The interface reports that its IPv4 operational state is up if its IPv6 operational state is up. Be aware that not all protocols observe the interface as up from an IPv4 perspective. This command is mostly intended to support BGP routing use cases. Refer to RFC 5549, Advertising IPv4 Network Layer Reachability Information with an IPv6 Next Hop, for further information.

The **no** form of this command restores the default behavior and prevents the interface from forwarding IPv4 packets if it has no configured IPv4 subnets.

Default

no forward-ipv4-packets

Full Context

configure filter ipv6-filter entry action forward-when

configure filter ip-filter entry action forward-when

Description

This command configures the forward-when action for the traffic that matches this filter entry.

Parameters

pattern

Specifies the traffic that can be forwarded based on a pattern found in the packet header or data payload.

expression

Specifies the hexadecimal pattern to match, up to eight bytes.

Values 0x0000000000000000 to 0xffffffffffffffff

mask

Specifies the mask for the pattern expression, up to eight bytes.

Values 0x0000000000000000 to 0xffffffffffffffff

offset-type

Specifies the starting point reference for the offset-value of this pattern.

Values layer-3, layer-4, data, dns-qtype

offset-value

Specifies the offset value for the pattern expression.

Values 0 to 255

no forwarding

Context

[Tree] (config>oam-pm>session>ip forwarding)

Full Context

configure oam-pm session ip forwarding

Description

This command influences the forwarding decision of the TWAMP Light packet. When this command is used, only one of the forwarding options can be enabled at any time.

The **no** form of this command removes the options and enables the default forwarding logic.

Parameters

ip-address

Specifies the IP address of the next hop on the path.

Values

ipv4-address:	a.b.c.d
ipv6-address:	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x: [0 to FFFF]H
	d: [0 to 255]D

interface-name

Specifies the name, up to 32 characters, to refer to the interface from which the packet is sent. The name must already exist in the **config>router>interface** context or within the appropriate **config>service** context.

bypass-routing

Specifies to send the packet to a host on a directly attached network, bypassing the routing table.

Full Context

configure service vprn bgp group graceful-restart long-lived forwarding-bits-set

configure service vprn bgp group neighbor graceful-restart long-lived forwarding-bits-set

configure service vprn bgp graceful-restart long-lived forwarding-bits-set

Description

This command determines the setting of the F bits in the GR and LLGR capabilities advertised by the router. When the F bit is set for an AFI/SAFI, it indicates that the advertising router was able to preserve forwarding state for the routes of that AFI/SAFI across the last restart. If a router restarts and does not set F=1, then when the session with a peer is re-established, the peer immediately deletes all LLGR stale routes it was preserving on behalf of the restarting router for the corresponding AFI/SAFI.

This command allows the F bits for all advertised AFI/SAFI to be set to 1, or only the F bits for non-forwarding AFI/SAFI to be set to 1. Non-forwarding AFI/SAFI are the following configuration-related address families: L2-VPN, route-target, flow-IPv4, and flow-IPv6.

Default

no forwarding-bits-set

Parameters

all

Specifies that the F bit for all AFI/SAFI should be set to 1.

non-fwd

Specifies that the F bit for only non-forwarding AFI/SAFI should be set to 1. These AFI/SAFI correspond to the following families: L2-VPN, route-target, flow-IPv4, and flow-IPv6.

Platforms

All

10.132 forwarding-policy

forwarding-policy

Syntax
[**no**] **forwarding-policy** *name*

Context
[Tree] (config>router>mpls>fwd-policies forwarding-policy)

Full Context
configure router mpls forwarding-policies forwarding-policy

Description

This command creates an MPLS forwarding policy.

There are two types of MPLS forwarding policy:

- endpoint policy
- label-binding policy

The endpoint policy allows the user to forward unlabeled packets over a set of user-defined direct (with option to push a label stack) or indirect next hops. Routes are bound to an endpoint policy when their next hop matches the endpoint address of the policy.

The label-binding policy provides the same capability for labeled packets. In this case, labeled packets matching the ILM of the policy binding label are forwarded over the set of next hops of the policy.

The data model of a forwarding policy represents each pair of {primary next hop, backup next hop} as a group and models the ECMP set as the set of Next-Hop Groups (NHGs). Flows of prefixes can be switched on a per-NHG basis from the primary next hop, when it fails, to the backup next hop without disturbing the flows forwarded over the other NHGs of the policy. The same can be performed when reverting back from a backup next hop to the restored primary next hop of the same NHG.

The MPLS forwarding policy supports two types of NHGs on a per policy basis:

- An NHG of resolution type indirect supported with the label-binding policy and in which forwarding over the primary/backup next hop is modeled as a swap operation from the binding label to an implicit-null label over multiple outgoing interfaces (multiple NHLFEs) corresponding to the resolved next hops of the indirect route.

  Within a given NHG, the primary next hop is the preferred active path in the absence of any failure of the NHG of resolution type indirect.

  The forwarding database tracks the primary or backup next hop in the routing table. A **route delete** of the primary indirect next hop causes CPM to program the backup indirect next hop in the data path.

  A **route modify** to the indirect primary or backup next hop causes CPM to update the its resolved next hops and to update the data path if it is the active indirect next hop.

  When the primary indirect next hop is restored and is added back into the routing table, CPM waits for an amount of time equal to the user-programmed revert timer before updating the data path. However, if the backup indirect next hop fails while the timer is running, CPM updates the data path immediately.
- An NHG of resolution type direct is modeled as follows:
  - For a label-binding policy, forwarding over the primary or backup next hop is modeled as a swap operation from the binding label to the configured label stack or to an implicit-null label (if the **pushed-labels** command not configured) over a single outgoing interface to the next hop.
  - For an endpoint policy, forwarding over the primary or backup next hop is modeled as a push operation from the binding label to the configured label stack or to an implicit-null label (if the **pushed-labels** command not configured) over a single outgoing interface to the next hop.
  - The labels configured by the **pushed-labels** command are not validated.

  Within a given NHG, the primary next hop is the preferred active path in the absence of any failure of the NHG of resolution type direct.

  The NHG supports uniform failover. The forwarding policy database assigns a Protect-Group ID (PG-ID) to each of the primary next hop and the backup next hop and programs both of them in data path. A failure of the active path switches traffic to the other path following the uniform failover procedures.

The forwarding database tracks the primary or backup next hop in the routing table. A **route delete** of the primary/backup direct next hop causes CPM to send the corresponding PG-ID switch to the data path.

A **route modify** to the direct primary or backup next hop causes CPM to update the MPLS forwarding database and to update the data path since both next hops are programmed.

When the primary direct next hop is restored and is added back into the routing table, CPM waits for an amount of time equal to the user programmed revert timer before activating it and updating the data path. However, if the backup direct next hop fails while the timer is running, CPM activates it and updates the data path immediately. The latter failover to the restored primary next hop is performed using the uniform failover procedure.

The forwarding policy database activates the best endpoint policy among the named policies sharing the same value of the endpoint parameter by selecting the lowest preference value policy. This policy is then programmed into the TTM and into the tunnel table in data path. If this policy goes down, then the forwarding policy database performs a re-evaluation and activates the named policy with the next lowest preference value for the same endpoint value. If a more preferred policy comes back up, the forwarding policy database reverts to it and activates it.

The forwarding policy database similarly activates the best label-binding policy among the named policies sharing the same binding label by selecting the lowest preference value policy. This policy is then programmed into the label FIB table in data path. If this policy goes down, then the forwarding policy database performs a re-evaluation and activates the names policy with the next lowest preference value for the same binding label value. If a more preferred policy comes back up, the forwarding policy database reverts to it and activates it.

Ingress statistics can be enabled as is associated with binding label, that is the ILM of the forwarding policy, and provides aggregate packet and byte counters for packets matching the binding label.

The **no** form of the command deletes the named MPLS forwarding policy.

Parameters

name

Specifies the name of the MPLS forwarding policy, up to 64 characters.

Platforms

All

10.133 forwarding-set

forwarding-set

Syntax

forwarding-set policy *policy-name* **set** *set-id*

no forwarding-set

Context

[Tree] (config>router>mpls>lsp>class-forwarding forwarding-set)

[Tree] (config>router>mpls>lsp-template>class-forwarding forwarding-set)

Full Context

configure router mpls lsp class-forwarding forwarding-set

configure router mpls lsp-template class-forwarding forwarding-set

Description

This command configures the mapping of a class-forwarding policy and forwarding set ID to an LSP (RSVP-TE or SR-TE) or an LSP template.

An MPLS LSP can only map to one single class forwarding policy and forwarding set. Multiple LSPs can map to the same policy and set. If the LSPs form part of an ECMP set of next-hops for an IPv4 or IPv6 prefix resolved to IGP shortcuts, the prefix packets with a matching FC are mapped to this set and are sprayed over these LSPs. This behavior is based on a modulo operation of the output of the hash routine on the packet's headers and the number of LSPs in the set.

Parameters

policy-name

Specifies the name of the class forwarding policy, to a maximum of 32 characters.

set-id

Specifies the class forwarding set.

Values 1 to 4 (in system profile None/A)
1 to 6 (in system profile B)

Platforms

All

10.134 forwarding-tree-topology

forwarding-tree-topology

Syntax

forwarding-tree-topology unicast [**st** | **spf**]

Context

[Tree] (config>service>vpls>spb>level forwarding-tree-topology)

Full Context

configure service vpls spb level forwarding-tree-topology

Description

This command sets the unicast forwarding to follow the shortest path tree defined by the ECT algorithm shortest path forwarding (spf) or to follow a single tree. (st). Shortest path trees make use of more link resources.

Multicast traffic is defaulted to follow the single tree topology. A single tree unicast would make Multicast and unicast follow the same path.

Default

forwarding-tree-topology unicast spf

Parameters

spf

Follows the shortest path tree.

st

Follows a single tree.

Platforms

All

10.135 fp

fp

Syntax

fp [*fp-number*]

Context

[Tree] (config>card fp)

Full Context

configure card fp

Description

This command enables access to the configuration of the forwarding planes on a card.

The default forwarding plane is 1. When entering the FP node, if the forwarding plane number is omitted, the system will assume forwarding plane number 1.

Commands can only be configured under **card>fp** if the hardware that the FP resides on (either a card or an XMA) is provisioned. Conversely, all commands under **card>fp** of the corresponding FPs are automatically removed when that hardware is unprovisioned.

Parameters

fp-number

Specifies that the FP number parameter is optional following the **fp** command.

Values 1 to 8

Default fp 1

Platforms

All

10.136 fp-redirect-group

fp-redirect-group

Syntax

fp-redirect-group *policer-type policer-id*

no fp-redirect-group *policer-type*

Context

[Tree] (config>qos>network>ingress>fc fp-redirect-group)

Full Context

configure qos network ingress fc fp-redirect-group

Description

This command is used to redirect the FC of a broadcast packet received in a VPLS service over a PW or network IP interface to an ingress forwarding plane queue-group.

It defines the mapping of an FC to a policer-id and redirects the lookup of the policer of the same ID in some ingress forwarding plane queue-group instance. However, the queue-group name and instance are explicitly provided only at the time the network QoS policy is applied to the ingress context of a spoke or mesh SDP or a network IP interface.

The broadcast-policer statement is ignored when the network QoS policy is applied to any object other than a VPLS spoke or mesh SDP or a network IP interface.

The **no** form of this command removes the redirection of the FC.

Parameters

policer-type

The policer type to be used. The *policer-type* is ignored when the network QoS policy is applied to any object other than a VPLS spoke or mesh SDP or a network IP interface.

Values broadcast-policer | mcast-policer | policer | unknown-policer

policer-id

The specified *policer-id* must exist within the queue-group template applied to the ingress context of the forwarding plane.

Values 1 to 32

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, 7950 XRS, VSR

10.137 fp-resource-policy

fp-resource-policy

Syntax

fp-resource-policy *name*

no fp-resource-policy

Context

[Tree] (config>card>fp fp-resource-policy)

Full Context

configure card fp fp-resource-policy

Description

This command configures the FP resource policy for the specified FP.

If the allocation configured within the FP resources policy is not achievable with the current ingress or egress queue consumption, the command fails. The configuration within the newly applied FP resource policy takes effect on the FP on which the FP resources policy is applied, and that includes removing an applied user created FP resource policy to return to the default policy, and causes the router to immediately reset the associated cards, XIOMs, and MDAs, except on the 7750 SR-1 where the configuration must be saved, and the router rebooted, immediately after committing the configuration transaction.

The **no** form of this command reverts to the default value by applying the default **fp-resource-policy** to the FP.

