication-ip

Context

[Tree] (config>service>system>vxlan assisted-replication-ip)

Full Context

configure service system vxlan assisted-replication-ip

Description

The assisted-replication-ip (AR-IP) command defines the IP address that supports the AR-R function in the router. The AR-IP address must also be defined as a loopback address in the base router and advertised in the IGP/BGP so that it is accessible to the remote NVE/PEs in the Overlay network.

If the AR-R function is enabled in a service, the Broadcast and Multicast frames encapsulated in VXLAN packets arriving at the router are replicated to the other VXLAN destinations within the service (except the destination pointing at the originator of the packet).

The **no** version of this command removes the AR IP address.

Default

no assisted-replication-ip

Parameters

ip-address

Specifies the assisted replication IP address.

Platforms

All

Full Context

configure service vpls sap pfcp association

Description

This command links this capture SAP to a PFCP association. This command enables CUPS for this capture SAP and makes any trigger packets eligible for forwarding to the BNG CUPS CPF.

The **no** form of this command disables CUPS for this capture SAP.

Parameters

name

Specifies the name of the association, up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

association

Syntax

association *ma-index* [**format** *ma-name-format*] **name** *ma-name* [**admin-name** *admin-name*]

association *ma-index*

no association *ma-index*

Context

[Tree] (config>eth-cfm>domain association)

Full Context

configure eth-cfm domain association

Description

This command configures the Maintenance Association (MA) for the domain.

Parameters

ma-index

Specifies the MA index value.

Values 1 to 4294967295

ma-name-format

Specifies a value that represents the type (format).

Values

icc-based:	Only applicable to a Y.1731 context where the domain format is configured as none. Allows for a name of exactly 13 characters.
integer:	0 to 65535 (integer value 0 means the MA is not attached to a VID)
string:	raw ascii
vid:	0 to 4095
vpn-id:	RFC-2685, *Virtual Private Networks Identifier* xxx:xxxx, where x is a value between 00 and FF, for example, 00164D:AABBCCDD

Default integer

ma-name

Specifies the part of the MA identifier that is unique within the maintenance domain name, up to 45 characters.

admin-name

Specifies a creation time required parameter that allows the operator to assign a name value to the domain container. This is used for information and migration purposes. This value cannot be modified without destroying the domain. If no *admin-name* exists, the configured *md-index* value is converted into a character string to become the *admin-name* reference. When upgrading from a release that does not include the **admin-name** configuration option, the *md-index* is converted into a character string. After an *admin-name* value is assigned, it cannot be modified.

5.315 async-mapping

async-mapping

Syntax

[**no**] **async-mapping**

Context

[Tree] (config>port>otu async-mapping)

Full Context

configure port otu async-mapping

Description

This command allows the user to configure the port to support asynchronous mapping of the payload inside the OTU. If the port is configured for async-mapping and the payload clock is asynchronous to the OTU clock, there will be positive or negative pointer justification that will show up in the OTU statistics and the data will be received error free. If the port is configured for synchronous mapping and the received data is asynchronously mapped, there will be errors in the received data.

async-mapping is the only mode of operation that is supported on the OTU3 encapsulated 40-Gigabit Ethernet and therefore the 'no async-mapping' is not supported on that port type and the default on the is async-mapping.

The **no** form of this command configures the port to receive synchronously mapped data.

Default

no async-mapping

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

5.316 asynchronous-execution

asynchronous-execution

Syntax

asynchronous-execution *seconds*

asynchronous-execution never

Context

[Tree] (config>system>management-interface>ops>global-timeout asynchronous-execution)

Full Context

configure system management-interface operations global-timeouts asynchronous-execution

Description

This command configures the period of time that operations launched as "asynchronous" are allowed to execute before being automatically stopped by the SR OS.

An asynchronous operation is not deleted from the system when it is stopped. See the **asynchronous-retention** command.

If a specific execution timeout is not included in the request for a particular asynchronous operation, this system-level timeout applies.

Note:
This execution timeout is part of the general global operations infrastructure and is separate and independent from any operation-specific timeouts (for example, the **ping** operation also has its own **timeout** parameter).

Default

asynchronous-execution 3600

Parameters

seconds

Specifies the period of time, in seconds, that asynchronous operations are allowed to execute.

Values 1 to 604800

never

Keyword to specify that an execution timeout is not applied to asynchronous operations.

Platforms

All

5.317 asynchronous-retention

asynchronous-retention

Syntax

asynchronous-retention *seconds*

asynchronous-retention never

Context

[Tree] (config>system>management-interface>ops>global-timeout asynchronous-retention)

Full Context

configure system management-interface operations global-timeouts asynchronous-retention

Description

This command configures the period of time that data related to operations launched as "asynchronous" is retained in the system. After the retention timeout expires, all information related to the operation is deleted, including any status information and result data.

If a specific retention timeout is not included in the request for a particular asynchronous operation, this system-level timeout applies.

Default

asynchronous-retention 86400

Parameters

seconds

Specifies the period of time, in seconds, that data related to asynchronous operations is retained in the system.

Values 1 to 604800

never

Keyword to specify that data related to asynchronous operations will persist in memory until explicitly deleted.

Platforms

All

5.318 attempts

attempts

Syntax

attempts *count* [**time** *minutes1* [**lockout** *minutes2*]

no attempts

Context

[Tree] (config>system>security>password attempts)

Full Context

configure system security password attempts

Description

This command configures a threshold value of unsuccessful login attempts allowed in a specified time frame.

If the threshold is exceeded, the user is locked out for a specified time period.

If multiple **attempts** commands are entered, each command overwrites the previously entered command.

The **no attempts** command resets all values to default.

Note:
This command applies to a local user, in addition to users on RADIUS, TACACS, and LDAP.

Default

attempts 3 time 5 lockout 10

Parameters

count

Specifies the number of unsuccessful login attempts allowed for the specified **time**. This is a mandatory value that must be explicitly entered.

Values 1 to 64

minutes

Specifies the period of time, in minutes, that a specified number of unsuccessful attempts can be made before the user is locked out.

Values 0 to 60

minutes

Specifies the lockout period, in minutes, during which the user is not allowed to login.

Values 0 to 1440, or infinite

If the user exceeds the attempted **count** times in the specified **time**, then that user is locked out from any further login attempts for the configured lockout time period.

Values 0 to 1440

Values infinite; user is locked out and must wait until manually unlocked before any further attempts.

Platforms

All

attempts

Syntax

attempts [*count*] [**time** *minutes1*] [**lockout** *minutes2*]

no attempts

Context

[Tree] (config>system>security>snmp attempts)

Full Context

configure system security snmp attempts

Description

This command configures a threshold value of unsuccessful SNMPv2 or SNMPv3 connection attempts allowed in a specified time frame. The command parameters are used to counter denial of service (DoS) attacks through SNMP.

If the threshold is exceeded, the host is locked out for the lockout time period.

The **no** form of the command restores the default values.

Default

attempts 20 time 5 lockout 10

Parameters

count

Specifies the number unsuccessful SNMP attempts allowed for the specified **time**.

Values 1 to 64

minutes1

Specifies period of time, in minutes, that a specified number of unsuccessful attempts can be made before the host is locked out.

Values 0 to 60

minutes2

Specifies the lockout period in minutes where the host is not allowed to login. When the host exceeds the attempted count times in the specified time, then that host is locked out from any further login attempts for the configured time period.

Values 0 to 144**0**

5.319 attrib

attrib

Syntax

attrib [**+r** | **-r**] *file-url*

attrib

Context

[Tree] (file attrib)

Full Context

file attrib

Description

This command sets or clears/resets the read-only attribute for a file in the local file system. To list all files and their current attributes enter **attrib** or **attrib x** where **x** is either the filename or a wildcard (*).

When an **attrib** command is entered to list a specific file or all files in a directory, the file's attributes are displayed with or without an "R" preceding the filename. The "R" implies that the **+r** is set and that the file is read-only. Files without the "R" designation implies that the **-r** is set and that the file is read-write-all. For example:

```
ALA-1>file cf3:\ # attrib
cf3:\bootlog.txt
cf3:\bof.cfg
cf3:\boot.ldr
cf3:\sr1.cfg
cf3:\test
cf3:\bootlog_prev.txt
cf3:\BOF.SAV
```

Parameters

file-url

Specifies the URL for the local file.

Values

local-url	[*cflash-id*/][*file-path*] up to 200 characters, including cflash-id directory length 99 chars max each
remote-url	[{ftp:// | tftp://}*login*:*pswd*@*remote-locn*/][*file-path*]
	up to 247 characters
	directory length up to 199 characters
remote-locn	[*hostname* | *ipv4-address* | [*ipv6-address*]]
ipv4-address	*a.b.c.d*

ipv6-address	*x:x:x:x:x:x:x:x*[*-interface*] *x:x:x:x:x:x:d.d.d.d*[*-interface*] *x* - [0 to FFFF]H *d* - [0 to 255]D interface - up to 32 characters, for link local addresses 255
cflash-id	cf1:, cf1-A:, cf1-B:, cf2:, cf2-A:, cf2-B:, cf3:, cf3-A:, cf3-B:

+r

Sets the read-only attribute on the specified file.

-r

Clears/resets the read-only attribute on the specified file.

attribute

Syntax

attribute [**vendor** *vendor-id*] **attribute-type** *attribute-type*

no attribute

Context

[Tree] (config>router>nat>inside>subscriber-identification attribute)

[Tree] (config>service>vprn>nat>inside>subscriber-identification attribute)

Full Context

configure router nat inside subscriber-identification attribute

configure service vprn nat inside subscriber-identification attribute

Description

This command defines the attribute that will in addition to framed-ip-address (inside IP address) and service-id be used for correlating BNG subscriber with the NAT subscriber.

Only a single attribute at the time can be configured. The attribute will be extracted from the BNG accounting start and/or interim-update messages via RADIUS accounting proxy server. This attribute can

be then optionally passed to the Large Scale NAT44 accounting server. User-name attribute (if included) in Large Scale NAT44 accounting messages will be automatically set to the subscriber-id string.

The attribute parameter can be changed at any given time and the change will be reflected automatically when the next interim-update message from the BNG host is received by the RADIUS accounting proxy.

In case that the BNG accounting message in RADIUS accounting proxy does not contain this attribute, subscriber aware Large Scale NAT44 functionality for this particular subscriber will be disabled.

Default

attribute vendor "nokia" attribute-type "alc-sub-string"

Parameters

vendor *vendor-id*

specifies the RADIUS vendor ID.

Values standard, nokia (6527), 3gpp

Default nokia

attribute-type *attribute-type*

Specifies the RADIUS attribute to be used as subscriber. identifier

Values **alc-sub-string (nokia)** — Subscriber-id string (Alc-Subsc-ID-Str) is cached in Large Scale NAT44 application and used to correlate Large Scale NAT44 subscriber to BNG subscriber.

user-name (stnd) — User-Name standard RADIUS attribute is cached in Large Scale NAT44 application and is used to correlate Large Scale NAT44 subscriber to BNG subscriber.

class (stnd) — Class standard RADIUS attribute is cached in Large Scale NAT44 application and is used to correlate Large Scale NAT44 subscriber to BNG subscriber. Class attribute is initially set and send by RADIUS server. As such it must be echoed by BNG in all accounting messages.

station-id (stnd) — Calling-Station-Id RADIUS attribute is cached in Large Scale NAT44 application and is used to correlate Large Scale NAT44 subscriber to BNG subscriber.

imsi (3gpp) — International Mobile Subscriber Identification is used in WiFi Offload applications as a SIM card identifier.

imei (3gpp) — International Mobile Equipment Identification is used in WiFi Offload applications as a physical phone device identifier.

attribute-table-size

Syntax

attribute-table-size *max-attributes*

no attribute-table-size

Context

[Tree] (config>service>vpls>mrp>mmrp attribute-table-size)

Full Context

configure service vpls mrp mmrp attribute-table-size

Description

This command controls the number of attributes accepted on a per B-VPLS basis. When the limit is reached, no new attributes will be registered.

If a new lower limit (smaller than the current number of attributes) from a local or dynamic I-VPLS is being provisioned, a CLI warning will be issued stating that the system is currently beyond the new limit. The value will be accepted, but any creation of new attributes will be blocked under the attribute count drops below the new limit; the software will then start enforcing the new limit.

Default

maximum number of attributes

Parameters

value

The maximum number of attributes accepted per B-VPLS.

Values 1 to 2048 (Full participants)

1 to 8191 (End-Station-Only participants)

Platforms

All

attribute-table-size

configure router ldp tcp-session-parameters auth-keychain

Description

This command configures the TCP authentication keychain to use for the TCP session. The per-peer authentication configuration takes precedence over the global authentication configuration.

Parameters

name

Specifies the name of the keychain, up to 32 characters. This keychain is used for the specified TCP session or sessions, and allows the rollover of authentication keys during the lifetime of a session. The peer address used must be the TCP session transport address.

Platforms

All

auth-keychain

Syntax

auth-keychain *name*

Context

[Tree] (config>router>rsvp>interface auth-keychain)

Full Context

configure router rsvp interface auth-keychain

Description

This command configures an authentication keychain to use for authentication of protocol messages sent and received over the associated interface. The keychain must include a valid entry to properly authenticate protocol messages, including a key, specification of a supported authentication algorithm, and

beginning time. Each entry may also include additional options to control the overall lifetime of each entry to allow for the seamless rollover of without affecting the protocol adjacencies.

The **no** form of the auth-keychain command removes the association between the routing protocol and any keychain currently used.

Default

no auth-keychain

Parameters

name

Specifies the name of the keychain, up to 32 characters, to use for the specified protocol session or sessions.

5.331 auth-method

auth-method

Syntax

auth-method {**psk** | **plain-psk-xauth** | **cert-auth** | **psk-radius** | **cert-radius** | **eap** | **auto-eap-radius** | **auto-eap**}

no auth-method

Context

[Tree] (config>ipsec>ike-policy auth-method)

Full Context

configure ipsec ike-policy auth-method

Description

This command specifies the authentication method used with this IKE policy.

The **no** form of this command removes the parameter from the configuration.

Default

no auth-method

Parameters

psk

Both client and gateway authenticate each other by a hash derived from a pre-shared secret. Both client and gateway must have the PSK. This work with both IKEv1 and IKEv2

plain-psk-xauth

Both client and gateway authenticate each other by pre-shared key and RADIUS. This work with IKEv1 only.

psk-radius

Use the pre-shared-key and RADIUS to authenticate. IKEv2 remote-access tunnel only.

cert-radius

Use the certificate, public/private key and RADIUS to authenticate. IKEv2 remote-access tunnel only.

eap

Use the EAP to authenticate peer. IKEv2 remote-access tunnel only

auto-eap-radius

Use EAP or potentially other method to authenticate the peer. IKEv2 remote-access tunnel only. Also see **config>ipsec>ike-policy auto-eap-method** and **config>ipsec>ike-policy auto-eap-own-method**.

auto-eap

Use the EAP or potentially other RADIUS-related method to authenticate the peer. IKEv2 remote-access tunnel only. Also see **config>ipsec>ike-policy auto-eap-method** and **config>ipsec>ike-policy auto-eap-own-method**.

[Tree] (config>service>vprn>ospf3>area>if authentication)

Full Context

configure service vprn ospf3 area virtual-link authentication

configure service vprn ospf3 area interface authentication

Description

This command configures OPSFv3 confidentiality authentication.

The **no** form of this command removes the SA name from the configuration.

Parameters

bidirectional *sa-name*

Specifies the IPsec security association name in case the OSPFv3 traffic on the interface has to be authenticated.

inbound *sa-name*

Specifies the IPsec security association name in case the OSPFv3 traffic on the interface has to be authenticated.

outbound *sa-name*

Specifies the IPsec security association name in case the OSPFv3 traffic on the interface has to be authenticated.

no authentication

Context

[Tree] (config>ipsec>static-sa authentication)

Full Context

configure ipsec static-sa authentication

Description

This command configures the authentication algorithm to use for an IPsec manual SA.

Default

no authentication

Parameters

auth-algorithm

Specifies the authentication algorithm to be used.

Values mda5, sha1

ascii-string

Specifies an ASCII key; 16 characters for **md5** and 20 characters for **sha1**.

hex-string

Specifies a HEX key; 32 hex nibbles for **md5** and 40 hex nibbles for **sha1**.

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

custom

Specifies the custom encryption to management interface.

Context

[Tree] (config>system>security>user>snmp authentication)

Full Context

configure system security user snmp authentication

Description

This command configures the SNMPv3 authentication and privacy protocols for the user to communicate with the router. The keys are stored in an encrypted format in the configuration.

The keys configured with these commands must be localized keys, which are a hash of the SNMP engine ID and a password. The password is not entered directly in this command. Use the **tools perform system management-interface snmp generate-key** command to generate localized authentication and privacy keys.

Default

authentication none

Parameters

none

Keyword to specify that no authentication protocol is used. If **none** is specified, privacy cannot be configured.

authentication-protocol

Specifies the SNMPv3 authentication protocol.

Values **hmac-md5-96** — Specifies use of the HMAC-MD5-96 authentication protocol.

hmac-sha1-96 — Specifies use of the HMAC-SHA-96 authentication protocol.

hmac-sha2-224 — Specifies use of the HMAC-SHA-224 authentication protocol.

hmac-sha2-256 — Specifies use of the HMAC-SHA-256 authentication protocol.

hmac-sha2-384 — Specifies use of the HMAC-SHA-384 authentication protocol.

hmac-sha-512 — Specifies use of the HMAC-SHA-512 authentication protocol.

authentication-key

Specifies the localized authentication key, which is entered as a hexadecimal string; the character length depends on the specified authentication protocol. The following table lists the authentication protocol key lengths.

Table 17: Authentication protocol key lengths

Authentication protocol	Character lengths
HMAC-MD5-96	32
HMAC-SHA-96	40
HMAC-SHA-224	56
HMAC-SHA-256	64
HMAC-SHA-384	96
HMAC-SHA-512	128

privacy-none

Keyword to specify that a privacy protocol is not used in the communication.

Default privacy none

privacy-protocol

Specifies the SNMPv3 privacy protocol.

Values **cbc-des** — Specifies the use of the CBC-DES privacy protocol. This parameter is not available in FIPS-140-2 mode.

cfb128-aes-128 — Specifies the use of the CFB128-AES-128 privacy protocol.

cfb128-aes-192 — Specifies the use of the CFB128-AES-192 privacy protocol.

cfb128-aes-256 — Specifies the use of the CFB128-AES-256 privacy protocol.

privacy-key

Specifies the localized privacy key, which is entered as a hexadecimal string; the character length depends on the specified privacy protocol. The following table lists the privacy protocol key lengths.

Table 18: Privacy protocol key lengths

Privacy protocol	Character length
CBC-DES	32
CFB128-AES-128	32
CFB128-AES-192	48
CFB128-AES-256	64

hash

Keyword that specifies the key is entered in an encrypted form. If the **hash** or **hash2** keyword is not specified, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

hash2

Keyword that specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone; that is, the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** keyword is not specified, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

custom

Keyword that specifies the custom encryption to the management interface.

[Tree] (config>router>ospf3>area>virtual-link authentication)

Full Context

configure router ospf3 area interface authentication

configure router ospf3 area virtual-link authentication

Description

This command configures the password used by the OSPF3 interface or virtual-link to send and receive OSPF3 protocol packets on the interface when simple password authentication is configured.

All neighboring routers must use the same type of authentication and password for proper protocol communication.

By default, no authentication key is configured.

The **no** form of this command removes the authentication.

Default

no authentication

Parameters

bidirectional sa-name

Specifies bidirectional OSPF3 authentication.

inbound sa-name

Specifies the inbound security association (SA) name for OSPF3 authentication.

outbound sa-name

Specifies the outbound SA name for OSPF3 authentication.

Platforms

authentication-check

Syntax

[**no**] **authentication-check**

Context

[Tree] (config>service>vprn>isis authentication-check)

Full Context

configure service vprn isis authentication-check

Description

This command sets an authentication check to reject PDUs that do not match the type or key requirements for the VPRN instance.

The default behavior when authentication is configured is to reject all IS-IS protocol PDUs that have a mismatch in either the authentication type or authentication key.

When **no authentication-check** is configured, authentication PDUs are generated and IS-IS PDUs are authenticated on receipt. However, mismatches cause an event to be generated and will not be rejected.

The **no** form of this command allows authentication mismatches to be accepted and generates a log event.

Default

authentication-check — Rejects authentication mismatches.

Platforms

All

authentication-check

Syntax

[**no**] **authentication-check**

Context

[Tree] (config>service>vprn>ntp authentication-check)

Full Context

configure service vprn ntp authentication-check

Description

This command provides the option to skip the rejection of NTP PDUs that do not match the authentication key-id, type or key requirements. The default behavior when authentication is configured is to reject all NTP protocol PDUs that have a mismatch in either the authentication key-id, type or key.

When **authentication-check** is enabled, NTP PDUs are authenticated on receipt. However, mismatches cause a counter to be increased, one counter for type and one for key-id, one for type, value mismatches. These counters are visible in a show command.

The **no** form of this command allows authentication mismatches to be accepted; the counters however are maintained.

Default

authentication-check — Rejects authentication mismatches.

Context

[Tree] (config>subscr-mgmt>bgp-prng-plcy authentication-key)

Full Context

configure subscriber-mgmt bgp-peering-policy authentication-key

Description

This command configures the BGP authentication key.

The MD5 message-based digest is used to perform authentication between neighboring routers before setting up the BGP session by verifying the password. The authentication key can be any combination of letters or numbers from 1 to 16.

The **no** form of this command removes the authentication password from the configuration and effectively disables authentication.

Parameters

authentication-key

Specifies an authentication key. The key can be up to 255 characters (unencrypted).

hash-key

Specifies the hash key. The key can be any combination of ASCII characters up to 342 characters (encrypted).

This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided.

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

configure redundancy multi-chassis peer authentication-key

Description

This command configures the authentication key used between this node and the multi-chassis peer. The authentication key can be any combination of letters or numbers. The **no** form of the command removes the authentication key.

Default

no authentication-key

Parameters

authentication-key

Specifies the authentication key. Allowed values are any string up to 20 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

hash-key

Specifies the hash key. The key can be any combination of ASCII characters up to 33 (hash1-key) or 55 (hash2-key) characters in length (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

configure subscriber-mgmt rip-policy authentication-key

Description

This command configures the BGP authentication key.

Authentication is performed between neighboring routers before setting up the BGP session by verifying the password. Authentication is performed using the MD5 message-based digest. The authentication key can be any combination of letters or numbers from 1 to 16.

The **no** form of this command removes the authentication password from the configuration and effectively disables authentication.

Default

Authentication is disabled and the authentication password is empty.

Parameters

authentication-key

Specifies the authentication key. The key can be any combination of ASCII characters up to 255 characters (unencrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

hash-key

Specifies the hash key. The key can be any combination of ASCII characters up to 342 characters (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided.

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

hash2

no authentication-key

Context

[Tree] (config>service>ies>if>vrrp authentication-key)

Full Context

configure service ies interface vrrp authentication-key

Description

The **authentication-key** command, within the **vrrp** *virtual-router-id* context, is used to assign a simple text password authentication key to generate master VRRP advertisement messages and validating received VRRP advertisement messages.

The authentication-key command is one of the few commands not affected by the presence of the owner keyword. If simple text password authentication is not required, the authentication-key command is not required. If the command is re-executed with a different password key defined, the new key will be used immediately. If a no authentication-key command is executed, the password authentication key is restored to the default value. The authentication-key command may be executed at any time.

To change the current in-use password key on multiple virtual router instances:

- Identify the current master
- Shutdown the virtual router instance on all backups
- Execute the authentication-key command on the master to change the password key
- Execute the authentication-key command and no shutdown command on each backup key

The **no** form of the command removes the authentication key.

Default

No default. The authentication data field contains the value 0 in all 16 octets.

Parameters

authentication-key

The *key* parameter identifies the simple text password used when VRRP Authentication Type 1 is enabled on the virtual router instance. Type 1 uses a string eight octets long that is inserted into all transmitted VRRP advertisement messages and compared against all received VRRP advertisement messages. The authentication data fields are used to transmit the key.

The *key* parameter is expressed as a string consisting up to eight alpha-numeric characters. Spaces must be contained in quotation marks (" "). The quotation marks are not considered part of the string.

The string is case sensitive and is left-justified in the VRRP advertisement message authentication data fields. The first field contains the first four characters with the first octet (starting with IETF RFC bit position 0) containing the first character. The second field holds the fifth through eighth characters. Any unspecified portion of the authentication data field is padded with the value 0 in the corresponding octet.

Values Any 7-bit printable ASCII character.

Exceptions:	Double quote (")	ASCII 34
	Carriage Return	ASCII 13
	Line Feed	ASCII 10
	Tab	ASCII 9
	Backspace	ASCII 8

hash-key

The hash key. The key can be any combination of ASCII characters up to 22 characters in length (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided.

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

Full Context

configure service vprn interface vrrp authentication-key

Description

The **authentication-key** command, within the **vrrp** *virtual-router-id* context, is used to assign a simple text password authentication key to generate master VRRP advertisement messages and validate received VRRP advertisement messages.

The **authentication-key** command is one of the few commands not affected by the presence of the **owner** keyword. If simple text password authentication is not required, this command is not required. If the command is re-executed with a different password key defined, the new key will be used immediately. If a no **authentication-key** command is executed, the password authentication key is restored to the default value. The **authentication-key** command may be executed at any time.

To change the current in-use password key on multiple virtual router instances:

- Identify the current master
- Shut down the virtual router instance on all backups
- Execute the **authentication-key** command on the master to change the password key
- Execute the **authentication-key** command and the **no shutdown** command on each backup key

The **no** form of this command restores the default null string to the value of key.

Parameters

authentication-key

The *key* parameter identifies the simple text password used when VRRP Authentication Type 1 is enabled on the virtual router instance. Type 1 uses a string eight octets long that is inserted into all transmitted VRRP advertisement messages and compared against all received VRRP advertisement messages. The authentication data fields are used to transmit the key.

The *key* parameter is expressed as a string consisting of up to eight alpha-numeric characters. Spaces must be contained in quotation marks (" ”). The quotation marks are not considered part of the string.

The string is case sensitive and is left-justified in the VRRP advertisement message authentication data fields. The first field contains the first four characters with the first octet (starting with IETF RFC bit position 0) containing the first character. The second field holds the fifth through eighth characters. Any unspecified portion of the authentication data field is padded with the value 0 in the corresponding octet.

Values Any 7-bit printable ASCII character.

Exceptions:	Double quote (")	ASCII 34
	Carriage Return	ASCII 13
	Line Feed	ASCII 10
	Tab	ASCII 9
	Backspace	ASCII 8

hash-key

The hash key. The key can be any combination of ASCII characters up to 22 characters in length (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ")

This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided.

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. [Tree] (config>service>vprn>isis>level authentication-key)

[Tree] (config>service>vprn>isis authentication-key)

Full Context

configure service vprn isis level authentication-key

configure service vprn isis authentication-key

Description

This command sets the authentication key used to verify PDUs sent by neighboring routers on the interface for the VPRN instance.

Neighboring routers use passwords to authenticate PDUs sent from an interface. For authentication to work, both the authentication *key* and the authentication *type* on a segment must match. The OSPF Commands statement must also be included.

To configure authentication on the global level, configure this command in the **config>router>isis** context. When this parameter is configured on the global level, all PDUs are authenticated including the Hello PDU.

To override the global setting for a specific level, configure the **authentication-key** command in the **config>router>isis>level** context. When configured within the specific level, hello PDUs are not authenticated.

The **no** form of this command removes the authentication key.

Default

no authentication-key — No authentication key is configured.

Parameters

authentication-key

The authentication key. The key can be any combination of ASCII characters up to 255 characters in length (un-encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

hash-key

The hash key. The key can be any combination of ASCII characters up to 342 characters in length (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided.

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

custom

Specifies the custom encryption to management interface.

[Tree] (config>service>vprn>msdp>group>peer authentication-key)

Full Context

configure service vprn msdp peer authentication-key

configure service vprn msdp group peer authentication-key

Description

This command configures a Message Digest 5 (MD5) authentication key to be used with a specific Multicast Source Discovery Protocol (MSDP) peering session. The authentication key must be configured per peer as such no global or group configuration is possible.

The **no** form of this command removes the authentication key.

Default

no authentication-key (All MSDP messages are accepted and the MD5 signature option authentication key is disabled.)

Parameters

authentication-key

Specifies the authentication key. Allowed values are any string up to 256 characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), enclose the entire string in quotation marks (" ").

hash-key

Specifies the hash key. The key can be any combination of ASCII characters up to 451 characters in length (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided.

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

custom

Specifies the custom encryption to management interface.

Platforms

All

authentication-key

Syntax

authentication-key *key-id* **key** *key* [**hash** | **hash2** | **custom**] **type** {**des** | **message-digest**}

no authentication-key *key-id*

Context

[Tree] (config>service>vprn>ntp authentication-key)

Full Context

configure service vprn ntp authentication-key

Description

This command sets the authentication key-id, type and key used to authenticate NTP PDUs sent by the broadcast server function toward external clients or to authenticate NTP PDUs received from external unicast clients within the VPRN routing instance. For authentication to work, the authentication key-id, type, and key value must match.

The **no** form of this command removes the authentication key.

Parameters

key-id

Configure the authentication key-id that will be used by the node when transmitting or receiving Network Time Protocol packets.

Entering the authentication-key command with a key-id value that matches an existing configuration key will result in overriding the existing entry.

Recipients of the NTP packets must have the same authentication key-id, type, and key value in order to use the data transmitted by this node. This is an optional parameter.

Values 1 to 255

key

The authentication key associated with the configured key-id, the value configured in this parameter is the actual value used by other network elements to authenticate the NTP packet.

The key can be any combination of ASCII characters up to 8 characters in length (unencrypted). If spaces are used in the string, enclose the entire string in quotation marks (".").

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys

are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

custom

Specifies the custom encryption to management interface.

type

This parameter determines if DES or message-digest authentication is used.

This is a required parameter; either DES or message-digest must be configured.

Values des — Specifies that DES authentication is used for this key. The des value is not supported in FIPS-140-2 mode.

message-digest — Specifies that MD5 authentication in accordance with RFC 2104 is used for this key.

Full Context

configure service vprn ospf area interface authentication-key

configure service vprn ospf area sham-link authentication-key

configure service vprn ospf area virtual-link authentication-key

Description

This command configures the password used by the OSPF interface or virtual-link to send and receive OSPF protocol packets on the interface when simple password authentication is configured.

This command is not valid in the OSPF3 context.

All neighboring routers must use the same type of authentication and password for proper protocol communication. If the **authentication-type** is configured as password, then this key must be configured.

By default, no authentication key is configured.

This command is not supported in the OSPF context.