Default

no fp-resource-policy

Parameters

name

Specifies the FP resource policy name, up to 64 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-s, 7950 XRS

fp-resource-policy

Syntax

fp-resource-policy *policy-name* [**create**]

no fp-resource-policy *policy-name*

Context

[Tree] (config>qos fp-resource-policy)

Full Context

configure qos fp-resource-policy

Description

This command configures an FP resource policy that is used to manage resources on an FP4 forwarding plane.

A default policy is created by the system and applied to all FP4 FPs by default. If an FP resource policy is removed from an FP, the system automatically applies the default policy to that FP. The system prevents the modification or deletion of the default policy, and the deletion of any user created policy that is applied to an FP. The system supports a maximum of 15 FP resource policies.

The **no** form of this command deletes the FP resources policy from the system.

Parameters

policy-name

Specifies the FP resource policy, up to 64 characters.

create

Creates the FP resource policy entry.

Platforms

7450 ESS, 7750 SR, 7750 SR-s, 7950 XRS

configure subscriber-mgmt category-map category exhausted-credit-service-level ingress-ip-filter-entries entry match fragment

configure subscriber-mgmt category-map category exhausted-credit-service-level egress-ip-filter-entries entry match fragment

Description

This command configures the fragmentation match condition.

The **no** form of this command reverts to the default.

Parameters

true

Enables fragmentation matching.

false

Disables fragmentation matching.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

[Tree] (config>qos>sap-egress>ip-criteria>entry>match fragment)

Full Context

configure qos sap-ingress ip-criteria entry match fragment

configure qos sap-egress ip-criteria entry match fragment

Description

This command configures fragmented or non-fragmented IP packets as a SAP QoS policy match criterion.

The **no** form of this command removes the match criterion and matches all packets regardless of whether they are fragmented or not.

Default

no fragment

Parameters

true

Configures a match on all fragmented IP packets. A match will occur for all packets that have either the MF (more fragment) bit set or have the Fragment Offset field of the IP header set to a non-zero value.

false

Configures a match on all non-fragmented IP packets. Non-fragmented IP packets are packets that have the MF bit set to zero and have the Fragment Offset field also set to zero.

fragment {**true** | **false** | **first-only** | **non-first-only**}

no fragment

Context

[Tree] (config>qos>sap-ingress>ipv6-criteria>entry>match fragment)

Full Context

configure qos sap-ingress ipv6-criteria entry match fragment

Description

This command configures fragmented or non-fragmented IPv6 packets as a SAP ingress QoS policy match criterion.

The **no** form of this command removes the match criterion and matches all packets regardless of whether they are fragmented or not.

Default

no fragment

Parameters

true

Specifies to match on all fragmented IPv6 packets. A match will occur for all packets that contain an IPv6 Fragmentation Extension Header.

false

Specifies to match on all non-fragmented IP packets. Non-fragmented IPv6 packets are packets that do not contain an IPv6 Fragmentation Extension Header.

first-only

Matches if a packet is an initial fragment of the fragmented IPv6 packet.

non-first-only

Matches if a packet is a non-initial fragment of the fragmented IPv6 packet.

configure filter ipv6-filter entry match fragment

configure filter ip-filter entry match fragment

Description

This command specifies match criterion for fragmented packets.

Matches can be based on the presence of a fragmented packet (or otherwise) on the ingress or egress interface.

Matches can also be based on the presence of the first fragment of a packet, or on the presence of a fragment that is not the first fragment on the ingress interface.

The **no** form of the command removes the match criterion.

Default

no fragment

Parameters

true

Specifies to match on all fragmented packets.

false

Specifies to match on all non-fragmented packets.

first-only

Matches if a packet is an initial fragment of a fragmented packet.

non-first-only

Matches if a packet is a non-initial fragment of a fragmented packet.

Platforms

no fragment

Context

[Tree] (cfg>sys>sec>cpm>ipv6-filter>entry>match fragment)

[Tree] (cfg>sys>sec>cpm>ip-filter>entry>match fragment)

Full Context

configure system security cpm-filter ipv6-filter entry match fragment

configure system security cpm-filter ip-filter entry match fragment

Description

This command specifies fragmented or non-fragmented IP packets as an IP filter match criterion.

Note:
An entry containing Layer 4 match criteria will not match non-initial (2nd, 3rd, etc) fragments of a fragmented packet since only the first fragment contains the Layer 4 information.

This command enables match on existence of IPv6 Fragmentation Extension Header in the IPv6 filter policy. To match first fragment of an IP fragmented packet, specify additional Layer 4 matching criteria in a filter policy entry. The **no** version of this command ignores IPv6 Fragmentation Extension Header presence/absence in a packet when evaluating match criteria of a given filter policy entry.

The **no** form of this command removes the match criterion.

This command enables match on existence of IPv6 Fragmentation Extension Header in the IPv6 filter policy. To match first fragment of an IP fragmented packet, specify additional Layer 4 matching criteria in a filter policy entry. The **no** version of this command ignores IPv6 Fragmentation Extension Header presence/absence in a packet when evaluating match criteria of a given filter policy entry.

Default

no fragment

Parameters

true

Specifies to match on all fragmented IP packets. A match will occur for all packets that have either the MF (more fragment) bit set or have the Fragment Offset field of the IP header set to a non-zero value. For IPv6, packet matches if it contains IPv6 Fragmentation Extension Header.

false

Specifies to match on all non-fragmented IP packets. Non-fragmented IP packets are packets that have the MF bit set to zero and have the Fragment Offset field also set

to zero. For IPv6, packet matches if it does not contain IPv6 Fragmentation Extension Header.

10.142 fragment-drop

fragment-drop

Syntax

fragment-drop {**all** | **out-of-order**} [**event-log** *event-log-name*]

no fragment-drop

Context

[Tree] (config>app-assure>group>policy>aqp>entry>action fragment-drop)

Full Context

configure application-assurance group policy app-qos-policy entry action fragment-drop

Description

This command specifies the action to apply to fragments.

Default

no fragment-drop

Parameters

all

All the fragments will be dropped.

out-of-order

All out of order fragments will be dropped.

event-log-name

Specifies if the dropping of fragments should be logged to the specified event log name.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

10.143 fragment-drop-all

fragment-drop-all

Syntax

fragment-drop-all *direction* [**create**]

no fragment-drop-all *direction*

Context

[Tree] (config>app-assure>group>statistics>tca fragment-drop-all)

Full Context

configure application-assurance group statistics threshold-crossing-alert fragment-drop-all

Description

This command configures a TCA for the counter capturing drops due to the fragment-drop- all AQP command. A fragment-drop-all TCA can be created for traffic generated from the subscriber side of AA (**from-sub**) or for traffic generated from the network toward the AA subscriber (**to-sub**). The **create** keyword is mandatory when creating a fragment-drop-all TCA.

Parameters

direction

Specifies the traffic direction.

Values from-sub, to-sub

create

Keyword used to create the TCA.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

10.144 fragment-drop-out-of-order

fragment-drop-out-of-order *direction* [**create**]

no fragment-drop-out-of-order *direction*

Context

[Tree] (config>app-assure>group>statistics>tca fragment-drop-out-of-order)

Full Context

configure application-assurance group statistics threshold-crossing-alert fragment-drop-out-of-order

Description

This command configures a TCA for the counter capturing drops due to the fragment-drop- out-of-order AQP command. A fragment-drop-out-of-order TCA can be created for traffic generated from the subscriber side of AA (**from-sub**) or for traffic generated from the network toward the AA subscriber (**to-sub**). The **create** keyword is mandatory when creating a fragment-drop-out-of-order TCA.

Parameters

direction

Specifies the traffic direction.

Values from-sub, to-sub

create

Keyword used to create the TCA.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

10.145 frame-based-accounting

frame-based-accounting

Syntax

[**no**] **frame-based-accounting**

Context

[Tree] (config>qos>scheduler-policy frame-based-accounting)

Full Context

configure qos scheduler-policy frame-based-accounting

Description

The frame-based-accounting command is used to enable frame-based accounting for both the children queues parented to the scheduling policy and for the schedulers within the scheduler policy.

When frame-based accounting is enabled on the policy, all queues associated with the scheduler (through the parent command on each queue) will have their rate and CIR values interpreted as frame-based values. When shaping, the queues will include the 12-byte Inter-Frame Gap (IFG) and 8 byte preamble

for each packet scheduled out the queue. The profiling CIR threshold will also include the 20-byte frame encapsulation overhead. Statistics associated with the queue do not include the frame encapsulation overhead.

The scheduler policy's scheduler rate and CIR values will be interpreted as frame-based values.

The configuration of **parent-location** and **frame-based-accounting** in a scheduler policy is mutually exclusive to ensure consistency between the different scheduling levels. Packet byte offset settings are not included in the applied rate when frame-based accounting is configured; however, the offsets are applied to the statistics.

The **no** form of this command is used to return all schedulers within the policy and queues associated with the policy to the default packet-based accounting mode. If **frame-based-accounting** is not currently enabled for the scheduling policy, the **no frame-based-accounting** command has no effect.

10.153 framing

framing

Syntax

framing {**sonet** | **sdh**}

Context

[Tree] (config>port>sonet-sdh framing)

Full Context

configure port sonet-sdh framing

Description

This command specifies SONET/SDH framing to be either SONET or SDH.

This command is supported by TDM satellite.

Default

framing sonet

Parameters

sonet

Configures the port for SONET framing.

sdh

Configures the port for SDH framing.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

framing

Syntax

framing {**esf** | **sf** | **unframed-ds1**}

Context

[Tree] (config>port>tdm>ds1 framing)

Full Context

configure port tdm ds1 framing

Description

This command specifies the DS-1 framing to be used with the associated channel.

Default

framing esf

Parameters

esf

Configures the DS-1 port for extended super frame framing.

sf

Configures the DS-1 port for super frame framing.

unframed-ds1

Specifies ds-1 unframed (G.703) mode for DS-1 interfaces. This parameter allows the configuration of an unstructured DS-1 channel on a CES MDA. In G.704, timeslot 0 is used to carry timing information by a service provider, thus, only 31 slots are made available to the end user. In G.703, all 32 time slots are available to the end user. Timing is provided by the end user. When an e1-unframed channel is shutdown, it sends the AIS pattern to the far-end DS-1 which does not react. The operational status remains up and no alarms are generated while the near-end (shutdown) is operationally down. This is normal behavior since the G.703 option does not have framing. G.703 framing is only applicable for FR, PPP, and cHDLC encapsulations.

Platforms

7450 ESS, 7750 SR-7/12/12e, 7750 SR-a, 7750 SR-e

framing

Syntax

framing {**no-crc-g704** | **g704** | **e1-unframed**}

Context

[Tree] (config>port>tdm>e1 framing)

Full Context

configure port tdm e1 framing

Description

This command specifies the E-1 framing to be used with the associated channel.

Default

framing g704

Parameters

g704

Configures the E-1 port for G.704 framing.

no-crc-g70

Configures the E-1 for G.704 with no CRC4.

e1-unframed

Specifies E-1 unframed (G.703) mode for E-1 interfaces. This parameter also allows the configuration of an unstructured E-1 channel on an ASAP or CES MDA. In G.704, timeslot 0 is used to carry timing information by a service provider, thus, only 31 slots are made available to the end user. In G.703, all 32 time slots are available to the end user. Timing is provided by the end user. When an e1-unframed channel is shutdown, it sends the AIS pattern to the far-end E-1 which does not react. The operational status remains up and no alarms are generated while the near-end (shutdown) is operationally down. This is normal behavior since the G.703 option does not have framing. G.703 framing is only applicable for FR, PPP, and cHDLC and CEM encapsulations.

Syntax

framing {**c-bit** | **m23** | **unframed-ds3**}

Context

[Tree] (config>port>tdm>ds3 framing)

Full Context

configure port tdm ds3 framing

Description

This command specifies DS-3 framing for the associated DS-3 port or channel.

Default

framing c-bit

Parameters

c-bit

Configures the DS-3 port/channels for C-Bit framing.

m23

Configures the DS-3 port/channel for M23 framing.

unframed-ds3

Specifies ds-3 unframed mode for DS-3 interfaces. This parameter allows the configuration of an unstructured DS-3 channel on a CES MDA.

Platforms

7450 ESS, 7750 SR-7/12/12e, 7750 SR-a, 7750 SR-e

framing

Syntax

framing {**g751** | **g832** | **unframed-e3**}

Context

[Tree] (config>port>tdm>e3 framing)

Full Context

configure port tdm e3 framing

Description

This command specifies E-3 framing for the associated E-3 port or channel.

Default

for E-3 non-ATM: framing g751 and cannot be changed. for E-3 ATM: framing g832 and cannot be changed.

Parameters

g751

Configures the E-3 port/channel for g751 framing.

g832

Configures the E-3 port/channel for g832 framing.

unframed-e3

Specifies e-3 unframed mode for E-3 interfaces. This parameter allows the configuration of an unstructured E-3 channel on a CES MDA.

Platforms

7450 ESS, 7750 SR-7/12/12e, 7750 SR-a, 7750 SR-e

10.154 frequency

frequency

Syntax

frequency *frequency*

no frequency

Context

[Tree] (config>port>dwdm frequency)

Full Context

configure port dwdm frequency

Description

This command configures the center frequency to use for a tunable DWDM optical interface. It replaces the **configure**>**port**>**dwdm**>**channel** command (used prior to Release 22.2.R1). The **frequency** command supports any frequency in the C band, but the actual operating frequency is dependent on the installed optic module.

Provisioning rules

The provisioned MDA type must have DWDM tunable optics (for example, p1-100g-tun-b) or the MDA must support the option of tunable DWDM optic modules. The following provisioning rules apply:

- The DWDM frequency must set to a non-zero value before the port is set to **no shutdown**.
- The port must be **shutdown** before changing the DWDM frequency.
- The port must be a physical port to set the DWDM frequency.

Default

frequency 0

Parameters

frequency

Specifies the frequency in MHz.

Values 0, 191100000 to 196150000

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

10.155 from

from

Syntax

from [**main**] [**security**] [**change**] [**debug-trace**]

no from

Context

[Tree] (config>service>vprn>log>log-id from)

Full Context

configure service vprn log log-id from

Description

This command selects the source stream to be sent to a log destination.

One or more source streams must be specified. The source of the data stream must be identified using the **from** command before you can configure the destination using the **to** command. The **from** command can identify multiple source streams in a single statement (for example: **from main change debug-trace**).

Only one **from** command may be entered for a single *log-id*. If multiple **from** commands are configured, then the last command entered overwrites the previous **from** command.

The **no** form of this command removes all previously configured source streams.

Default

No source stream is configured.

Parameters

main

Instructs all events in the main event stream to be sent to the destination defined in the **to** command for this destination *log-id*. The main event stream contains the events that are not explicitly directed to any other event stream. To limit the events forwarded to the destination, configure filters using the **filter** command.

security

Instructs all events in the security event stream to be sent to the destination defined in the **to** command for this destination *log-id*. The security event stream contains all events that pertain to attempts to breach system security. To limit the events forwarded to the destination, configure filters using the **filter** command.

change

Instructs all events in the user activity stream to be sent to the destination configured in the **to** command for this destination *log-id*. The change event stream contains all events that directly affect the configuration or operation of this node. To limit the events forwarded to the change stream destination, configure filters using the filter command.

debug-trace

Instructs all events in the debug-trace event stream to be sent to the destination defined in the **to** command for this destination *log-id*. The debug-trace event stream contains all events that pertain to trace or other debugging information. To limit the events forwarded to the destination, configure filters using the **filter** command.

Context

[Tree] (config>router>mpls>lsp from)

[Tree] (config>router>mpls>lsp-template from)

Full Context

configure router mpls lsp from

configure router mpls lsp-template from

Description

This optional command specifies the IP address of the ingress router for the LSP. When this command is not specified, the system IP address is used. IP addresses that are not defined in the system are allowed. If an invalid IP address is entered, LSP bring-up fails and an error is logged.

If an interface IP address is specified as the **from** address, and the egress interface of the LSP nexthop IP address is a different interface, the LSP is not signaled. As the egress interface changes due to changes in the routing topology, it is recommended to set the **from** IP address to the system IP address or to the address of a loopback interface to ensure the LSP recovers.

Only one **from** address can be configured.

Default

The system IP address

Parameters

ip-address

Specifies the IP address of the ingress router. This can be either the interface, the system or a loopback interface IP address. If the IP address is local, the LSP must egress through that local interface which ensures local strictness. When the LSP type is **sr-te**, then an IPv6 address can be used.

Values ipv4-address — a.b.c.d

ipv6-address — x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x — 0 to FFFF (hexadecimal)

d — 0 to 255 (decimal)

from

Syntax

from li

no from

Context

[Tree] (config>li>log>log-id from)

Full Context

configure li log log-id from

Description

This command configures a bit mask that specifies the log event source stream(s) to be forwarded to the destination specified in the log destination (memory, session, SNMP). Events from more than one source can be forwarded to the log destination.

Parameters

li

Specifies the **li** event stream that contains all events configured for Lawful Intercept activities.

If the requester does not have access to the **li** context, the event stream will fail.

Platforms

All

Syntax

from *ipv4-address*

no from

Context

[Tree] (config>oam-pm>session>mpls>lsp>rsvp-auto from)

Full Context

configure oam-pm session mpls lsp rsvp-auto from

Description

One of three mandatory configuration statements that are required to identify automatically create RSVP LSPs, created using **config>router>mpls>lsp-template**. The **config>router>mpls>auto-lsp** *lsp-template* links three distinct functions. The **config>router>policy-options>prefix-list**, **config>router>policy-options>policy-statement>entry>from** and config>router>mpls> lsp-template. The from address under the test context is the same as the config>router>mpls>lsp-template>from address.

The three required identifiers are from, lsp-template and to, all under this container.

The **no** form of this command deletes the IP address from the configuration.

Parameters

ipv4-address

Specifies the IPv4 address.

Values a.b.c.d.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

from

Syntax

from {[**main**] [**security**] [**change**] [**debug-trace**]}

no from

Context

[Tree] (config>log>log-id from)

Full Context

configure log log-id from

Description

This command selects the source stream to be sent to a log destination.

One or more source streams must be specified. The source of the data stream must be identified using the **from** command before you can configure the destination using the **to** command. The **from** command can identify multiple source streams in a single statement (for example: **from main change debug-trace**).

Only one **from** command may be entered for a single *log-id*. If multiple **from** commands are configured, then the last command entered overwrites the previous **from** command.

The **no** form of this command removes all previously configured source streams.

Parameters

main

Instructs all events in the main event stream to be sent to the destination defined in the **to** command for this destination *log-id*. The main event stream contains the events that are not explicitly directed to any other event stream. To limit the events forwarded to the destination, configure filters using the **filter** command.

security

Instructs all events in the security event stream to be sent to the destination defined in the **to** command for this destination *log-id*. The security stream contains all events that affect attempts to breach system security such as failed login attempts, attempts to access MIB tables to which the user is not granted access or attempts to enter a branch of the CLI to which access has not been granted. To limit the events forwarded to the destination, configure filters using the **filter** command.

change

Instructs all events in the user activity stream to be sent to the destination configured in the **to** command for this destination *log-id*. The change event stream contains all events that directly affect the configuration or operation of this node. To limit the events forwarded to the change stream destination, configure filters using the **filter** command.

debug-trace

Instructs all debug-trace messages in the debug stream to be sent to the destination configured in the **to** command for this destination *log-id*. Filters applied to debug messages are limited to application and subject.

Platforms

All

from

Syntax

[**no**] **from**

Context

[Tree] (config>router>policy-options>policy-statement>entry from)

Full Context

configure router policy-options policy-statement entry from

Description

This command creates the context to configure policy match criteria based on a route's source or the protocol from which the route is received.

If no condition is specified, all route sources are considered to match.

The **no** form of this command deletes the source match criteria for the route policy statement entry.

Platforms

7450 ESS, 7750 SR, 7750 SR-s, 7950 XRS, VSR

10.166 function-length

function-length

Syntax

function-length *function-length*

no function-length

Context

[Tree] (config>router>segment-routing>srv6>locator function-length)

Full Context

configure router segment-routing segment-routing-v6 locator function-length

Description

This command configures the length of the function field of an SRv6 locator.

The sum of the function length and the locator prefix length must not exceed 128 bits. This is enforced by CLI validation. Configuring a function length of 16 requires the configuration of the locator level **label-block**.

The **no** form of this command reverts to the default value.

Default

function-length 20

Parameters

function-length

Specifies the function length, in bits.

Values 16, 20 to 96

Platforms

7450 ESS, 7750 SR, 7750 SR-s, 7950 XRS, VSR

11 g Commands

11.1 garp-flood-evpn

garp-flood-evpn

Syntax

[**no**] **garp-flood-evpn**

Context

[Tree] (config>service>vpls>proxy-arp garp-flood-evpn)

Full Context

configure service vpls proxy-arp garp-flood-evpn

Description

This command controls whether the system floods GARP-requests and GARP-replies to the EVPN. The GARPs impacted by this command are identified by the sender's IP being equal to the target's IP and the MAC DA being broadcast.

The **no** form of the command only floods to local SAPs or binds but not to EVPN destinations.

Disabling this command is only recommended in networks where CEs are routers that are directly connected to the PEs. Networks using aggregation switches between the host/routers and the PEs should flood GARP messages in the EVPN to ensure that the remote caches are updated and the BGP does not miss the advertisement of these entries.

Default

garp-flood-evpn

no gateway name *name* **tunnel-subnet** *ip-prefix/ip-prefix-length*

Context

[Tree] (debug>ipsec gateway)

Full Context

debug ipsec gateway

Description

This command enables debugging for dynamic IPsec tunnels that terminate on the specified IPsec gateway.

The tunnel to be debugged can be specified by either its source address or source subnet. If a subnet is specified, the system will enable debugging for all tunnels with source addresses in the specified subnet.

Parameters

name

Specifies the name of the IPsec gateway up to 32 characters.

ip-address:port

Specifies the tunnel IP address of the remote peer and, optionally, the remote UDP port of IKE.

nat-ip:port

Specifies the inside IP address of the NAT tunnel and, optionally, the port.

detail

Specifies to display detailed debug information.

no-dpd-debug

Specifies to stop logging IKEv1 and IKEv2 DPD events during debug in order to produce less noise.

ip-prefix/ip-prefix-length

Specifies the subnet of the peer’s tunnel address.

display-keys

Specifies the IKE-SA and CHILD-SA keys for inclusion in the debug output.

Context

[Tree] (admin>certificate gen-keypair)

Full Context

admin certificate gen-keypair

Description

This command generates RSA, DSA, or ECDSA private key or public key pairs at the specified location.

Parameters

url-string

Specifies the path of the key file.

Values	url-string	<local-url> [up to 99 characters]
	local-url	<cflash-id>/<file-path>
	cflash-id	cf1: | cf2: | cf3:

curve

Generates an ECDSA key with a specified curve.

Values secp256r1, secp384r1, secp521r1

key-size

Specifies the key size in bits.

The minimum key-size is 1024 when running in FIPS-140-2 mode.

Values 512 to 8192

Default 2048

type

Specifies the type of key.

Values rsa, dsa

Default rsa

Platforms

11.4 gen-local-cert-req

gen-local-cert-req

Syntax

gen-local-cert-req keypair *url-string* **subject-dn** *subject-dn* [**domain-name** *name*] [**ip-addr** *ip-address*] **file** *cert-req-file-url* [**hash-alg hash-algorithm**]

Context

[Tree] (admin>certificate gen-local-cert-req)

Full Context

admin certificate gen-local-cert-req

Description

This command generates a PKCS#10 formatted certificate request by using a local existing key pair file.

Parameters

url-string

Specifies the name of the keyfile in cf3:\system-pki\key that is used to generate a certificate request.

Values

url-string	<local-url> [up to 99 characters]
local-url	<cflash-id>/<file-path>
cflash-id	cf1: | cf2: | cf3:

subject-dn

Specifies the distinguish name that is used as the subject in a certificate request, including:

- C-Country
- ST-State
- O-Organization name
- OU-Organization Unit name
- CN-common name

This parameter is formatted as a text string including any of the above attributes. The attribute and its value is linked by using "=", and "," is used to separate different attributes.

For example: C=US,ST=CA,O=ALU,CN=SR12

Values attr1=val1,attr2=val2... where: attrN={C| ST| O| OU| CN}, 256 chars max

domain-name

Specifies a domain name string can be specified and included as the dNSName in the Subject Alternative Name extension of the certificate request.

ip-address

Specifies an IPv4 address string can be specified and included as the ipAddress in the Subject Alternative Name extension of the certificate request.

cert-req-file-url

Specifies the certificate URL. This URL could be either a local CF card path and filename to save the certificate request; or an FTP URL to upload the certificate request.

hash-algorithm

Specifies the hash algorithm to be used in a certificate request.

Values sha1, sha224, sha256, sha384, sha512

get-data

Syntax

[**no**] **get-data**

Context

[Tree] (configure>system>security>profile>netconf>base-op-authorization get-data)

Full Context

configure system security profile netconf base-op-authorization get-data

Description

This command enables the NETCONF get-data operation.

The **no** form of this command disables the operation.

Default

no get-data

Note:
The operation is enabled by default in the built-in system-generated administrative profile.

Platforms

All

11.12 get-schema

get-schema

Syntax

[**no**] **get-schema**

Context

[Tree] (configure>system>security>profile>netconf>base-op-authorization get-schema)

Full Context

configure system security profile netconf base-op-authorization get-schema

Description

This command enables the NETCONF get-schema operation.