The **no** form of this command removes the authentication key.

Default

no authentication-key — No authentication key is defined.

Parameters

authentication-key

The authentication key. The key can be any combination of ASCII characters up to 8 characters in length (unencrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

hash-key

The hash key. The key can be any combination of ASCII characters up to 22 characters in length (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided.

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

[Tree] (config>service>vprn>rip>group authentication-key)

Full Context

configure service vprn rip group neighbor authentication-key

configure service vprn rip authentication-key

configure service vprn rip group authentication-key

Description

This command sets the authentication password to be passed between RIP neighbors.

The authentication type and authentication key must match exactly to authenticate and then process the RIP message.

The **no** form of this command removes the authentication password from the configuration and disables authentication.

Default

no authentication-key

Parameters

authentication-key

The authentication key. The key can be any combination of ASCII characters up to 16 characters in length (unencrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

hash-key

The hash key. The key can be any combination of ASCII characters up to 33 characters in length (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided.

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

Context

[Tree] (config>router>ldp>tcp-session-params authentication-key)

[Tree] (config>router>ldp>tcp-session-params>peer-transport authentication-key)

Full Context

configure router ldp tcp-session-parameters authentication-key

configure router ldp tcp-session-parameters peer-transport authentication-key

Description

This command specifies the authentication key used to establish a session between LDP peers. Authentication uses the MD5 message-based digest. The peer address used in authentication must be the TCP session transport address. If one or more transport addresses used in the Hello adjacencies to the same peer LSR are different from the LSR-ID value, the user must add each transport address to the authentication-key configuration as a separate peer. As a result, when the TCP connection is bootstrapped by a specific Hello adjacency, the authentication can operate over that TCP connection by using its specific transport address. The per peer authentication configuration takes precedence over global authentication configuration, and authentication keychain configuration takes precedence over authentication key configuration.

The **no** form of this command disables authentication.

Parameters

authentication-key

Specifies the authentication key. The key can be any combination of ASCII characters, up to 255 characters (unencrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

hash-key

Specifies the hash key. The key can be any combination of up to 33 alphanumeric characters. If spaces are used in the string, enclose the entire string in quotation marks (" ").

This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided.

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified

hash2

Specifies the key is entered in a more complex, encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

Context

[Tree] (config>router>rsvp>interface authentication-key)

Full Context

configure router rsvp interface authentication-key

Description

This command specifies the authentication key for use between RSVP neighbors to authenticate RSVP messages. Authentication uses the MD5 message-based digest.

When enabled on an RSVP interface, authentication of RSVP messages operates in both directions of the interface. A router maintains a security association using one authentication key for each interface to an RSVP neighbor.

An RSVP neighbor transmits an authenticating digest of the RSVP message that is computed using the shared authentication key and a keyed-hash algorithm. The message digest is included in an INTEGRITY object, which also contains a flags field, a key identifier field, and a sequence number field. An RSVP neighbor uses the key together with the authentication algorithm to process received RSVP messages. The RSVP MD5 authentication complies to the procedures for RSVP message generation in RFC 2747, *RSVP Cryptographic Authentication*.

The MD5 implementation does not support the authentication challenge procedures in RFC 2747.

The **no** form of this command disables authentication.

Default

no authentication-key - The authentication key value is the null string.

Parameters

authentication-key

Specifies the authentication key. The key can be any combination of ASCII characters up to 16 characters in length (unencrypted). If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

hash-key

Specifies the hash key. The key can be any combination of up 33 alphanumeric characters. If spaces are used in the string, enclose the entire string in quotation marks (" ")

This is useful when a user must configure the parameter, but for security purposes, the actual unencrypted key value is not provided.

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

Full Context

configure router msdp group peer authentication-key

configure router msdp peer authentication-key

Description

This command configures a Message Digest 5 (MD5) authentication key to be used with a specific Multicast Source Discovery Protocol (MSDP) peering session. The authentication key must be configured per peer as such no global or group configuration is possible.

The **no** form of the command configures acceptance of all MSDP messages and disables the MD5 signature option authentication key.

Default

no authentication-key

Parameters

authentication-key

Specifies the authentication key. The key can be any combination of printable, 7-bit ASCII characters, up to 255 characters long in the config>router>msdp>peer context, or up to 127 characters long in the config>router>msdp>group>peer context. If the string contains special characters (#, $, spaces, and so on), enclose the entire string in quotation marks (" ”).

hash-key

Specifies a hash key. The key can be any combination of ASCII characters up to 451 characters in length (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ”).

This is useful when a user must configure the parameter, although, for security purposes, the actual unencrypted key value is not provided.

hash

Specifies that the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified

hash2

Specifies that the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

Context

[Tree] (config>router>if>vrrp authentication-key)

Full Context

configure router interface vrrp authentication-key

Description

This command sets the simple text authentication key used to generate master VRRP advertisement messages and validates VRRP advertisements.

If simple text password authentication is not required, the **authentication-key** command is not required.

The command is configurable in both non-owner and owner **vrrp** nodal contexts.

The *key* parameter identifies the simple text password to be used when VRRP Authentication Type 1 is enabled on the virtual router instance. Type 1 uses an eight octet long string that is inserted into all transmitted VRRP advertisement messages and is compared against all received VRRP advertisement messages. The authentication data fields are used to transmit the *key*.

The *key* string is case sensitive and is left justified in the VRRP advertisement message authentication data fields. The first field contains the first four characters with the first octet (starting with IETF RFC bit position 0) containing the first character. The second field similarly holds the fifth through eighth characters. Any unspecified portion of the authentication data field is padded with a 0 value in the corresponding octet.

If the command is re-executed with a different password key defined, the new key is used immediately.

The **authentication-key** command can be executed at anytime.

To change the current in-use password key on multiple virtual router instances:

Identify the current master.

1. Shutdown the virtual router instance on all backups.
2. Execute the **authentication-key** command on the master to change the password key.
3. Execute the **authentication-key** command and **no shutdown** command on each backup.

The **no** form of the command reverts to the default value.

Default

no authentication-key — The authentication key value is the null string.

Parameters

authentication-key

The authentication key. Allowed values are any string up to 8 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

hash-key

The hash key. The key can be any combination of ASCII characters up to 22 (hash-key1) or 121 (hash-key2) characters in length (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

This is useful when a user must configure the parameter, but for security purposes, the actual unencrypted key value is not provided.

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

Full Context

configure system time ntp authentication-key

Description

This command sets the authentication key-id, type and key used to authenticate NTP PDUs sent to or received by other network elements participating in the NTP protocol. For authentication to work, the authentication key-id, type and key value must match.

The **no** form of the command removes the authentication key.

Parameters

key-id

Configures the authentication key-id that will be used by the node when transmitting or receiving Network Time Protocol packets

Entering the authentication-key command with a key-id value that matches an existing configuration key will result in overriding the existing entry.

Recipients of the NTP packets must have the same authentication key-id, type, and key value in order to use the data transmitted by this node. This is an optional parameter.

Values 1 to 255

key

Specifies the authentication key associated with the configured key-id, the value configured in this parameter is the actual value used by other network elements to authenticate the NTP packet.

The key can be any combination of ASCII characters up to 32 characters for message-digest (md5) or 8 characters for des (length limits are unencrypted lengths). If spaces are used in the string, enclose the entire string in quotation marks (".").

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

custom

Specifies the custom encryption to management interface.

type

Determines if DES or message-digest authentication is used.

This is a required parameter; either DES or message-digest must be configured.

des

Specifies that DES authentication is used for this key. The des option is not permitted in FIPS-140-2 mode.

message-digest

Specifies that MD5 authentication in accordance with RFC 2104 is used for this key.

Context

[Tree] (config>router>isis authentication-key)

[Tree] (config>router>isis>level authentication-key)

Full Context

configure router isis authentication-key

configure router isis level authentication-key

Description

This command sets the authentication key used to verify PDUs sent by neighboring routers on the interface.

Neighboring routers use passwords to authenticate PDUs sent from an interface. For authentication to work, both the authentication *key* and the authentication *type* on a segment must match. The **authentication-type** command must also be included.

To configure authentication on the global level, configure this command in the **config>router>isis** context. When this parameter is configured on the global level, all PDUs are authenticated, including the hello PDU.

To override the global setting for a specific level, configure the **authentication-key** command in the **config>router>isis>level** context. When configured within the specific level, hello PDUs are not authenticated.

The **no** form of this command removes the authentication key.

Default

no authentication-key

Parameters

authentication-key

Specifies the authentication key. The key can be any combination of ASCII characters up to 255 characters in length (unencrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

hash-key

Specifies the hash key. The key can be any combination of ASCII characters up to 342 characters in length (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

This is useful when a user must configure the parameter but, for security purposes, the actual unencrypted key value is not provided.

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. no authentication-order

Context
[Tree] (config>system>security>password authentication-order)

Full Context
configure system security password authentication-order

Description

This command configures the sequence in which password authentication, authorization, and accounting is attempted among the local user database, RADIUS servers, TACACS+ servers, and LDAP servers.

The authentication order should be from the most preferred authentication method to the least preferred. The presence of all methods in the command line does not guarantee that they are all operational. Specifying options that are not available delays user authentication.

If all (operational) methods are attempted and no authentication for a particular login has been granted, then an entry in the security log documents the failed attempt. Both the attempted login identification and originating IP address are logged with a timestamp.

The **no** form of this command reverts to the default authentication sequence.

The authentication-order is not applicable to SNMPv3. SNMPv3 messages ignore the configured authentication-order and are authorized using the locally configured users only. TACACS+, RADIUS, and LDAP are not supported for SNMPv3 authentication.

Note:
This command applies to a local user, in addition to users on RADIUS, TACACS, and LDAP.

Default

authentication-order radius tacplus ldap local

Parameters

method-1

Specifies the first password authentication method to attempt.

Values local, radius, tacplus, ldap

method-2

Specifies the second password authentication method to attempt.

Values local, radius, tacplus, ldap

method-3

Specifies the third password authentication method to attempt.

Values local, radius, tacplus, ldap

method-4

Specifies the fourth password authentication method to attempt.

Values local, radius, tacplus, ldap

local

Specifies the password authentication based on the local password database.

radius

Specifies RADIUS authentication.

tacplus

Specifies TACACS+ authentication.

ldap

Specifies LDAP authentication.

exit-on-reject

When enabled and if one of the AAA methods configured in the authentication order sends a reject, then the next method in the order will not be tried. If the **exit-on-reject** keyword is not specified and if one AAA method sends a reject, the next AAA method will be attempted. If in this process, all the AAA methods are exhausted, it will be considered as a reject.

A rejection is distinct from an unreachable authentication server. When the **exit-on-reject** keyword is specified, authorization and accounting will only use the method that provided an affirmation authentication; only if that method is no longer readable or is removed from the configuration will other configured methods be attempted. If the **local** keyword is the first authentication and:

- **exit-on-reject** is configured and the user does not exist, the user is not authenticated
- the user is authenticated locally, then other methods, if configured, it is used for authorization and accounting
- the user is configured locally but without console access, login is denied

5.345 authentication-over-bypass

authentication-over-bypass

Syntax

authentication-over-bypass [**enable** | **disable**]

Context

[Tree] (config>router>rsvp authentication-over-bypass)

Full Context

configure router rsvp authentication-over-bypass

Description

This command configures the MD5 authentication over the bypass LSP of all Point of Local Repairs (PLRs) and Merge Points (MPs) on the router. Only enable this command when the TE interfaces in the RSVP-TE network use the same MD5 authentication parameters.

When a Point of Local Repair (PLR) activates a bypass LSP towards a Merge Point (MP), by default, the INTEGRITY object corresponding to the bypass LSP interface is not added to a transmitted RSVP message except for packets of routed RSVP messages (Resv, Srefresh, and ACK), and only when the packet is intended for a bypass LSP endpoint (PLR or MP) that is a directly connected neighbor.

When this command is enabled, the INTEGRITY object of the interface corresponding to the bypass LSP is added to a transmitted RSVP message regardless of whether the bypass LSP endpoint (PLR or MP) is a directly connected RSVP neighbor. The INTEGRITY object is included with the following RSVP messages: Path, PathTear, PathErr, Resv, ResvTear, ResvErr, Srefresh, and ACK.

In all cases, an RSVP message received from a PLR or a MP (sender address in the SenderTemplate/ FilterSpec is different from an Extended Tunnel Id in a Session Object), and which includes the INTEGRITY object is authenticated against the bypass LSP interface. An RSVP message received from a PLR or MP without the INTEGRITY object is also accepted.

Default

authentication-over-bypass disable

Parameters

enable

Enables the MD5 authentication over the bypass LSP of all PLRs on the node.

disable

Disables the MD5 authentication over the bypass LSP of all PLRs on the node.

5.347 authentication-type

authentication-type

Syntax

authentication-type {**none** | **password** | **message-digest** | **message-digest-20**}

no authentication-type

Context

[Tree] (config>subscr-mgmt>rip-plcy authentication-type)

Full Context

configure subscriber-mgmt rip-policy authentication-type

Description

This command sets the type of authentication to be used between RIP neighbors. The type and password must match exactly for the RIP message to be considered authentic and processed.

The **no** form of this command removes the authentication type from the configuration and effectively disables authentication.

Parameters

none

Disables authentication at a given level (global, group, neighbor). If the command does not exist in the configuration, the parameter is inherited.

password

Specifies enable simple password (plain text) authentication. If authentication is enabled and no authentication type is specified in the command, simple password authentication is enabled.

message-digest

Configures 16 byte message digest for MD5 authentication. If this option is configured, then at least one message-digest-key must be configured.

message-digest-20

Configures 20 byte message digest for MD5 authentication in accordance with RFC 2082, RIP-2 MD5 Authentication. If this option is configured, then at least one message-digest-key must be configured.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

authentication-type

[Tree] (config>service>vprn>isis authentication-type)

[Tree] (config>service>vprn>isis>level authentication-type)

Full Context

configure service vprn isis authentication-type

configure service vprn isis level authentication-type

Description

This command enables either simple password or message digest authentication or must go in either the global IS-IS or IS-IS level context.

Both the authentication key and the authentication type on a segment must match. The **authentication-key** statement must also be included.

Configure the authentication type on the global level in the **config>router>isis** context.

Configure or override the global setting by configuring the authentication type in the **config>router>isis>level** context.

The **no** form of this command disables authentication.

Default

no authentication-type — No authentication type is configured and authentication is disabled.

Parameters

password

Specifies that simple password (plain text) authentication is required.

message-digest

Specifies that MD5 authentication in accordance with RFC2104 is required.

Platforms

All

authentication-type

Syntax

authentication-type {**password** | **message-digest**}

Full Context

configure service vprn ospf area sham-link authentication-type

configure service vprn ospf area interface authentication-type

configure service vprn ospf area virtual-link authentication-type

Description

This command enables authentication and specifies the type of authentication to be used on the OSPF interface, virtual-link, and sham-link.

This command is not valid in the OSPF3 context.

Both simple **password** and **message-digest** authentication are supported.

The **no** form of this command disables authentication on the interface.

Default

no authentication-type — No authentication is enabled on an interface.

Parameters

password

This keyword enables simple password (plain text) authentication. If authentication is enabled and no authentication type is specified in the command, simple **password** authentication is enabled.

message-digest

This keyword enables message digest MD5 authentication in accordance with RFC1321. If this option is configured, then at least one message-digest-key must be configured.

[**no**] **authorization** [**use-priv-lvl**]

Context

[Tree] (config>service>vprn>aaa>remote-servers>tacplus authorization)

[Tree] (config>system>security>tacplus authorization)

Full Context

configure service vprn aaa remote-servers tacplus authorization

configure system security tacplus authorization

Description

This command controls how TACACS+ is used for command authorization.

If this command is enabled without the **use-priv-lvl** option, then each command is sent to the TACACS+ server for authorization (this is true whether the **tacplus use-default-template** setting is enabled or not).

If the **tacplus authorization** command is disabled, and the **tacplus use-default-template** setting is enabled, then the local profile in the **user-template tacplus_default** is used for command authorization.

Default

no authorization

Parameters

use-priv-lvl

Automatically performs a single authorization request to the TACACS+ server for cmd* (all commands) immediately after login, and then use the local profile associated (via the **priv-lvl-map**) with the priv-lvl returned by the TACACS+ server for all subsequent authorization (except **enable-admin**). After the initial authorization for cmd*, no further authorization requests are sent to the TACACS+ server (except **enable-admin**). If the TACACS+ server does not return a priv-lvl for a user, the profile from the **user-template tacplus_default** is used for command authorization (as long as **tacplus use-default-template** is enabled, otherwise all commands are rejected).

configure service vpls bgp-evpn mpls auto-bind-tunnel

configure service epipe bgp-evpn mpls auto-bind-tunnel

configure service vprn bgp-ipvpn mpls auto-bind-tunnel

Description

Commands in this context configure automatic binding of a VPRN service using tunnels to MP-BGP peers.

The **auto-bind-tunnel** node is simply a context to configure the binding of BGP IPVPN or EVPN routes to tunnels. The user must configure the **resolution** option to enable auto-bind resolution to tunnels in TTM. If the **resolution** option is explicitly set to **disabled**, the auto-binding to tunnel is removed.

If resolution is set to **any**, any supported tunnel type in the Epipe/VPRN/VPLS context is selected following TTM preference. If one or more explicit tunnel types are specified using the **resolution-filter** option, then only these tunnel types are selected again following the TTM preference.

The user must set **resolution** to **filter** in order to activate the list of tunnel-types configured under resolution-filter.

In VPRN services and for BGP-IPVPN, when an explicit SDP to a BGP next hop is configured (**config**>**service**>v**prn**>**spoke-sdp**), it overrides the auto-bind-tunnel selection for that BGP next hop only. There is no support for reverting automatically to the auto-bind-tunnel selection if the explicit SDP goes down. The user must delete the explicit spoke-sdp in the VPRN service context to resume using the auto-bind-tunnel selection for the BGP next hop.

no auto-boot

Context

[Tree] (bof auto-boot)

Full Context

bof auto-boot

Description

This command enables the **auto-boot** flag in the BOF and configures the **auto-boot** options for ZTP. When modifying **auto-boot** options using CLI, all required options must be explicitly configured, as the default cases will no longer be used.

The **no** form of this command disables the **auto-boot** flag.

Default

no auto-boot

Parameters

management-port

Specifies that the out-of-band management port (Mgmt port) should be used for ZTP.

inband

Specifies that in-band management through an Ethernet port should be used for ZTP. Unless the **vlan-discovery** flag is used, the **inband** option disables VLAN discovery.

vlan-id

Specifies an in-band VLAN to use for the auto-boot process.

Values 1 to 4094

vlan-discovery

Floods all VLANs (1 to 4094) with DHCP discovery messages and is supported only on **inband** ports. The first offer received on a specific VLAN is processed.

ipv4

Enables IPv4 DHCP discovery. This parameter is mandatory if the **ipv6** parameter is not specified.

ipv6

Enables IPv6 DHCP solicitation. This parameter is mandatory if the **ipv4** parameter is not specified.

ascii-string

Specifies a DHCP client identification string, up to 58 ASCII characters, to be used for Option 61 (IPv4) or Option 1 (IPv6).

hex-string

Specifies a DHCP client identification string, up to 116 hexadecimal nibbles, to be used for Option 61 (IPv4) or Option 1 (IPv6).

Values 0x0 to 0xFFFFFFFF

chassis-mac

Specifies that the chassis MAC address should be used as the DHCP client identification string for Option 61 (IPv4) or Option 1 (IPv6).

include-user-class

Specifies that Option 77 should be included in DHCP messages.

client-identifier

Specifies that a custom client ID should be used in network discovery requests.

minutes

Specifies the time interval after which, if the auto-boot process is unsuccessful (in the case of auto-boot using OSPF, if no OSPF adjacency is found), the node is rebooted and the auto-boot process is retried.

Values 30 to 1440

Default 30

ospf

Specifies that OSPF auto-discovery should be used.

neid-hex-string

Specifies a hexadecimal network element identification string.

Values 0x10101to 0xFEFEFE

ip-address

Specifies the IPv4 address for the network element.

Values a.b.c.d

Default *vendor-id.neid-hex-string*

ipv6-address

Specifies the IPv6 address for the network element.

Values

x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x [0 to FFFF]H

d [0 to 255]D

Default The IPv6 version of *vendor-id.neid-hex-string*

vendor-id

Specifies the vendor identification number. The number 140 corresponds to "Nokia”.

Values 1 to 254

Default 140

ip-mtu-bytes

Specifies the OSPF MTU in bytes.

Values 512 to 9786

Default 1500

mtu-bytes

Specifies the port MTU in bytes.

Values 512 to 9800

Default The default MTU of the port type.

auto-config

Syntax

[**no**] **auto-config**

Context

[Tree] (config>service>epipe>spoke-sdp-fec auto-config)

Full Context

configure service epipe spoke-sdp-fec auto-config

Description

This command enables single sided automatic endpoint configuration of the spoke SDP. The router acts as the passive T-PE for signaling this MS-PW.

Automatic Endpoint Configuration allows the configuration of a spoke SDP endpoint without specifying the TAII associated with that spoke SDP. It allows a single-sided provisioning model where an incoming label mapping message with a TAII that matches the SAII of that spoke SDP to be automatically bound to that endpoint. In this mode, the far end T-PE actively initiates MS-PW signaling and will send the initial label mapping message using T-LDP, while the router T-PE for which auto-config is specified will act as the passive T-PE.

The **auto-config** command is blocked in CLI if signaling active has been enabled for this spoke SDP. It is only applicable to spoke SDPs configured under the Epipe, IES and VPRN interface context.

The **no** form of this command means that the router T-PE either acts as the active T-PE (if signaling active is configured) or automatically determines which router will initiate MS-PW signaling based on the prefix values configured in the SAII and TAII of the spoke SDP. If the SAII has the greater prefix value, then the router will initiate MS-PW signaling without waiting for a label mapping message from the far end. However, if the TAII has the greater value prefix, then the router will assume that the far end T-PE will initiate MS-PW signaling and will wait for that label mapping message before responding with a T-LDP label mapping message for the MS-PW in the reverse direction.

Context

[Tree] (config>service>vprn>mvpn auto-discovery)

Full Context

configure service vprn mvpn auto-discovery

Description

This command enables MVPN membership auto-discovery through BGP. When auto-discovery is enabled, PIM peering on the inclusive provider tunnel is disabled. Changing auto-discovery configuration requires shutdown of this VPRN instance.

The **no** form of this command disables MVPN membership auto-discovery through BGP.

Default

auto-discovery default

Parameters

default

Enables AD route exchange based on format defined in NG-MVPN (RFC6514).

mdt-safi

Enables AD route exchange based on mdt-safi format defined in *draft-rosen-vpn-mcast.*

This command optionally specifies a **source-address** - an IP address to be used by Rosen MVPN or NG-MVPN for core diversity, non-default IGP instances (not using system IP). Two unique IP addresses for PIM or GRE MVPNs are supported. The two unique IP address restriction does not apply to MVPNs with MPLS tunnels (for example, RSVP and MLDP). For instances using default System IP, source address configuration should not be specified to avoid consuming one of the addresses.

Explicitly defining a **source-address** allows GRE-encapsulated Rosen MVPN or NG-MVPN multicast traffic (Default and Data MDT) to originate from a configured IP address, so the source IP address of the GRE packets will not be the default system IP address.

Value:

ip-address

An IPv4 address. To achieve the desired functionality the address should be a pre-configured non-default ISIS or OSPF loopback address for an IGP instance using loopback address different from the system IP loopback.

configure ipsec ike-policy auto-eap-method

Description

This command enables following behavior for IKEv2 remote-access tunnel when auth-method is configured as auto-eap-radius:

- If there is no AUTH payload in IKE_AUTH request, then system use EAP to authenticate client and also will own-auth-method to generate AUTH payload.
- If there is AUTH payload in IKE_AUTH request:
  - if auto-eap-method is psk, then system proceed as auth-method:psk-radius
  - if auto-eap-method is cert, then system proceed as auth-method:cert-radius
  - if auto-eap-method is psk-or-cert, then:
    - if the "Auth Method" field of AUTH payload is PSK, then system proceed as auth-method:psk-radius

- if the "Auth Method" field of AUTH payload is RSA or DSS, then system proceed as auth-method:cert-radius

– The system will use **auto-eap-own-method** to generate AUTH payload.

This command only applies when **auth-method** is configured as **auto-eap-radius**.

Default

auto-eap-method cert

Parameters

psk

Uses the pre-shared-key as the authentication method.

cert

Uses the certificate as the authentication method.

psk-or-cert

Uses either the pre-shared-key or certificate based on the "Auth Method" field of the received AUTH payload.

Platforms

auto-esi

Syntax

auto-esi {**none** | **type-1**}

Context

[Tree] (config>service>system>bgp-evpn>eth-seg auto-esi)

Full Context

configure service system bgp-evpn ethernet-segment auto-esi

Description

This command configures the auto-ESI type to use in the Ethernet segment (ES).

The default mode is **none** and forces the user to configure a manual ESI. When **type-1** is configured, a manual ESI cannot be configured and the ESI is auto-derived in accordance with the RFC 7432 ESI type 1 definition.

An ESI type 1 encodes 0x01 in the ESI type octet (T=0x01) and indicates that IEEE 802.1AX LACP is used between the PEs and CEs.

The ESI is auto-derived from the LACP PDUs by concatenating the following parameters:

- CE LACP system MAC address (6 octets)

  The CE LACP system MAC address is encoded in the high-order 6 octets of the ESI value field.
- CE LACP port Key (2 octets)

  The CE LACP port key is encoded in the 2 octets next to the system MAC address.
- the remaining octet is set to 0x00.

Parameters

type-1

Specifies an auto-generated ESI value.

none

Specifies the configuration of a manual ESI.

5.367 auto-learn-mac-protect

auto-learn-mac-protect

Syntax

[**no**] **auto-learn-mac-protect**

Context

[Tree] (config>service>pw-template>split-horizon-group auto-learn-mac-protect)

[Tree] (config>service>vpls>endpoint auto-learn-mac-protect)

Full Context

configure service pw-template split-horizon-group auto-learn-mac-protect

configure service vpls endpoint auto-learn-mac-protect

Description

This command enables the automatic protection of source MAC addresses learned on the associated object. MAC protection is used in conjunction with the **restrict-protected-src**, **restrict-unprotected-dst**, and **mac-protect** commands. When **auto-learn-mac-protect** command is applied or removed, the MAC addresses are cleared from the related object.

When the **auto-learn-mac-protect** is enabled on an SHG the action only applies to the associated SAPs (no action is taken by default for spoke SDPs in the SHG). To enable this function for spoke SDPs within a SHG, the **auto-learn-mac-protect** command must be enabled explicitly under the spoke SDP. If required, the **auto-learn-mac-protect** command can also be enabled explicitly under specific SAPs within the SHG.

The **no** form of the command reverts to the default.

Default

no auto-learn-mac-protect

Platforms

Full Context

configure service vpls spoke-sdp auto-learn-mac-protect

configure service vpls mesh-sdp auto-learn-mac-protect

configure service vpls split-horizon-group auto-learn-mac-protect

configure service pw-template auto-learn-mac-protect

configure service vpls sap auto-learn-mac-protect

Description

This command specifies whether to enable automatic population of the MAC protect list with source MAC addresses learned on the associated object under which the command is configured.

When configured, dynamically learned MAC Source Addresses (SA) are protected only if they are learned on an object with ALMP configured and there is no exclude list associated to the same object or if there is an exclude list but the MAC does not match any entry.

The same list can be used in multiple objects of the same or different service. If the list is empty, ALMP does not exclude any learned MAC from protection on the object.

The **no** form of the command disables the automatic population of the MAC protect list.

Default

auto-learn-mac-protect

Parameters

name

Specifies the name of the exclude list, up to 32 characters.

auto-lsp

Syntax

auto-lsp lsp-template *template-name* {**policy** *peer-prefix-policy* [**peer-prefix-policy**] | **one-hop**}

no auto-lsp lsp-template *template-name*

Context

[Tree] (config>router>mpls auto-lsp)

Full Context

configure router mpls auto-lsp

Description

This command enables the automatic creation of an RSVP point-to-point LSP to a destination node whose router ID matches a prefix in the specified peer prefix policy. This LSP type is referred to as auto-LSP of type mesh.

The user can associate multiple templates with same or different peer prefix policies. Each application of an LSP template with a given prefix in the prefix list results in the instantiation of a single CSPF computed LSP primary path using the LSP template parameters as long as the prefix corresponds to a router ID for a node in the TE database. This command does not support the automatic signaling of a secondary path for an LSP. If the signaling of multiple LSPs to the same destination node is required, the user must apply a separate LSP template to the same or different prefix list that contains the same destination node. Each instantiated LSP will have a unique LSP ID and a unique tunnel ID. This command also does not support the signaling of a non-CSPF LSP. The selection of the **no cspf** option in the LSP template is blocked.

Up to five peer prefix policies can be associated with a given LSP template at all times. Each time the user runs the **auto-lsp** command with the same or different prefix policy associations, or the user changes a prefix policy associated with an LSP template, the system re-evaluates the prefix policy. The outcome of the re-evaluation tells MPLS if an existing LSP needs to be torn down or if a new LSP needs to be signaled to a destination address that is already in the TE database.

If a /32 prefix is added to (removed from) or if a prefix range is expanded (shrunk) in a prefix list associated with an LSP template, the preceding prefix policy re-evaluation is performed.

The user must perform a **no shutdown** of the template before the template takes effect. After a template is in use, the user must shut down the template before effecting any changes to the parameters, except for those LSP parameters for which the change can be handled with the Make-Before-Break (MBB) procedures. These parameters are **bandwidth** and enabling **fast-reroute** with or without the **hop-limit** or **node-protect** options. For all other parameters, the user must shut down the template, makes the change, and perform a **no shutdown**. This results in the existing instances of the LSP using this template to be torn down and re-signaled.

When a router with a router ID that matches a prefix in the prefix list appears in the TE database, it is a trigger to signal the LSP. The signaled LSP is installed in the Tunnel Table Manager (TTM) and is available to applications such as LDP-over-RSVP, resolution of BGP label routes, resolution of BGP, IGP, and static routes. It is, however, not available for use as a provisioned SDP for explicit binding or auto-binding by services.

Except for the MBB limitations to the configuration parameter change in the LSP template, MBB procedures for manual and timer based re-signaling of the LSP, for TE Graceful Shutdown and for soft preemption are supported.

The **one-to-one** option under **fast-reroute**, the LSP Diff-Serv **class-type** and **backup-class-type** parameters are not supported. If **diffserv-te** is enabled under RSVP, the auto-created LSP is still signaled but with the default LSP class type.

If the **one-hop** option is specified instead of a prefix list, this command enables the automatic signaling of one-hop point-to-point LSPs using the specified template to all directly connected neighbors. This LSP type is referred to as auto-LSP of type one-hop. Although the provisioning model and CLI syntax differ from that of a mesh LSP only by the absence of a prefix list, the actual behavior is quite different. When this command is executed, the TE database keeps track of each TE link that comes up to a directly connected IGP neighbor whose router ID is discovered. It then instructs MPLS to signals an LSP with a destination address matching the router ID of the neighbor and with a strict hop consisting of the address of the interface used by the TE link. Thus, the **auto-lsp** command with the **one-hop** option results in one or more LSPs signaled to the neighboring router.

An auto-created mesh or one-hop LSP can collect egress statistics at the ingress LER by adding the **egress-statistics** node configuration into the LSP template. The user can also collect ingress statistics at the egress LER by using the same **ingress-statistics** node configuration. The user must specify the full LSP name as signaled by the ingress LER in the RSVP session name field of the Session Attribute object in the received Path message.

This feature also provides for the auto-creation of an SR-TE mesh LSP and for an SR-TE one-hop LSP.

The SR-TE mesh LSP feature specifically binds a **mesh-p2p-srte** LSP template with one or more prefix lists. When the TE database discovers a router that has a router ID matching an entry in the prefix list, it triggers MPLS to instantiate an SR-TE LSP to that router using the LSP parameters in the LSP template.

The SR-TE one-hop LSP feature specifically activates a **one-hop-p2p-srte** LSP template. In this case, the TE database keeps track of each TE link that comes up to a directly connected IGP neighbor. It then instructs MPLS to instantiate a SR-TE LSP with the following parameters:

- the source address of the local router
- an outgoing interface matching the interface index of the TE-link
- a destination address matching the router ID of the neighbor on the TE link

In both types of SR-TE auto-LSP, the router’s hop-to-label translation computes the label stack required to instantiate the LSP.

Note:
An SR-TE auto-LSP can be reported to a PCE but cannot be delegated or have its paths computed by PCE.

The **no** form of this command deletes all LSPs signaled using the specified template and prefix policy. When the **one-hop** option is used, it deletes all one-hop LSPs signaled using the specified template to all directly-connected neighbors.

Parameters

lsp-template *template-name*

Specifies an LSP template name, up to 32 characters in length.

policy *peer-prefix-policy*

Specifies an peer prefix policy name, up to 32 characters in length.

one-hop

Enables the automatic signaling of one-hop point-to-point LSPs.

no auto-rp-discovery

Context

[Tree] (config>service>vprn>pim>rp auto-rp-discovery)

Full Context

configure service vprn pim rp auto-rp-discovery

Description

This command enables the auto-RP protocol in discovery mode. In discovery mode, RP-mapping and RP-candidate messages are received and forwarded to downstream nodes. RP-mapping messages are received locally to learn the availability of RP nodes present in the network. In a VPRN configuration, Nokia recommends that a local loopback interface should be created with the same IP address as the system IP address.

The following configuration guidelines apply.

- Either **bsr-candidate** for IPv4 or **auto-rp-discovery** can be configured; the two mechanisms cannot be enabled together.
- **bsr-candidate** for IPv6 and **auto-rp-discovery** for IPv4 can be enabled together.
- **auto-rp-discovery** cannot be enabled together with **mdt-type sender-only** or **mdt-type receiver-only**, or **wildcard-spmsi** configurations.

This command also enables the auto-RP listener functionality. The auto-RP listener forwards the candidate 224.0.1.39 and mapping 224.0.1.40 messages over the PIM interfaces.

The **no** form of this command disables auto-RP discovery, auto-RP listener, candidate, and mapping-agent.

Default

no auto-rp-discovery

Parameters

candidate

Specifies that the RP is a candidate RP. The auto-RP C-RP announces the candidate RP messages on the 224.0.1.39 multicast address. This functionality is in addition to the listener functionality enabled by the auto RP discovery.

The default value is **no candidate**.

mapping agent

Specifies the mapping agent on the node. The auto-RP MA observes the **auto-rp-announcement** messages, selects the RP, and generates the RP discovery 224.0.1.40 messages. This functionality is in addition to the auto RP discovery functionality.

The default value is **no mapping-agent**.

Platforms

All

auto-rp-discovery

Syntax

auto-rp-discovery [**candidate**] [**mapping-agent**]

no auto-rp-discovery

Context

[Tree] (config>router>pim>rp auto-rp-discovery)

Full Context

configure router pim rp auto-rp-discovery

Description

This command enables the auto-RP protocol in discovery mode. In discovery mode, RP-mapping and RP candidate messages are received and forwarded to downstream nodes. RP-mapping messages are received locally to learn the availability of RP nodes present in the network.

The following configuration guidelines apply.

- Either **bsr-candidate** for IPv4 or **auto-rp-discovery** can be configured; the two mechanisms cannot be enabled together.
- **bsr-candidate** for IPv6 and **auto-rp-discovery** for IPv4 can be enabled together.

This command also enables the auto-RP listener functionality. The auto-RP listener forwards the candidate 224.0.1.39 and mapping 224.0.1.40 messages over the PIM interfaces.

The **no** form of this command disables auto-RP discovery, auto-RP listener, candidate, and mapping-agent.

Default

no auto-rp-discovery

Parameters

candidate

Specifies that the RP is a candidate RP. The auto-RP C-RP announces the candidate RP messages on the 224.0.1.39 multicast address. This functionality is in addition to the listener functionality enabled by the auto RP discovery.

The default value is **no candidate**.

mapping agent

Specifies the mapping agent on the node. The auto-RP MA observes the **auto-rp-announcement** messages, selects the RP, and generates the RP discovery 224.0.1.40 messages. This functionality is in addition to the auto RP discovery functionality.

The default value is **no mapping-agent**.

Full Context

configure port ethernet autonegotiate

Description

This command enables speed and duplex autonegotiation on Fast Ethernet ports and enables far-end fault indicator support on Gb ports.

There are three possible settings for autonegotiation:

- "on” or enabled with full port capabilities advertised
- "off” or disabled where there are no autonegotiation advertisements
- "limited” where a single speed/duplex is advertised.

When autonegotiation is enabled on a port, the link attempts to automatically negotiate the link speed and duplex parameters. If autonegotiation is enabled, the configured duplex and speed parameters are ignored.

When autonegotiation is disabled on a port, the port does not attempt to autonegotiate and will only operate at the **speed** and **duplex** settings configured for the port. Note that disabling autonegotiation on Gb ports is not allowed as the IEEE 802.3 specification for Gb Ethernet requires autonegotiation be enabled for far end fault indication.

If the **autonegotiate limited** keyword option is specified the port will auto-negotiate but will only advertise a specific speed and duplex. The speed and duplex advertised are the **speed** and **duplex** settings configured for the port. One use for limited mode is for multi-speed Gb ports to force Gb operation while keeping autonegotiation enabled for compliance with IEEE 802.3.

Router requires that autonegotiation be disabled or limited for ports in a Link Aggregation Group to guarantee a specific port speed.

The **no** form of this command disables autonegotiation on this port.

Default

autonegotiate

Parameters

limited

The Ethernet interface will automatically negotiate link parameters with the far end, but will only advertise the speed and duplex mode specified by the Ethernet **config>port>ethernet speed** and **config>port>ethernet duplex** commands.

Platforms

All

configure oam-pm session ip twamp-light loss-events avg-flr-event

configure oam-pm session ethernet lmm loss-events avg-flr-event

configure oam-pm session ethernet slm loss-events avg-flr-event

Description

This command sets the frame loss ratio threshold configuration to be applied and checked at the end of the measurement interval for the specified direction. This is a percentage based on average frame loss ratio over the entire measurement interval. If the *clear-threshold-percent* value is not specified, the traffic crossing alarm is stateless. Stateless means the state is not carried forward to other measurement intervals. Each measurement interval is analyzed independently and without regard to any previous window. Each unique event can only be raised once within measurement interval. If the optional *clear-threshold-percent* value is specified, the traffic crossing alarm uses stateful behavior. Stateful means each unique previous event state is carried forward to following measurement intervals. If a threshold crossing event is raised another is not raised until a measurement interval completes and the clear threshold has not been exceeded. A clear event is raised under that condition.

The **no** form of this command removes the event threshold for frame loss ratio. The direction must be included with the **no** command.

Default

no avg-flr-event forward

no avg-flr-event backward

Parameters

forward

Specifies the threshold is applied to the forward direction value.

backward

Specifies the threshold is applied to the backward direction value.

raise-threshold-percentage

Specifies the rising percentage that determines when the event is to be generated.

Values 0.001 to 100.000

clear-threshold-percentage

Specifies an optional value used for stateful behavior that allows the operator to configure a percentage of loss value lower than the rising percentage to indicate when the clear event should be generated.

Values 0.000 to 99.999

A value 0.000 means that the FLR must be 0.000.

5.387 avg-frame-overhead

avg-frame-overhead

Syntax

avg-frame-overhead *percent*

no avg-frame-overhead

Context

[Tree] (config>subscr-mgmt>sla-prof>egress>qos>queue avg-frame-overhead)

Full Context

configure subscriber-mgmt sla-profile egress qos queue avg-frame-overhead

Description

This command configures the average frame overhead to define the average percentage that the offered load to a queue will expand during the frame encapsulation process before sending traffic on-the-wire. While the avg-frame-overhead value may be defined on any queue, it is only used by the system for queues that egress a SONET or SDH port or channel. Queues operating on egress Ethernet ports automatically calculate the frame encapsulation overhead based on a 20 byte per packet rule (8 bytes for preamble and 12 bytes for Inter-Frame Gap).

When calculating the frame encapsulation overhead for port scheduling purposes, the system determines the following values:

- Offered-load — The offered-load of a queue is calculated by starting with the queue depth in octets, adding the received octets at the queue and subtracting queue discard octets. The result is the number of octets the queue has available to transmit. This is the packet based offered-load.
- Frame encapsulation overhead — Using the avg-frame-overhead parameter, the frame encapsulation overhead is simply the queues current offered-load (how much has been received by the queue) multiplied by the avg-frame-overhead. If a queue had an offered load of 10000 octets and the avg-frame-overhead equals 10%, the frame encapsulation overhead would be 10000 x 0.1 or 1000 octets.

For egress Ethernet queues, the frame encapsulation overhead is calculated by multiplying the number of offered-packets for the queue by 20 bytes. If a queue was offered 50 packets then the frame encapsulation overhead would be 50 x 20 or 1000 octets.

- Frame based offered-load — The frame based offered-load is calculated by adding the offered-load to the frame encapsulation overhead. If the offered-load is 10000 octets and the encapsulation overhead was 1000 octets, the frame based offered-load would equal 11000 octets.
- Packet to frame factor — The packet to frame factor is calculated by dividing the frame encapsulation overhead by the queues offered-load (packet based). If the frame encapsulation overhead is 1000 octets and the offered-load is 10000 octets then the packet to frame factor would be 1000 / 10000 or 0.1. When in use, the avg-frame-overhead is the same as the packet to frame factor making this calculation unnecessary.
- Frame based CIR — The frame based CIR is calculated by multiplying the packet to frame factor with the queues configured CIR and then adding that result to that CIR. If the queue CIR is set at 500 octets and the packet to frame factor equals 0.1, the frame based CIR would be 500 x 1.1 or 550 octets.
- Frame based within-cir offered-load — The frame based within-cir offered-load is the portion of the frame based offered-load considered to be within the frame-based CIR. The frame based within-cir offered-load is the lesser of the frame based offered-load and the frame based CIR. If the frame based offered-load equaled 11000 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would be limited to 550 octets. If the frame based offered-load equaled 450 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would equal 450 octets (or the entire frame based offered-load).

As a special case, when a policer, queue or associated intermediate scheduler is configured with a CIR-weight equal to 0, the system automatically sets the queue's frame based within-cir offered-load to 0, preventing it from receiving bandwidth during the port scheduler's within-cir pass.

- Frame based PIR — The frame based PIR is calculated by multiplying the packet to frame factor with the queue's configured PIR and then adding the result to that PIR. If the queue PIR is set to 7500 octets and the packet to frame factor equals 0.1, the frame based PIR would be 7500 x 1.1 or 8250 octets.
- Frame based within-pir offered-load — The frame based within-pir offered-load is the portion of the frame based offered-load considered to be within the frame based PIR. The frame based within-pir offered-load is the lesser of the frame based offered-load and the frame based PIR. If the frame based offered-load equaled 11000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered-load would be limited to 8250 octets. If the frame based offered-load equaled 7000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered load would equal 7000 octets.

Port scheduler operation using frame transformed rates — The port scheduler uses the frame based rates to determine the maximum rates that each queue may receive during the within-cir and above-cir bandwidth allocation passes. During the within-cir pass, a queue may receive up to its frame based within-cir offered-load. The maximum it may receive during the above-cir pass is the difference between the frame based within-pir offered load and the amount of actual bandwidth allocated during the within-cir pass.

SAP and subscriber SLA-profile average frame overhead override — The average frame overhead parameter on a sap-egress may be overridden at an individual egress queue basis. On each SAP and within the sla-profile policy used by subscribers an avg-frame-overhead command may be defined under the queue-override context for each queue. When overridden, the queue instance will use its local value for the average frame overhead instead of the sap-egress defined overhead.

The **no** form of this command reverts to the default. When set to 0, the system uses the packet based queue statistics for calculating port scheduler priority bandwidth allocation. If the no avg-frame-overhead command is executed in a queue-override queue id context, the avg-frame-overhead setting for the queue within the sap-egress QoS policy takes effect.

Default

avg-frame-overhead 0

Parameters

percent

Specifies the average amount of packet-to-frame encapsulation overhead expected for the queue. This value is not used by the system for egress Ethernet queues.

Values 0.00 to 100.00, default

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

configure service ies interface sap ingress queue-override queue avg-frame-overhead

configure service ies subscriber-interface group-interface sap egress queue-override queue avg-frame-overhead

configure service ies interface sap egress queue-override queue avg-frame-overhead

Description

This command configures the average frame overhead to define the average percentage that the offered load to a queue expands during the frame encapsulation process before sending traffic on-the-wire. While the avg-frame-overhead value may be defined on any queue, it is only used by the system for queues that egress a Sonet or SDH port or channel. Queues operating on egress Ethernet ports automatically calculate the frame encapsulation overhead based on a 20 byte per packet rule (8 bytes for preamble and 12 bytes for Inter-Frame Gap).

When calculating the frame encapsulation overhead for port scheduling purposes, the system determines the following values:

- Offered-Load — The offered-load of a queue is calculated by starting with the queue depth in octets, adding the received octets at the queue and subtracting queue discard octets. The result is the number of octets the queue has available to transmit. This is the packet-based offered-load.
- Frame-encapsulation overhead — Using the avg-frame-overhead parameter, the frame-encapsulation overhead is simply the queue's current offered-load (how much has been received by the queue) multiplied by the avg-frame-overhead. If a queue had an offered load of 10,000 octets and the avg-frame-overhead equals 10%, the frame-encapsulation overhead would be 10,000 x 0.1 or 1,000 octets.

For egress Ethernet queues, the frame-encapsulation overhead is calculated by multiplying the number of offered-packets for the queue by 20 bytes. If a queue was offered 50 packets then the frame-encapsulation overhead would be 50 x 20 or 1,000 octets.

- Frame-based offered-load — The frame-based offered-load is calculated by adding the offered-load to the frame-encapsulation overhead. If the offered-load is 10,000 octets and the encapsulation overhead was 1,000 octets, the frame-based offered-load would equal 11,000 octets.
- Packet to frame factor — The packet to frame factor is calculated by dividing the frame-encapsulation overhead by the queue's offered-load (packet-based). If the frame-encapsulation overhead is 1,000 octets and the offered-load is 10,000 octets then the packet to frame factor would be 1,000 / 10,000 or 0.1. When in use, the avg-frame-overhead is the same as the packet to frame factor making this calculation unnecessary.
- Frame-based CIR — The frame-based CIR is calculated by multiplying the packet to frame factor with the queue's configured CIR, then adding that result to that CIR. If the queue CIR is set at 500 octets and the packet to frame factor equals 0.1, the frame-based CIR would be 500 x 1.1 or 550 octets.

- Frame-based within-CIR offered-load — The frame-based within-CIR offered-load is the portion of the frame-based offered-load considered to be within the frame-based CIR. The frame-based within-CIR offered-load is the lesser of the frame-based offered-load and the frame-based CIR. If the frame-based offered-load equaled 11000 octets and the frame-based CIR equaled 550 octets, the frame-based within-CIR offered-load would be limited to 550 octets. If the frame-based offered-load equaled 450 octets and the frame-based CIR equaled 550 octets, the frame-based within-CIR offered-load would equal 450 octets (or the entire frame-based offered-load).

As a special case, when a queue or associated intermediate scheduler is configured with a CIR-weight equal to 0, the system automatically sets the queue's frame-based within-CIR offered-load to 0, preventing it from receiving bandwidth during the port scheduler's within-CIR pass.

- Frame-based PIR — The frame-based PIR is calculated by multiplying the packet to frame factor with the queue's-configured PIR, then adding the result to that PIR. If the queue PIR is set to 7500 octets and the packet to frame factor equals 0.1, the frame-based PIR would be 7,500 x 1.1 or 8,250 octets.
- Frame-based within-pir offered-load — The frame-based within-pir offered-load is the portion of the frame-based offered-load considered to be within the frame-based PIR. The frame-based within-pir offered-load is the lesser of the frame-based offered-load and the frame-based PIR. If the frame-based offered-load equaled 11,000 octets and the frame-based PIR equaled 8250 octets, the frame-based within-pir offered-load would be limited to 8,250 octets. If the frame-based offered-load equaled 7,000 octets and the frame-based PIR equaled 8,250 octets, the frame-based within-pir offered load would equal 7,000 octets.

Port Scheduler Operation Using Frame Transformed Rates — The port scheduler uses the frame-based rates to figure the maximum rates that each queue may receive during the within-CIR and above-CIR bandwidth allocation passes. During the within-CIR pass, a queue may receive up to its frame-based within-CIR offered-load. The maximum it may receive during the above-CIR pass is the difference between the frame-based within-pir offered load and the amount of actual bandwidth allocated during the within-CIR pass.

SAP and Subscriber SLA-Profile Average Frame Overhead Override — The average frame overhead parameter on a sap-egress may be overridden on an individual egress queue basis; on each SAP and within the sla-profile policy used by subscribers. An avg-frame-overhead command may be defined under the queue-override context for each queue. When overridden, the queue instance uses its local value for the average frame overhead instead of the sap-egress defined overhead.

The **no** form of this command restores the average frame overhead parameter for the queue to the default value of 0 percent. When set to 0, the system uses the packet-based queue statistics for calculating port scheduler priority bandwidth allocation. If the **no avg-frame-overhead** command is executed in a queue-override queue id context, the avg-frame-overhead setting for the queue within the sap-egress QoS policy takes effect.

Default

avg-frame-overhead 0

Parameters

percent

Sets the average amount of packet-to-frame encapsulation overhead expected for the queue. This value is not used by the system for egress Ethernet queues. This parameter only applies to the 7450 ESS and 7750 SR.

Values 0.00 to 100.00

Platforms

Full Context

configure service vpls sap egress queue-override queue avg-frame-overhead

Description

This command configures the average frame overhead to define the average percentage that the offered load to a queue will expand during the frame encapsulation process before sending traffic on-the-wire. While the avg-frame-overhead value may be defined on any queue, it is only used by the system for queues that egress a SONET or SDH port or channel. Queues operating on egress Ethernet ports automatically calculate the frame encapsulation overhead based on a 20 byte per packet rule (8 bytes for preamble and 12 bytes for Inter-Frame Gap).

When calculating the frame encapsulation overhead for port scheduling purposes, the system determines the following values:

- Offered-load — The offered-load of a queue is calculated by starting with the queue depth in octets, adding the received octets at the queue and subtracting queue discard octets. The result is the number of octets the queue has available to transmit. This is the packet based offered-load.
- Frame encapsulation overhead — Using the avg-frame-overhead parameter, the frame encapsulation overhead is simply the queue's current offered-load (how much has been received by the queue) multiplied by the avg-frame-overhead. If a queue had an offered load of 10000 octets and the avg-frame-overhead equals 10%, the frame encapsulation overhead would be 10000 x 0.1 or 1000 octets.

For egress Ethernet queues, the frame encapsulation overhead is calculated by multiplying the number of offered-packets for the queue by 20 bytes. If a queue was offered 50 packets then the frame encapsulation overhead would be 50 x 20 or 1000 octets.

- Frame based offered-load — The frame based offered-load is calculated by adding the offered-load to the frame encapsulation overhead. If the offered-load is 10000 octets and the encapsulation overhead was 1000 octets, the frame based offered-load would equal 11000 octets.
- Packet to frame factor — The packet to frame factor is calculated by dividing the frame encapsulation overhead by the queue's offered-load (packet based). If the frame encapsulation overhead is 1000 octets and the offered-load is 10000 octets then the packet to frame factor would be 1000 / 10000 or 0.1. When in use, the avg-frame-overhead will be the same as the packet to frame factor making this calculation unnecessary.

- Frame based CIR — The frame based CIR is calculated by multiplying the packet to frame factor with the queue's configured CIR and then adding that result to that CIR. If the queue CIR is set at 500 octets and the packet to frame factor equals 0.1, the frame based CIR would be 500 x 1.1 or 550 octets.
- Frame based within-cir offered-load — The frame based within-cir offered-load is the portion of the frame based offered-load considered to be within the frame-based CIR. The frame based within-cir offered-load is the lesser of the frame based offered-load and the frame based CIR. If the frame based offered-load equaled 11000 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would be limited to 550 octets. If the frame based offered-load equaled 450 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would equal 450 octets (or the entire frame based offered-load).

As a special case, when a queue or associated intermediate scheduler is configured with a CIR-weight equal to 0, the system automatically sets the queue's frame based within-cir offered-load to 0, preventing it from receiving bandwidth during the port scheduler's within-cir pass.

- Frame based PIR — The frame based PIR is calculated by multiplying the packet to frame factor with the queue's configured PIR and then adding the result to that PIR. If the queue PIR is set to 7500 octets and the packet to frame factor equals 0.1, the frame based PIR would be 7500 x 1.1 or 8250 octets.
- Frame based within-pir offered-load — The frame based within-pir offered-load is the portion of the frame based offered-load considered to be within the frame based PIR. The frame based within-pir offered-load is the lesser of the frame based offered-load and the frame based PIR. If the frame based offered-load equaled 11000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered-load would be limited to 8250 octets. If the frame based offered-load equaled 7000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered load would equal 7000 octets.

Port scheduler operation using frame transformed rates — The port scheduler uses the frame based rates to calculate the maximum rates that each queue may receive during the within-cir and above-cir bandwidth allocation passes. During the within-cir pass, a queue may receive up to its frame based within-cir offered-load. The maximum it may receive during the above-cir pass is the difference between the frame based within-pir offered load and the amount of actual bandwidth allocated during the within-cir pass.

SAP and subscriber SLA-profile average frame overhead override — The average frame overhead parameter on a sap-egress may be overridden at an individual egress queue basis. On each SAP and within the sla-profile policy used by subscribers an avg-frame-overhead command may be defined under the queue-override context for each queue. When overridden, the queue instance will use its local value for the average frame overhead instead of the sap-egress defined overhead.

The **no** form of this command restores the average frame overhead parameter for the queue to the default value of 0 percent. When set to 0, the system uses the packet based queue statistics for calculating port scheduler priority bandwidth allocation. If the no avg-frame-overhead command is executed in a queue-override queue id context, the avg-frame-overhead setting for the queue within the sap-egress QoS policy takes effect.

Default

avg-frame-overhead 0

Parameters

percent

This parameter sets the average amount of packet-to-frame encapsulation overhead expected for the queue. This value is not used by the system for egress Ethernet queues.

Description

This command configures the average frame overhead to define the average percentage that the offered load to a queue will expand during the frame encapsulation process before sending traffic on-the-wire. While the avg-frame-overhead value may be defined on any queue, it is only used by the system for queues that egress a SONET or SDH port or channel. Queues operating on egress Ethernet ports automatically calculate the frame encapsulation overhead based on a 20 byte per packet rule (8 bytes for preamble and 12 bytes for Inter-Frame Gap).

When calculating the frame encapsulation overhead for port scheduling purposes, the system determines the following values:

- Offered-load — The offered-load of a queue is calculated by starting with the queue depth in octets, adding the received octets at the queue and subtracting queue discard octets. The result is the number of octets the queue has available to transmit. This is the packet based offered-load.
- Frame encapsulation overhead — Using the avg-frame-overhead parameter, the frame encapsulation overhead is simply the queue's current offered-load (how much has been received by the queue) multiplied by the avg-frame-overhead. If a queue had an offered load of 10000 octets and the avg-frame-overhead equals 10%, the frame encapsulation overhead would be 10000 x 0.1 or 1000 octets.

  For egress Ethernet queues, the frame encapsulation overhead is calculated by multiplying the number of offered-packets for the queue by 20 bytes. If a queue was offered 50 packets, then the frame encapsulation overhead would be 50 x 20 or 1000 octets.

- Frame based offered-load — The frame based offered-load is calculated by adding the offered-load to the frame encapsulation overhead. If the offered-load is 10000 octets and the encapsulation overhead was 1000 octets, the frame based offered-load would equal 11000 octets.
- Packet to frame factor — The packet to frame factor is calculated by dividing the frame encapsulation overhead by the queue's offered-load (packet based). If the frame encapsulation overhead is 1000 octets and the offered-load is 10000 octets, then the packet to frame factor would be 1000 / 10000 or 0.1. When in use, the avg-frame-overhead will be the same as the packet to frame factor making this calculation unnecessary.
- Frame based CIR — The frame based CIR is calculated by multiplying the packet to frame factor with the queue's configured CIR and then adding that result to that CIR. If the queue CIR is set at 500 octets and the packet to frame factor equals 0.1, the frame based CIR would be 500 x 1.1 or 550 octets.
- Frame based within-cir offered-load — The frame based within-cir offered-load is the portion of the frame based offered-load considered to be within the frame-based CIR. The frame based within-cir offered-load is the lesser of the frame based offered-load and the frame based CIR. If the frame based offered-load equaled 11000 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would be limited to 550 octets. If the frame based offered-load equaled 450 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would equal 450 octets (or the entire frame based offered-load).

  As a special case, when a queue or associated intermediate scheduler is configured with a CIR-weight equal to 0, the system automatically sets the queue's frame based within-cir offered-load to 0, preventing it from receiving bandwidth during the port scheduler's within-cir pass.
- Frame based PIR — The frame based PIR is calculated by multiplying the packet to frame factor with the queue's configured PIR and then adding the result to that PIR. If the queue PIR is set to 7500 octets and the packet to frame factor equals 0.1, the frame based PIR would be 7500 x 1.1 or 8250 octets.
- Frame based within-pir offered-load — The frame based within-pir offered-load is the portion of the frame based offered-load considered to be within the frame based PIR. The frame based within-pir offered-load is the lesser of the frame based offered-load and the frame based PIR. If the frame based offered-load equaled 11000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered-load would be limited to 8250 octets. If the frame based offered-load equaled 7000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered load would equal 7000 octets.

Port scheduler operation using frame transformed rates — The port scheduler uses the frame based rates to figure the maximum rates that each queue may receive during the within-cir and above-cir bandwidth allocation passes. During the within-cir pass, a queue may receive up to its frame based within-cir offered-load. The maximum it may receive during the above-cir pass is the difference between the frame based within-pir offered load and the amount of actual bandwidth allocated during the within-cir pass.

On the 7450 ESS and 7750 SR, SAP and subscriber SLA-profile average frame overhead override — The average frame overhead parameter on a sap-egress may be overridden at an individual egress queue basis. On each SAP and within the sla-profile policy used by subscribers an avg-frame-overhead command may be defined under the queue-override context for each queue. When overridden, the queue instance will use its local value for the average frame overhead instead of the sap-egress defined overhead.

The **no** form of this command restores the average frame overhead parameter for the queue to the default value of 0 percent. When set to 0, the system uses the packet based queue statistics for calculating port scheduler priority bandwidth allocation. If the no avg-frame-overhead command is executed in a queue-override queue id context, the avg-frame-overhead setting for the queue within the sap-egress QoS policy takes effect.

configure service vprn interface sap egress queue-override queue avg-frame-overhead

Description

This command configures the average frame overhead to define the average percentage that the offered load to a queue will expand during the frame encapsulation process before sending traffic on-the-wire. While the avg-frame-overhead value may be defined on any queue, it is only used by the system for queues that egress a Sonet or SDH port or channel. Queues operating on egress Ethernet ports automatically calculate the frame encapsulation overhead based on a 20 byte per packet rule (8 bytes for preamble and 12 bytes for Inter-Frame Gap).

When calculating the frame encapsulation overhead for port scheduling purposes, the system determines the following values:

- Offered-load — The offered-load of a queue is calculated by starting with the queue depth in octets, adding the received octets at the queue and subtracting queue discard octets. The result is the number of octets the queue has available to transmit. This is the packet based offered-load.

- Frame encapsulation overhead — Using the avg-frame-overhead parameter, the frame encapsulation overhead is simply the queue's current offered-load (how much has been received by the queue) multiplied by the avg-frame-overhead. If a queue had an offered load of 10000 octets and the avg-frame-overhead equals 10%, the frame encapsulation overhead would be 10000 x 0.1 or 1000 octets.

For egress Ethernet queues, the frame encapsulation overhead is calculated by multiplying the number of offered-packets for the queue by 20 bytes. If a queue was offered 50 packets then the frame encapsulation overhead would be 50 x 20 or 1000 octets.

- Frame based offered-load — The frame based offered-load is calculated by adding the offered-load to the frame encapsulation overhead. If the offered-load is 10000 octets and the encapsulation overhead was 1000 octets, the frame based offered-load would equal 11000 octets.
- Packet to frame factor — The packet to frame factor is calculated by dividing the frame encapsulation overhead by the queue's offered-load (packet based). If the frame encapsulation overhead is 1000 octets and the offered-load is 10000 octets then the packet to frame factor would be 1000 / 10000 or 0.1. When in use, the avg-frame-overhead will be the same as the packet to frame factor making this calculation unnecessary.
- Frame based CIR — The frame based CIR is calculated by multiplying the packet to frame factor with the queue's configured CIR and then adding that result to that CIR. If the queue CIR is set at 500 octets and the packet to frame factor equals 0.1, the frame based CIR would be 500 x 1.1 or 550 octets.
- Frame based within-cir offered-load — The frame based within-cir offered-load is the portion of the frame based offered-load considered to be within the frame-based CIR. The frame based within-cir offered-load is the lesser of the frame based offered-load and the frame based CIR. If the frame based offered-load equaled 11000 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would be limited to 550 octets. If the frame based offered-load equaled 450 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would equal 450 octets (or the entire frame based offered-load).