The **no** form of this command disables the operation.

Default

no get-schema

Note:
The operation is enabled by default in the built-in system-generated administrative profile.

Platforms

All

11.13 ggsn

ggsn

Syntax

ggsn

Context

[Tree] (config>subscr-mgmt>gtp>peer-profile ggsn)

Full Context

configure subscriber-mgmt gtp peer-profile ggsn

Description

Commands in this context configure communication with a GGSN Mobile Gateway.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

11.14 ggsn-address

ggsn-address

Syntax

ggsn-address {**ipv4** | **ipv6**}

no ggsn-address

Context

[Tree] (config>subscr-mgmt>diam-appl-plcy>gy>avp ggsn-address)

Full Context

configure subscriber-mgmt diameter-application-policy gy include-avp ggsn-address

Description

The command includes the GGSN-Address AVP value in all Diameter DCCA CCR messages. The value is either the local IPv4 address or local IPv6 address used to set up the diameter peer.

The **no** form of this command removes the GGSN-Address AVP from the Diameter DCCA CCR messages.

Parameters

ipv4* | *ipv6

Specifies to include either the IPv4 or IPv6 address.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

11.15 gi-address

gi-address

Syntax

gi-address *ip-address*

no gi-address

Context

[Tree] (config>subscr-mgmt>loc-user-db>ipoe>host gi-address)

Full Context

configure subscriber-mgmt local-user-db ipoe host gi-address

Description

This command allows selection of GI addresses based on the host entry in LUDB.

The gi-address must be a valid address (associated with an interface) within the routing context that received the DHCP message on the access side.

The **no** form of this command reverts to the default.

Parameters

ip-address

Specifies the IPv4 gi-address.

Values a.b.c.d

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

gi-address

Syntax

gi-address *ip-address* [**src-ip-address**]

no gi-address

Context

[Tree] (config>service>vprn>sub-if>dhcp gi-address)

[Tree] (config>service>ies>sub-if>dhcp gi-address)

[Tree] (config>service>ies>if>dhcp gi-address)

[Tree] (config>service>vprn>if>dhcp gi-address)

[Tree] (config>service>ies>sub-if>grp-if>dhcp gi-address)

Full Context

configure service vprn subscriber-interface dhcp gi-address

configure service ies subscriber-interface dhcp gi-address

configure service ies interface dhcp gi-address

configure service vprn interface dhcp gi-address

configure service ies subscriber-interface group-interface dhcp gi-address

Description

This command configures the gateway interface address for the DHCP relay. A subscriber interface can include multiple group interfaces with multiple SAPs. The GI address is needed, when the router functions as a DHCP relay, to distinguish between the different subscriber interfaces and potentially between the group interfaces defined.

By default, the GI address used in the relayed DHCP packet is the primary IP address of a normal IES interface. Specifying the GI address allows the user to choose a secondary address. For group interfaces a GI address must be specified under the group interface DHCP context or subscriber-interface DHCP context in order for DHCP to function.

The **no** form of this command reverts to the default.

Parameters

ip-address

Specifies the host IP address to be used for DHCP relay packets.

Values a.b.c.d

src-ip-address

Specifies that this GI address is to be the source IP address for DHCP relay packets. This parameter is not applicable for PPPoE DHCP client messages (**dhcp client-applications ppp**).

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

- configure service ies subscriber-interface dhcp gi-address
- configure service ies subscriber-interface group-interface dhcp gi-address
- configure service vprn subscriber-interface dhcp gi-address

All

- configure service vprn interface dhcp gi-address
- configure service ies interface dhcp gi-address

gi-address

Syntax

gi-address *ip-address*

no gi-address

Context

[Tree] (config>service>ies>if>sap>ipsec-gw>dhcp gi-address)

[Tree] (config>service>vprn>if>sap>ipsec-gw>dhcp gi-address)

Full Context

configure service ies interface sap ipsec-gw dhcp gi-address

configure service vprn interface sap ipsec-gw dhcp gi-address

Description

This command specifies the gateway IP address of the DHCPv4 packets sent by the system. IPsec DHCP Relay uses only the **gi-address** configuration found under the IPsec gateway and does not take into account **gi-address** with **src-ip-addr** configuration below other interfaces.

Default

no gi-address

Parameters

ip-address

Specifies the host IP address to be used for DHCP relay packets.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

gi-address

Syntax

gi-address *ip-address* [**src-ip-addr**]

no gi-address

Context

[Tree] (config>router>if>dhcp gi-address)

Full Context

configure router interface dhcp gi-address

Description

This command configures the gateway interface address for the DHCP relay. The GI address is needed, when the router functions as a DHCP relay, to distinguish between the different subscriber interfaces and potentially between the group interfaces defined.

Default

no gi-address

Parameters

ip-address

Specifies the host IP address to be used for DHCP relay packets.

src-ip-addr

Uses the GI address as the source IP.

Platforms

All

11.16 global

global

Syntax

global *file-url*

no global

Context

[Tree] (config>system>login-control>login-scripts global)

Full Context

configure system login-control login-scripts global

Description

This command enables an operator to define a common CLI script that executes when any user logs into a CLI session. This login exec script is executed when any user (authenticated by any means including local user database, TACACS+, or RADIUS) opens a CLI session. This allows a user, for example, to define a common set of CLI aliases that are made available on the router for all users. This global login exec script is executed before any user-specific login exec files that may be configured.

This CLI script executes in the context of the user who opens the CLI session. Any commands in the script that the user is not authorized to execute will fail.

The **no** form of this command disables the execution of a global login-script.

Default

no global

Parameters

file-url

The path or directory name.

Platforms

All

11.17 global-id

global-id

Syntax

global-id *global-id*

no global-id

Context

[Tree] (config>router>mpls>mpls-tp global-id)

Full Context

configure router mpls mpls-tp global-id

Description

This command configures the MPLS-TP Global ID for the node. This is used as the 'from' Global ID used by MPLS-TP LSPs originating at this node. If a value is not entered, the Global ID is taken to be Zero. This is used if the global-id is not configured. If an operator expects that inter-domain LSPs will be configured, then it is recommended that the global ID should be set to the local ASN of the node, as configured under **config**>**system**. If two-byte ASNs are used, then the most significant two bytes of the global-id are padded with zeros.

In order to change the value of the **global-id**, **config**>**router**>**mpls**>**mpls-tp** must be in the shutdown state. This will bring down all of the MPLS-TP LSPs on the node. New values a propagated to the system when a no shutdown is performed.

Default

no global-id

Parameters

global-id

Specifies the global ID for the node.

Values 0 to 4294967295

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

11.18 global-sampling-rate

global-sampling-rate

Syntax

global-sampling-rate *sampling-rate*

no global-sampling-rate

Context

[Tree] (config>mirror global-sampling-rate)

Full Context

configure mirror global-sampling-rate

Description

This command configures the global sampling rate. The global sampling rate provides a higher sampling rate than the sampling rate specified on the mirror destination. The global sampling rate, when set, applies to all mirror destination services with the **use-global-sampling-rate** command configured.

The global sampling rate takes precedence over the sampling rate specified on a mirror destination. This means that when both the **global-sampling-rate** command and **configure mirror mirror-dest sampling-rate** command are configured under the same mirror destination, the system automatically samples using higher rate configured with the **global-sampling-rate** command and ignores the lower rate configured with the **sampling-rate** command.

The **no** form of this command removes all mirror destinations associated with the global sampling rate and causes all mirror destinations to mirror at the full rate, which means every packet is mirrored unless a mirror destination rate is specified. You must first remove the **use-global-sampling-rate** configuration, before you remove the **global-sampling-rate** configuration.

Default

no global-sampling-rate

Parameters

sampling-rate

Specifies the global sampling rate. The highest global sampling rate is 1 out of 2 packets and the lowest rate is 1 out of 255. For example, when 2 is the configured rate, the mirror destination samples 1 out of every 2 packets, or equivalent to sampling 50% of packets.

Values 2 to 255

Platforms

All

11.19 global-sid-entries

global-sid-entries

Syntax

global-sid-entries *global-sid-entries*

Context

[Tree] (conf>router>sr>srv6>micro-segment global-sid-entries)

Full Context

configure router segment-routing segment-routing-v6 micro-segment global-sid-entries

Description

This command configures the maximum number of unique micro-segment locators that can be configured network wide. The value is expressed as the number of multiples of 1024 and must be the same on every platform network wide.

Default

global-sid-entries 16

Parameters

global-sid-entries

Specifies the maximum number of unique micro-segment locators.

Values 4 to 60 (in steps of 4)

Platforms

7450 ESS, 7750 SR, 7750 SR-s, 7950 XRS, VSR

11.20 global-timeouts

global-timeouts

Syntax

global-timeouts

Context

[Tree] (config>system>management-interface>ops global-timeouts)

Full Context

configure system management-interface operations global-timeouts

Description

Commands in this context configure system timeout parameters for operational commands.

Timeout parameters provide default system-level control for various types of operational commands in model-driven interfaces. The timeout values are used when specific execution and retention timeouts are not requested for a specific operation.

Platforms

All

11.21 global-variables

global-variables

Syntax

global-variables

no global-variables

Context

[Tree] (config>router>policy-options global-variables)

Full Context

configure router policy-options global-variables

Description

This command enables the **global-variables** configuration context.

The **no** form of this command removes all global variables.

Platforms

gnmi-capabilities

Syntax

gnmi-capabilities {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization gnmi-capabilities)

Full Context

configure system security profile grpc rpc-authorization gnmi-capabilities

Description

This command permits the use of Capability RPC for a user associated with the given format.

The **no** form of this command reverts to the default value.

Default

gnmi-capabilities permit

Parameters

permit

Specifies that the use of the Capability RPC is permitted.

deny

Specifies that the use of the Capability RPC is denied.

Platforms

All

11.24 gnmi-get

gnmi-get

Syntax

gnmi-get {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization gnmi-get)

Full Context

configure system security profile grpc rpc-authorization gnmi-get

Description

This command permits the use of Get RPC.

The **no** form of this command reverts to the default value.

Default

gnmi-get permit

Parameters

permit

Specifies that the use of the Get RPC is permitted.

deny

Specifies that the use of the Get RPC is denied.

Platforms

All

11.25 gnmi-set

gnmi-set

Syntax

gnmi-set {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization gnmi-set)

Full Context

configure system security profile grpc rpc-authorization gnmi-set

Description

This command permits the use of Set RPC.

The **no** form of this command reverts to the default value.

Default

gnmi-set permit

Parameters

permit

Specifies that the use of the Set RPC is permitted.

deny

Specifies that the use of the Set RPC is denied.

Platforms

All

11.26 gnmi-subscribe

gnmi-subscribe

Syntax

gnmi-subscribe {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization gnmi-subscribe)

Full Context

configure system security profile grpc rpc-authorization gnmi-subscribe

Description

This command permits the use of Subscribe RPC.

The **no** form of this command reverts to the default value.

Default

gnmi-subscribe permit

Parameters

permit

Specifies that the use of the Subscribe RPC is permitted.

deny

Specifies that the use of the Subscribe RPC is denied.

Platforms

All

11.27 gnoi-cert-mgmt-cangenerate

gnoi-cert-mgmt-cangenerate

Syntax

Syntax

gnoi-cert-mgmt-getcert {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization gnoi-cert-mgmt-getcert)

Full Context

configure system security profile grpc rpc-authorization gnoi-cert-mgmt-getcert

Description

This command permits the use of gNOI GetCertificate RPCs for the user profile.

The **no** form of this command reverts to the default value.

Default

gnoi-cert-mgmt-getcert deny

Parameters

permit

Specifies that the use of the gNOI GetCertificate RPCs for the user profile is permitted.

deny

Specifies that the use of the gNOI GetCertificate RPCs for the user profile is denied.

Platforms

All

11.29 gnoi-cert-mgmt-install

gnoi-cert-mgmt-install

Syntax

gnoi-cert-mgmt-install {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization gnoi-cert-mgmt-install)

Full Context

configure system security profile grpc rpc-authorization gnoi-cert-mgmt-install

Description

This command permits the use of gNOI Install RPCs for the user profile.

The **no** form of this command reverts to the default value.

Default

gnoi-cert-mgmt-install deny

Parameters

permit

Specifies that the use of the gNOI Install RPCs for the user profile is permitted.

deny

Specifies that the use of the gNOI Install RPCs for the user profile is denied.

Platforms

All

11.30 gnoi-cert-mgmt-revoke

gnoi-cert-mgmt-revoke

Syntax

gnoi-cert-mgmt-revoke {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization gnoi-cert-mgmt-revoke)

Full Context

configure system security profile grpc rpc-authorization gnoi-cert-mgmt-revoke

Description

This command permits or denies the use of gNOI RevokeCertificates RPCs for the user profile.

The **no** form of this command reverts to the default value.

Default

gnoi-cert-mgmt-revoke deny

Parameters

permit

Specifies that the use of gNOI RevokeCertificates RPCs for the user profile is permitted.

deny

Specifies that the use of gNOI RevokeCertificates RPCs for the user profile is denied.

Platforms

All

11.31 gnoi-cert-mgmt-rotate

Full Context

configure system security profile grpc rpc-authorization gnoi-file-stat

Description

This command permits the use of gNOI File Stat RPC to retrieve metadata for a file from the specified target location.

Default

gnoi-file-stat permit

Parameters

permit

Specifies that the use of the gNOI File Stat RPC is permitted.

deny

Specifies that the use of the gNOI File Stat RPC is denied.

Platforms

All

11.36 gnoi-file-transfertoremote

gnoi-file-transfertoremote

Syntax

gnoi-file-transfertoremote {**permit** | **deny**}

Context

[Tree] (config>system>security>profile>grpc>rpc-authorization gnoi-file-transfertoremote)

Full Context

configure system security profile grpc rpc-authorization gnoi-file-transfertoremote

Description

This command permits the use of the gNOI File TransferToRemote RPC to transfer the file from the target node to a specified remote location.

Default

gnoi-file-transfertoremote permit

Parameters

permit

Specifies that the use of the gNOI File TransferToRemote RPC is permitted.

deny

Specifies that the use of the gNOI File TransferToRemote RPC is denied.

Platforms

All

11.37 gnoi-system-cancelreboot

goto

Syntax

goto *line*

Context

[Tree] (candidate goto)

Full Context

candidate goto

Description

This command changes the edit point of the candidate configuration. The edit point is the point after which new commands are inserted into the candidate configuration as an operator navigates the CLI and issues commands in edit-cfg mode.

Parameters

line

Indicates which line to change starting at the point indicated by the following options.

Values line, offset, **first**, **edit-point**, **last**

line	absolute line number
offset	relative line number to current edit point. Prefixed with '+' or '-'
first	keyword - first line
edit-point	keyword - current edit point
last	keyword - last line that is not 'exit'

Description

This command enables the inclusion of the 3GPP QoS specification in AAA protocols as signaled in the incoming GTP setup message.

The **no** form of this command disables the inclusion of the attribute.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

11.48 gr-helper

gr-helper

Syntax

gr-helper [**enable** | **disable**]

Context

[Tree] (config>router>rsvp>if gr-helper)

Full Context

configure router rsvp interface gr-helper

Description

This command enables the RSVP Graceful Restart Helper feature.

The RSVP-TE Graceful Restart helper mode allows the SR OS based system (the helper node) to provide another router that has requested it (the restarting node) a grace period, during which the system will continue to use RSVP sessions to neighbors requesting the grace period. This is typically used when another router is rebooting its control plane but its forwarding plane is expected to continue to forward traffic based on the previously available Path and Resv states.

The user can enable Graceful Restart helper on each RSVP interface separately. When the GR helper feature is enabled on an RSVP interface, the node starts inserting a new Restart_Cap Object in the Hello packets to its neighbor. The restarting node does the same and indicates to the helper node the desired Restart Time and Recovery Time.

The GR Restart helper consists of a couple of phases. Once it loses Hello communication with its neighbor, the helper node enters the Restart phase. During this phase, it preserves the state of all RSVP sessions to its neighbor and waits for a new Hello message.

Once the Hello message is received indicating the restarting node preserved state, the helper node enters the recovery phase in which it starts refreshing all the sessions that were preserved. The restarting node will activate all the stale sessions that are refreshed by the helper node. Any Path state which did not get a Resv message from the restarting node once the Recovery Phase time is over is considered to have expired and is deleted by the helper node causing the proper Path Tear generation downstream.

The duration of the restart phase (recovery phase) is equal to the minimum of the neighbor's advertised Restart Time (Recovery Time) in its last Hello message and the locally configured value of the max-restart (max-recovery) parameter.

When GR helper is enabled on an RSVP interface, its procedures apply to the state of both P2P and P2MP RSVP LSP to a neighbor over this interface.

Default

Platforms

All

11.49 gr-helper-time

gr-helper-time

Syntax

gr-helper-time max-recovery *recovery-interval* **max-restart** *restart-interval*

no gr-helper-time

Context

[Tree] (config>router>rsvp gr-helper-time)

Full Context

configure router rsvp gr-helper-time

Description

This command configures the local values for the max-recovery and the max-restart intervals used in the RSVP Graceful Restart Helper feature.

The values are configured globally in RSVP but separate instances of the timers are applied to each RSVP interface that has the RSVP Graceful Restart Helper enabled.

The **no** version of this command re-instates the default value for the delay timer.

Default

gr-helper-time max-recovery 300 max-restart 120

Parameters

recovery-interval

Specifies the max recovery interval value in seconds.

Values 1 to 1800

restart-interval

Specifies the max restart interval value in seconds.

Values 1 to 300

[Tree] (config>port>ethernet>efm-oam grace-tx-enable)

Full Context

configure system ethernet efm-oam grace-tx-enable

configure port ethernet efm-oam grace-tx-enable

Description

Enables the sending of grace for all the enabled EFM-OAM sessions on the node. Disabled by default at the system level and enabled by default at the port level. The combination of the system level and port level configuration will determine if the grace function is enabled on the individual ports. Both the system level and the port level must be enabled in order to support grace on a specific port. If either level is disabled, grace is not enabled on those ports. Enabling grace during an active ISSU or soft reset does not invoke the grace function for the active event.

When both **grace-tx-enable** and **config>system>ethernet>efm-oam dying-gasp-tx-on-reset**, **config>port>ethernet>efm-oam dying-gasp-tx-on-reset** are active on the same port, **grace-tx-enable** takes precedence when a soft reset is invoked if the Peer Vendor OUI being received is 00:16:4d (ALU) or the configured **config>port>ethernet>efm-oam grace-vendor-oui** value. The **grace-tx-enable** command should not be configured if the Nokia Vendor Specific Grace TLV is not supported on the remote peer.

The **no** form of this command disables the sending of the Nokia Vendor Specific Grace TLV.

Default

config>system>ethernet>efm-oam>no grace-tx-enable

config>port>ethernet>efm-oam>grace-tx-enable

grace-tx-enable

Syntax

[**no**] **grace-tx-enable**

Context

[Tree] (config>eth-cfm>system grace-tx-enable)

Full Context

configure eth-cfm system grace-tx-enable

Description

This command enables ETH-CFM grace transmission at the system level when a soft reset message is received and processed by the ETH-CFM module. Individual MEP configuration determines which of the two supported grace functions, ETH-VSM or ETH-ED, is used to announce grace.

This command controls the overall capability to transmit grace and does not control which grace announcement to use. This command also has no impact on the reception and processing of grace-style PDUs.

The **no** form of this command disables ETH-CFM grace transmission at the system level.

Default

grace-tx-enable

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

11.52 grace-vendor-oui

grace-vendor-oui

Syntax

grace-vendor-oui *oui*

no grace-vendor-oui

Context

[Tree] (config>port>ethernet>efm-oam grace-vendor-oui)

Full Context

configure port ethernet efm-oam grace-vendor-oui

Description

This optional command configures an additional peer vendor OUI which indicates support for the Vendor Specific EFM-OAM Grace functionality, allowing grace to be preferred over dying gasp when both are configured. This is in addition to the Nokia Vendor OUI 00:16:4d.

When both **grace-tx-enable (config>system>ethernet>efm-oam grace-tx-enable**, **config>port>ethernet>efm-oam grace-tx-enable)** and **dying-gasp-tx-on-reset (config>system>ethernet>efm-oam dying-gasp-tx-on-reset**, **config>port>ethernet>efm-oam dying-gasp-tx-on-reset)** are active on the same port, **grace-tx-enable** takes precedence when a soft reset is invoked if the Peer Vendor OUI being received is 00:16:4d (ALU) or the configured **grace-vendor-oui** value. The **grace-tx-enable** command should not be configured if the Nokia Vendor Specific Grace TLV is not supported on the remote peer, including Nokia 7750 SR equipment prior to release 11.0 R4.

The **no** form of this command removes the additional Vendor OUI but does not remove the Nokia 00:16:4d value.

Default

no grace-vendor-oui

Parameters

oui

Hex value in the range 00:00:00 to FF:FF:FF.

Context

[Tree] (config>router>rsvp>interface graceful-shutdown)

[Tree] (config>router>rsvp graceful-shutdown)

Full Context

configure router rsvp interface graceful-shutdown

configure router rsvp graceful-shutdown

Description

This command initiates a graceful shutdown of the specified RSVP interface or all RSVP interfaces on the node if applied at the RSVP level. These are referred to as maintenance interface and maintenance node, respectively.

To initiate a graceful shutdown the maintenance node generates a PathErr message with a specific error sub-code of Local Maintenance on TE Link required for each LSP that is exiting the maintenance interface.

The node performs a single make-before-break attempt for all adaptive CSPF LSPs it originates and LSP paths using the maintenance interfaces. If an alternative path for an affected LSP is not found, then the LSP is maintained on its current path. The maintenance node also tears down and re-signals any detour LSP path using listed maintenance interfaces as soon as they are not active.

The maintenance node floods an IGP TE LSA/LSP containing Link TLV for the links under graceful shutdown with TE metric set to 0xffffffff and Unreserved Bandwidth parameter set to zero (0).

A head-end LER node, upon receipt of the PathErr message performs a single make-before-break attempt on the affected adaptive CSPF LSP. If an alternative path is not found, then the LSP is maintained on its current path.

A node does not take any action on the paths of the following originating LSPs after receiving the PathErr message:

a. An adaptive CSPF LSP for which the PathErr indicates a node address in the address list and the node corresponds to the destination of the LSP. In this case, there are no alternative paths which can be found.

b. An adaptive CSPF LSP whose path has explicit hops defined using the listed maintenance interface(s)/ node(s).

c. A CSPF LSP with the adaptive option disabled and which current path is over the listed maintenance interfaces in the PathErr message. These are not subject to make-before-break.

d. A non CSPF LSP which current path is over the listed maintenance interfaces in the PathErr message.

The head-end LER node upon receipt of the updates IPG TE LSA/LSP for the maintenance interfaces updates the TE database. This information will be used at the next scheduled CSPF computation for any LSP which path may traverse any of the maintenance interfaces.

The **no** form of this command disables the graceful shutdown operation at the RSVP interface level or at the RSVP level. The configured TE parameters of the maintenance links are restored and the maintenance node floods the links.

11.56 granularity

granularity

Syntax

granularity {**percent** *percent-of-admin-pir* | **rate** *rate-in-kilobits-per-second*}

no granularity

Context

[Tree] (config>qos>adv-config-policy>child-control>bandwidth-distribution granularity)

Full Context

configure qos adv-config-policy child-control bandwidth-distribution granularity

Description

This command is used to create a step-like behavior where the operational PIR will round up to the nearest increment of the specified granularity before being applied to the child. The only exception is when the distributed bandwidth is less than 1% above a lower step value, in which case the lower step value is used.

This step-like behavior may be useful when the bandwidth used by an active child is well known. While the **above-offered-cap** command automatically adds a specified amount to the operational PIR of a child, the **granularity** command only increments the operational PIR to the next step value. While not expected to be used in conjunction, the **above-offered-cap** and **granularity** commands may be used simultaneously, in which case the above-offered-cap increase will be applied first, followed by the granularity rounding to the next step value.

If the **granularity** command is used with a percent-based value, the rounding up function of the configured PIR value on the policer or queue is based on the child's administrative PIR. In this case, care should be taken that the child is either configured with an explicit PIR rate (other than max) or the child's administrative PIR is defined using the percent-rate command with the local parameter enabled if an explicit value is not desired. When a maximum PIR is in use on the child, the system attempts to interpret the maximum child forwarding rate. This rate could be very large if the child is associated with multiple ingress or egress ports.

If the child's administrative PIR is modified while a percent-based granularity is in effect, the system automatically uses the new relative rounding value the next time the child's operational PIR is determined.

When this command is not specified or removed, the system makes no attempt to round up the child's determined operational PIR.

The **no** form of this command is used to remove the operational PIR rounding behavior from all child policers and queues associated with the policy.

Parameters

percent-of-admin-pir

When the percent qualifier is used, the following percent-of-admin-pir parameter specifies the percentage of the child's administrative PIR that should be used as the rounding step value. If a value of 0 or 0.00 is used, the system will interpret this equivalent to no granularity.