As a special case, when a queue or associated intermediate scheduler is configured with a CIR-weight equal to 0, the system automatically sets the queue's frame based within-cir offered-load to 0, preventing it from receiving bandwidth during the port scheduler's within-cir pass.

- Frame based PIR — The frame based PIR is calculated by multiplying the packet to frame factor with the queue's configured PIR and then adding the result to that PIR. If the queue PIR is set to 7500 octets and the packet to frame factor equals 0.1, the frame based PIR would be 7500 x 1.1 or 8250 octets.
- Frame based within-pir offered-load — The frame based within-pir offered-load is the portion of the frame based offered-load considered to be within the frame based PIR. The frame based within-pir offered-load is the lesser of the frame based offered-load and the frame based PIR. If the frame based offered-load equaled 11000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered-load would be limited to 8250 octets. If the frame based offered-load equaled 7000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered load would equal 7000 octets.

Port scheduler operation using frame transformed rates — The port scheduler uses the frame based rates to determine the maximum rates that each queue may receive during the within-cir and above-cir bandwidth allocation passes. During the within-cir pass, a queue may receive up to its frame based within-cir offered-load. The maximum it may receive during the above-cir pass is the difference between the frame based within-pir offered load and the amount of actual bandwidth allocated during the within-cir pass.

SAP and subscriber SLA-profile average frame overhead override — The average frame overhead parameter on a sap-egress may be overridden at an individual egress queue basis. On each SAP and within the sla-profile policy used by subscribers an avg-frame-overhead command may be defined under

the queue-override context for each queue. When overridden, the queue instance will use its local value for the average frame overhead instead of the sap-egress defined overhead.

The **no** form of this command restores the average frame overhead parameter for the queue to the default value of 0 percent. When set to 0, the system uses the packet based queue statistics for calculating port scheduler priority bandwidth allocation. If the no avg-frame-overhead command is executed in a queue-override queue id context, the avg-frame-overhead setting for the queue within the sap-egress QoS policy takes effect.

configure qos sap-egress queue avg-frame-overhead

Description

This command configures the average frame overhead to define the average percentage that the offered load to a queue will expand during the frame encapsulation process before sending traffic on-the-wire. While the avg-frame-overhead value may be defined on any queue, it is only used by the system for queues that egress a Sonet or SDH port or channel. Queues operating on egress Ethernet ports automatically calculate the frame encapsulation overhead based on a 20 byte per packet rule (8 bytes for preamble and 12 bytes for Inter-Frame Gap).

When calculating the frame encapsulation overhead for port scheduling purposes, the system determines the following values:

- Offered-Load — The offered-load of a queue is calculated by starting with the queue depth in octets, adding the received octets at the queue and subtracting queue discard octets. The result is the number of octets the queue has available to transmit. This is the packet-based offered-load.
- Frame-encapsulation overhead — Using the avg-frame-overhead parameter, the frame-encapsulation overhead is simply the queue's current offered-load (how much has been received by the queue) multiplied by the avg-frame-overhead. If a queue had an offered load of 10,000 octets and the avg-frame-overhead equals 10%, the frame-encapsulation overhead would be 10,000 x 0.1 or 1,000 octets.

For egress Ethernet queues, the frame-encapsulation overhead is calculated by multiplying the number of offered-packets for the queue by 20 bytes. If a queue was offered 50 packets, then the frame-encapsulation overhead would be 50 x 20 or 1,000 octets.

- Frame-based offered-load — The frame-based offered-load is calculated by adding the offered-load to the frame-encapsulation overhead. If the offered-load is 10,000 octets and the encapsulation overhead was 1,000 octets, the frame-based offered-load would equal 11,000 octets.
- Packet to frame factor — The packet to frame factor is calculated by dividing the frame-encapsulation overhead by the queue's offered-load (packet-based). If the frame-encapsulation overhead is 1,000 octets and the offered-load is 10,000 octets, then the packet to frame factor would be 1,000 / 10,000 or 0.1. When in use, the avg-frame-overhead will be the same as the packet to frame factor making this calculation unnecessary.
- Frame-based CIR — The frame-based CIR is calculated by multiplying the packet to frame factor with the queue's configured CIR, then adding that result to that CIR. If the queue CIR is set at 500 octets and the packet to frame factor equals 0.1, the frame-based CIR would be 500 x 1.1 or 550 octets.
- Frame-based within-CIR offered-load — The frame-based within-CIR offered-load is the portion of the frame-based offered-load considered to be within the frame-based CIR. The frame-based within-CIR offered-load is the lesser of the frame-based offered-load and the frame-based CIR. If the frame-based offered-load equaled 11000 octets and the frame-based CIR equaled 550 octets, the frame-based within-CIR offered-load would be limited to 550 octets. If the frame-based offered-load equaled 450 octets and the frame-based CIR equaled 550 octets, the frame-based within-CIR offered-load would equal 450 octets (or the entire frame-based offered-load).

As a special case, when a queue or associated intermediate scheduler is configured with a CIR-weight equal to 0, the system automatically sets the queue's frame-based within-CIR offered-load to 0, preventing it from receiving bandwidth during the port scheduler's within-CIR pass.

- Frame-based PIR — The frame-based PIR is calculated by multiplying the packet to frame factor with the queue's-configured PIR, then adding the result to that PIR. If the queue PIR is set to 7500 octets and the packet to frame factor equals 0.1, the frame-based PIR would be 7,500 x 1.1 or 8,250 octets.
- Frame-based within-pir offered-load — The frame-based within-pir offered-load is the portion of the frame-based offered-load considered to be within the frame-based PIR. The frame-based within-pir offered-load is the lesser of the frame-based offered-load and the frame-based PIR. If the frame-based offered-load equaled 11,000 octets and the frame-based PIR equaled 8250 octets, the frame-based within-pir offered-load would be limited to 8,250 octets. If the frame-based offered-load equaled 7,000 octets and the frame-based PIR equaled 8,250 octets, the frame-based within-pir offered load would equal 7,000 octets.

Port Scheduler Operation Using Frame Transformed Rates — The port scheduler uses the frame-based rates to figure the maximum rates that each queue may receive during the within-CIR and above-CIR bandwidth allocation passes. During the within-CIR pass, a queue may receive up to its frame-based within-CIR offered-load. The maximum it may receive during the above-CIR pass is the difference between the frame-based within-pir offered load and the amount of actual bandwidth allocated during the within-CIR pass.

SAP and Subscriber SLA-Profile Average Frame Overhead Override — The average frame overhead parameter on a sap-egress may be overridden on an individual egress queue basis; on each SAP and within the sla-profile policy used by subscribers. An avg-frame-overhead command may be defined under the queue-override context for each queue. When overridden, the queue instance will use its local value for the average frame overhead instead of the sap-egress defined overhead.

The **no** form of this command restores the average frame overhead parameter for the queue to the default value of 0 percent. When set to 0, the system uses the packet-based queue statistics for calculating port scheduler priority bandwidth allocation. If the **no avg-frame-overhead** command is executed in a queue-override queue id context, the avg-frame-overhead setting for the queue within the sap-egress QoS policy takes effect.

Default

no avg-frame-overhead

Parameters

percent

This parameter sets the average amount of packet-to-frame encapsulation overhead expected for the queue. This value is not used by the system for egress Ethernet queues. This parameter only applies to the 7450 ESS and 7750 SR.

configure qos network-queue queue avg-frame-overhead

Description

This command configures the average frame overhead to define the average percentage that the offered load to a queue will expand during the frame encapsulation process before sending traffic on-the-wire. While the avg-frame-overhead value may be defined on any queue, it is only used by the system for queues that egress a SONET or SDH port or channel. Queues operating on egress Ethernet ports automatically calculate the frame encapsulation overhead based on a 20 byte per packet rule (8 bytes for preamble and 12 bytes for Inter-Frame Gap).

When calculating the frame encapsulation overhead for port scheduling purposes, the system determines the following values:

- Offered-Load — The offered-load of a queue is calculated by starting with the queue depth in octets, adding the received octets at the queue and subtracting queue discard octets. The result is the number of octets the queue has available to transmit. This is the packet-based offered-load.
- Frame-encapsulation overhead — Using the avg-frame-overhead parameter, the frame-encapsulation overhead is the queue's current offered-load (how much has been received by the queue) multiplied by the avg-frame-overhead. If a queue had an offered load of 10 000 octets and the avg-frame-overhead equals 10%, the frame-encapsulation overhead would be 10 000 x 0.1 or 1000 octets.

For egress Ethernet queues, the frame-encapsulation overhead is calculated by multiplying the number of offered-packets for the queue by 20 bytes. If a queue was offered 50 packets, the frame-encapsulation overhead would be 50 x 20 or 1000 octets.

- Frame-based offered-load — The frame-based offered-load is calculated by adding the offered-load to the frame-encapsulation overhead. If the offered-load is 10,000 octets and the encapsulation overhead was 1000 octets, the frame-based offered-load would equal 11 000 octets.
- Packet to frame factor — The packet to frame factor is calculated by dividing the frame-encapsulation overhead by the queue's offered-load (packet-based). If the frame-encapsulation overhead is 1000 octets and the offered-load is 10 000 octets, then the packet to frame factor would be 1000 / 10 000 or 0.1. When in use, the avg-frame-overhead will be the same as the packet to frame factor, making this calculation unnecessary.
- Frame-based CIR — The frame-based CIR is calculated by multiplying the packet to frame factor with the queue's-configured CIR, then adding that result to that CIR. If the queue CIR is set at 500 octets and the packet to frame factor equals 0.1, the frame-based CIR would be 500 x 1.1 or 550 octets.
- Frame-based within-CIR offered-load — The frame-based within-CIR offered-load is the portion of the frame-based offered-load considered to be within the frame-based CIR. The frame-based within-CIR offered-load is the lesser of the frame-based offered-load and the frame-based CIR. If the frame-based offered-load equaled 11 000 octets and the frame-based CIR equaled 550 octets, the frame-based within-CIR offered-load would be limited to 550 octets. If the frame-based offered-load equaled 450 octets and the frame-based CIR equaled 550 octets, the frame-based within-CIR offered-load would equal 450 octets (or the entire frame-based offered-load).

As a special case, when a queue or associated intermediate scheduler is configured with a CIR-weight equal to 0, the system automatically sets the queue's frame-based within-CIR offered-load to 0, preventing it from receiving bandwidth during the port scheduler's within-CIR pass.

- Frame-based PIR — The frame-based PIR is calculated by multiplying the packet to frame factor with the queue's-configured PIR, then adding the result to that PIR. If the queue PIR is set to 7500 octets and the packet to frame factor equals 0.1, the frame-based PIR would be 7500 x 1.1 or 8250 octets.
- Frame-based within-pir offered-load — The frame-based within-pir offered-load is the portion of the frame-based offered-load considered to be within the frame-based PIR. The frame-based within-pir offered-load is the lesser of the frame-based offered-load and the frame-based PIR. If the frame-based offered-load equaled 11,000 octets and the frame-based PIR equaled 8250 octets, the frame-based within-pir offered-load would be limited to 8,250 octets. If the frame-based offered-load equaled 7,000 octets and the frame-based PIR equaled 8,250 octets, the frame-based within-pir offered load would equal 7,000 octets.

Port Scheduler Operation Using Frame Transformed Rates — The port scheduler uses the frame-based rates to figure the maximum rates that each queue may receive during the within-CIR and above-CIR bandwidth allocation passes. During the within-CIR pass, a queue may receive up to its frame-based within-CIR offered load. The maximum it may receive during the above-CIR pass is the difference between

the frame-based within-PIR offered load and the amount of actual bandwidth allocated during the within-CIR pass.

SAP and Subscriber SLA-Profile Average Frame Overhead Override (applies only to the 7450 ESS and 7750 SR) — The average frame overhead parameter on a sap-egress may be overridden at an individual egress queue basis. On each SAP and within the sla-profile policy used by subscribers, an avg-frame-overhead command may be defined under the queue-override context for each queue. When overridden, the queue instance will use its local value for the average frame overhead instead of the sap-egress-defined overhead.

The **no** form of this command restores the average frame overhead parameter for the queue to the default value of 0%. When set to 0, the system uses the packet-based queue statistics for calculating port scheduler priority bandwidth allocation. If the **no avg-frame-overhead** command is executed in a queue-override queue id context, the avg-frame-overhead setting for the queue within the sap-egress QoS policy takes effect.

Default

no avg-frame-overhead

Parameters

percent

This parameter sets the average number of packet-to-frame encapsulation overhead expected for the queue. This value is not used by the system for egress Ethernet queues.

Values 0.00 to 100.00

configure service vprn l2tp avp-hiding

Description

This command configures Attribute Value Pair (AVP) hiding. This capability can be used to avoid the passing of sensitive data, such as user passwords, as cleartext in an AVP.

The **no** form of this command reverts to the default value.

Default

no avp-hiding

Parameters

sensitive

AVP hiding is used only for sensitive information (such as username/password).

always

AVP hiding is always used.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

avp-hiding

Syntax

configure service vprn l2tp group avp-hiding

Description

This command configures Attribute Value Pair (AVP) hiding. This capability can be used to avoid the passing of sensitive data, such as user passwords, as cleartext in an AVP.

The **no** form of this command returns the value to **never** allow AVP hiding.

Default

no avp-hiding

Parameters

avp-hiding

Specifies the method to be used for the authentication of the tunnels in this L2TP group.

Values sensitive — AVP hiding is used only for sensitive information (such as username/password).

always — AVP hiding is always used.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

avp-hiding

Syntax

Context

[Tree] (config>isa>aa-grp backup)

Full Context

configure isa application-assurance-group backup

Description

This command assigns an AA ISA or ESA-VM configured in the specified location to this application assurance group. The backup module provides the application assurance group with warm redundancy when the primary module in the group is configured. Primary and backup modules have equal operational status and when both module are coming up, the ones that becomes operational first becomes the active module. A module can serve as a backup for multiple AA ISA cards but only one can fail to it at one time.

On an activity switch from the primary module, configurations are already on the backup MDA but flow state information must be re-learned. Any statistics not yet spooled will be lost. Auto-switching from the backup to primary, once the primary becomes available again, is not supported.

Operator is notified through SNMP events when:

- When the AA service goes down (all modules in the group are down) or comes back up (a module in the group becomes active).
- When AA redundancy fails (one of the modules in the group is down) or recovers (the failed module comes back up).
- When an AA activity switch occurred.

The **no** form of this command removes the specified module from the application assurance group.

Parameters

mda-id

Specifies the slot and MDA, identifying a provisioned module to use as a backup module.

Values

slot/*mda*	
slot	1 to 10, depending on chassis model
mda	1 to 2

esa-vm-id

Specifies the ESA and VM, identifying a provisioned module to use as a backup module; for example, an ESA 1 with VM2 would be referred to as **esa-1/2**.

Values	esa-*esa-id*/*vm-id*	
	esa-id	1 to 16
	vm-id	1 to 4

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

backup

Syntax

backup *mda-id*

no backup

Context

[Tree] (config>isa>tunnel-grp backup)

Full Context

configure isa tunnel-group backup

Description

This command assigns a tunnel ISA configured in the specified slot to this IPsec group. The backup module provides the IPsec group with warm redundancy when the primary module in the group is configured. An IPsec group must always have a primary configured.

Primary and backup modules have equal operational status and when both modules are coming up, the one that becomes operational first becomes the active module. An IPsec module can serve as a backup for multiple IPsec groups but the backup can become active for only one ISA IPsec group at a time.

All configuration information is pushed down to the backup MDA from the CPM once the CPM gets notice that the primary module has gone down. This allows multiple IPsec groups to use the same backup module. Any statistics not yet spooled will be lost. Auto-switching from the backup to primary, once the primary becomes available again, is supported.

The operator is notified through SNMP events when:

- When the ISA IPsec service goes down (all modules in the group are down) or comes back up (a module in the group becomes active).
- When ISA IPsec redundancy fails (one of the modules in the group is down) or recovers (the failed module comes back up).
- When an ISA IPsec activity switch took place.

The **no** form of this command removes the specified module from the IPsec group.

Default

no backup

Parameters

mda-id

Specifies the card/slot identifying a provisioned module to be used as a backup module.

Values mda-id: *slot*/*mda* slot 1 to up to 10 depending on chassis model mda 1 to 2

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

backup

Syntax

[**no**] **backup** *ip-address*

Context

[Tree] (config>router>if>vrrp backup)

Full Context

configure router interface vrrp backup

Description

This command associates router IP addresses with the parental IP interface IP addresses.

The **backup** command has two distinct functions when used in an **owner** or a **non-owner** context of the virtual router instance.

Non-owner virtual router instances actually create a routable IP interface address that is operationally dependent on the virtual router instance mode (master or backup). The **backup** command in **owner** virtual router instances does not create a routable IP interface address; it simply defines the existing parental IP interface IP addresses that are advertised by the virtual router instance.

For **owner** virtual router instances, the **backup** command defines the IP addresses that are advertised within VRRP advertisement messages. This communicates the IP addresses that the master is representing to backup virtual routers receiving the messages. Advertising a correct list is important. The specified *ip-address* must be equal to one of the existing parental IP interface IP addresses (primary or secondary) or the **backup** command fails.

For non-owner virtual router instances, the **backup** command actually creates an IP interface IP address used for routing IP packets and communicating with the system when the access commands are defined (**ntp-reply, ping-reply**, **telnet-reply**, and **ssh-reply**). The specified *ip-address* must be an IP address that is within one of the parental IP interface local subnets created with the **address** or **secondary** commands. If a local subnet does not exist that includes the specified *ip-address* or if *ip-address* is the same IP address as the parental IP interface IP address, the **backup** command fails.

The new interface IP address created with the **backup** command assumes the mask and parameters of the corresponding parent IP interface IP address. The *ip-address* is only active when the virtual router instance is operating in the master state. When not operating as master, the virtual router instance acts as if it is operationally down. It does not respond to ARP requests to *ip-addr*ess, nor does it route packets received with its *vrid* derived source MAC address. A non-master virtual router instance always silently

discards packets destined to *ip-address*. A single virtual router instance may only have a single virtual router IP address from a given parental local subnet. Multiple virtual router instances can define a virtual router IP address from the same local subnet as long as each is a different IP address.

In IPv4, up to sixteen **backup** *ip-address* commands can be executed within the same virtual router instance. Executing **backup** multiple times with the same *ip-addr*ess results in no operation performed and no error generated. At least one successful **backup** *ip-address* command must be executed before the virtual router instance can enter the operational state.

When operating as (non-owner) master, the default functionality associated with *ip-address* is ARP response to ARP requests to *ip-address*, routing of packets destined to the virtual router instance source MAC address and silently discarding packets destined to *ip-address*. Enabling the non-owner-access parameters selectively allows ping, Telnet and SSH connectivity to *ip-address* when the virtual router instance is operating as master.

The **no** form of the command removes the specified virtual router IP address from the virtual router instance. For non-owner virtual router instances, this causes all routing and local access associated with the *ip-address* to cease. For **owner** virtual router instances, the **no backup** command only removes *ip-addr*ess from the list of advertised IP addresses. If the last *ip-address* is removed from the virtual router instance, the virtual router instance will enter the operationally down state

Default

no backup — No virtual router IP address is assigned.

Parameters

ip-address

The virtual router IP address expressed in dotted decimal notation. The IP virtual router IP address must be in the same subnet of the parental IP interface IP address or equal to one of the primary or secondary IP addresses for **owner** virtual router instances.

Values 1.0.0.1 to 223.255.255.254

Platforms

All

backup

Syntax

[**no**] **backup** *ipv6-address*

Context

[Tree] (config>router>if>ipv6>vrrp backup)

Full Context

configure router interface ipv6 vrrp backup

Description

This command associates router IPv6 addresses with the parental IP interface IP addresses.

The **backup** command has two distinct functions when used in an **owner** or a **non-owner** context of the virtual router instance.

Non-owner virtual router instances actually create a routable IP interface address that is operationally dependent on the virtual router instance mode (master or backup). The **backup** command in **owner** virtual router instances does not create a routable IP interface address; it simply defines the existing parental IP interface IP addresses that are advertised by the virtual router instance.

For **owner** virtual router instances, the **backup** command defines the IP addresses that are advertised within VRRP advertisement messages. This communicates the IP addresses that the master is representing to backup virtual routers receiving the messages. Advertising a correct list is important. The specified *ipv6-addr* must be equal to one of the existing parental IP interface IP addresses (link-local or global) or the **backup** command will fail.

For non-owner virtual router instances, the **backup** command actually creates an IP interface IP address used for routing IP packets and communicating with the system when the access commands are defined (**ntp-reply, ping-reply**, **telnet-reply**, and **ssh-reply**). The specified *ipv6-addr* must be an IP address that is within one of the parental IP interface local subnets created with the **link-local-address or address** commands. If a local subnet does not exist that includes the specified *ipv6-addr* or if *ipv6-addr* is the same IP address as the parental IP interface IP address, the **backup** command will fail.

The new interface IP address created with the **backup** command assumes the mask and parameters of the corresponding parent IP interface IP address. The *ipv6-addr* is only active when the virtual router instance is operating in the master state. For IPv6 VRRP, the parental interface's IP address that is in the same subnet as the backup address must be manually-configured, non EUI-64 and configured to be in the preferred state.

When not operating as master, the virtual router instance acts as if it is operationally down. It will not respond to Neighbor Solicitation (NS) requests to *ipv6-addr*, nor will it route packets received with its *vrid* derived source MAC address. A non-master virtual router instance always silently discards packets destined to *ipv6-addr*.

IPv6 allows the configuration of a link-local IPv6 address and multiple global IPv6 addresses on an interface. For each of these configured subnets, a virtual router IP address can be configured. Each IPv6 enabled device on a particular IPv6 subnet dynamically learns the connected IPv6 routers and correlated subnets in addition to the IPv6 default gateway using IPv6 neighbor discovery protocol (RFC4861). This protocol behavior is revised from IPv4 where the default gateway is manually configured or derived from supporting protocols (for example, DHCP). During the IPv6 neighbor discovery process, VRRP enabled routers will use backup IPv6 addresses and correlated derived virtual MAC addresses. Multiple virtual router instances can define a virtual router IP address from the same local subnet as long as each is a different IP address.

Executing **backup** multiple times with the same *ipv6-addr* results in no operation performed and no error generated. At least one successful **backup** *ipv6-addr* command must be executed before the virtual router instance can enter the operational state.

When operating as (non-owner) master, the default functionality associated with *ipv6-addr* results in the IPv6 Neighbor Advertisement response to IPv6 Neighbor Solicitation requests to *ip-addr*, routing of packets destined to the virtual router instance source MAC address, and silently discarding packets destined to *ipv6-addr*. An IPv6 virtual router instance can enter the operational state only if one of the configured backup addresses is a link-local address and the router advertisement of the interface is configured to use the virtual MAC address. Enabling the non-owner-access parameters selectively allows ping, Telnet, and traceroute connectivity to *ipv6-addr* when the virtual router instance is operating as master.

The **no** form of the command removes the specified virtual router IP address from the virtual router instance. For non-owner virtual router instances, this causes all routing and local access associated with the *ipv6-addr* to cease. For **owner** virtual router instances, the **no backup** command only removes *ipv6-*

addr from the list of advertised IP addresses. If the last *ipv6-addr or the link-local address* is removed from the virtual router instance, the virtual router instance will enter the operationally down state

Default

no backup — No virtual router IP address is assigned.

Parameters

ipv6-address

The virtual router IP address is represented as eight groups of four hexadecimal digits, each group representing 16 bits (two octets). The groups are separated by colons (:). The IP virtual router IP address must be in the same subnet of the parental IP interface IP address or equal to one of the parent interface addresses for **owner** virtual router instances.

Values

ipv6-address	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x::d.d.d.d
	x: [0..FFFF]H

6.4 backup-class-type

backup-class-type

Syntax

backup-class-type ct-number

no backup-class-type

Context

[Tree] (config>router>mpls>lsp>primary backup-class-type)

Full Context

configure router mpls lsp primary backup-class-type

Description

This command enables the use of the Diff-Serv backup Class-Type (CT), instead of the Diff-Serv main CT, to signal the LSP primary path when it fails and goes into retry. The Diff-Serv main CT is configured at the LSP level or at the primary path level using the following commands:

config>router>mpls>lsp>class-type *ct-number*

config>router>mpls>lsp>primary>class-type *ct-numbe*r

When an LSP primary path retries due a failure, for example, it fails after being in the UP state, or undergoes any type of Make-Before-Break (MBB), MPLS will retry a new path for the LSP using the main CT. If the first attempt failed, the head-end node performs subsequent retries using the backup CT. This procedure must be followed regardless if the currently used CT by this path is the main or backup CT. This applies to both CSPF and non-CSPF LSPs.

The triggers for using the backup CT after the first retry attempt are:

1. A local interface failure or a control plane failure (hello timeout and so on).
2. Receipt of a PathErr message with a notification of a FRR protection becoming active downstream and/or Receipt of a Resv message with a 'Local-Protection-In-Use' flag set. This invokes the FRR Global Revertive MBB.
3. Receipt of a PathErr message with error code=25 ("Notify") and sub-code=7 ("Local link maintenance required") or a sub-code=8 ("Local node maintenance required"). This invokes the TE Graceful Shutdown MBB.
4. Receipt of a Resv refresh message with the 'Preemption pending' flag set or a PathErr message with error code=34 ("Reroute") and a value=1 ("Reroute request soft preemption"). This invokes the soft preemption MBB.
5. Receipt of a ResvTear message.
6. A configuration change MBB.
7. The user executing the **clear**>**router**>**mpls**>**lsp** command.

When an unmapped LSP primary path goes into retry, it uses the main CT until the number of retries reaches the value of the new **main-ct-retry-limit** parameter. If the path did not come up, it must start using the backup CT at that point in time. By default, this parameter is set to infinite value. The new main-ct-retry-limit parameter has no effect on an LSP primary path which retries due to a failure event.

An unmapped LSP primary path is a path which has never received a Resv in response to the first Path message sent. This can occur when performing a 'shut/no-shut' on the LSP or LSP primary path or when the node reboots. An unmapped LSP primary path goes into retry if the retry timer expired or the head-end node received a PathErr message before the retry timer expired.

When the re-signal timer expires, CSPF will try to find a path with the main CT. The head-end node must re-signal the LSP even if the new path found by CSPF is identical to the existing one since the idea is to restore the main CT for the primary path. A path with main CT is not found, the LSP remains on its current primary path using the backup CT.

When the user performs a manual re-signal of the primary path, CSPF will try to find a path with the main CT. The head-end node must re-signal the LSP as in current implementation.

The **no** form of this command disables the use of the Diff-Serv backup CT.

Default

no backup-class-type

Parameters

ct-number

Specifies the Diff-Serv Class Type number. One or more system forwarding classes can be mapped to a CT.

Values 0 to 7, integer

Context

[Tree] (config>router>ospf>segm-rtng backup-node-sid)

Full Context

configure router ospf segment-routing backup-node-sid

Description

This command enables LFA Protection using segment routing backup node SID.

The objective of this feature is to reduce the label stack pushed in a LFA tunnel next hop of inter-area and inter-domain prefixes. This is applicable in MPLS deployments across multiple IGP areas or domains such in seamless MPLS design.

The user enables the feature by configuring a backup node SID at an ABR/ASBR that is acting as a backup to the primary exit ABR/ASBR of inter-area or inter-as routes learned as BGP labeled routes. The user can enter either a label or an index for the backup node SID.

When a node in a IGP domain resolves a BGP label route for an inter-area or inter-domain prefix via the primary ABR exit router, it will use the backup node SID of this router, which is advertised by the backup ABR/ABR, as the LFA backup instead of the SID to the remote LFA PQ node to save on the pushed label stack.

This feature only allows the configuration of a single backup node SID per IGP instance and per ABR/ASBR. In other words, only a pair of ABR/ASBR nodes can back up each other in an IGP domain. Each time the user invokes the above command within the same IGP instance, it will override any previous

configuration of the backup node SID. The same ABR/ASBR can, however, participate in multiple IGP instances and provide backup support within each instance.

Default

no backup-node-sid

Parameters

ip-prefix/prefix-length

Specifies the IP prefix in dotted decimal notation for the range used by the ABR to advertise that summarizes the area into another area.

Values ip-prefix/mask:

- ip-prefix a.b.c.d (host bits must be 0)

ipv6-prefix:

- x:x:x:x:x:x:x:x (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d
- x: [0 to FFFF]H
- d: [0 to 255]D

prefix-length: 0 to 128

index

Specifies the index for this backup node SID.

Full Context

configure service vprn bgp backup-path

Description

This command enables the computation and use of a backup path for IPv4 and/or IPv6 BGP-learned prefixes belonging to the base router or a particular VPRN. Multiple paths must be received for a prefix to take advantage of this feature. When a prefix has a backup path and its primary paths fail, the affected traffic is rapidly diverted to the backup path without waiting for control plane reconvergence to occur. When many prefixes share the same primary paths, and in some cases also the same backup path, the time to failover traffic to the backup path is independent of the number of prefixes.

By default, IPv4 and IPv6 prefixes do not have a backup path installed in the IOM.

Default

no backup-path

Parameters

ipv4

Keyword that enables the use of a backup path for BGP-learned unlabeled IPv4 prefixes.

ipv6

Keyword that enables the use of a backup path for BGP-learned unlabeled IPv6 prefixes.

label-ipv4

Keyword that enables the use of a backup path for BGP-learned labeled-IPv4 prefixes.

label-ipv6

Keyword that enables support for labeled-unicast IPv6 routes.

configure service vprn interface sap ip-tunnel backup-remote-ip

configure service ies interface sap ip-tunnel backup-remote-ip

Description

This command configures the alternate destination IPv4 or IPv6 address to use for an IP tunnel. This destination address is used only if the primary destination configured with the **remote-ip** command is

unreachable in the delivery service. The **source** address, **remote-ip** address and **backup-remote-ip** address of a tunnel must all belong to the same address family (IPv4 or IPv6). When the backup-remote-ip address contains an IPv6 address it must be a global unicast address.

The **no** form of this command deletes the backup-destination address from the tunnel configuration.

Default

no backup-remote-ip

Parameters

ip-address

Specifies the destination IPv4 address or IPv6 address of the tunnel.

Values ipv4-address:

- a.b.c.d

ipv6-address:

- x:x:x:x:x:x:x:x (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d

[Tree] (config>service>vprn>static-route-entry backup-tag)

Full Context

configure router static-route-entry backup-tag

configure service vprn static-route-entry backup-tag

Description

This command associates a 4-byte backup route tag with the static route when the **backup-next-hop** command is activated. The tag value is an identifier that can be used in route policies to control distribution of the static route into other protocols when the backup-next-hop is activated for the associated static route.