Values 0.00 to 100.00

rate-in-kilobits-per-second

When the rate qualifier is used, the following rate-in-kilobits-per-second parameter specifies an explicit rate, in kb/s, that should be used as the child's rounding step value. If a rate step of 0 is specified, the system interprets this equivalent to no granularity.

Values 0 to 100,000,000

Platforms

All

granularity

Syntax

granularity {**percent** *percent-of-admin-pir* | **rate** *rate-in-kilobits-per-second*}

no granularity

Context

[Tree] (config>qos>adv-config-policy>child-control>offered-measurement granularity)

Full Context

configure qos adv-config-policy child-control offered-measurement granularity

Description

This command is used to adjust the sensitivity of the virtual scheduler to changes in the child offered rate. As the child offered rate is determined, it is compared to the previous offered rate. If the delta does not exceed the sensitivity threshold determined for the current offered rate, the change in offered rate is ignored for that iteration.

While it is assumed that changing the offered rate change sensitivity will be a rare occurrence, it may be prudent to react to smaller changes in the offered rate of a particular child policer or queue. Another possible reason for changing the sensitivity is that it may be desired to lower the impact of changes in offered rate on the virtual scheduler for a particular child by raising the granularity.

A side effect of higher sensitivity (lower granularity) is that the virtual scheduler may need to adjust the distributed bandwidth between all children more often, resulting in the possibility of lowering resources available to other virtual scheduler instances on the slot.

A side effect of lower sensitivity (higher granularity) is that the parent virtual scheduler may distribute insufficient bandwidth to the child resulting in dropped packets.

If the granularity command is used with a percent-based value, the sensitivity is a function of the configured PIR value on the policer or queue. In this case, care should be taken that the child is either configured with an explicit PIR rate (other than max) or the child's administrative PIR is defined using the percent-rate command with the local parameter enabled if an explicit value is not desired. When a maximum PIR is in use on the child, the system attempts to interpret the maximum child forwarding rate. This rate could be very large if the child is associated with multiple ingress or egress ports.

Except for the overall cap on the offered input into the virtual scheduler, the child's administrative PIR has no effect on the calculated sensitivity if an explicit rate is specified.

If the child's administrative PIR is modified while a percent-based granularity is in effect, the system automatically uses the new relative sensitivity value the next time the child's offered rate is determined.

The **no** form of this command is used to restore the default offered rate sensitivity behavior to all child policers and queues associated with the policy.

Parameters

percent-of-admin-pir

When the percent qualifier is used, this parameter specifies the percentage of the child's administrative PIR that are used as the threshold sensitivity to offered rate change. If a value of 0 or 0.00 is used, the system will interpret this equivalent to no granularity.

Values 1.00 to 100.00

rate-in-kilobits-per-second

When the rate qualifier is used, this parameter specifies an explicit rate, in kb/s, that are used as the child's offered rate change sensitivity value. If a rate sensitivity of 0 is specified, the system interprets this equivalent to no granularity.

gratuitous-arp {one-per-sap| one-per-outer-tag}

Context

[Tree] (config>subscr-mgmt>up-resiliency>fsg-template gratuitous-arp)

Full Context

configure subscriber-mgmt up-resiliency fate-sharing-group-template gratuitous-arp

Description

This command configures the granularity with which Gratuitous ARP packets are sent upon switchover events.

Parameters

one-per-sap

Specifies to send a single GARP per SAP. The Sender Protocol Address is any subnet associated with the SAP. If no subnet is available, the system IP is used.

one-per-outer-tag

Specifies to send a single GARP for all q-in-q SAPs sharing the same outer tag. For dot1q SAPs this behaves the same as **one-per-sap**. The Sender Protocol Address is any subnet associated with the SAP. If no subnet is available, the system IP is used.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

11.58 gratuitous-rtr-adv

gratuitous-rtr-adv

Syntax

[**no**] **gratuitous-rtr-adv**

Context

[Tree] (config>service>vprn>sub-if>ipoe-linking gratuitous-rtr-adv)

[Tree] (config>service>ies>sub-if>grp-if>ipoe-linking gratuitous-rtr-adv)

[Tree] (config>service>ies>sub-if>ipoe-linking gratuitous-rtr-adv)

[Tree] (config>service>vprn>sub-if>grp-if>ipoe-linking gratuitous-rtr-adv)

Full Context

configure service vprn subscriber-interface ipoe-linking gratuitous-rtr-adv

configure service ies subscriber-interface group-interface ipoe-linking gratuitous-rtr-adv

configure service ies subscriber-interface ipoe-linking gratuitous-rtr-adv

configure service vprn subscriber-interface group-interface ipoe-linking gratuitous-rtr-adv

Description

This command enables the generation of unsolicited Router-advertisement on creation of v4 host.

The **no** form of this command disables **gratuitous-rtr-adv.**

Default

gratuitous-rtr-adv

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

11.59 gre

gre

Syntax

[**no**] **gre**

Context

[Tree] (config>subscr-mgmt>wlan-gw>tunnel-query>type gre)

Full Context

configure subscriber-mgmt wlan-gw tunnel-query type gre

Description

This command enables matching on GRE tunnels.

The **no** form of this command disables matching on GRE tunnels, unless no other tunnel type specifier is configured.

Default

no gre

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

gre

Syntax

[**no**] **gre**

Context

[Tree] (config>service>vprn>bgp-ipvpn>mpls>auto-bind-tunnel>resolution-filter gre)

Full Context

configure service vprn bgp-ipvpn mpls auto-bind-tunnel resolution-filter gre

Description

This command enables setting the tunnel type for the auto bind tunnel.

The **gre** encapsulation of the MPLS service packet uses the base 4-byte header as per RFC 2890. The optional fields Checksum (plus Reserved field), Key, and Sequence Number are not inserted.

The **no** form of this command disables the setting the tunnel type for the auto bind tunnel.

Default

no gre

Platforms

All

gre

Syntax

gre

Context

[Tree] (config>test-oam>build-packet>header gre)

Full Context

configure test-oam build-packet header gre

Description

This command creates a GRE header for inclusion in test OAM build packet instance.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

gre

Syntax

gre

Context

[Tree] (config>service>vprn>auto-bind-tunnel>res-filter gre)

Full Context

configure service vprn auto-bind-tunnel resolution-filter gre

Description

Note: This command is no longer supported and will be removed in a future release.

Platforms

All

11.60 gre-eth-bridged

gre-eth-bridged

Syntax

gre-eth-bridged

Context

[Tree] (config>service>system gre-eth-bridged)

Full Context

configure service system gre-eth-bridged

Description

Commands in this context configure parameters related to termination of a GRE tunnel carrying Ethernet payload onto a PW port by using Forwarding Path Extensions (FPE).

Platforms

All

11.61 gre-header

gre-header

Syntax

gre-header send-key *send-key* **receive-key** *receive-key*

no gre-header

Context

[Tree] (config>service>vprn>if>sap>ip-tunnel gre-header)

[Tree] (config>service>ies>if>sap>ip-tunnel gre-header)

Full Context

configure service vprn interface sap ip-tunnel gre-header

configure service ies interface sap ip-tunnel gre-header

Description

This command configures the type of the IP tunnel. If the **gre-header** command is configured then the tunnel is a GRE tunnel with a GRE header inserted between the outer and inner IP headers. If the **no** form of this command is configured then the tunnel is a simple IP-IP tunnel.

Default

no gre-header

Parameters

send-key *send-key*

Specifies a 32-bit unsigned integer.

Values 0 to 4294967295

receive-key *receive-key*

Specifies a 32-bit unsigned integer.

Values 0 to 4294967295

Platforms

All

11.62 gre-key

gre-key

Syntax

gre-key if-index

no gre-key

Context

[Tree] (config>filter>gre-tun-tmp>ipv4 gre-key)

Full Context

configure filter gre-tunnel-template ipv4 gre-key

Description

This command enables the population of the GRE key field in the GRE header sent with the encapsulated IP packet.

The **no** form of this command disables the population of the optional GRE key field when the matching IP packet is sent encapsulated in a GRE tunnel.

Parameters

if-index

Causes the GRE key field to be populated with the ifIndex of the ingress interface on which the matching IP packet was received.

Platforms

All

11.63 gre-termination

gre-termination

Syntax

[**no**] **gre-termination**

Context

[Tree] (config>router>if gre-termination)

Full Context

configure router interface gre-termination

Description

This command enables the termination of MPLS-over-GRE and IP-over-GRE packets on destination IP addresses from a user-defined subnet. The user defines a subnet for the termination of GRE packets by applying the **gre-termination** command to a numbered network IP interface, including a loopback interface.

For more information, refer to "IP-over-GRE and MPLS-over-GRE Termination on a User-Configured Subnet" in the 7450 ESS, 7750 SR, 7950 XRS, and VSR Router Configuration Guide.

The **no** form of this command disables the termination of MPLS-over-GRE and IP-over-GRE packets on the subnet of the interface. Packets are dropped.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

11.64 gre-tunnel-template

gre-tunnel-template

Syntax

gre-tunnel-template *name* [**create**]

no gre-tunnel-template *name*

Context

[Tree] (config>filter gre-tunnel-template)

Full Context

configure filter gre-tunnel-template

Description

Commands in this context configure a GRE tunnel template parameters to be used to tunnel associated traffic.

The **no** form of this command removes the GRE tunnel template from the configuration.

Parameters

name

Specifies a GRE tunnel template name up to 32 characters.

create

This keyword is required to create the configuration context. Once it is created, the context can be enabled with or without the **create** keyword.

Platforms

All

11.65 group

group

Syntax

group *name* [**create**]

no group *name*

Context

[Tree] (config>qos>hw-agg-shap-sched-plcy group)

Full Context

configure qos hw-agg-shaper-scheduler-policy group

Description

This command creates a group within a hardware aggregate shaper scheduler policy.

The **no** form of this command removes the group from the policy.

Parameters

name

Specifies a group name, up to 32 characters.

Platforms

7750 SR-1, 7750 SR-s

group

Syntax

group *tunnel-group-name* [**service-id** *service-id*]

no group

Context

[Tree] (config>subscr-mgmt>loc-user-db>ppp>host>l2tp group)

Full Context

configure subscriber-mgmt local-user-db ppp host l2tp group

Description

This command configures the L2TP tunnel group. The tunnel-group-name is configured in the **config>router>l2tp** context. Refer to the *7450 ESS, 7750 SR, 7950 XRS, and VSR Router Configuration Guide*.

Parameters

tunnel-group-name

Specifies an existing tunnel L2TP group, up to 63 characters.

service-id ***service-id***

Specifies an existing service ID or service name.

Values *service-id*: 1 to 214748364

service-name: up to 64 characters

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

group

Syntax

group *tunnel-group-name* [**create**]

group *tunnel-group-name* [**create**] [**protocol** *protocol*]

no group *tunnel-group-name*

Context

[Tree] (config>service>vprn>l2tp group)

[Tree] (config>router>l2tp group)

Full Context

configure service vprn l2tp group

configure router l2tp group

Description

This command configures an L2TP tunnel group.

The **no** form of this command reverts removes the tunnel group name from the configuration.

Parameters

tunnel-group-name

Specifies a name string to identify a L2TP group up to 63 characters in length.

create

This keyword is mandatory when creating a tunnel group name. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

protocol

Specifies the l2tp protocol for use.

Values v2, v3, v3draft

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

group

Syntax

group *tunnel-group-name*

Context

[Tree] (debug>router>l2tp group)

Full Context

debug router l2tp group

Description

This command enables and configures debugging for an L2TP group.

Parameters

tunnel-group-name

Specifies the tunnel group name, up to 63 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

group

Syntax

group *name* [**create**]

no group *name*

Context

[Tree] (config>service>vpls>gsmp group)

[Tree] (config>service>vprn>gsmp group)

Full Context

configure service vpls gsmp group

configure service vprn gsmp group

Description

This command specifies a GSMP name. A GSMP group name is unique only within the scope of the service in which it is defined.

The **no** form of this command reverts to the default.

Parameters

name

Specifies a GSMP name up to 32 characters.

create

Keyword used to create the GSMP group name. The **create** keyword requirement can be enabled or disabled in the **environment>create** context.

Platforms

All

group

Syntax

[**no**] **group** *ip-address*

Context

[Tree] (config>subscr-mgmt>igmp-policy>static group)

Full Context

configure subscriber-mgmt igmp-policy static group

Description

This command adds or removes a static multicast group.

The **no** form of this command reverts to the default value.

Parameters

ip-address

Specifies the multicast group IP address.

Values a.b.c.d

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

group

Syntax

[**no**] **group** *grp-ipv6-address*

Context

[Tree] (config>subscr-mgmt>mld-policy>static group)

Full Context

configure subscriber-mgmt mld-policy static group

Description

This command configures a static multicast group.

The **no** form of this command reverts to the default.

Parameters

grp-ipv6-address

Specifies the IPv6 address.

Values ipv6-address - x:x:x:x:x:x:x:x (eight 16-bit pieces) x:x:x:x:x:x:d.d.d.d

x - [0 to FFFF]H

d - [0 to 255]D

- multicast group IPv6 address

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

group

Syntax

[**no**] **group** *group-name*

Context

[Tree] (config>service>vprn>rip group)

[Tree] (config>service>ies>rip group)

Full Context

configure service vprn rip group

configure service ies rip group

Description

This command creates a context for configuring a RIP group of neighbors. RIP groups are a way of logically associating RIP neighbor interfaces to facilitate a common configuration for RIP interfaces.

The **no** form of this command deletes the RIP neighbor interface group. Deleting the group also removes the RIP configuration of all the neighbor interfaces currently assigned to this group.

Default

no group

Parameters

group-name

The RIP group name. Allowed values are any string, up to 32 characters, composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

Platforms

All

group

Syntax

group *group-id* **rate** *rate*

no group *group-id*

Context

[Tree] (config>port>ethernet>egress>hs-sched-ovr group)

Full Context

configure port ethernet egress hs-scheduler-overrides group

Description

This command overrides a group rate configured in the HS scheduler policy applied to the port egress.

The **no** form of this command removes the rate override from the port egress configuration.

Parameters

group-id

Specifies the group ID.

Values 1

rate

Specifies the maximum rate in megabits per second. When the **max** keyword follows the **rate** keyword, the bandwidth limitation is removed from the group. The **max** keyword is mutually exclusive to the **rate** parameter. Either the **max** keyword or a rate value must follow the **rate** keyword.

Values 1 to 100000, max

Platforms

7750 SR-7/12/12e

group

Syntax

group *sonet-sdh-index* **payload** {**tu3** | **vt2** | **vt15**}

Context

[Tree] (config>port>sonet-sdh group)

Full Context

configure port sonet-sdh group

Description

This command configures payload of the SONET/SDH group.

This command is supported by TDM satellite, however the **tu3** parameter is not.

For example:

config>port>sonet-sdh#

group tug3-1.1 payload tu3 group tug3-1.2 payload vt2 group tug3-1.3 payload vt2 group tug3-2.1 payload vt15 group tug3-2.2 payload vt15 group tug3-2.3 payload tu3 group tug3-3.1 payload tu3 group tug3-3.2 payload tu3 group tug3-3.3 payload tu3

Parameters

sonet-sdh-index

Specifies the components making up the specified SONET/SDH path. Depending on the type of SONET/SDH port the *sonet-sdh-index* must specify more path indexes to specify the payload location of the path.

tu3

Specifies the Tributary Unit Group (TUG3) on a path. Configures the port or channel for transport network use.

vt2

Configures the path as a virtual tributary group of type vt2.

vt15

Configures the path as a virtual tributary group of type vt15.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

group

Syntax

[**no**] **group** *name*

Context

[Tree] (config>router>bgp group)

Full Context

configure router bgp group

Description

Commands in this context configure a BGP peer group.

The **no** form of this command deletes the specified peer group and all configurations associated with the peer group. The group must be shut down before it can be deleted.

Default

no group

Parameters

name

Specifies the peer group name. Allowed values are any string, up to 64 characters, composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

Platforms

All

group

Syntax

[**no**] **group** *grp-ip-address*

configure service vpls mesh-sdp mld-snooping static group

configure service vpls igmp-snooping static group

configure service vpls spoke-sdp mld-snooping static group

configure service vpls sap mld-snooping static group

configure service vpls spoke-sdp igmp-snooping static group

Description

Commands in this context add a static multicast group as a (*, G) or as one or more (S,G) records. When a static MLD or IGMP group is added, multicast data for that (*,G) or (S,G) is forwarded to the specific SAP or SDP without receiving any membership report from a host.

Parameters

grp-ip-address

Specifies an IGMP multicast group address that receives data on an interface. The IP address must be unique for each static group.

grp-ipv6-address

Specifies an MLD multicast group address that receives data on an interface. The IP address must be unique for each static group.

Values ipv6-address:

- x:x:x:x:x:x:x:x (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d
- x: [0 to FFFF]H
- d: [0 to 255]D

Platforms

All

group

Syntax

group *name* [**esm-dynamic-peer**]

no group *name*

Context

[Tree] (config>service>vprn>bgp group)

Full Context

configure service vprn bgp group

Description

This command creates a context to configure a BGP peer group.

The **no** form of this command deletes the specified peer group and all configurations associated with the peer group. The group must be shut down before it can be deleted.

Parameters

name

Specifies the peer group name. Allowed values is a string up to 64 characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed between double quotes.

esm-dynamic-peer

Specifies that the given BGP group is used by BGP peers created dynamically based on subscriber-hosts pointing to corresponding BGP peering policy. There can be only one BGP group with this flag set in any given VPRN. No BGP neighbors can be manually configured in a BGP group with this flag set.

Default disabled

Platforms

All

[**no**] **group start** *grp-ip-address* **end** *grp-ip-address* [**step** *ip-address*]

Context

[Tree] (config>service>vprn>igmp>if>static group)

Full Context

configure service vprn igmp interface static group

Description

This command adds a static multicast group either as a (*,G) or one or more (S,G) records. Use IGMP static group memberships to test multicast forwarding without a receiver host. When IGMP static groups are enabled, data is forwarded to an interface without receiving membership reports from host members.

When static IGMP group entries on point-to-point links that connect routers to a rendezvous point (RP) are configured, the static IGMP group entries do not generate join messages toward the RP.

Parameters

grp-ip-address

Specifies an IGMP multicast group address that receives data on an interface. The IP address must be unique for each static group. The address must be in dotted decimal notation.

start *grp-ip-address*

Specifies the start multicast group address.

end *grp-ip-address*

Specifies the end multicast group address.

step *ip-address*

Specifies the step increment.

Platforms

All

group

Syntax

[**no**] **group** *grp-ipv6-address*

[**no**] **group start** *grp-ipv6-address* **end** *grp-ipv6-address* [**step** *ipv6-address*]

Context

[Tree] (config>service>vprn>mld>if>static group)

Full Context

configure service vprn mld interface static group

Description

Commands in this context add a static multicast group either as a (*,G) or one or more (S,G) records. Use MLD static group memberships to test multicast forwarding without a receiver host. When MLD static groups are enabled, data is forwarded to an interface without receiving membership reports from host members.

When static MLD group entries on point-to-point links that connect routers to a rendezvous point (RP) are configured, the static MLD group entries do not generate join messages toward the RP.

The **no** form of this command removes the IPv6 address from the configuration.

Parameters

grp-ipv6-address

Specifies an MLD multicast group address that receives data on an interface. The IP address must be unique for each static group.

Values ipv6-address:

- x:x:x:x:x:x:x:x (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d
- x: [0 to FFFF]H
- d: [0 to 255]D

start *grp-ipv6-address*

Specifies the start multicast group address.

Values ipv6-address:

- x:x:x:x:x:x:x:x (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d

- x: [0 to FFFF]H
- d: [0 to 255]D

end ***grp-ipv6-address***

Specifies the end multicast group address.

Values ipv6-address:

- x:x:x:x:x:x:x:x (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d
- x: [0 to FFFF]H
- d: [0 to 255]D

step ***ipv6-address***

Specifies the step increment.

Platforms

All

group

Syntax

[**no**] **group** *group-name*

Context

[Tree] (config>service>vprn>msdp group)

Full Context

configure service vprn msdp group

Description

This command enables access to the context to create or modify a Multicast Source Discovery Protocol (MSDP) group. To configure multiple MSDP groups, include multiple group statements.

By default, the group's options are inherited from the global MSDP options. To override these global options, group-specific options within the group statement can be configured.

If the group name provided is already configured then this command only provides the context to configure the options pertaining to this group.

If the group name provided is not already configured, then the group name must be created and the context to configure the parameters pertaining to the group should be provided. In this case, the $ prompt to indicate that a new entity (group) is being created should be used.

For a group to be of use, at least one peer must be configured.

Default

no group

Parameters

group-name

Specifies a unique name for the MSDP group.

Platforms

All

group

Syntax

[**no**] **group** *ip-address* [/*mask*]

Context

[Tree] (config>service>vprn>mvpn>pt>selective>multistream-spmsi group)

Full Context

configure service vprn mvpn provider-tunnel selective multistream-spmsi group

Description

This command creates group prefixes that map to the multicast stream. At least one source must be specified for the policy to be active.

Parameters

Ip-address/mask

Specifies the IP address.

Values

ipv4-prefix	a.b.c.d	
	ipv4-prefix-le	[0..32]
ipv6-prefix		x:x:x:x:x:x:x:x (eight 16-bit pieces)
		x:x:x:x:x:x:d.d.d.d
	x	[0..FFFF]H
	d	[0..255]D

Specifies the step increment.

Platforms

All

group

Syntax

[**no**] **group** *grp-ip-address*

Context

[Tree] (config>router>igmp>tunnel-interface>static group)

Full Context

configure router igmp tunnel-interface static group

Description

Commands in this context add a static multicast group either as a (*,G) or one or more (S,G) records.

The user can assign static multicast group joins to a tunnel interface associated with an RSVP P2MP LSP.

A given (*,G) or (S,G) can only be associated with a single tunnel interface.

A multicast packet which is received on an interface and which succeeds the RPF check for the source address will be replicated and forwarded to all OIFs which correspond to the branches of the P2MP LSP. The packet is sent on each OIF with the label stack indicated in the NHLFE of this OIF. The packets will also be replicated and forwarded natively on all OIFs which have received IGMP or PIM joins for this (S,G).

The multicast packet can be received over a PIM or IGMP interface which can be an IES interface, a spoke SDP terminated IES interface, or a network interface.

Parameters

grp-ip-address

Specifies a multicast group address that receives data on a tunnel interface. The IP address must be unique for each static group.

Platforms

All

group

Syntax

[**no**] **group** *grp-ipv6-address*

[**no**] **group start** *grp-ipv6-address* **end** *grp-ipv6-address* [**step** *ipv6-address*]

Context

[Tree] (config>router>mld>if>static group)

Full Context

configure router mld interface static group

Description

Commands in this context add a static multicast group either as a (*,G) or one or more (S,G) records. Use MLD static group memberships to test multicast forwarding without a receiver host. When MLD static groups are enabled, data is forwarded to an interface without receiving membership reports from host members.

When static MLD group entries on point-to-point links that connect routers to a rendezvous point (RP) are configured, the static MLD group entries do not generate join messages toward the RP.

The **no** form of this command removes the IPv6 address from the configuration.

Parameters

grp-ipv6-address

Specifies an MLD multicast group address that receives data on an interface. The IP address must be unique for each static group.

Values ipv6-address:

- x:x:x:x:x:x:x:x (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d
- x: [0 to FFFF]H
- d: [0 to 255]D

start *grp-ipv6-address*

Specifies the start multicast group address.

Values ipv6-address:

- x:x:x:x:x:x:x:x (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d
- x: [0 to FFFF]H
- d: [0 to 255]D

end *grp-ipv6-address*

Specifies the end multicast group address.

Values ipv6-address:

- x:x:x:x:x:x:x:x (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d
- x: [0 to FFFF]H
- d: [0 to 255]D

step *ipv6-address*

Specifies the step increment.

Platforms

All

group

Syntax

[**no**] **group** *group-name*

Context

[Tree] (config>router>msdp group)

Full Context

configure router msdp group

Description

This command enables access to the context to create or modify a Multicast Source Discovery Protocol (MSDP) group. To configure multiple MSDP groups, include multiple group statements.

By default, the group's options are inherited from the global MSDP options. To override these global options, group-specific options within the group statement can be configured.

If the group name provided is already configured then this command only provides the context to configure the options pertaining to this group.

If the group name provided is not already configured, then the group name must be created and the context to configure the parameters pertaining to the group should be provided. In this case, the $ prompt to indicate that a new entity (group) is being created should be used.

For a group to be of use, at least one peer must be configured.

The **no** form of this command removes the *group-name* from the MSDP configuration.

Default

no group

Parameters

group-name

Species a MSDP group name, up to 32 characters.

Platforms

All

group

Syntax

group *group-id* **rate** *rate*

no group *group-id*

Context

[Tree] (config>qos>hs-scheduler-policy group)

Full Context

configure qos hs-scheduler-policy group

Description

This command defines the maximum rate allowed for the scheduling classes mapped to the specified *group-id*. A group is a scheduling component used to combine up to six consecutive scheduling classes into a single strict priority level. Each scheduling class within the group has an associated weight. When the scheduler is servicing the strict level associated with the group, the ratio of bandwidth allocated to each

scheduling class within the group during congestion is relative to the ratio of the weight of each active member.