The tag specified at this level of the static route causes the tag values that are configured under the **next-hop**, **black-hole**, and **indirect** contexts of the static route to be ignored.

The **no** form of this command removes the tag association.

Default

no backup-tag

Parameters

tag-id

Specifies an integer tag value.

Values 1 to 4294967295

configure lag access bandwidth

configure port ethernet access bandwidth

Description

This command configures the administrator bandwidth assigned and available to ports and LAGs for use by SAP bandwidth Connection Admission Control (CAC). The administrator bandwidth on a port or LAG can be overbooked or underbooked using the **booking-factor** command.

Port or LAG: Increasing the port or LAG admin bandwidth will increase the available admin bandwidth on that port or LAG. Reducing the port or LAG admin bandwidth will reduce the available admin bandwidth on that port or LAG, however, if the reduction of available admin bandwidth would cause it to be insufficient to cover the sum of the current SAP admin bandwidth on the port or LAG then the command will fail.

The **no** form of this command reverts to the default value.

Default

no bandwidth

Parameters

bandwidth

Specifies the administrator bandwidth, in kb/s, that is assigned to the port or LAG.

Values 1 to 6400000000

Full Context

configure service ipipe spoke-sdp bandwidth

configure service cpipe spoke-sdp bandwidth

configure service epipe spoke-sdp bandwidth

Description

This command specifies the bandwidth to be used for VLL bandwidth accounting by the VLL CAC feature.

The service manager keeps track of the available bandwidth for each SDP. The maximum value is the sum of the bandwidths of all constituent LSPs in the SDP. The SDP available bandwidth is adjusted by the user configured booking factor.

If an LSP consists of a primary and many secondary standby LSPs, then the bandwidth used in the maximum SDP available bandwidth is that of the active path. Any change to and LSP active path bandwidth will update the maximum SDP available bandwidth. Note however that a change to any constituent LSP bandwidth due to re-signaling of the primary LSP path or the activation of a secondary path which causes overbooking of the maximum SDP available bandwidth causes a warning and a trap to be issued but no further action is taken. The activation of a bypass or detour LSP in the path of the primary LSP does not change the maximum SDP available bandwidth.

When the user binds a VLL service to this SDP, an amount of bandwidth equal to bandwidth is subtracted from the SDP available bandwidth adjusted by the booking factor. When the user deletes this VLL service binding from this SDP, an amount of bandwidth equal to bandwidth is added back into the SDP available bandwidth.

If the total SDP available bandwidth when adding this VLL service is about to overbook, a warning is issued and the binding is rejected. This means that the spoke SDP bandwidth does not update the maximum SDP available bandwidth. In this case, the spoke SDP is put in operational down state and a status message of "pseudowire not forwarding" is sent to the remote SR-series PE node. A trap is also generated. The service manager will not put the spoke SDP into an operationally up state until the user executes a **shutdown** command and then a **no-shutdown** command of the spoke SDP and the bandwidth check succeeds. Therefore, the service manager will not automatically audit spoke SDPs subsequently to their creation to check if bandwidth is available.

If the VLL service contains an endpoint with multiple redundant spoke SDPs, each spoke SDP will have its bandwidth checked against the available bandwidth of the corresponding SDP.

If the VLL service performs a pseudowire switching (VC switching) function, each spoke SDP is separately checked for bandwidth against the corresponding SDP.

This feature does not alter the way service packets are sprayed over multiple RSVP LSPs, which are part of the same SDP. That is, by default load balancing of service packets occurs over the SDP LSPs based on service-id, or based on a hash of the packet header if ingress SAP shared queuing is enabled. In both cases, the VLL bandwidth is not checked against the available bandwidth of the selected LSPs but on the total SDP available bandwidth. Therefore, if there is a single LSP per SDP, these two matches.

If class-forwarding is enabled on the SDP, VLL service packets are forwarded to the SDP LSP which the packet forwarding class maps to, or if this is down to the default LSP. However, the VLL bandwidth is not checked against the selected LSP available bandwidth but on the total SDP available bandwidth. If there is a single LSP per SDP, these two matches.

If a non-zero bandwidth is specified for a VLL service and attempts to bind the service to an LDP or a GRE SDP, a warning is issued that CAC failed but the VLL is established. A trap is also generated.

The **no** form of this command reverts to the default value.

Parameters

bw-value

The bandwidth to be used for VLL bandwidth accounting by the VLL CAC feature, in kilobits per second.

Values 0 to 100000000

Default 0

Platforms

All

6.12 bandwidth-policer

bandwidth-policer

Syntax

bandwidth-policer *policer-name*

no bandwidth-policer

Context

[Tree] (config>app-assure>group>policy>aqp>entry>action bandwidth-policer)

Full Context

configure application-assurance group policy app-qos-policy entry action bandwidth-policer

Description

This command assigns an existing bandwidth policer as an action on flows matching this AQP entry. The match criteria for the AQP entry must specify a uni-directional traffic direction before a policer action can be configured. If a policer is used in one direction in an AQP match entry the same policer name cannot be used by another AQP entry which uses a different traffic direction match criteria.

When multiple policers apply to a single flow, the final action on a packet is the worst case of all policer outcomes (for example, if one of the policers marks packet out of profile, the final marking will reflect that).

The **no** form of this command removes bandwidth policer from actions on flows matching this AQP entry.

Default

no bandwidth-policer

Parameters

policer-name

Specifies the name of the existing flow setup rate policer for this application assurance profile. The *policer-name* is configured in the **config>app-assure>group>policer** context.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

6.13 bandwidth-policy

bandwidth-policy

Syntax

bandwidth-policy *policy-name* [**create**]

no bandwidth-policy *policy-name*

Context

[Tree] (config>mcast-mgmt bandwidth-policy)

Full Context

configure mcast-management bandwidth-policy

Description

This command creates a multicast bandwidth policy. Bandwidth policies are used to manage the ingress multicast path bandwidth. Each forwarding plane supports multicast forwarding paths into the switch fabric. By default, two paths are available; the multicast high priority path and the multicast low priority path. Multicast packets are forwarded on either path based on the expedited or non-expedited (best-effort) nature of the queue the packets are scheduled from. The ingress forwarding plane uses the classification rules to determine the forwarding class of each multicast packet and uses the forwarding class to queue mapping to decide which ingress multipoint queue forwards the packet.

When multicast path management is enabled, the ingress forwarding plane allows IP multicast snooped or routed packets to be placed on to the two multicast paths independently of the ingress classification rules. The high priority multicast path is treated as the primary path and the low priority multicast path is treated as the secondary path. The ingress bandwidth manager evaluates each multicast FIB (M-FIB) record to determine which path is best based on ingress bandwidth, number of switch fabric destinations and the fill level of each path. Explicit path association is also supported.

Dynamic Bandwidth Activity Monitoring

When ingress multicast path management is enabled on an MDA, the system monitors the in-use bandwidth associated with each Layer 2 and Layer 3 ingress multicast record. When records are first populated by static, snooping or routing protocols, they are first assumed to be inactive. An inactive record is not considered to be currently consuming ingress multicast path bandwidth.

Within the multicast-info-policy, the bandwidth activity of the new record was configured to be either managed based on an administrative bandwidth, or based on the dynamic bandwidth rate table. The bandwidth-policy associated with ingress MDA contains the configuration parameters for creating the dynamic bandwidth rate table. The purpose of the table is to allow for the system to monitor the bandwidth activity associated with a multicast record and compare the current rate against several rate thresholds. Rate thresholds are used to allow a multicast streams rate to fluctuate between a given range while keeping the managed rate at a certain level. Multiple dynamic managed rates are supported in the table to allow monitoring of different types of multicast traffic. Each rate threshold is associated with a rising and falling threshold that defines when the specified rate should be used and when the next lower rate should be used.

Once a record’s monitored current rate rises to the first dynamic rising threshold, the record is active and the system then manages the bandwidth the record represents based on the parameters associated with the record in the records multicast-info-policy and the configured path information in the MDAs associated bandwidth-policy.

Ingress Multicast Path Parameters

The bandwidth-policy also contains the configuration parameters for each of the managed ingress multicast paths. The queue default parameters can be overridden for each primary and secondary path. In addition, the number of secondary paths (and by implication the number of primary paths) can be overridden.

Default Bandwidth Policy

A bandwidth policy with the name 'default’ always exists and is used as the default bandwidth policy when ingress multicast path management is enabled without an explicit bandwidth policy defined on an FP. The default policy cannot be deleted or edited.

The **no** form of this command removes the specified bandwidth policy from the system. The bandwidth policy associations must be removed from MDA configurations before it can be removed.

Default

bandwidth-policy "default”

Parameters

policy-name

Specifies the name of the bandwidth policy, up to 32 characters. Each bandwidth policy must be uniquely named within the system. 32 policies can be configured per system.

create

This keyword is required if creating a new bandwidth policy when the system is configured to require the explicit use of the keyword to prevent accidental object creation. Objects may be accidentally created when this protection is disabled and an object name is mistyped when attempting to edit the object. This keyword is not required when the protection is disabled. The keyword is ignored when the bandwidth policy name already exists.

Platforms

7450 ESS, 7750 SR-1x-48D, 7750 SR-1x-92S, 7750 SR-7/12/12e, 7750 SR-s, 7950 XRS, VSR

bandwidth-policy

Syntax

bandwidth-policy *policy-name*

no bandwidth-policy

Context

[Tree] (config>card>fp>ingress>mcast-path-management bandwidth-policy)

Full Context

configure card fp ingress mcast-path-management bandwidth-policy

Description

This command explicitly associates a bandwidth policy to a forwarding plane. The bandwidth policy defines the dynamic rate table and the multicast paths bandwidth and queuing parameters.

If a bandwidth policy is not explicitly associated with a forwarding plane, the default bandwidth policy is used when ingress multicast path management is enabled.

The **no** form of this command removes an explicit bandwidth policy from a forwarding plane or MDA and restores the default bandwidth policy.

Parameters

policy-name

The policy-name parameter is required and defines the bandwidth policy that should be associated with the MDA or forwarding plane for ingress multicast path management. If the policy name does not exist, the bandwidth-policy command will fail. The name can be up to 32 characters long.

Values Any existing bandwidth policy name.

Default default

Platforms

7450 ESS, 7750 SR-1x-48D, 7750 SR-1x-92S, 7750 SR-7/12/12e, 7750 SR-s, 7950 XRS, VSR

configure port tdm e1 bert

configure port tdm e3 bert

configure port tdm ds1 bert

Description

This command initiates or restarts a Bit Error Rate Test (BERT) on the associated DS-1/E-1 or DS-3/E-3 circuit.

The associated DS-1, E-1, DS-3, or E-3 must be in a shutdown (admin down) state to initiate this test.

The **no** form of this command terminates the BERT test if it has not yet completed.

Notes:

- This command is not saved in the router configuration between boots.
- The 4-port OC-3/STM-1 and the 1-port OC-12/STM-4 ASAP MDA supports up to 28 concurrent BERT tests per MDA. The 4-port and 12-port DS-3/E-3 ASAP MDAs support a single BERT test per MDA. An attempt to configure more BERT tests can result in an error indicating an operation failure due to resource exhaustion.
- If the ASAP MDA BERT error insertion **rate** command is executed when tests are running, it will not take effect until test is restarted.

Default

bert 2e3

Parameters

duration

Sets the duration for the BERT test.

Values Up to 24 hours, in seconds or hh:mm:ss format

ones

Sends an all ones pattern.

zeros

Sends an all zeros pattern.

alternating

Sends an alternating ones and zeros pattern.

2e3

Sends a pseudo-random 2^3 -1 pattern.

2e9

Sends a pseudo-random 2^9 -1 pattern.

2e15

Sends a pseudo-random 2^15 -1 pattern.

2e20

Sends a pseudo-random 2^20 -1 pattern. Not available on channelized ASAP MDAs.

2e23

Sends a pseudo-random 2^23 -1 pattern.

Full Context

configure service ies interface ipv6 bfd

configure service vprn interface ipv6 bfd

configure service ies interface bfd

configure service vprn network-interface bfd

configure service vprn interface bfd

Description

This command specifies the BFD parameters for the associated IP interface. If no parameters are defined the default value are used.

The multiplier specifies the number of consecutive BFD messages that must be missed from the peer before the BFD session state is changed to down and the upper level protocols (OSPF, IS-IS, BGP or PIM) is notified of the fault.

The **no** form of this command removes BFD from the interface.

Note:
On the 7750 SR, the *transmit-interval,* **receive** *receive-interval, and* **echo-receive** *echo-interval* values can only be modified to a value less than 100 when:

1. The **type cpm-np option** is explicitly configured.
2. The service is shut down (**shutdown**)
3. The interval is specified 10 to 100000.
4. The service is re-enabled (**no shutdown**)

To remove the **type cpm-np** option, re-issue the **bfd** command without specifying the **type** parameter.

Parameters

transmit-interval

Sets the transmit interval for the BFD session.

Values 100 to 100000
10 to 100000 (for the 7750 SR only; see the note above)

Default 100

receive ***receive-interval***

Sets the receive interval for the BFD session.

Values 100 to 100000
10 to 100000 (for the 7750 SR only; see the note above)

Default 100

multiplier ***multiplier***

Sets the multiplier for the BFD session.

Values 3 to 20

Default 3

echo-receive *echo-interval*

Sets the minimum echo receive interval, in milliseconds, for the BFD session.

Values 100 to 100000

10 to 100000 (for the 7750 SR only; see the Note above)

Default 100

type cpm-np

For the 7750 SR only, specifies that BFD sessions associated with this interface is created on the CPM network processor to allow for fast timers down to 10 ms granularity.

Platforms

All

Full Context

configure service vprn subscriber-interface bfd

configure service vprn subscriber-interface group-interface bfd

configure service vprn subscriber-interface group-interface ipv6 bfd

configure service vprn subscriber-interface ipv6 bfd

Description

This command specifies the BFD attributes for the associated retail subscriber interface or group interface. If no parameters are defined the default value are used.

The **no** form of this command removes BFD from the interface.

To remove the **type cpm-np** option, re-issue the **bfd** command without specifying the **type** parameter.

Default

no bfd

Parameters

transmit-interval

Sets the transmit interval for the BFD session.

Values 10 to 100000

Default 100

Note:
On the 7750 SR, the *transmit-interval* can only be modified to a value less than 100 when the **type cpm-np option** is explicitly configured.

receive-interval

Sets the receive interval for the BFD session.

Values 10 to 100000

Default 100

Note:
On the 7750 SR, the *receive-interval* can only be modified to a value less than 100 when the **type cpm-np option** is explicitly configured.

multiplier

Sets the multiplier for the BFD session. A multiplier of less than 3 should not be used in production environments. The multiplier specifies the number of consecutive BFD messages that must be missed from the peer before the BFD session state is changed to down and the upper level protocol (BGP) is notified of the fault.

Values 1 to 20

Default 3

echo-interval

Sets the minimum echo receive interval, in milliseconds, for the BFD session.

Values 100 to 100000

Default 0

type cpm-np

Sets the CPM network processor as the local termination point for the BFD session to allow for fast timers down to 10ms granularity.

Syntax

bfd *transmit-interval* [**receive** *receive-interval*] [**multiplier** *multiplier*] [**echo-receive** *echo-interval*] [**type cpm-np**]

no bfd

Context

[Tree] (config>router>if bfd)

[Tree] (config>router>if>ipv6 bfd)

Full Context

configure router interface bfd

configure router interface ipv6 bfd

Description

This command specifies the bidirectional forwarding detection (BFD) parameters for the associated IP interface. If no parameters are defined the default values are used.

The multiplier specifies the number of consecutive BFD messages that must be missed from the peer before the BFD session state is changed to down and the upper level protocols (OSPF, IS-IS, BGP or PIM) is notified of the fault.

The **no** form of this command removes BFD from the router interface regardless of the IGP/RSVP.

Important notes: On the 7750 SR and 7950 XRS SR OS, the *transmit-interval* and **receive receive-interval** values can only be modified to a value less than 100 ms when:

1. The **type cpm-np option** is explicitly configured.
2. The service is shut down (**shutdown**)
3. The interval is specified 10 to 100000.
4. The service is re-enabled (**no shutdown**)

To remove the **type cpm-np** option, re-issue the **bfd** command without specifying the **type** parameter.

Default

no bfd

Parameters

transmit-interval

Sets the transmit interval, in milliseconds, for the BFD session.

Values 10 to 100000 (see Important Notes above) The minimum value is 300 msec for central BFD sessions in the 7950 XRS.

Default 100

receive-interval

Sets the receive interval, in milliseconds, for the BFD session.

Values 10 to 100000 (see Important Notes above)

Default 100

multiplier

Sets the multiplier for the BFD session. A multiplier of less than 3 should not be used in production environments.

Values 1 to 20

Default 3

echo-interval

Sets the minimum echo receive interval, in milliseconds, for the session.

Values 100 to 100000

Default 0

cpm-np

Selects the CPM network processor type as the local termination point for the BFD session for the 7750 SR and 7950 XRS. See Important Notes, above.

Full Context

configure service ies subscriber-interface group-interface srrp bfd-enable

configure service vprn subscriber-interface group-interface srrp bfd-enable

Description

This commands assigns a bi-directional forwarding (BFD) session providing heart-beat mechanism for the given VRRP/SRRP instance. There can be only one BFD session assigned to any given VRRP/SRRP instance, but there can be multiple SRRP/VRRP sessions using the same BFD session. If the interface configured with BFD is using a LAG or a spoke-SDP, the BFD transmit and receive intervals need to be set to a minimum of 300 ms.

BFD control the state of the associated interface. By enabling BFD on a given protocol interface, the state of the protocol interface is tied to the state of the BFD session between the local node and the remote node. The parameters used for the BFD are set via the BFD command under the IP interface. The specified interface may not be configured with BFD; when it is, the virtual router will then initiate the BFD session.

The **no** form of this command removes BFD from the configuration.

Parameters

service-id

Specifies the service ID of the interface running BFD. If no *svc-id* is specified then it indicates that the interface is a network interface in the Base router instance.

This variant of the command is only supported in 'classic' configuration-mode (**configure system management-interface configuration-mode classic**). The **bfd-enable interface** *interface-name* **dst-ip** *ip-address* **name** *name* variant can be used in all configuration modes.

Values {*id* | *svc-name*}

id:	1 to 2147483647
svc-name:	Specifies an existing service name up to 64 characters (*svc-name* is an alias for input only. The *svc-name* gets replaced with an id automatically by SR OS in the configuration)

interface *interface-name*

Specifies the name of the interface running BFD, up to 32 characters.

dst-ip *ip-address*

Specifies the destination address for the BFD session.

name *service-name*

Specifies a service name, up to 64 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

configure service vprn isis interface bfd-enable

Description

This command enables the use of bi-directional forwarding (BFD) to control IPv4 or adjacencies. By enabling BFD on an IPv4 or IPv6 protocol interface, the state of the protocol interface is tied to the state of the BFD session between the local node and the remote node. The parameters used for the BFD are set by the BFD command under the IP interface. This command must be given separately to enable or disable BFD for IPv4 and IPv6.

The **no** form of this command removes BFD from the associated adjacency.

Default

no bfd-enable ipv4

no bfd-enable ipv6

Parameters

ipv4

Keyword to enable BFD to control IPv4 adjacencies.

ipv6

Keyword to enable BFD to control IPv6 adjacencies.

include-bfd-tlv

Enables support for the IS-IS BFD TLV options in accordance with RFC 6213, which specifies that a BFD session must be established before an IS-IS adjacency can transition to the established state. This option must be enabled on all IS-IS neighbors on a shared interface.

Platforms

[Tree] (config>service>vprn>ospf>area>if bfd-enable)

Full Context

configure service vprn ospf3 area interface bfd-enable

configure service vprn ospf area interface bfd-enable

Description

This command configures Bidirectional Forwarding Detection (BFD) to control the state of the associated protocol interface. By enabling BFD on a protocol interface, the state of the protocol interface is tied to the state of the BFD session between the local node and the remote node. The parameters used for the BFD session are set using the **bfd** command in the associated IP interface context.

The **no** form of this command removes BFD from the associated IGP protocol adjacency.

Default

no bfd-enable

Parameters

remain-down-on-failure

Keyword to force adjacency down on BFD failure.

strict

Keyword to specify that the system uses BFD strict-mode, which requires that an active BFD session exists between the OSPF neighbors before establishing a full adjacency. When this keyword is configured, the router uses Link-Local Signaling (LLS) with the B-flag set to instruct OSPF neighbors that BFD must be enabled on the link. BFD strict-mode requires that both sides have the B-flag set.

During OSPFv3 BFD strict-mode operations, the router advertises the Local Interface IPv4 Address TLV using LLS, but the SR OS router continues to use IPv6-based BFD sessions for both the IPv4 and IPv6 address families.

strict-mode-holddown *number*

Specifies a delay in bringing up the OSPF adjacency after the BFD session is established. Holddown helps mitigate potential routing churn when BFD sessions are unstable. The holddown timer is reset on an adjacency when a BFD session operationally toggles.

Values 1 to 600

configure service vprn rip bfd-enable

configure service vprn ripng group bfd-enable

configure service vprn rip group neighbor bfd-enable

configure service vprn ripng bfd-enable

Description

This command enables bi-directional forwarding (BFD) to control the state of the associated protocol adjacency. By enabling BFD on a given protocol interface, the state of the RIP neighbor is tied to the state of the BFD session between the local node and the remote node. The parameters used for the BFD are set using the **bfd** command under the IP interface configuration context.

The **no** form of this command removes BFD from the associated protocol adjacency.

no bfd-enable

Context

[Tree] (config>router>ldp>if-params>if bfd-enable)

Full Context

configure router ldp interface-parameters interface bfd-enable

Description

This command enables tracking of the Hello adjacency to an LDP peer using BFD.

The **ipv6** option for this command is not supported on the 7450 ESS.

When this command is enabled on an LDP interface, LDP registers with BFD and starts tracking the LSR-id of all peers it formed Hello adjacencies with over that LDP interface. The LDP hello mechanism is used to determine the remote address to be used for the BFD session. The parameters used for the BFD session, that is, transmit-interval, receive-interval, and multiplier are those configured under the IP interface in existing implementation: **config>router>if>bfd**.

The operation of BFD over an LDP interface tracks the next-hop of the IPv4 and IPv6 prefixes in addition to tracking the LDP peer address of the Hello adjacency over that link. This is required since LDP can resolve both IPv4 and IPv6 prefix FECs over a single IPv4 or IPv6 LDP session and as such the next-hop of a prefix will not necessarily match the LDP peer source address of the Hello adjacency.

The failure of either or both of the BFD session tracking the FEC next-hop and the one tracking the Hello adjacency will cause the LFA backup NHLFE for the FEC to be activated or the FEC to be re-resolved if there is no FRR backup.

When multiple links exist to the same LDP peer, a Hello adjacency is established over each link and a separate BFD session is enabled on each LDP interface. If a BFD session times out on a specific link, LDP will immediately associate the LDP session with one of the remaining Hello adjacencies and trigger the LDP FRR procedures. As soon as the last Hello adjacency goes down due to BFD timing out, the LDP session goes down and the LDP FRR procedures will be triggered.

The **no** form of this command disables BFD on the LDP interface.

Full Context

configure router mpls lsp protect-tp-path mep bfd-enable

configure router mpls lsp working-tp-path mep bfd-enable

Description

The command associates the operational state of an MPLS-TP path with a BFD session whose control packets flow on the path. The BFD packets are encapsulated in a generic associated channel (G-ACh) on the path. The timer parameters of the BFD session are taken from the OAM template of the MEP.

A value of **cc** means that the BFD session is only used for continuity check of the MPLS-TP path. In this case, the CC timer parameters of the OAM template apply. A value of **cv** means that the BFD session is used for both continuity checking and connectivity verification, and the CV timers of the OAM template apply.

This form of the **bfd-enable** command is only applicable when it is configured under a MEP used on an MPLS-TP working or protection path.

Default

no bfd-enable

Parameters

cc

Indicates that BFD runs in CC only mode. This mode uses G-ACh channel type 0x07.

cc_cv

Indicates that BFD runs in combined CC and CV mode. This mode uses channel type 0x22 for MPLS-TP CC packets, and 0x23 for MPLS-TP CV packets.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

bfd-enable

Syntax

[**no**] **bfd-enable**

Context

[Tree] (config>router>rsvp>interface bfd-enable)

Full Context

configure router rsvp interface bfd-enable

Description

This command enables the use of bi-directional forwarding (BFD) to control the state of the associated RSVP interface. This causes RSVP to register the interface with the BFD session on that interface.

The user configures the BFD session parameters, such as, **transmit-interval**, **receive-interval**, and **multiplier**, under the IP interface in the **config>router> if>bfd** context.

Note:
It is possible that the BFD session on the interface was started because of a prior registration with another protocol, for example, OSPF or IS-IS.

The registration of an RSVP interface with BFD is performed at the time of neighbor gets its first session. This means when this node sends or receives a new Path message over the interface. If however the session did not come up, due to not receiving a Resv for a new path message sent after the maximum number of re-tries, the LSP is shutdown and the node de-registers with BFD. In general, the registration of RSVP with BFD is removed as soon as the last RSVP session is cleared.

The registration of an RSVP interface with BFD is performed independent of whether RSVP hello is enabled on the interface or not. However, hello timeout will clear all sessions towards the neighbor and RSVP de-registers with BFD at clearing of the last session.

An RSVP session is associated with a neighbor based on the interface address the path message is sent to. If multiple interfaces exist to the same node, each interface is treated as a separate RSVP neighbor. The user will have to enable BFD on each interface and RSVP will register with the BFD session running with each of those neighbors independently

Similarly the disabling of BFD on the interface results in removing registration of the interface with BFD.

When a BFD session transitions to DOWN state, the following actions are triggered. For RSVP signaled LSPs, this triggers activation of FRR bypass/detour backup (PLR role), global revertive (head-end role), and switchover to secondary if any (head-end role) for affected LSPs with FRR enabled. It triggers switchover to secondary if any and scheduling of re-tries for signaling the primary path of the non-FRR affected LSPs (head-end role).

The **no** form of this command removes BFD from the associated RSVP protocol adjacency.

configure service vprn interface ipsec ipsec-tunnel bfd-enable

configure service vprn interface sap ipsec-tunnel bfd-enable

configure router interface ipsec ipsec-tunnel bfd-enable

Description

This command assigns a BFD session to provide a heart-beat mechanism for a given IPsec tunnel. There can be only one BFD session assigned to any given IPsec tunnel, but there can be multiple IPsec tunnels using same BFD session. BFD controls the state of the associated tunnel. If the BFD session goes down, the system will also bring down the associated non-designated IPsec tunnel.

Parameters

service-name

Specifies the service name, up to 64 characters, on which the BFD session resides.

interface-name

Specifies the name, up to 32 characters, of the interface used by the BFD session.

ip-address

Specifies the destination address to be used for the BFD session.

Platforms

[Tree] (config>router>if>vrrp bfd-enable)

Full Context

configure router interface ipv6 vrrp bfd-enable

configure router interface vrrp bfd-enable

Description

This commands assigns a bidirectional forwarding detect (BFD) session to a specific VRRP/SRRP instance. This BFD sessions provided a heartbeat mechanism that can be used to speed up the transition of the standby VRRP router to an active state. If the associated BFD session fails, the VRRP routers will immediately send a VRRP Advertisement message. In addition, the standby VRRP router(s) will transition to a Master state to speed convergence. The normal VRRP election process will then take place based on the Advertisement messages sent by all VRRP routers.

There can be only one BFD session assigned to any given VRRP/SRRP instance, but there can be multiple SRRP/VRRP sessions using the same BFD session.

The parameters used for the BFD sessions are set by the BFD command under the IP interface.

The **no** form of this command removes BFD from the configuration.

Parameters

interface-name

Specifies the name of the interface running BFD. The specified interface may not yet be configured with BFD. However, when it is, this virtual router will then initiate the BFD session.

ip-address

Specifies the destination address to be used for the BFD session.

svc-id

Specifies the service ID of the interface running BFD.

Values *service-id*:1 to 2147483647

svc-name: 64 characters maximum

configure router isis interface bfd-enable

Description

This command enables the use of bidirectional forwarding detection (BFD) to control IPv4 or IPv6 adjacencies. By enabling BFD on an IPv4 or IPv6 protocol interface, the state of the protocol interface is tied to the state of the BFD session between the local node and the remote node. The parameters used for the BFD are set by the BFD command under the IP interface. This command must be given separately to enable or disable BFD for both IPv4 and IPv6.

The **no** form of this command removes BFD from the associated adjacency.

Default

no bfd-enable ipv4

no bfd-enable ipv6

Parameters

ipv4

Keyword to enable BFD to control IPv4 adjacencies.

ipv6

Keyword to enable BFD to control IPv6 adjacencies.

include-bfd-tlv

Enables support for the IS-IS BFD TLV options in accordance with RFC 6213, which specifies that a BFD session must be established before an IS-IS adjacency can transition to the established state. This option must be enabled on all IS-IS neighbors on a shared interface.

Platforms

[Tree] (config>router>ospf>area>interface bfd-enable)

Full Context

configure router ospf3 area interface bfd-enable

configure router ospf area interface bfd-enable

Description

This command configures BFD to control the state of the associated protocol interface. By enabling BFD on a protocol interface, the state of the protocol interface is tied to the state of the BFD session between the local node and the remote node. The parameters used for the BFD session are set through the **bfd** command under the IP interface.

The **no** form of this command removes BFD from the associated OSPF protocol adjacency.

Default

no bfd-enable

Parameters

remain-down-on-failure

Keyword to specify that OSPF brings down the adjacency and waits on BFD again if the BFD session does not come back up within 10 seconds. This can cause OSPF neighbors to flap, because OSPF will form the adjacency and then bring it down if the BFD session is still down. If this parameter is not configured, the OSPF adjacency will form even if the BFD adjacency does not come back up after a failure.

strict

Keyword to specify that the system uses BFD strict-mode, which requires that an active BFD session exists between the OSPF neighbors before establishing a full adjacency. When this keyword is configured, the router uses Link-Local Signaling (LLS) with the B-flag set to instruct OSPF neighbors that BFD must be enabled on the link. BFD strict-mode requires that both sides have the B-flag set.

During OSPFv3 BFD strict-mode operations, the router advertises the Local Interface IPv4 Address TLV using LLS, but the SR OS router continues to use IPv6-based BFD sessions for both the IPv4 and IPv6 address families.

strict-mode-holddown *number*

Keyword to specify a delay in bringing up the OSPF adjacency after the BFD session is established. Holddown helps mitigate potential routing churn when BFD sessions are unstable. The holddown timer is reset on an adjacency when a BFD session operationally toggles.

Values 1 to 600

[Tree] (config>service>vpls>spoke-sdp>bfd bfd-template)

Full Context

configure service vpls mesh-sdp bfd bfd-template

configure service vpls spoke-sdp bfd bfd-template

Description

This command configures a named BFD template to be used by VCCV BFD on the PW belonging to the VPLS spoke-SDP or mesh-SDP. The template specifies parameters, such as the minimum transmit and receive control packet timer intervals, to be used by the BFD session. Template parameters are configured under the **config>router>bfd** context.

The **no** form of this command removes the binding of the BFD template to the spoke-SDP.

Default

no bfd-template

Parameters

name

Specifies the BFD template name as a text string, up to 32 characters, in printable 7-bit ASCII, enclosed in double quotes.

Platforms

All

bfd-template

Syntax

bfd-template *name*

no bfd-template

configure service vpls bgp pw-template-binding bfd-template

configure service vpls bgp-ad pw-template-binding bfd-template

Description

This command configures a named BFD template to be used by VCCV BFD on PWs belonging to the BGP VPWS, or BGP AD VPLS service. The template specifies parameters, such as the minimum transmit and receive control packet timer intervals, to be used by the BFD session. Template parameters are configured under the **config>router>bfd** context.

Default

no bfd-template

Parameters

name

Specifies the BFD template name as a text string, up to 32 characters, in printable 7-bit ASCII, enclosed in double quotes.

Platforms

All

bfd-template

Syntax

bfd-template *name*

no bfd-template

Description

This command references a named BFD template to be used by LSP BFD. The template specifies parameters, such as the minimum transmit and receive control packet timer intervals, to be used by the BFD session. Templates are configured under the **config>router>bfd** context.

The **no** form of this command removes the association of the named BFD template to the LSP.

Default

no bfd-template

Parameters

name

Specifies a text string name for the template of up to 32 characters in printable 7-bit ASCII, enclosed in double quotes.

Platforms

All

bfd-template

Syntax

[**no**] **bfd-template** *name*

Context

[Tree] (config>router>bfd bfd-template)

Full Context

configure router bfd bfd-template

Description

This command configures a BFD template. A BFD template defines the set of configurable parameters used by a BFD session. These include the transmit and receive timer intervals used for BFD CC packets, the transmit timer interval used when the session is providing a CV function, the multiplier value, the echo-receive interval, and whether the BFD session terminates in the CPM network processor.

The **no** form of this command reverts to the default value.

Default

no bfd-template

Parameters

name

Specifies a text string name for the template, up to 32 characters in printable 7-bit ASCII, enclosed in double quotes.

Platforms

All

bfd-template

Syntax

bfd-template *bfd-template*

no bfd-template

Context

[Tree] (config>router>segment-routing>maintenance-policy bfd-template)

Full Context

configure router segment-routing maintenance-policy bfd-template

Description

This command references a named BFD template that is used by seamless BFD. The template specifies parameters, such as the minimum transmit and receive control packet timer intervals, that are used by the BFD session. Templates are configured under the **config**>**router**>**bfd** context.

A BFD template must exist on the system before being referenced from a maintenance policy.

The **no** form of this command removes the configured template.

Parameters

bfd-template

Specifies the name of the BFD template, up to 32 characters.

Platforms

All

6.32 bfd-trap-suppression

bfd-trap-suppression

Syntax

Full Context

configure router mpls lsp protect-tp-path mep bfd-trap-suppression

configure router mpls lsp working-tp-path mep bfd-trap-suppression

Description

This command enables AIS packets on a working or protection path of an MPLS-TP LSP to suppress BFD Down traps if a BFD session goes down on that path. It also causes BFD Up traps to be suppressed, and enables the 2.5 s hold-down timer.

Suppression only occurs as a result of a received AIS packet. Traps generated as a result of a local failure at an LER are not suppressed.

The **no** form of this command disables BFD Down/Up trap suppression when AIS packets are received.

Default

no bfd-trap-suppression

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

6.33 bfr-id

bfr-id

Syntax

bfr-id *bfr-id*

no bfr-id

Context

[Tree] (config>router>bier>template>sub-domain bfr-id)

Full Context

configure router bier template sub-domain bfr-id

Description

This command specifies the BIER-ID for this sub-domain. BIER-IDs should be assigned sequentially as the SI and BIER bit position are driven by the IDs. The equation used to drive BIER SI and bit positions from the ID is as follows:

SI = (BFR-id -1) /BitStringLength

bit position = ((BFR-id -1) modulo BitStringLength) +1

If the BIER-ID is sequential then the all bit positions in a bit string length will be utilized before moving on to the next SetID (SI).

BFR ID configuration is only necessary for BFIR and BFER, and not for transit BFRs

The **no** form of this command removes the BIER-ID.

Parameters

bfr-id

The BIER-ID of the router.

Values 1 to 4096

Platforms

configure service vprn bgp-ipvpn mpls auto-bind-tunnel resolution-filter bgp

Description

This command selects the BGP tunnel type.

This command instructs BGP EVPN to search for a BGP LSP to the address of the BGP next hop. If the user does not enable the BGP tunnel type, inter-area or inter-as prefixes are not resolved.

The **no** form of this command removes the BGP tunnel type configuration.

Default

bgp

Platforms

All

bgp

Syntax

bgp *bgp-instance*

no bgp *bgp-instance*

Context

[Tree] (config>service>vpls bgp)

Full Context

configure service vpls bgp

Description

Commands in this context configure the BGP related parameters for BGP VPLS.

A maximum of two BGP instances can be configured in a VPLS service. The *bgp-instance* parameter value can be configured as 1 or 2. If it is not specified, the parameter value is configured as 1 by default.

The **route-distinguisher** configured in BGP instance 1 and 2 must be different. However, the route-target value may be configured the same or different for the two instances.

Only BGP-EVPN MPLS is allowed to be assigned to instance 2. Instance 1 must be used for the VXLAN and L2VPN address families.

BGP-EVPN VXLAN and BGP-EVPN MPLS can only be configured as **no shutdown** in the same service if they are associated with different instances (When the two BGP instances are created, the **bgp-instance** command must be configured in the **bgp-evpn mpls** context).

The **evi** value in **bgp-evpn** can be used to auto-derive the route distinguisher in instance 1 only. However, the **evi** value can be used to auto-derive the **route-target** in both instances.

The **no** version of the command removes the BGP instance.

Parameters

bgp-instance

Specifies the value associated with the BGP instance.

Values 1 to 2

Platforms

All

bgp

Syntax

[**no**] **bgp**

Context

[Tree] (config>router bgp)

Full Context

configure router bgp

Description

This command creates the BGP protocol instance and BGP configuration context. BGP is administratively enabled upon creation.

The **no** form of this command deletes the BGP protocol instance and removes all configuration parameters for the BGP instance. BGP must be **shutdown** before deleting the BGP instance. An error occurs if BGP is not **shutdown** first.

no bgp-auto-rd-range

Context

[Tree] (config>service>system bgp-auto-rd-range)

Full Context

configure service system bgp-auto-rd-range

Description

This command defines the type-1 route-distinguisher IPv4 address and community value range within which the system will select a route-distinguisher for the **bgp-enabled** services using **auto-rd**.

Interactions:

This command is used along with the **route-distinguisher auto-rd** command supported in VPLS, VPRN and Epipe services. The system forces the user to create a **bgp-auto-range** before the **auto-rd** option can be used in the services.

The system will keep allocating values for services configured with **route-distinguisher auto-rd** as long as there are available community values within the configured range. After the command is added, the following changes are allowed:

- The ip-address can be changed without modifying the *comm-val* range, even if services using **auto-rd** are present. The affected routes will be withdrawn and re-advertised with the new route-distinguishers.
- The *comm-val* range can be modified as long as no conflicting values are present in the new range. For example, the user may expand the range as long as the new range does not overlap with existing manual route-distinguishers. The user may also reduce the range as long as the new range can accommodate the already allocated auto-RDs.

Parameters

ip-address

Specifies the IPv4 address used in the first 4 octets of all the type-1 auto route-distinguishers selected by the system.

comm-val

Specifies the community value of the type-1 auto route-distinguisher.

Values 1 to 65535

Full Context

configure router policy-options policy-statement default-action bgp-high-priority

configure router policy-options policy-statement entry action bgp-high-priority

Description

This command enables eligible BGP routes matched by the policy entry or policy default-action that are tagged for faster route table updates.

This action applies only when the policy is applied as a BGP import policy to a base router BGP peer or VPRN BGP peer and applies only to the following route types:

- IPv4
- label-IPv4
- IPv6
- label-IPv6

This command is useful when the BGP RIB contains a large number of routes and quick routing table updates are needed for a small subset of these routes. The effectiveness of this command decreases as the subset becomes a larger proportion of the total RIB.

The **no** form of this command disables the routes that are tagged for faster route table updates.

Default

no bgp-high-priority

Full Context

configure router policy-options policy-statement default-action bgp-leak

configure router policy-options policy-statement entry action bgp-leak

Description

This command causes qualifying matched BGP routes to be marked as leakable, meaning they are candidates to be leaked into other routing instances (copied with their complete set of path attributes). A BGP route is a qualifying route if it is an IPv4 route (unlabeled), IPv6 route (unlabeled) or a label-IPv4 route.

Note:
A leakable BGP route is not actually leaked into another routing instance unless it is accepted by a leak-import policy of that other routing instance.

The **bgp-leak** command has an effect only when the policy is applied as a BGP import policy in the base router or a VPRN context.

Default

no bgp-leak

Platforms

All

6.43 bgp-med

bgp-med

Syntax

bgp-med adjust *expression*

bgp-med set {**igp** | **min-igp**}

[Tree] (config>router>policy-options>policy-statement>default-action bgp-med)

Full Context

configure router policy-options policy-statement entry action bgp-med

configure router policy-options policy-statement default-action bgp-med

Description

This command changes the BGP MED attribute value in BGP routes matched by the route policy entry (or the policy default action).

If the matched route already has a MED attribute, this command overwrites the existing value. If the matched route does not have a MED attribute, then one is added and the value is set based on the parameters of this command.

This command has no effect on non-BGP routes. The default, **no bgp-med**, does not modify MED values.

Default

no bgp-med

Parameters

expression

Specifies a logical expression parsed as a string. The string can contain:

- parentheses () to change the order of operations
- mathematical operators: + (addition), - (subtraction) and * (multiplication)
- directly entered decimal values that act as operands of the mathematical operators. Each decimal value supports up to three decimal places precision in the range of 0.000 to 4294967295.000
- decimal values represented by parameter names (using the usual @parameter-name@ syntax) that act as operands of the mathematical operators. Each parameterized decimal value supports up to three decimal places precision in the range of 0.000 to 4294967295.000

igp

Instructs the policy to set the MED based on the current route table or tunnel table cost to resolve the BGP next-hop address.

min-igp

Instructs the policy to set the MED based on the minimum route table or tunnel table cost to resolve the BGP next-hop of the route, over its lifetime in the local RIB.

med-value

Specifies a new MED value (or parameter name to use for the new MED value) to use with the route.

Values *value*

- 0 to 4294967295

param-name

- up to 32 characters
- Must start and end with an at-sign (@)

Full Context

configure filter match-list ipv6-prefix-list apply-path bgp-peers

configure filter match-list ip-prefix-list apply-path bgp-peers

Description

This command configures auto-generation of IPv4 or IPv6 address prefixes (as required by the context that the command is executed within) based on the base router BGP instance configuration.

The **no** form of this command removes the bgp-peers configuration for auto-generation of address prefixes for the specified index value.

Parameters

service-name

Specifies the service name, up to 64 characters in length.

group

Configures a match against the base router BGP instance group configuration.

Regex match (.*) can be used to match against any group.

neighbor

Configures a match against the base router BGP instance neighbor configuration.

Regex match (.*) can be used to match against any neighbor.

criterion-index

Specifies an integer from 1 to 255 enumerating BGP peers auto-generation configuration within this list.

router-instance

Specifies the router name or service ID.

Values router-instance: *router-name* or *vprn-svc-id*

router-name: "Base"

vprn-svc-id: 1 to 2147483647

service-name: Specifies the service name, up to 64 characters in length.

router

Configures a match against the base router BGP instance configuration.

reg-exp

Specifies a regular expression that defines a match string, up to 255 characters in length, to be used to auto-generate address prefixes. Matching is performed from the least-significant digit. For example, a string **10.0** matches all neighbors with addresses starting with **10**, such as **10.0.x.x** or **10.0xx.x.x**.

[Tree] (config>router>mpls>lsp bgp-transport-tunnel)

Full Context

configure router mpls lsp-template bgp-transport-tunnel

configure router mpls lsp bgp-transport-tunnel

Description

This command allows or blocks RSVP-TE LSP to be used as a transport LSP for BGP tunnel routes.

Default

bgp-transport-tunnel include

Parameters

include

Allows RSVP-TE LSP to be used as transport LSP from the ASBR to local PE router, from ingress PE to ASBR in the local AS or between multi-hop External Border Gateway Protocol (EBGP) peers with ASBR to ASBR adjacency.

exclude

Blocks RSVP-TE LSP to be used as transport LSP from the ASBR to local PE router, from ingress PE to ASBR in the local AS or between multi-hop EBGP peers with ASBR to ASBR adjacency.

Platforms

All

6.50 bgp-tunnel

bgp-tunnel

Syntax

[**no**] **bgp-tunnel**

Context

[Tree] (config>service>sdp bgp-tunnel)

Full Context

configure service sdp bgp-tunnel

Description

This command allows the use of BGP route tunnels available in the tunnel table to reach SDP far-end nodes. Use of BGP route tunnels are only available with MPLS-SDP. Only one of the transport methods is allowed per SDP - LDP, RSVP-LSP BGP, SR-ISIS, or SR-OSPF. This restriction is relaxed for some combinations of the transport methods when the mixed-lsp-mode option is enabled within the SDP.

The **no** form of the command disables resolving BGP route tunnel LSP for SDP far-end.

Default

no bgp-tunnel (BGP tunnel route to SDP far-end is disabled)

no bgp-tunnel-metric

Context

[Tree] (config>router>bgp bgp-tunnel-metric)

Full Context

configure router bgp bgp-tunnel-metric

Description

This command sets the TTM metric of all BGP tunnels to a fixed value or a value derived from the AIGP or the MED metric of the BGP-LU route, if the BGP-LU route has an AIGP or MED path attribute. Otherwise, the TTM metric is set to the number specified using the *value* parameter. BGP import policies override the configuration of this command.

By default, BGP tunnels are installed with a fixed cost of 1000 in the tunnel table. This can overstate or understate their true cost when compared to other tunnels with IGP-derived costs.

The **no** form of the command configures the router to use the default value.

Default

no bgp-tunnel-metric

Parameters

value

Specifies the BGP tunnel metric.

Values 0 to 4294967295

prefer-aigp

Specifies that the TTM metric is based on the AIGP metric value of the BGP-LU route. When a BGP-LU route is selected for installation in TTM and is not matched by a BGP import policy entry that overrides the BGP tunnel metric action, the TTM metric of the tunnel is set to the AIGP metric value of the BGP-LU route with the resolved cost to the BGP next hop of the route added to it. Otherwise, the metric is set to the value configured using the *value* parameter.

prefer-med

Specifies that the TTM metric is based on the MED metric value of the BGP-LU route. When a BGP-LU route is selected for installation in TTM and is not matched by a BGP import policy entry that overrides the BGP tunnel metric action, the TTM metric of the tunnel is set to the MED metric value of the BGP-LU route with the resolved cost to the

BGP next hop of the route added to it. Otherwise, the metric is set to the value configured using the *value* parameter.

Note: prefer-aigp takes precedence over this parameter if the received BGP-LU has both attributes.

Full Context

configure router policy-options policy-statement entry action bgp-tunnel-metric

configure router policy-options policy-statement default-action bgp-tunnel-metric

Description

This command sets the TTM metric of all BGP tunnels matched by the policy entry or the policy default action to a fixed value or a value derived from the AIGP or the MED metric of the BGP-LU route, if the BGP-LU route has an AIGP or MED path attribute. Otherwise, the TTM metric is set to the number specified using the *value* parameter.

The **no** form of this command configures the router to use the default value.

Default

no bgp-tunnel-metric

Parameters

value

Specifies the BGP tunnel metric.

Values 0 to 4294967295

param-name

Specifies the parameter name, up to 32 characters that starts and ends with an at-sign (@).

prefer-aigp

Specifies that if a BGP-LU route is selected for installation in the TTM and is matched by this action in a BGP import policy, the TTM metric of the tunnel is set to the AIGP metric value of the BGP-LU route with the IGP cost to reach the BGP next hop added to it.

prefer-med

Specifies that if a BGP-LU route is selected for installation in the TTM and is matched by this action in a BGP import policy, the TTM metric of the tunnel is set to the MED metric value of the BGP-LU route with the IGP cost to reach the BGP next hop added to it.

6.52 bgp-tunnel-preference

bgp-tunnel-preference

Syntax

bgp-tunnel-preference [*preference*]

no bgp-tunnel-preference

Context

[Tree] (config>router>bgp bgp-tunnel-preference)

Full Context

configure router bgp bgp-tunnel-preference

Description

This command configures the tunnel table preference for BGP-LU tunnel type away from its default value.

The tunnel table preference applies to the next-hop resolution of BGP routes of the following families: EVPN, IPv4, IPv6, VPN-IPv4, VPN-IPv6, label-IPv4, and label-IPv6 in the tunnel table.

This feature does not apply to a VPRN, VPLS, or VLL service with explicit binding to an SDP which enabled the **mixed-lsp-mode** option. The tunnel preference, in such an SDP, is fixed and is controlled by the service manager. The configuration of the tunnel table preference parameter does not modify the behavior of such an SDP and the services that bind to it.

It is recommended to not set two or more tunnel types to the same preference value. In such a situation, the tunnel table prefers the tunnel type which was first introduced in SR OS implementation historically.

The **no** form of this command reverts to the default value.

Default

bgp-tunnel-preference 12

Parameters

preference

Specifies the BGP tunnel preference.

Values 1 to 255

Default 12

Context

[Tree] (config>service>vpls>sap bgp-vpls-mh-ve-id)

Full Context

configure service vpls sap bgp-vpls-mh-ve-id

Description

This command upon the configuration of the ve-id under the SAP and if BGP-VPLS is configured and is operationally up, causes the PE to advertise a bgp-mh route for the ve-id (the route does not contain label information). The bgp-mh route contains the F and D flags properly set based on the SAP operational state. Upon switchover, the former active PE (DF in case of EVPN-MH) sends an update with a transition of the F bit from 1 to 0. This is an indication for the remote PEs to flush their MACs associated to the advertising PE.

This command is required when MC-LAG or EVPN-MH is used for multi-homing redundancy and mac-flush is required at remote BGP-VPLS PEs when there is a failure in the active PE.

The **no** form of this command withdraws the L2 VPN route.

Parameters

number

Specifies the BGP-VPLS multi-homing virtual-edge identifier.

Values 1 to 65535

oam bier-ping

Description

This command performs connectivity tests on the BIER data plane.

Parameters

sub-domain-id

Specifies the ID of the sub-domain where the BIER OAM packet is generated.

Values 0 to 255

Default 0

bfr-id

Specifies the BIER-ID of the router.

Values 1 to 4096

ipv4-address

Specifies the routable IPv4 address of the BFR, used by BIER to identify the BFR. Up to 16 IPv4 addresses can be specified.

Values a.b.c.d

detail

Keyword to display more information.

fc-name

Specifies the FC and profile parameters that are used to indicate the forwarding class and profile of the BIER echo request packet.

Values be, l2, af, l1, h2, ef, h1, nc

Default be

{in | out}

Specifies the profile state of the BIER echo request packet.

Default out

timeout

Specifies the number, in seconds, used to override the default *timeout* value and is the amount of time that the router waits for a message reply after sending the message request. Upon the expiration of the timeout, the test is marked complete and no more packets are processed.

Values 1 to 120

Default 10

ttl

Specifies the TTL value for the BIER ping test, expressed as a decimal integer.

Values 1 to 255

Default 255

Full Context

oam bier-trace

Description

This command performs trace tests on the BIER data plane.

Parameters

sub-domain-id

Specifies the ID of the sub-domain where the BIER OAM packet is generated.

Values 0 to 255

Default 0

bfr-id

Specifies the BIER-ID of the router.

Values 1 to 4096

ipv4-address

Specifies the routable IPv4 address of the BFR, used by BIER to identify the BFR.

Values a.b.c.d

detail

Keyword to display more information.

fc-name

Specifies the FC and profile parameters that are used to indicate the forwarding class and profile of the BIER OAM packet.

Values be, l2, af, l1, h2, ef, h1, nc

Default be

{in | out}

Specifies the profile state of the BIER echo request packet.

Default out

min-ttl

Specifies the minimum TTL value for the BIER trace test, expressed as a decimal integer.

Values 1 to 255

Default 1

max-ttl

Specifies the maximum TTL value for the BIER trace test, expressed as a decimal integer.

Values 1 to 255

Default 30

probes-per-hop

Specifies the probes-per-hop count, expressed as number of packets.

Values 1 to 10

Default 1

timeout

Specifies the number, in seconds, used to override the default *timeout* value and is the amount of time that the router waits for a message reply after sending each probe for a specific test. Upon the expiration of the timeout, the test is marked complete and no more packets are processed for the request probe.

When the test consists of multiple probes, the timeout is the interval, in seconds, between request probes.

A BIER trace test terminates after five consecutive timeouts.

Values 1 to 60

Default 3

no bin-group *bin-group-number*

Context

[Tree] (config>oam-pm bin-group)

Full Context

configure oam-pm bin-group

Description

This command allows the operator to configure the parameters for a specific bin group. Bin-group 1 is a default **bin-group** and cannot be modified. If no bin group is assigned to an oam-pm session, this is assigned by default. The default values for bin-group 1 are (fd-bin-count 3 bin 1 lower-bound 5000us, bin 2 lower-bound 10000us fdr-bin-count 2 bin 1lower-bound 5000us and ifdv-bin-count 2 bin 1lower-bound 5000us)

The **no** form of this command disables the OAM Performance Monitoring bin group.

Parameters

bin-group-number

Specifies an identifier for a bin-group that is referenced by oam-pm sessions. A bin group can only shutdown and modified when all the PM Sessions referencing the bin group have been shutdown. The only exception is the description parameter.

Values 1 to 255

fd-bin-count

Specifies the number of frame delay bins that are created.

Values 2 to 10

fdr-bin-count

Specifies the number of frame delay range bins that are created.

Values 2 to 10

ifdv-bin-count

Specifies the number of inter-frame delay variation bins that are created.

Values 2 to 10

create

Keyword that creates the bin group.

6.64 bind-authentication

bind-authentication

Syntax

bind-authentication *root-dn* [**password** *password*] [**hash** | **hash2** | **custom**]

no bind-authentication

Context

[Tree] (config>system>security>ldap>server bind-authentication)

Full Context

configure system security ldap server bind-authentication

Description

This command configures the LDAP binding used to log into LDAP server. A string of domain components (DC) and common names (CN) can be programmed to identify the user in addition to the password field. The password is hashed. For example, "cn=admin,dc=nokia,dc=com" indicates the user admin in domain nokia.com. Table 19: LDAP Attributes lists the LDAP attributes.

The **no** version of this command removes the bind-authentication.

Table 19: LDAP Attributes

Object Class	Naming Attribute Display Name	Naming Attribute LDAP Name
user	Common-Name	cn
organizationalUnit	Organizational-Unit-Name	ou
domain	Domain-Component	dc

Parameters

root-dn

Up to 512 characters.

password

Configures the password which enables a user to bind to the LDAP server. The maximum length is 128 characters.

hash

Specifies that the password is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the password is assumed to be in an unencrypted, clear text form. For security, all passwords are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified

hash2

Specifies the password is entered in a more complex encrypted form that involves more variables than the password value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the password is assumed to be in an unencrypted, clear text form. For security, all passwords are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

custom

Specifies the custom encryption to management interface.

Syntax

bit-rate-high-wmark *high-watermark*

Context

[Tree] (config>application-assurance bit-rate-high-wmark)

Full Context

configure application-assurance bit-rate-high-wmark

Description

This command configures the high watermark for bit rate alarms.

Default

bit-rate-high-wmark max

Parameters

high-watermark

Specifies the high watermark for bit rate alarms, in Mb/s. The value must be larger than or equal to the low watermark value.

Values 1 to 40000, **max** (disabled)

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

6.73 bit-rate-low-wmark

Syntax

bits-interface-type {**ds1** [{**esf** | **sf**}] | **e1** [{**pcm30crc** | **pcm31crc**}

no bits-interface-type

Context

[Tree] (config>system>sync-if-timing>ref2 bits-interface-type)

[Tree] (config>system>sync-if-timing>ref1 bits-interface-type)

Full Context

configure system sync-if-timing ref2 bits-interface-type

configure system sync-if-timing ref1 bits-interface-type

Description

This command configures the interface type of the BITS timing reference.

The **no** form of the command reverts to the default configuration

Parameters

ds1 esf

Specifies Extended Super Frame (ESF). This is a framing type used on DS1 circuits that consists of 24 192-bit frames, The 193rd bit provides timing and other functions.

ds1 sf

Specifies Super Frame (SF), also called D4 framing. This is a common framing type used on DS1 circuits. SF consists of 12 192-bit frames. The 193rd bit provides error checking and other functions. ESF supersedes SF.

e1 pcm30crc

Specifies the pulse code modulation (PCM) type. PCM30CRC uses PCM to separate the signal into 30 user channels with CRC protection.

e1 pcm31crc

Specifies the pulse code modulation (PCM) type. PCM31CRC uses PCM to separate the signal into 31 user channels with CRC protection.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

6.76 black-hole

black-hole

Syntax

[**no**] **black-hole**

Context

[Tree] (config>service>vprn>static-route-entry black-hole)

Full Context

configure service vprn static-route-entry black-hole

Description

This command specifies that the route is a black hole route. If the destination address on a packet matches this static route, it will be silently discarded.

Default

no black-hole

Platforms

All

black-hole

Syntax

[**no**] **black-hole**

Context

[Tree] (config>router>static-route-entry black-hole)

Full Context

configure router static-route-entry black-hole

Description

This command specifies that the route is a black hole route. If the destination address on a packet matches this static route, it will be silently discarded.

Default

no black-hole

Platforms

All

6.77 black-hole-dup-mac

black-hole-dup-mac

Syntax

[**no**] **black-hole-dup-mac**

Context

[Tree] (config>service>vpls>bgp-evpn>mac-duplication black-hole-dup-mac)

Full Context

configure service vpls bgp-evpn mac-duplication black-hole-dup-mac

Description

The **black-hole-dup-mac** command is disabled by default. If enabled, a duplicated MAC detected in the network is programmed as a black-hole MAC in the FDB and displayed in the **show service id fdb detail** command as follows:

- Source-Identifier—black-hole
- Type—EvpnD:P

Because the MAC is now programmed in the FDB as a black-hole, all received frames with MAC DA matching the duplicate MAC are discarded. The duplicate black-hole MACs are installed as Protected, therefore, all received frames with MAC SA matching the duplicate MAC are discarded by default.

A BGP-EVPN (MPLS or VXLAN) shutdown is required to add or remove the **black-hole-dup-mac** command.

The **no** form of the command removes the feature, and duplicate MACs are no longer programmed as black-hole MACs.

Default

no black-hole-dup-mac

Platforms

All

6.78 blackhole-aggregate

blackhole-aggregate

Syntax

[**no**] **blackhole-aggregate**

Context

[Tree] (config>service>vprn>ospf>area blackhole-aggregate)

[Tree] (config>service>vprn>ospf3>area blackhole-aggregate)

Full Context

configure service vprn ospf area blackhole-aggregate

configure service vprn ospf3 area blackhole-aggregate

Description

This command installs a low priority blackhole route for the entire aggregate. Existing routes that make up the aggregate have a higher priority and only the components of the range for which no route exists are blackholed.

It is possible that when performing area aggregation, addresses may be included in the range for which no actual route exists. This can cause routing loops. To avoid this problem, configure the **blackhole-aggregate** command.

The **no** form of this command removes this configuration.

Default

blackhole-aggregate

Platforms

All

blackhole-aggregate

Syntax

Full Context

configure router segment-routing segment-routing-v6 micro-segment-locator block

Description

This command configures an association between a pre-defined block and the micro-segment locator.

The **no** form of this command removes the configured block.

Default

no block

Parameters

ms-block-name

Specifies a block name, up to 64 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-s, 7950 XRS, VSR

6.80 block-length

block-length

Syntax

block-length *block-length*

no block-length

Context

[Tree] (config>router>segment-routing>srv6>locator block-length)

Full Context

configure router segment-routing segment-routing-v6 locator block-length

Description

This command configures the length of the block field of a SRv6 locator.

The **no** form of this command reverts to the default value.

Default

block-length 0

Parameters

block-length

Specifies the block length, in bits, for the SRv6 locator. This value must be less than the locator prefix length and is enforced by CLI validation.

Values 0 to 96

Platforms

7450 ESS, 7750 SR, 7750 SR-s, 7950 XRS, VSR

Description

This command configures the maximum number of port blocks per NAT subscriber.

The **no** form of the command reverts to the default.

Default

block-limit 1

Parameters

number

Specifies the maximum number of port blocks per NAT subscriber.

Values 1 to 10

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

6.82 block-on-mesh-failure

block-on-mesh-failure

Syntax

[**no**] **block-on-mesh-failure**

Context

[Tree] (config>service>vpls>spoke-sdp block-on-mesh-failure)

[Tree] (config>service>vpls>endpoint block-on-mesh-failure)

Full Context

configure service vpls spoke-sdp block-on-mesh-failure

configure service vpls endpoint block-on-mesh-failure

Description

This command enables blocking (brings the entity to an operationally down state) after all configured SDPs or endpoints are in operationally down state. This event is signaled to corresponding T-LDP peer by withdrawing service label (status-bit-signaling non-capable peer) or by setting "PW not forwarding" status bit in T-LDP message (status-bit-signaling capable peer).

The **no** form of this command reverts to the default.

Default

no block-on-mesh-failure

Platforms

All

6.83 block-on-peer-fault

block-on-peer-fault

Syntax

[**no**] **block-on-peer-fault**

Context

[Tree] (config>service>epipe>spoke-sdp block-on-peer-fault)

Full Context

configure service epipe spoke-sdp block-on-peer-fault

Description

When enabled, this command blocks the transmit direction of a PW when any of the following PW status codes is received from the far end PE:

0x00000001	Pseudowire Not Forwarding
0x00000002	Local Attachment Circuit (ingress) Receive Fault
0x00000004	Local Attachment Circuit (egress) Transmit Fault
0x00000008	Local PSN-facing PW (ingress) Receive Fault
0x00000010	Local PSN-facing PW (egress) Transmit Fault

The transmit direction is unblocked when the following PW status code is received:

0x00000000	Pseudowire forwarding (clear all failures)

This command is mutually exclusive with **no pw-status-signaling**, and **standby-signaling-slave**. It is not applicable to spoke SDPs forming part of an MC-LAG or spoke SDPs in an endpoint.

Default

no block-on-peer-fault

Platforms

All

block-on-peer-fault

Syntax

[**no**] **block-on-peer-fault**

Context

[Tree] (config>service>pw-template block-on-peer-fault)

Full Context

configure service pw-template block-on-peer-fault

Description

When enabled, this command blocks the transmit direction of a pseudowire when any of the following pseudowire status codes is received from the far end PE:

0x00000001	Pseudowire Not Forwarding
0x00000002	Local Attachment Circuit (ingress) Receive Fault
0x00000004	Local Attachment Circuit (egress) Transmit Fault
0x00000008	Local PSN-facing PW (ingress) Receive Fault
0x00000010	Local PSN-facing PW (egress) Transmit Fault

The transmit direction is unblocked when the following pseudowire status code is received:

0x00000000	Pseudowire forwarding (clear all failures)

This command is mutually exclusive with **no pw-status-signaling**, and **standby-signaling-slave**. It is not applicable to spoke SDPs forming part of an MC-LAG or spoke SDPs in an endpoint.

Default

Context

[Tree] (config>router>bgp>group block-prefix-sid)

[Tree] (config>router>bgp>group>neighbor block-prefix-sid)

[Tree] (config>router>bgp block-prefix-sid)

Full Context

configure router bgp group block-prefix-sid

configure router bgp group neighbor block-prefix-sid

configure router bgp block-prefix-sid

Description

This command specifies whether all prefix SID attributes are removed from label IPv4 and label IPv6 routes when they are exchanges with EBGP and IBGP peers covered by the scope of the command. Even locally-imposed prefix SID attributes are removed.

A change of this configuration causes the affected BGP sessions to flap.

The **no** form of this command allows prefix SID attributes associated with label IPv4 and label IPv6 routes to be propagated without restriction.

Default

no block-prefix-sid

6.87 bof

bof

Syntax

bof

Context

[Tree] (bof)

Full Context

bof

Description

This command creates or edits the boot option file (BOF) for the specified local storage device.

A BOF file specifies where the system searches for runtime images, configuration files, and other operational parameters during system initialization.

BOF parameters can be modified. Changes can be saved to a specified compact flash. The BOF must be located in the root directory of either an internal or external compact flash local to the system and have the mandatory filename of *bof.cfg*.

When modifications are made to in-memory parameters that are currently in use or operating, the changes are effective immediately. For example, if the IP address of the management port is changed, the change takes place immediately.

Only one entry of the BOF configuration command statement can be saved once the statement has been found to be syntactically correct.

When opening an existing BOF that is not the BOF used in the most recent boot, a message is issued notifying the user that the parameters will not affect the operation of the node.

No default boot option file exists. The router boots with the factory default boot sequence and options.

6.92 booking-factor

booking-factor

Syntax

booking-factor *factor*

no booking-factor

Context

[Tree] (config>lag>access booking-factor)

[Tree] (config>port>ethernet>access booking-factor)

Full Context

configure lag access booking-factor

configure port ethernet access booking-factor

Description

This command specifies the booking factor applied against the port or LAG administrator bandwidth by SAP administrator bandwidth CAC.

The service manager keeps track of the available administrator bandwidth for each port or LAG configured with an administrator bandwidth. The port or LAG available administrator bandwidth is adjusted by the user configured booking factor, allowing the port or LAG bandwidth to be overbooked or under booked.

If the booking factor is increased then available administrator bandwidth on the port or LAG increases. If the booking factor is decreased then available administrator bandwidth on the port or LAG decreases. However, if the reduction of available administrator bandwidth is insufficient to cover the sum of the current SAP administrator bandwidth on the port or LAG, the command fails.

The **no** form of this command reverts to the default value.

Default

booking-factor 100

Parameters

factor

Specifies the percentage of the port or LAG admin bandwidth for SAP bandwidth CAC.

Values 1 to 1000

Platforms

All

booking-factor

Syntax

booking-factor *percentage*

no booking-factor

Context

[Tree] (config>service>sdp booking-factor)

Full Context

configure service sdp booking-factor

Description

This command specifies the booking factor applied against the maximum SDP available bandwidth by the VLL CAC feature.

The service manager keeps track of the available bandwidth for each SDP. The maximum value is the sum of the bandwidths of all constituent LSPs in the SDP. The SDP available bandwidth is adjusted by the user configured booking factor. A value of 0 means no VLL can be admitted into the SDP.

The **no** form of the command reverts to the default value.

Default

no booking-factor

Parameters

percentage

Specifies the percentage of the SDP maximum available bandwidth for VLL call admission. When the value of this parameter is set to zero (0), no new VLL spoke SDP bindings with non-zero bandwidth are permitted with this SDP. Overbooking, >100% is allowed.

Values 0 to 1000%

Default 100

Platforms

All

6.93 boot-bad-exec

boot-bad-exec

Syntax

boot-bad-exec *file-url*

no boot-bad-exec

Context

[Tree] (config>system boot-bad-exec)

Full Context

configure system boot-bad-exec

Description

Use this command to configure a URL for a CLI script to **exec** following a failure of a bootup configuration. The command specifies a URL for the CLI scripts to be run following the completion of the bootup configuration. A URL must be specified or no action is taken.

The commands are persistent between router (re)boots and are included in the configuration saves (**admin>save**).

Related Commands

exec — This command executes the contents of a text file as if they were CLI commands entered at the console.

Default

no boot-bad-exec

Parameters

file-url

Specifies the location and name of the CLI script file executed following failure of the bootup configuration file execution. When this parameter is not specified, no CLI script file is executed.

Ipv6-address only applies to the 7750 SR and 7950 XRS.

Values

file url	*local-url* | *remote-url*	255 chars max
local-url	[*cflash-id*/][*file-path*]	
remote-url	[{ftp://} *login:pswd@remote-locn*/][*file-path*]	
	remote-locn	[*hostname* | *ipv4-address* | [*ipv6- address*]]
	ipv4-address	*a.b.c.d*

6.95 boot-timer

boot-timer

Syntax

boot-timer *interval*

no boot-timer

Context

[Tree] (config>redundancy>multi-chassis>peer>mc-ep boot-timer)

Full Context

configure redundancy multi-chassis peer mc-endpoint boot-timer

Description

This command configures the boot timer interval. This command applies only when the node reboots. It specifies the time the MC-EP protocol keeps trying to establish a connection before assuming a failure of the remote peer. This is different from the keep-alive mechanism which is used just after the peer-peer communication was established. After this time interval passed all the mc-endpoints configured under services will revert to single chassis behavior, activating the best local PW.

The **no** form of this command sets the interval to default.

Default

no boot-timer

Parameters

interval

Specifies the boot timer interval.

Values 1 to 600

Platforms

All

boot-timer

Syntax

boot-timer *seconds*

Context

[Tree] (config>redundancy>bgp-evpn-multi-homing boot-timer)

Full Context

configure redundancy bgp-evpn-multi-homing boot-timer

Description

This command allows the necessary time for the control plane protocols to come up upon PE boot-up before bringing up the ESs and running the DF algorithm.

The following considerations apply to this command:

- The **boot-timer** command must provide enough time to allow the IOMs and BGP sessions to come up before exchanging ES routes and running the DF election for each EVI or ISID.
- The boot-timer is synchronized across CPMs and is relative to the system up time; it is not changed or reset upon CPM switchover.
- The boot-timer is never interrupted (the e**s-activation-timer**, however, can be interrupted if there is a new event triggering the DF election).
- The boot-timer runs per EVI or ISID on the ESs in the system. If the system up time (time the system has been up since the last reboot) is less than the **boot-timer** value, the system does not run the DF

election for any EVI or ISID. When the **boot-timer** value expires, the DF election runs, and if the system is elected DF for the EVI or ISID, the **es-activation-timer** is triggered.

- The system does not advertise ES routes until the boot timer expires, which guarantees that the peer ES PEs only run the DF election when the PE is ready to become the DF, if required.

Default

boot-timer 10

Parameters

seconds

Specifies the number of seconds for the boot-timer.

Values 0 to 1800

Platforms

6.98 boundary-type

boundary-type

Syntax

boundary-type {**clock-aligned** | **test-relative**}

no boundary-type

Context

[Tree] (config>oam-pm>session>meas-interval boundary-type)

Full Context

configure oam-pm session meas-interval boundary-type

Description

This command establishes the alignment of the start of the measurement interval with either the time of day clock or the start of the test. Alignment with the time of day clock always defaults to the representative top of the hour. Clock-aligned 15-minute measurement intervals divide the hour into four equal sections 00, 15, 30, 45. Clock-aligned 1-hour measurement intervals start at 00. Clock-aligned 1-day measurement intervals start at midnight. Test relative start times launches the measurement interval when the individual test enters the active (**no shutdown**) state. It is typical for the first measurement interval of a clock-aligned test to have the suspect flag set to yes because it is unlikely the **no shutdown** exactly corresponds to the clock based measurement interval start time. Clock-aligned measurement intervals can include an additional offset.

The **no** form of this command sets the boundary to the default clock-aligned.

Default

boundary-type clock-aligned

Parameters

clock-aligned

Aligns the start of the measurement interval with the time of day clock.

test-relative

Aligns the start of the measurement interval with the start of the test.

Platforms

Full Context

configure service vpls spoke-sdp bpdu-translation

configure service vpls sap bpdu-translation

Description

This command enables the translation of BPDUs to a specified format, meaning that all BPDUs transmitted on a specified SAP or spoke-SDP will have a specified format.

The **no** form of this command reverts to the default.

Default

no bpdu-translation

Parameters

auto

Specifies that appropriate format will be detected automatically, based on type of BPDUs received on such port.

auto-rw

Specifies that appropriate format will be detected automatically and the VLAN ID will be rewritten as follows:

- BPDU sent on egress of dot1q SAP will contain the VLAN ID of the SAP in BPDU-PVID TLV
- BPDU sent on egress of default QinQ SAP will contain the outer VLAN ID of the SAP in BPDU-PVID TLV
- BPDU sent on egress of QinQ SAP will contain the inner VLAN ID of the SAP in BPDU-PVID TLV

pvst

Specifies the BPDU-format as PVST. Note: the correct VLAN tag is included in the payload (depending on encapsulation value of outgoing SAP).

pvst-rw

Specifies the BPDU-format as PVST. The VLAN ID will be rewritten as follows:

- BPDU sent on egress of dot1q SAP will contain the VLAN ID of the SAP in BPDU-PVID TLV

- BPDU sent on egress of default QinQ SAP will contain the outer VLAN ID of the SAP in BPDU-PVID TLV
- BPDU sent on egress of QinQ SAP will contain the inner VLAN ID of the SAP in BPDU-PVID TLV

stp

Specifies the BPDU-format as STP.

Platforms

6.101 breakout

breakout

Syntax

breakout *breakout*

no breakout

Context

[Tree] (config>port>connector breakout)

Full Context

configure port connector breakout

Description

This command configures the transceiver port breakout for use in the connector. Specifying the breakout type triggers the creation of accessible ports for the connector.

When a QSFP28 connector uses an SFP+ optical module with the QSFP28-to-SFP+/SFP28 adapter, the user should set the *breakout* parameter to c1-10g, which indicates the presence of this adapter.

The options for breakout on specific connectors depend on both the card type and level (or XMA type and level). See the applicable installation guides for details.

For some connectors (such as QSFPDD), there can be overlap in the breakout for different host interfaces. The same port breakout can be supported on an optical module that uses a host interface of CAUI-4 as another optical module that uses 100GAUI-2. To distinguish from the CAUI-4 host interface, the '-aui2' suffix is used on some breakout options. This is only necessary where there is overlap. In other situations, the SR OS will set the host interface correctly without requiring the distinction in the breakout option.

The **no** form of this command removes the ports under the connector.

Default

no breakout

Parameters

breakout

Specifies the breakout type.

Values c1-40g, c4-10g, c1-100g, c4-25g, c10-10g, c1-400g, c2-100g, c4-100g, c1-10g, c1-25g, c1-50g, c8-50g, c1-800g, c3-100g, c8-100g, c2-400g, c1-100g-aui2, c2-100g-aui2

Full Context

configure subscriber-mgmt vrgw brg brg-profile

Description

This command creates the profile for Bridged Residential Gateway (BRG) devices. The BRG profile specifies default parameters that are used for host management under a single BRG.

The **no** form of this command removes the profile name from the configuration.

Parameters

profile-name

Specifies the name of the BRG profile.

create

Keyword used to create a BRG profile. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

6.106 bridge-identifier

bridge-identifier

Syntax

bridge-identifier *bridge-id* **vlan** *vlan-id*

Context

[Tree] (config>eth-cfm>default-domain bridge-identifier)

Full Context

configure eth-cfm default-domain bridge-identifier

Description

This command configures the cross-reference required to link the CFM function with the service context. The link is created when the **bridge-id**, **service-id**, and **vlan-id** (for a primary VLAN) match.

This command allows the entry of MIP-specific parameters for the index (**bridge-identifier** and **vlan**) in the default-domain table.

Parameters

bridge-id

Specifies the ID for a link to a specific service. Note that there is no verification that a service has been created with a matching service ID.

Values 1 to 2147483647

vlan-id

Specifies the VLAN ID for the **default-domain** index. The complete index allows the user to reference specific MIP entries in the **default-domain** table. The *vlan-id* value must match the configured **primary-vlan-enable** *vlan-id* corresponding to the **bridge-identifier**. If the MIP does not have **primary-vlan-enable** configured, the *vlan-id* must be configured as "none". When the *vlan-id* is configured as none, the MIP relies on the service delineation for extraction and installs no additional VLAN in that portion of the index.

Values 1 to 4094 | none

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

bridge-identifier

Syntax

bridge-identifier {*bridge-id* | **bridge-name** *bridge-name*}

no bridge-identifier {*bridge-id* | **bridge-name** *bridge-name*}

Context

[Tree] (config>eth-cfm>domain>assoc bridge-identifier)

Full Context

configure eth-cfm domain association bridge-identifier

Description

This command configures the cross-reference required to link the CFM function with the service context. The link is created when the *bridge-id*, or *bridge-name* matches the *service-id*, or *service-name*, respectively.

The **no** form of this command removes the bridge identifier and the link between the ETH-CFM configuration and the matching service.

There is no verification that any service has been created with a matching value. An existing bridge identifier configuration can be overwritten with the alternate type, as long as the new reference does not change the existing service linkage.

Parameters

bridge-id

Specifies the ID to link to a specific service. Note that there is no verification that a service was created with a matching *service-id*.

This *bridge-id* variant of the command is only supported in classic configuration mode (**configure system management-interface configuration-mode classic**). The **bridge-identifier bridge-name** *bridge-name* variant can be used in all configuration modes. All

references to **bridge-identifier** *bridge-id* must be changed to the **bridge-identifier bridge-name** *bridge-name* option as a prerequisite to model-driven mode.

Values 1 to 2147483647

bridge-name

Specifies a link to a service with a matching service-name, up to 64 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

6.107 bridge-priority

bridge-priority

Syntax

bridge-priority *bridge-priority*

no bridge-priority

Context

[Tree] (config>service>vpls>spb>level bridge-priority)

Full Context

configure service vpls spb level bridge-priority

Description

This command configures the four bit bridge priority for Shortest Path Bridging. This value is added to the 6 byte bridge Identifier (which is the system-id) in the top four bits of a two byte field. Note the actual value will be bit shifted 12 bits left effective putting this in the high bits of the 16 bits added to system ID.

The bridge priority is important in choosing the Root Bridge for the single tree algorithm (lowest value = best). Bridge priority also factors into the tie breaker for SPF algorithms as described in the SPB standard. The bridge-identifier (system-id) of the control B-VPLS determines the tiebreaker when the bridge-priorities are equal.

Default

bridge-priority 8

Parameters

bridge-priority

The bridge-priority value.

Values 0 to 15

Platforms

All

6.108 broadcast

broadcast

Syntax

broadcast {**interface** *ip-int-name*} [**key-id** *key-id*] [**version** *version*] [**ttl** *ttl*]

no broadcast {**interface** *ip-int-name*}

Context

[Tree] (config>service>vprn>ntp broadcast)

Full Context

configure service vprn ntp broadcast

Description

This command configures the node to transmit NTP packets on a given interface. Broadcast and multicast messages can easily be spoofed, thus, authentication is strongly recommended.

The **no** form of this command removes the address from the configuration.

Parameters

ip-int-name

Specifies the local interface on which to transmit NTP broadcast packets. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed between double quotes.

Values 32 character maximum

key-id *key-id*

Identifies the configured authentication key and authentication type used by this node to receive and transmit NTP packets to and from an NTP server and peers. If an NTP packet is received by this node both authentication key and authentication type must be valid otherwise the packet will be rejected and an event/trap generated.

Values 1 to 255

version *version*

Specifies the NTP version number that is generated by this node. This parameter does not need to be configured when in client mode in which case all versions will be accepted.

Values 2 to 4

Default 4

ttl *ttl*

Specifies the IP Time To Live (TTL) value.

Values 1 to 255

Platforms

Context

[Tree] (config>system>time>ntp broadcast)

Full Context

configure system time ntp broadcast

Description

This command configures the node to transmit NTP packets on a given interface. Broadcast and multicast messages can easily be spoofed, thus, authentication is strongly recommended.

The **no** form of this command removes the address from the configuration.

Parameters

router-name

Specifies the router name used to transmit NTP packets. Base is the default. Select management to use the management port (Ethernet port on the CPM). Note that broadcast server capability can also be enabled on an interface within a VPRN context. Refer to "NTP Within a VPRN Service" in the *7450 ESS, 7750 SR, 7950 XRS, and VSR Layer 3 Services Guide: IES and VPRN* for more information.

Values Base | Management

Default Base

ip-int-name

Specifies the local interface on which to transmit NTP broadcast packets, up to 32 characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

key-id

Identifies the configured authentication key and authentication type used by this node to receive and transmit NTP packets to and from an NTP server and peers. If an NTP packet is received by this node both authentication key and authentication type must be valid otherwise the packet will be rejected and an event or trap generated.

Values 1 to 255

version

Specifies the NTP version number that is generated by this node. This parameter does not need to be configured when in client mode in which case all versions will be accepted.

Values 2 to 4

Default 4

ttl

Specifies the IP Time To Live (TTL) value.

6.110 broadcast-policer

broadcast-policer

Syntax

broadcast-policer *policer-id* [**fp-redirect-group**]

no broadcast-policer

Context

[Tree] (config>qos>sap-ingress>fc broadcast-policer)

Full Context

configure qos sap-ingress fc broadcast-policer

Description

Within a **sap-ingress** QoS policy forwarding class context, the **broadcast-policer** command is used to map packets that match the forwarding class and are considered broadcast in nature to the specified policer-id. The specified policer-id must already exist within the **sap-ingress** QoS policy. While the system is determining the forwarding class of a packet, it is also looking up its forwarding destination based on the ingress service type and the service instance forwarding records. If the service type is VPLS and the destination MAC address is the broadcast address (ff:ff:ff:ff:ff:ff), the packet is classified into the broadcast forwarding type.

Broadcast forwarding type packets are mapped to either an ingress multipoint queue (using the **broadcast** *queue-id* or **broadcast** *queue-id* **group** *ingress-queue-group* commands) or an ingress policer (**broadcast-policer** *policer-id*). The **broadcast** and **broadcast-policer** commands within the forwarding class context are mutually exclusive. By default, the broadcast forwarding type is mapped to the SAP ingress default multipoint queue. If the **broadcast-policer** *policer-id* command is executed, any previous policer mapping or queue mapping for the broadcast forwarding type within the forwarding class is overridden if the policer mapping is successful.

A policer defined within the **sap-ingress** policy is not actually created on an ingress SAP or a subscriber using an **sla-profile** where the policy is applied until at least one forwarding type (unicast, broadcast, unknown, or multicast) from one of the forwarding classes is mapped to the policer. If insufficient policer resources exist to create the policer for a SAP or subscriber or multiservice site, or ingress policing is not supported on the port associated with the SAP or subscriber or multiservice site, the initial forwarding class forwarding type mapping will fail.

The **broadcast-policer** command is ignored for instances of the policer applied to SAPs or subscribers' multiservice site where broadcast packets are not supported.

When the broadcast forwarding type within a forwarding class is mapped to a policer, the broadcast packets classified to the subclasses within the forwarding class are also mapped to the policer.

The **no** form of this command is used to restore the mapping of the broadcast forwarding type within the forwarding class to the default multipoint queue. If all forwarding class forwarding types had been removed from the default multipoint queue, the queue will not exist on the SAPs or subscribers or multiservice site associated with the QoS policy and the **no broadcast-policer** command will cause the system to attempt to create the default multipoint queue on each object. If the system cannot create the queue on each instance, the **no broadcast-policer** command will fail and the broadcast forwarding type within the forwarding class will continue its mapping to the existing policer-id. If the **no broadcast-policer** command results in a policer without any current mappings, the policer will be removed from the SAPs and subscribers associated with the QoS policy. All statistics associated with the policer on each SAP and subscriber will be lost.

Parameters

policer-id

When the forwarding class **broadcast-policer** command is executed, a valid *policer-id* must be specified. The parameter *policer-id* references a *policer-id* that has already been created within the sap-ingress QoS policy.

Values 1 to 63

fp-redirect-group

Redirects a forwarding class to a forwarding plane queue-group as specified in a SAP QoS policy.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, 7950 XRS, VSR

6.111 broadcast-queue

broadcast-queue

Syntax

broadcast-queue *queue-id* [**group** *queue-group-name*]

no broadcast queue

Context

[Tree] (config>qos>sap-ingress>fc broadcast-queue)

Full Context

configure qos sap-ingress fc broadcast-queue

Description

This command overrides the default broadcast forwarding type queue mapping for **fc** *fc-name*. The specified *queue-id* must exist within the policy as a multipoint queue before the mapping can be made.

When the forwarding class mapping is executed, all broadcast traffic on a SAP using this policy will be forwarded using the *queue-id*.

The broadcast forwarding type usually tracks the multicast forwarding type definition. This command overrides that default behavior.

The **no** form of this command sets the broadcast forwarding type *queue-id* back to the default of tracking the multicast forwarding type queue mapping.

Parameters

queue-id

The *queue-id* parameter must be an existing, multipoint queue defined in the config>qos>sap-ingress context.

Values Any valid multipoint queue ID in the policy including 2 through 32.

Default 11

group *queue-group-name*

This optional parameter is used to redirect the forwarding type within the forwarding class to the specified queue-id within the queue-group-name. When the policy is applied, all packets matching the forwarding class and forwarding type will be redirected to the queue within the specified queue group. The *queue-group-name* are configured in the **config>qos>queue-group-templates** egress and ingress contexts.

Platforms

All

broadcast-queue

Syntax

broadcast-queue *queue-id*

Context

[Tree] (config>qos>shared-queue>fc broadcast-queue)

Full Context

configure qos shared-queue fc broadcast-queue

Description

This command configures the broadcast forwarding type queue mapping for **fc** *fc-name*. The specified *queue-id* must exist within the policy as a multipoint queue before the mapping can be made. When the forwarding class mapping is executed, all broadcast traffic on a SAP using this policy will be forwarded using the *queue-id*.

The broadcast forwarding type usually tracks the multicast forwarding type definition. This command overrides that default behavior.

The **no** form of this command sets the broadcast forwarding type *queue-id* back to the default of tracking the multicast forwarding type queue mapping.

Parameters

queue-id

The *queue-id* parameter must specify an existing multipoint queue defined in the **config>qos>sap-ingress** context policer-output-queues profile. For the 7950 XRS, this is not configurable in the policer-output-queues profile.

Values 17 to 24

Platforms

All

6.112 broadcastclient

broadcastclient

Syntax

broadcastclient [**router** *router-instance* | **service-name** *service-name*] {**interface** *ip-int-name*} [**authenticate**]

no broadcastclient [**router** *router-instance* | **service-name** *service-name*] {**interface** *ip-int-name*}

Context

[Tree] (config>system>time>ntp broadcastclient)

Full Context

configure system time ntp broadcastclient

Description

When configuring NTP, the node can be configured to receive broadcast packets on a specified subnet. This command configures a specific interface to listen for broadcast NTP messages. The interface may exist within a VPRN service.

Broadcast and multicast messages can easily be spoofed, so authentication is strongly recommended. If broadcast is not configured, then any received NTP broadcast traffic will be ignored. Use the **show** command to view the state of the configuration.

The **no** form of this command removes the interface from the configuration.

Parameters

router-instance

Specifies the routing context that contains the interface in the form of *router-name* or *service-id*.

Values *router-name* — Base | Management
service-id — 1 to 2147483647

Default Base

service name

Specifies the service name for the VPRN. The name can be up to 64 characters in length. Note that CPM routing instances are not supported.

ip-int-name

Specifies the VPRN interface on which to receive NTP broadcast packets. If the string contains special characters (such as #, $, or spaces) the entire string must be enclosed within double quotes.

authenticate

Specifies whether or not to require authentication of NTP PDUs. When enabled, NTP PDUs are authenticated upon receipt.

6.116 buffer-allocation

buffer-allocation

Syntax

buffer-allocation min *percentage* **max** *percentage*

no buffer-allocation

Context

[Tree] (config>card>fp>egress>wred-queue-control buffer-allocation)

Full Context

configure card fp egress wred-queue-control buffer-allocation

Description

The buffer-allocation command defines the amount of buffers that will be set aside for WRED queue buffer pools. Note that the **min** *percentage* and max *percentage* parameters must be set to the same value. The forwarding plane protects against cross application buffer starvation by implementing a hierarchy of buffer pools. At the top of the hierarchy are mega-pools. Mega-pools are used to manage buffers at a system application level. Two mega-pools are currently used by the system. The first (default) mega-pool services all non-WRED type queues and when WRED queues are not enabled will contain all available forwarding plane queue buffers. When WRED queuing is enabled, the second mega-pool (the WRED mega-pool) is given buffers from the default mega-pool based on the buffer-allocation command.

The mega-pools provide buffers to the second tier buffer pools. The default mega-pool services all default pools. As the name implies, the WRED mega-pool services all the WRED buffer pools created for the WRED queues. The WRED mega-pool allows each WRED queue pool to be configured to an appropriate size while allowing the sum of the WRED queue pool sizes to oversubscribe the total amount set aside for WRED queue buffering without affecting the queues using the default pools.

No buffers are allocated to the WRED mega-pool until the wred-queue-control shutdown command is set to no shutdown. When the shutdown command is executed, all buffers allocated to the WRED mega-pool are returned to the default mega-pool and all WRED queues are returned to their default buffer pool.

The **no** form of this command immediately restores the default min and max percentage values for sizing the WRED mega-pool.

Default

buffer-allocation min 25.00 max 25.00

Parameters

min *percentage*

Specifies that the required keyword defines the minimum percentage of total egress forwarding plane queue buffers that will be applied to the WRED mega-pool. The value given for *percentage* must be less than or equal to the value given for the **max** *percentage*. Percentages are defined with an accuracy of hundredths of a percent in the nn.nn format (15.65 = 15.65%).

Values 0.00 to 99.99

Default 25.00

max *percentage*

Specifies that the required keyword defines the maximum percentage of total egress forwarding plane queue buffers that may be applied to the WRED mega-pool. The value given for *percentage* must be equal to or greater than the value given for the **min** *percentage*. Percentages are defined with an accuracy of hundredths of a percent in the nn.nn format (15.65 = 15.65%).

Values 0.01 to 99.99

Default 25.00

buffer-type

Syntax

buffer-type *buffer-type*

Context

[Tree] (config>app-assure>group>evt-log buffer-type)

Full Context

configure application-assurance group event-log buffer-type

Description

This command specifies the type of buffer to be used in the event log.

Default

buffer-type linear

Parameters

buffer-type

Specifies the type of event type.

Values **linear** — Specifies a linear buffer which once full will stop recording events until it is cleared.

circular — Specifies a circular buffer whereby older entries will be overwritten by newer entries.

syslog—Specifies that events are stored offline on a syslog host.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

6.118 buffering

buffering

Syntax

[**no**] **buffering**

Context

[Tree] (config>call-trace buffering)

Full Context

configure call-trace buffering

Description

This command specifies whether messages should be buffered for sessions where the trace key is not yet known, for example, a username for a PPP session. When the key indicates a match for a traced session, the router sends the buffered messages immediately. If the key does not match a trace, the router discards the buffered messages. By default, the router does not buffer any message and thus initial messages may not be traced.

The **no** form of this command reverts to the default value.

Default

no buffering

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

configure port tdm buildout

Description

This command specifies line buildout (cable length) for physical DS-1/DS-3 ports.

Default

buildout short

Parameters

long

Sets the line buildout for length runs up to 450 feet.

short

Sets the line buildout for length runs up to 225 feet.

Platforms

7450 ESS, 7750 SR-7/12/12e, 7750 SR-a, 7750 SR-e

6.121 bundle

bundle

Syntax

bundle *bundle-name* [**create**]

no bundle *bundle-name*

Context

[Tree] (config>mcast-mgmt>mcast-info-plcy bundle)

Full Context

configure mcast-management multicast-info-policy bundle

Description

This command creates or edits channel bundles within a multicast information policy. Bundles are used for two main purposes. First, bundles are used by the multicast CAC function to group multicast channels into a common bandwidth context. The CAC function limits the ability for downstream nodes to join multicast channels based on the egress interfaces ability to handle the multicast traffic. Bundling allows multicast channels with common preference or application to be managed into a certain percentage of the available bandwidth.

The second function of bundles is to provide a simple provisioning mechanism. Each bundle within a multicast information policy has a set of default channel parameters. If each channel provisioned in to the bundle can use the default parameters for the bundle, the provisioning and configuration storage requirements are minimized.

Up to 31 explicit bundles may be defined within a multicast information policy (32 including the default bundle).

Once a bundle is created, the default channel parameters should be configured and the individual channel ranges should be defined. Within each channel range, override parameters may be defined that override the default channel parameters. Further overrides are supported within the channel range based on explicit source overrides.

A bundle can be deleted at any time (except for the default bundle). When a bundle is deleted, all configuration information within the bundle is removed including multicast channel ranges. Any multicast records using the bundle should be reevaluated. Multicast CAC and ECMP managers should also be updated.

Default Bundle

Each multicast information policy contains a bundle named **default**. The default bundle cannot be deleted. Any multicast channel that fails to match a channel range within an explicit bundle is automatically associated with the default bundle.

The **no** form of this command removes a bundle from the multicast information policy. The default bundle cannot be removed from the policy.

Default

bundle "default”

Parameters

bundle-name

Specifies bundle expressed as an ASCII string with up to 16 characters and must follow normal naming conventions. If bundle-name already exists, the system enters the bundle context for editing purposes. If bundle-name does not exist, the system creates the defined bundle in the policy and enter the bundle context for editing purposes.

create

The create keyword is required if creating a new multicast information policy bundle when the system is configured to require the explicit use of the keyword to prevent accidental object creation. Objects may be accidentally created when this protection is disabled and an object name is mistyped when attempting to edit the object. This keyword is not

required when the protection is disabled. The keyword is ignored when the bundle name already exists.

Platforms

debug router rsvp packet bundle

Description

This command debugs bundle events.

The **no** form of the command disables the debugging.

Parameters

detail

Displays detailed information about bundle events.

Platforms

All

bundle

Syntax

bundle *bundle-name* [**create**]

no bundle *bundle-name*

Context

[Tree] (config>router>mcac>policy bundle)

Full Context

configure router mcac policy bundle

Description

This command creates the context that enables the grouping of MCAC group addresses into bundles.

When a number of multicast groups or BTV channels are grouped into a single bundle, then policing, if a join for a particular MC-group (BTV channel), can depend on whether:

1. There is enough physical bandwidth on the egress interface.
2. The given channel is a mandatory or optional channel.
   - If optional, is there sufficient bandwidth according to the policy settings for the relevant interface.
   - If optional, is there sufficient bandwidth within the bundle.

The **no** form of this command removes the named bundle from the configuration.

Parameters

bundle-name

Specifies the multicast bundle name. Allowed values are any string up to 32 characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be no enclosed within double quotes.

create

Mandatory keyword when creating a bundle instance. The create keyword requirement can be enabled or disabled in the **environment**>**create** context.

6.122 burst-limit

burst-limit

Syntax

burst-limit {**default** | *size* [**bytes** | **kilobytes**]}

no burst-limit

Context

[Tree] (config>service>vprn>sub-if>grp-if>sap>egress>queue-override>queue burst-limit)

Full Context

configure service vprn subscriber-interface group-interface sap egress queue-override queue burst-limit

Description

The queue **burst-limit** command defines an explicit shaping burst size for a queue. The configured size defines the shaping leaky bucket threshold level that indicates the maximum burst over the queue's shaping rate.

The **no** form of this command restores the default burst limit to the specified queue. This is equivalent to specifying burst-limit default within the QoS policies. When specified within a queue-override queue context, any current burst limit override for the queue is removed and the queue's burst limit is controlled by its defining policy.

Default

no burst-limit

Parameters

default

Reverts the queue's burst limit to the system default value.

size

When a numeric value is specified (size), the system interprets the value as an explicit burst limit size. The value is expressed as an integer and, by default, is interpreted as the burst limit in kilobytes. If the value is intended to be interpreted in bytes, the **bytes** qualifier must be added following size.

Values 0 to 13671 kilobytes

0 to 14000000 bytes

Default No default for *size*; use the **default** keyword to specify default burst limit.

bytes

Specifies that the value given for *size* must be interpreted as the burst limit in bytes.

kilobytes

Specifies that the value given for *size* must be interpreted as the burst limit in kilobytes. If neither bytes nor kilobytes is specified, the default qualifier is **kilobytes**.

burst-limit

Syntax

burst-limit {**default** | *size* [**bytes** | **kilobytes**]}

Parameters

default

Reverts the queue's burst limit to the system default value.

size

When a numeric value is specified (size), the system interprets the value as an explicit burst limit size. The value is expressed as an integer and, by default, is interpreted as the burst limit in kilobytes. If the value is intended to be interpreted in bytes, the **bytes** qualifier must be added following size.

Values 1 to 14000000

bytes

Specifies that the value given for *size* must be interpreted as the burst limit in bytes.

kilobytes

Specifies that the value given for *size* must be interpreted as the burst limit in kilobytes. If neither bytes nor kilobytes is specified, the default qualifier is **kilobytes**.

Platforms

All

burst-limit

Syntax

burst-limit *size* [**bytes** | **kilobytes**]

no burst-limit

Context

[Tree] (config>qos>sap-ingress>queue burst-limit)

Full Context

configure qos sap-ingress queue burst-limit

Description

The **queue burst-limit** command is used to define an explicit shaping burst size for a queue. The configured size defines the shaping leaky bucket threshold level that indicates the maximum burst over the queue's shaping rate.

The **burst-limit** command is supported under the sap-ingress and sap-egress QoS policy queues. The command is also supported under the ingress and egress queue-group-templates queues.

The **no** form of this command is used to restore the default burst limit to the specified queue. This is equivalent to specifying burst-limit default within the QoS policies or queue group templates. When specified within a **queue-override queue** context, any current burst limit override for the queue will be removed and the queue's burst limit will be controlled by its defining policy or template.

Default

no burst-limit

Parameters

size

Specifies an explicit burst limit size. The value is expressed as an integer and, by default, is interpreted as the burst limit in kilobytes. If the value is intended to be interpreted in bytes, the byte qualifier must be added following size.

Values 1 to 13,671 kbytes or 14,000,000 bytes

Default No default for size; use the default keyword to specify default burst limit.

bytes

Specifies that the value given for size must be interpreted as the burst limit in bytes.

kilobytes

Specifies that the value given for size must be interpreted as the burst limit in kilobytes. If neither bytes nor kilobytes is specified, the default qualifier is kilobytes.

Platforms

All

Syntax

burst-limit {**default** | *size* [**bytes** | **kilobytes**]}

no burst-limit

Context

[Tree] (config>qos>sap-egress>queue burst-limit)

Full Context

configure qos sap-egress queue burst-limit

Description

The **queue burst-limit** command defines an explicit shaping burst size for a queue. The configured size defines the shaping leaky bucket threshold level that indicates the maximum burst over the queue's shaping rate.

The **burst-limit** command is supported under the **sap-ingress** and **sap-egress** QoS policy queues. The command is also supported under the ingress and egress **queue-group-templates** queues.

The **no** form of this command restores the default burst limit to the specified queue. This is equivalent to specifying burst-limit default within the QoS policies or queue group templates. When specified within a **queue-override queue** context, any current burst limit override for the queue is removed and the queue's burst limit is controlled by its defining policy or template.

Default

no burst-limit

Parameters

default

Reverts the queue's burst limit to the system default value.

size

Specifies an explicit burst limit size. The value is expressed as an integer and by default is interpreted as the burst limit in kilobytes. If the value is intended to be interpreted in bytes, the **bytes** keyword must be added following *size*.

Values 1 to 13671 kilobytes

0 to 14,000,000 bytes

Default No default for *size*; use the **default** keyword to specify default burst limit.

bytes

Specifies that the value given for size must be interpreted as the burst limit in bytes.

kilobytes

Specifies that the value given for size must be interpreted as the burst limit in kilobytes. If neither bytes nor kilobytes is specified, the default qualifier is **kilobytes**.

Platforms

6.123 bw-activity

bw-activity

Syntax

bw-activity {**use-admin-bw** | **dynamic** [**falling-delay** *seconds*]} [**black-hole-rate** *kbps*]

no bw-activity

Context

[Tree] (config>mcast-mgmt>mcast-info-plcy>bundle>source-override bw-activity)

[Tree] (config>mcast-mgmt>mcast-info-plcy>bundle bw-activity)

[Tree] (config>mcast-mgmt>mcast-info-plcy>bundle>channel bw-activity)

Full Context

configure mcast-management multicast-info-policy bundle source-override bw-activity

configure mcast-management multicast-info-policy bundle bw-activity

configure mcast-management multicast-info-policy bundle channel bw-activity

Description

This command defines how the multicast ingress path manager determines the amount of bandwidth required by a multicast channel. The default setting is dynamic which causes the bandwidth manager to use the bandwidth policies dynamic rate table entries to determine the current rate. The alternative setting is **use-admin-bw** which causes the bandwidth manager to use the configured admin-bw associated with the channel. The **use-admin-bw** setting also requires an active and inactive threshold to be defined which allows the bandwidth manager to determine when the channel is actively using ingress path bandwidth and when the channel is idle.

The **use-admin-bw** setting requires that the channel be configured with an admin-bw value that is not equal to 0 in the same context as the **bw-activity** command using the setting. Once a context has the **use-admin-bw** command configured, the context's admin-bw value cannot be set to 0 and the no admin-bw command fails.

This command also supports an optional **black-hole-rate** *kbps* command that defines at which current rate a channel should be placed in the black-hole state. This is intended to provide a protection mechanism against multicast channels that exceed a reasonable rate and cause outages in other channels.

The **no** form of this command restores the default bandwidth activity monitoring setting (dynamic or null depending on the context).

Parameters

use-admin-bw | dynamic

The **use-admin-bw** and **dynamic** keywords are mutually exclusive and one must be specified when executing the **bw-activity** command. The **use-admin-bw** keyword indicates the channels current ingress bandwidth should be derived from the **admin-bw** setting. The **admin-bw** setting must not currently be set to 0 for the **use-admin-bw** setting to succeed. The **dynamic** keyword indicates that the multicast ingress path manager should use the dynamic rate table (as defined in the bandwidth-policy) to derive the channels current ingress rate.

falling-delay *seconds*

Specifies the value the bandwidth manager uses the falling-delay threshold to hold on to the previous highest bandwidth until the delay time has expired while operating in dynamic bandwidth mode. This allows the bandwidth manager to ignore momentary drops in channel bandwidth.

Values 10 to 3600

Default 30

Bundle default:	dynamic
Channel default:	Null (undefined)
Source-override default:	Null (undefined)

black-hole-rate *kbps*

Specifies a rate at which a channel is placed in the black-hole state. This parameter is expressed, in kb/s, as an integer and represents multiples of 1,000 bits per second.

Values 1 to 40000000

Platforms

7450 ESS, 7750 SR-1x-48D, 7750 SR-1x-92S, 7750 SR-7/12/12e, 7750 SR-s, 7950 XRS, VSR

6.124 bypass-resignal-timer

bypass-resignal-timer

Syntax

bypass-resignal-timer *minutes*

no bypass-resignal-timer

Context

[Tree] (config>router>mpls bypass-resignal-timer)

Full Context

configure router mpls bypass-resignal-timer

Description

This command triggers the periodic global re-optimization of all dynamic bypass LSP paths associated with RSVP P2P LSP. The operation is performed at each expiry of the user configurable bypass LSP resignal timer.

When this command is enabled, MPLS requests CSPF for the best path for each dynamic bypass LSP originated on this node. The constraints, hop-limit, SRLG and admin-group constraints, of the first associated LSP primary path that originally triggered the signaling of the bypass LSP must be satisfied. To do this, MPLS saves this initial Path State Block (PSB) of that LSP primary path, even if the latter is torn down.

CSPF first updates the SRLG membership of the current bypass LSP path and checks if the path violates the SRLG constraint of the initial PSB. It then attempts a new path computation for the bypass LSP using the initial PSB constraints. If CSPF returns no path or returns a new path with a cost that is lower than the current path, MPLS does not signal the new bypass path. If CSPF returns a new path with a cost that is lower than the current one, MPLS signals it. Also, if the new bypass path is SRLG strict disjoint with the primary path of the original PSB while the current path is SRLG loose disjoint, the manual bypass path is resignaled regardless of cost comparison.

Once the new path is successfully signaled, MPLS evaluates each PSB of each PLR (that is, each unique avoid-node or avoid-link constraint) associated with the current bypass LSP path to check if the corresponding LSP primary path constraints are still satisfied by the new bypass LSP path. If so, the PSB association is moved to the new bypass LSP.

Each PSB for which the constraints are not satisfied remains associated with the PLR on the current bypass LSP and is checked at the next timer or manual bypass re-optimization. Additionally, if SRLG FRR loose disjointness is configured using the **configure router mpls srlg-frr** command and the current bypass LSP is SRLG disjoint with a primary path while the new bypass LSP is not SRLG disjoint, the PSB association is not moved. When CSPF does not return a new bypass path or it returns a less optimal one, the PSBs remain associated with the current bypass path. However, it is possible that CSPF found the current bypass LSP path no longer satisfies the SRLG constraint of one or more PLRs after the update of the current path SRLG information. In that case, MPLS detaches from current bypass path the PSB associations of these PLRs. These orphaned PSBs are re-evaluated by the FRR background task which checks unprotected PSBs on a regular basis and following the same above procedure.

If a specific PLR associated with a bypass LSP is active, the corresponding PSBs remain associated with the current PLR until the Global Revertive Make-Before-Break (MBB) tears down all corresponding primary paths, which also causes the current PLR to be removed.

Note:
While it is in the preceding state, the older PLR does not get any new PSB association until the specific PLR with an active bypass LSP is removed. When the last PLR is removed, the older bypass LSP is torn down.

This feature is not supported with inter-area dynamic bypass LSP and bypass LSP protecting S2L paths of a P2MP LSP.

The **no** form of this command disables the periodic global re-optimization of dynamic bypass LSP paths.

Default

no bypass-resignal timer.

Parameters

minutes

Specifies the time, in minutes, MPLS waits before attempting to resignal dynamic bypass LSP paths originated on the system.

Values 1 to 10080

Platforms

All

7 c Commands

7.1 c-mcast-signaling

c-mcast-signaling

Syntax

c-mcast-signaling {**bgp** | **pim**}

no c-mcast-signaling

Context

[Tree] (config>service>vprn>mvpn c-mcast-signaling)

Full Context

configure service vprn mvpn c-mcast-signaling

Description

This command specifies BGP or PIM, for PE-to-PE signaling of CE multicast states. When this command is set to PIM and neighbor discovery by BGP is disabled, PIM peering will be enabled on the inclusive tree.

Changes may only be made to this command when the mvpn node is shutdown.

The **no** form of this command reverts it back to the default.

Default

c-mcast-signaling bgp

Parameters

bgp

Specifies to use BGP for PE-to-PE signaling of CE multicast states. Auto-discovery must be enabled.

pim

Specifies to use PIM for PE-to-PE signaling of CE multicast states.

Platforms

All

7.2 ca-name

ca-name

Syntax

ca-name *ca-name*

no ca-name

Context

[Tree] (config>port>ethernet>dot1x>macsec>sub-port ca-name)

Full Context

configure port ethernet dot1x macsec sub-port ca-name

Description

This command configures the Connectivity Association (CA) linked to this MACsec sub-port. The specified CA provides the MACsec parameter to be used or negotiated with other peers.

The **no** form of this command removes the CA from the MACsec sub-port.

Parameters

ca-name

Specifies the appropriate ca to be used under this MACsec sub-port, up to 32 characters.

Platforms

All

7.3 ca-profile

ca-profile

Syntax

[**no**] **ca-profile** *name*

Context

[Tree] (config>ipsec>cert-profile>entry>send-chain ca-profile)

Full Context

configure ipsec cert-profile entry send-chain ca-profile

Description

This command specifies a CA certificate in the specified **ca-profile** to be sent to the peer.

Multiple configurations (up to seven) of this command are allowed in the same entry.

Parameters

name

Specifies the profile name up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

ca-profile

Syntax

ca-profile *name* [**create**]

no ca-profile *name*

Context

[Tree] (config system security pki ca-profile)

Full Context

configure system security pki ca-profile

Description

This command creates a new **ca-profile** or enters the configuration context of an existing **ca-profile**. Up to 128 ca-profiles can be created in the system. A **shutdown** of the **ca-profile** will not affect the current up and running **ipsec-tunnel** or **ipsec-**gw that is associated with the **ca-profile**. However, authentication afterwards will fail with a **shutdown ca-profile**.

Executing a **no shutdown** command in this context causes the system to reload the configured cert-file and crl-file.

A **ca-profile** can be applied under the **ipsec-tunnel** or **ipsec-gw** configuration.

The **no** form of this command removes the name parameter from the configuration. A ca-profile cannot be removed until all the associated entities (ipsec-tunnel/gw) have been removed.

Parameters

name

Specifies the name of the **ca-profile** up to 32 characters.

create

Keyword used to create a new **ca-profile**. The **create** keyword requirement can be enabled or disabled in the **environment>create** context.

Platforms

All

Full Context

debug certificate cmpv2 ca-profile

debug certificate auto-crl-update ca-profile

debug certificate ocsp ca-profile

Description

This command debugs output of the specified CA profile.

- Protection method of each message is logged.
- All HTTP messages are logged. Format allows offline analysis using Wireshark.
- In the event of failed transactions, saved certificates are not deleted from file system for further debug and analysis.
- The system allows CMPv2 debugging for multiple ca-profile at the same time.

Parameters

profile-name

Specifies the name of the CA profile, up to 32 characters.

Platforms

All

ca-profile

Syntax

[**no**] **ca-profile** *name*

Context

[Tree] (config>system>security>tls>cert-profile>entry>send-chain ca-profile)

Full Context

configure system security tls cert-profile entry send-chain ca-profile

Description

This command enables a certificate authority (CA) certificate in the specified CA profile to be sent to the peer. Up to seven configurations of this command are permitted in the same entry.

The **no** form of the command disables the transmission of a CA certificate from the specified CA profile.

Parameters

name

Specifies the name of the certificate authority profile, up to 32 characters in length.

Platforms

All

7.4 cacert

cacert

Syntax

cacert est-profile *name* **output** *output-cert-filename* [**force**]

cak

Syntax

cak *hex-string* [**hash** | **hash2** | **custom**]

no cak

Context

[Tree] (config>macsec>conn-assoc>static-cak>pre-shared-key cak)

Full Context

configure macsec connectivity-association static-cak pre-shared-key cak

Description

Specifies the connectivity association key (CAK) for a pre-shared key. Two values are derived from CAK.

- Key Encryption Key (KEK), this is used to encrypt the MKA and SAK (symmetric key used for data path PDUs) to be distributed between all members.
- Integrity Check Value (ICK), this is used to authenticate the MKA and SAK PDUs to be distributed between all members.

The **no** form of this command removes the value.

Parameters

hex-string

Specifies the value of the CAK.

Values up to 64 hexadecimal characters, 32 hexadecimal characters for 128-bit key and 64 hexadecimal characters for 256-bit key

hash

Keyword, specifying the hash scheme.

hash2

Keyword, specifying the hash scheme.

custom

Specifies the custom encryption for management interface.

configure subscriber-mgmt authentication-policy include-radius-attribute calling-station-id

configure service vpls sap calling-station-id

configure service vprn interface sap calling-station-id

configure service vprn subscriber-interface group-interface sap calling-station-id

Description

This command enables the inclusion of the **calling-station-id** attribute in RADIUS authentication requests and RADIUS accounting messages.

The **no** form of this command reverts to the default.

Default

calling-station-id sap-string

Parameters

llid

Specifies that the logical link identifier (LLID) is mapping from a physical to logical identification of a subscriber line and supplied by a RADIUS llid-server.

mac

Specifies that the MAC address is sent.

remote-id

Specifies that the remote ID is sent.

sap-id

Specifies that the SAP ID is sent.

sap-string

Specifies that the value is the inserted value set at the SAP level. If no **calling-station-id** value is set at the SAP level, the **calling-station-id** attribute will not be sent.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

configure subscriber-mgmt diameter-application-policy nasreq include-avp calling-station-id

configure subscriber-mgmt diameter-application-policy gx include-avp calling-station-id

Description

This command includes the calling-station-id AVP in the specified format.

The **no** form of this command reverts to the default.

Parameters

type

Specifies the format of the Calling-Station-ID AVP.

Values **llid** — The logical link identifier (LLID) is the mapping from a physical to logical identification of a subscriber line and supplied by a RADIUS llid-serv

mac — Specifies that the MAC address is sent.

remote-id — Specifies that the remote ID is sent

sap-id — Specifies that the sap-id is sent

sap-string — Specifies that the value is the inserted value set at the SAP level. If no **calling-station-id** value is set at the SAP level, the **calling-station-id** attribute will not be sent.

7.16 candidate

candidate

Syntax

candidate

Context

[Tree] (candidate)

Full Context

candidate

Description

Commands in this context edit candidate configurations.

Commands in the **candidate** CLI branch, except **candidate edit**, are available only when in edit-cfg mode.

Platforms

All

candidate

Syntax

[**no**] **candidate**

Context

[Tree] (config>system>netconf>capabilities candidate)

Full Context

configure system netconf capabilities candidate

Description

This command allows the SR OS NETCONF server to access the candidate configuration datastore. Configuring this command also enables using **commit** and **discard-changes**.

When **configure system management-interface configuration-mode** is set to **classic**, the candidate capability is disabled, even if this command is configured.

The **no** form of the command disables the SR OS NETCONF server from accessing the candidate datastore. If the candidate is disabled, requests that reference the candidate datastore return an error, and when a NETCONF client establishes a new session, the candidate capability is not advertised in the SR OS NETCONF Hello message.

Default

7.17 cannot-change-password

cannot-change-password

Syntax

[**no**] **cannot-change-password**

Context

[Tree] (config>system>security>user>console cannot-change-password)

Full Context

configure system security user console cannot-change-password

Description

This command allows a user the privilege to change their password for both FTP and console login.

To disable a user's privilege to change their password, use the **cannot-change-password** form of this command.

Note:
The **cannot-change-password** flag is not replicated when a user copy is performed. A new-password-at-login flag is created instead.

Default

no cannot-change-password

Platforms

7.18 capacity-cost

capacity-cost

Syntax

capacity-cost *cost*

no capacity-cost

Context

[Tree] (config>app-assure>group>policy>app-profile capacity-cost)

Full Context

configure application-assurance group policy app-profile capacity-cost

Description

This command configures an application profile capacity cost. Capacity-Cost based load balancing allows a cost to be assigned to diverted SAPs (with the app-profile) and this is then used for load-balancing SAPs between ISAs as well as for a threshold that notifies the operator if/when capacity planning has been exceeded.

Default

capacity-cost 1

Parameters

cost

Specifies the profile capacity cost.

Values 1 to 65535

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

7.19 captive-redirect

captive-redirect

Syntax

captive-redirect

Context

[Tree] (config>app-assure>group>http-redirect captive-redirect)

Full Context

configure application-assurance group http-redirect captive-redirect

Description

This command configures the captive redirect capability for an HTTP redirect policy. HTTP redirect policies using captive redirect can be used in conjunction with a session filter policy and will terminate TCP flows in the ISA-AA card before reaching the Internet to redirect subscribers to the predefined redirect URL. Non-HTTP TCP flows are TCP reset. Captive redirect uses the provisioned VLAN id to send the HTTP response to subscribers; therefore this VLAN id must be properly assigned in the same VPN as the subscriber. The operator can select the URL arguments to include in the redirect URL using either a specific template id or by configuring the redirect URL using one of the supported macro substitution keywords.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

7.20 capture

capture

Syntax

capture [{**start** | **stop**}]

Context

[Tree] (debug>pcap capture)

Full Context

debug pcap capture

Description

This command starts and stops the packet capture process for the specified *session-name*.

Parameters

start

Starts the packet capture process and also start or restarts the FTP or TFTP session. If the FTP or TFTP server is unreachable, the command prompt rejects further input until the retires are timed out after 24 seconds (after four attempts of about six seconds each). If the same file name is unchanged in the **config**>**mirror**>**mirror-dest**>**pcap** context between captures, this command overwrites the file content.

stop

Stops the packet capture process and also stops the FTP or TFTP session. If the FTP or TFTP server is unreachable, the command prompt rejects further input until the retires are timed out after 24 seconds (after four attempts of about six seconds each).

no capture-sap *sap-id*

Context

[Tree] (debug>dynsvc>data-triggers capture-sap)

Full Context

debug dynamic-services data-triggers capture-sap

Description

This command enables or disables the generation of dynamic services data trigger debug events, such as:

- data trigger received
- authentication
- data trigger SAP created
- dynamic service SAP created
- dropped data trigger with drop reason such as data trigger exists or lockout active.

Multiple capture SAPs can be specified simultaneously.

Optionally, a single **encap-val** per **capture-sap** can be specified to limit the output of the debug events to the data trigger events with the specified encapsulation.

Optionally, the debug output can be restricted to dropped data trigger events only.

Parameters

sap-id

Specifies the dynamic services data trigger capture SAP for which debug events should be logged.

encap-val qtag[.qtag]

Optionally restrict the debug output to data trigger events with the specified encapsulation.

Values 1 to 4094

mode

Optionally restrict the debug output to specific events.

Values all—log all data trigger events

dropped-only—log only dropped data trigger events

7.22 card

card

Syntax

[**no**] **card** *slot-number*

Context

[Tree] (config card)

Full Context

configure card

Description

This mandatory command enables access to the chassis and context. In SR OS cards cover IOM, IMM, and XCM.

The **no** form of this command removes the card from the configuration. All associated ports, services, and MDAs must be shutdown.

Default

no card

Parameters

slot-number

Specifies the slot number of the card in the chassis. The maximum slot number is platform dependent. Refer to the hardware installation guides.

Values 1 to 10

Platforms

All

7.23 card-type

card-type

Syntax

card-type *card-type* [**level** *card-level*]

no card-type

Context

[Tree] (config>card card-type)

Full Context

configure card card-type

Description

This mandatory command adds an IOM/XCM to the device configuration for the slot. The card type can be preprovisioned, meaning that the card does not need to be installed in the chassis.

A card must be provisioned before an MDA, connector, or port can be configured.

A card can only be provisioned in a slot that is vacant, meaning no other card can be provisioned (configured) for that particular slot. To reconfigure a slot position, use the **no** form of this command to remove the current information.

A card can only be provisioned in a slot if the card type is allowed in the slot. An error message is generated if an attempt is made to provision a card type that is not allowed.

If a card is inserted that does not match the configured card type for the slot, then a log event and facility alarm is raised. The alarm is cleared when the correct card type is installed or the configuration is modified.

A log event and facility alarm are is raised if an administratively enabled card is removed from the chassis. The alarm is cleared when the correct card type is installed or the configuration is modified. A log event is issued when a card is removed that is administratively disabled.

Because IMMs do not have the capability to install separate MDAs, the configuration of the MDA is automatic. This configuration only includes the default parameters such as default buffer policies. Commands to manage the MDA such as **shutdown** and so on, remain in the MDA configuration context.

Some card hardware can support two different firmware loads. One load includes the base Ethernet functionality, including 10G WAN mode, but does not include 1588 port-based timestamping. The second load includes the base Ethernet functionality and 1588 port-based timestamping, but does not include 10G

WAN mode. These are identified as two card types that are the same, except for a "-ptp” suffix to indicate the second loadset; for example, *imm40-10gb-sfp* and *imm40-10gb-sfp-ptp*. A hard reset of the card occurs when switching between the two provisioned types.

An appropriate alarm is raised if a partial or complete card failure is detected. The alarm is cleared when the error condition ceases.

New generations of cards include variants controlled by hardware and software licensing. For these cards, the license level must be provisioned in addition to the card type. A card cannot become operational unless the provisioned license level matches the license level of the card installed into the slot. The set of license levels varies by card type.

The provisioned level controls aspects related to connector provisioning and the consumption of hardware egress queues and egress policers. Changes to the provisioned license level may be blocked if configuration exists that would not be permitted with the new target license level.

If the license level is not specified, the level is set to the highest license level for that card.

The **no** form of this command removes the card from the configuration.

Default

no card-type

Parameters

card-type

Specifies the type of card to be configured and installed in that slot. Values for this attribute vary by platform and release. The release notes include a listing of all supported card-types and their CLI strings. In addition, the command can be queried to check which card-types are relevant for the active platform type. Some examples include iom4-e-b and imm-2pac-fp3.

card-level

Specifies the license level of the card, up to 32 characters. Possible values vary by card type.

7.28 cbs

cbs

Syntax

cbs *percent-of-resv-cbs*

no cbs

Context

[Tree] (config>mcast-mgmt>bw-plcy>t2-paths>primary-paths>queue-parameters cbs)

[Tree] (config>mcast-mgmt>bw-plcy>t2-paths>secondary-paths>queue-parameters cbs)

Full Context

configure mcast-management bandwidth-policy t2-paths primary-paths queue-parameters cbs

configure mcast-management bandwidth-policy t2-paths secondary-paths queue-parameters cbs

Description

This command overrides the default Committed Buffer Size (CBS) for each individual path's queue. The queues CBS threshold is used when requesting buffers from the systems ingress buffer pool to indicate whether the requested buffer should be removed from the reserved portion of the buffer pool or the shared portion. When the queue's fill depth is below or equal to the CBS threshold, the requested buffer comes from the reserved portion. Once the queues depth exceeds the CBS threshold, buffers come from the shared portion.

The **cbs** *percent-of-resv-cbs* parameter is defined as a percentage of the reserved portion of the pool. The system allows the sum of all CBS values to equal more than 100% allowing for oversubscription of the reserved portion of the pool. If the reserved portion is oversubscribed and the queues are currently using

more reserved space than provisioned in the pool, the pool automatically starts using the shared portion of the pool for within-CBS buffer allocation. The shared early detection slopes can assume more buffers that exist within the shared portion that may cause the early detection function to fail.

For the primary-path and secondary-path queues, the percentage is applied to a single queue for each path.

The **no** form of this command restores the path queues default CBS value.

Parameters

percent-of-resv-cbs

Specifies the percent of buffers reserved from the total buffer pool space, expressed as a decimal integer. If 10 MB is the total buffers in the buffer pool, a value of 10 would reserve 1MB (10%) of buffer space for the forwarding class queue. The value 0 specifies that no reserved buffers are required by the queue (a minimal reserved size can be applied for scheduling purposes).

Values 0 to 100

Default

Primary: 5

Secondary: 30

cbs

Syntax

cbs *size-in-kbytes*

no cbs

Context

[Tree] (config>subscr-mgmt>sla-prof>egress>qos>queue cbs)

[Tree] (config>subscr-mgmt>sla-prof>ingress>qos>queue cbs)

Full Context

configure subscriber-mgmt sla-profile egress qos queue cbs

configure subscriber-mgmt sla-profile ingress qos queue cbs

Description

This command can be used to override specific attributes of the specified queue's CBS parameters. It is permissible, and possibly desirable, to oversubscribe the total CBS reserved buffers for a given access port egress buffer pool. Oversubscription may be desirable due to the potential large number of service queues and the economy of statistical multiplexing the individual queues' CBS settings into the defined reserved total.

When oversubscribing the reserved total, it is possible for a queue depth to be lower than its CBS setting and still not receive a buffer from the buffer pool for an ingress frame. As more queues are using their

CBS buffers and the total in use exceeds the defined reserved total, essentially the buffers are being removed from the shared portion of the pool without the shared in use average and total counts being decremented. This can affect the operation of the high and low priority RED slopes on the pool, causing them to miscalculate when to start randomly drop packets.

The **no** form of this command returns the CBS size to the size as configured in the QoS policy.

Default

no cbs

Parameters

size-in-kbytes

The size parameter is an integer expression of the number of kilobytes reserved for the queue. If a value of 10KBytes is desired, enter the value 10. A value of 0 specifies that no reserved buffers are required by the queue (a minimal reserved size can still be applied for scheduling purposes).

Values 0 to 1048576, **default**