The **no** form of the command reverts to the default.

Default

group 1 rate max

Parameters

group-id

Specifies the group ID. The group always exists and does not need to be created prior to defining group membership.

Values 1

rate

Specifies the maximum rate in megabits per second. When the **max** keyword follows the rate keyword, the bandwidth limitation is removed from the group. The **max** keyword and the *rate* parameter are mutually exclusive. Either **max** or a rate value must follow the **rate** keyword.

Values 1 to 100000, max

Platforms

7750 SR-7/12/12e

group

Syntax

group *name* [**create**]

no group *name*

Context

[Tree] (config>qos>port-scheduler-policy group)

Full Context

configure qos port-scheduler-policy group

Description

This command defines a weighted scheduler group within a port scheduler policy.

The port scheduler policy defines a set of eight priority levels. The weighted scheduler group allows for the application of a scheduling weight to groups of child queues competing at the same priority level of the port scheduler policy applied to a Vport defined in the context of the egress of an Ethernet port or applied to the egress of an Ethernet port.

Up to eight groups can be defined within each port scheduler policy. One or more levels can map to the same group. A group has a rate and, optionally, a cir-rate, and inherits the highest scheduling priority of its member levels. A group receives bandwidth from the port or from the Vport and distributes it within the member levels of the group according to the weight of each level within the group.

Each priority level will compete for bandwidth within the group based on its weight under a congestion situation. If there is no congestion, a priority level can achieve up to its rate (cir-rate) worth of bandwidth.

CLI will enforce that mapping of levels to a group are contiguous. A user would not be able to add a priority level to a group unless the resulting set of priority levels is contiguous.

The **no** form of this command removes the group from the port scheduler policy.

Parameters

name

Specifies the name of the weighted scheduler group and can be up to 32 ASCII characters.

create

This keyword is mandatory when creating the specified group.

Platforms

All

group

Syntax

group *aa-group-id*

Context

Full Context

admin application-assurance group

Description

Commands in this context perform a group-specific upgrade.

Parameters

aa-group-id

Specifies an AA ISA group ID.

Values 1 to 255

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

group

Syntax

group *group-name*

no group

Context

[Tree] (config>system>security>user>snmp group)

Full Context

configure system security user snmp group

Description

This command associates (or links) a user to a group name. The group name must be configured with the **config>system>security>user >snmp>group** command. The **config>system>security>user access** command links the group with one or more views, security model (s), security level (s), and read, write, and notify permissions.

Parameters

group-name

Enter the group name (between 1 and 32 alphanumeric characters) that is associated with this user. A user can be associated with one group-name per security model.

Platforms

All

group

Syntax

[**no**] **group** *group-name*

Context

[Tree] (config>router>ripng group)

[Tree] (config>router>rip group)

Full Context

configure router ripng group

configure router rip group

Description

This command creates a context for configuring a RIP group of neighbor interfaces.

RIP groups are a way of logically associating RIP neighbor interfaces to facilitate a common configuration for RIP interfaces.

The **no** form of the command deletes the RIP neighbor interface group. Deleting the group will also remove the RIP configuration of all the neighbor interfaces currently assigned to this group.

Default

no group

Parameters

group-name

Specifies the RIP group name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

Platforms

All

group

Syntax

[**no**] **group** *ip-address* [/*mask*]

Context

Syntax

group down *time* | **no group down**

group up *time* | **no group up**

Context

[Tree] (config>service>oper-group>hold-time group)

Full Context

configure service oper-group hold-time group

Description

The **group down** form of the command configures the number of seconds to wait before notifying clients monitoring this group when its operational status transitions from up to down.

The **group up** form of the command configures the number of seconds to wait before notifying clients monitoring this group when its operational status transitions from down to up. A value of zero indicates that transitions are reported immediately to monitoring clients. The up time option is a must to achieve fast convergence: when the group comes up, the monitoring MH site that tracks the group status may wait without impacting the overall convergence; there is usually a pair MH site that is already handling the traffic.

The **no** form of the command sets the values back to the default.

Default

group down 0

group up 4

Parameters

time

Specifies the group up or group down time value.

Values 0 to 3600

Platforms

All

11.66 group-address

group-address

Syntax

group-address *prefix-list-name*

no group-address

Context

[Tree] (config>router>policy-options>policy-statement>entry>from group-address)

Full Context

configure router policy-options policy-statement entry from group-address

Description

This command specifies the multicast group-address prefix list containing multicast group-addresses that are embedded in the join or prune packet as a filter criterion. The prefix list must be configured prior to entering this command. Prefix lists are configured in the **config>router>policy-options>prefix-list** context.

The **no** form of this command removes the criterion from the configuration.

Default

no group-address

Parameters

prefix-list-name

Specifies the prefix-list name. Allowed values are any string up to 64 characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

The *prefix-list-name* is defined in the **config>router>policy-options>prefix-list** context.

Context

[Tree] (config>router>igmp>if group-interface)

[Tree] (config>router>igmp group-interface)

Full Context

configure router igmp interface group-interface

configure router igmp group-interface

Description

This command enables IGMP on a group-interface in a VRF context. Activating IGMP under the group-interface is a prerequisite for subscriber replication. The group-interface is also needed so that MCAC can be applied and various IGMP parameters defined.

This command can be used in a regular, wholesaler or retailer type of VRF. The retailer VRF does not have the concept of group-interfaces under the subscriber-interface hierarchy. In the case that this command is applied to a retailer VRF instance, the optional **fwd-service** command must be configured. The **fwd-service** command is referencing the wholesaler VRF in which the traffic is ultimately replicated. Redirection in the retailer VRF is supported.

This command enables IGMP on a group-interface in the Global Routing Table (GRT). The group-interface in GRT is defined under the IES service. Activating IGMP under the group-interface is a prerequisite for subscriber replication. The group-interface is also needed so that MCAC can be applied and various IGMP parameters defined.

Parameters

ip-int-name

Specifies the name of the group interface.

Platforms

All

group-name *group-name* **value** *group-value*

no group-name *group-name*

Context

[Tree] (config>service>sdp-group group-name)

Full Context

configure service sdp-group group-name

Description

This command defines SDP administrative groups, referred to as SDP admin groups.

SDP admin groups provide a way for services using a pseudowire template to automatically include or exclude specific provisioned SDPs. SDPs sharing a specific characteristic or attribute can be made members of the same admin group. When users configure a pseudowire template, they can include and/or exclude one or more admin groups. When the service is bound to the pseudowire template, the SDP selection rules will enforce the admin group constraints specified in the **sdp-include** and **sdp-exclude** commands.

A maximum of 32 admin groups can be created. The group value ranges from zero (0) to 31. It is uniquely associated with the group name at creation time. If the user attempts to configure another group name for a group value that is already assigned to an existing group name, the SDP admin group creation is failed. The same happens if the user attempts to configure an SDP admin group with a new name but associates it to a group value already assigned to an existing group name.

The **no** option of this command deletes the SDP admin group but is only allowed if the group-name is not referenced in a PW template or SDP.

Parameters

group-name

Specifies the name of the SDP admin group. A maximum of 32 characters can be entered.

group-value

Specifies the group value associated with this SDP admin group. This value is unique within the system.

Values 0 to 31

no group-prefix any

Context

[Tree] (config>service>vprn>pim>rpf-select>grt-extranet group-prefix)

Full Context

configure service vprn pim rpf-select grt-extranet group-prefix

Description

This command configures multicast group IPv4 prefixes for the multicast GRT/VRF with per group mapping extranet functionality. Multiple lines are allowed. Duplicate prefixes are ignored. Operator can either configure specific groups for extranet or specify all groups by using key-word any. The two options are mutually exclusive in configuration.

When the starg option is specified, extranet functionality is enabled for PIM ASM as for the specified group. When the option is not specified (not recommended with PIM ASM), the PIM ASM join will be mapped and data plane will be established, but the control plane will not be updated on SPT switchover, unless the switchover is driven by a CPE router on a receiver side.

The **no** form of this command deletes specified prefix from the list, or removes mapping of all prefixes if group-prefix any was specified.

Parameters

ip-address/mask

Specifies the IPv4 multicast address prefix with mask.

group-prefix

Syntax

[**no**] **group-prefix grp-ipv6-address/prefix-length**

Context

[Tree] (config>service>vprn>pim>rp>ipv6>static group-prefix)

Full Context

configure service vprn pim rp ipv6 static group-prefix

Description

The group-prefix for a static-rp defines a range of multicast-ip-addresses for which this static RP is applicable.

The **no** form of this command removes the criterion.

Parameters

grp-ipv6-address

Specifies the multicast IPv6 address.

prefix-length

Specifies the address prefix length.

Values	grp-ipv6-address	: x:x:x:x:x:x:x:x (eight 16-bit pieces)
		x:x:x:x:x:x:d.d.d.d
		x [0 to FFFF]H
		d [0 to 255]D
	prefix-length	[8 to 128]

Platforms

group-prefix

Syntax

[**no**] **group-prefix** {*grp-ip-addressImask* | *grp-ip-address netmask*}

Context

[Tree] (config>service>vprn>pim>rp>static group-prefix)

Full Context

configure service vprn pim rp static group-prefix

Description

The **group-prefix** for a static-rp defines a range of multicast-ip-addresses for which a certain RP is applicable.

The **no** form of this command removes the criterion.

Parameters

grp-ip-address

Specifies the multicast IP address.

mask

Defines the mask of the multicast-ip-address.

Values 4 to 32

netmask

The subnet mask in dotted decimal notation.

Values 0.0.0.0 to 255.255.255.255 (network bits all 1 and host bits all 0)

Platforms

All

group-prefix

Syntax

[Tree] (config>router>pim>rp>static>address group-prefix)

Full Context

configure router pim rp ipv6 static address group-prefix

configure router pim rp static address group-prefix

Description

This command specifies the range of multicast group addresses which should be used by the router as the Rendezvous Point (RP). The **config**>**router**>**pim**>**rp**>**static**> **address** *a.b.c.d* implicitly defaults to deny all for all multicast groups (224.0.0.0/4). A group-prefix must be specified for that static address. This command does not apply to the whole group range.

The **no** form of this command removes the group-prefix from the configuration.

Parameters

grp-ipv6-address

Specifies the multicast group IPv6 address expressed in dotted decimal notation.

Values grp-ipv6-address x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x [0..FFFF]H

d [0..255]D

prefix-length

Specifies the prefix length of the IPv6 address.

Values 8 to 128

configure router pim ssm-groups group-range

Description

This command configures the address ranges of the multicast groups for this router. When there are parameters present, the command configures the SSM group ranges for IPv6 addresses and netmasks.

The **no** form of this command removes the parameter from the configuration.

Parameters

ip-prefix/mask

Specifies the IP prefix in dotted decimal notation for the range used by the ABR to advertise that summarizes the area into another area ipv6-prefix.

Values ipv4-prefix:

- a.b.c.d

ipv4-prefix-le: 0 to 32

ipv6-address:

- x:x:x:x:x:x:x:x (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d
- x: [0 to FFFF]H

- d: [0 to 255]D

ipv6-prefix-le: 0 to 128

Values 0 to 32 (mask length), 0.0.0.0 to 255.255.255.255 (dotted decimal)

netmask

Specifies the subnet mask in dotted decimal notation.

Values 0.0.0.0 to 255.255.255.255 (network bits all 1 and host bits all 0)

gtp-filter *filter-name*

Context

[Tree] (config>app-assure>group>statistics>tca gtp-filter)

Full Context

configure application-assurance group statistics threshold-crossing-alert gtp-filter

Description

This command configures TCA generation for a GTP filter.

Parameters

filter-name

Specifies the name of the GTP filter, up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

gtp-filter

Syntax

gtp-filter *gtp-filter-name* [**create**]

no gtp-filter *gtp-filter-name*

Context

[Tree] (config>app-assure>group>gtp gtp-filter)

Full Context

configure application-assurance group gtp gtp-filter

Description

This command allows AA to treat traffic on UDP port number 2152 as GTP-u. Without further specifying any other parameters within this GTP context, AA performs basic GTP-u header sanity checks and discards packets that are malformed. This GTP context allows the operator to configure various GTP filters (maximum of 128 GTP filters).

Parameters

gtp-filter-name

Specifies a GTP filter name, up to 32 characters.

create

Keyword used to create the GTP filter name and parameters.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

11.92 gtp-filter-stats

Full Context

configure service vprn wlan-gw dsm gtp-peer-clear-timeout

Description

This command configures a GTP peer cleanup timeout to terminate a handover wait state.

Parameters

seconds

Specifies a GTP peer cleanup timeout, in seconds, to terminate a handover wait state.

Values 0 to 3600

11.97 gtp-ping

gtp-ping

Syntax

gtp-ping *gtp-interface* [**router** *router-instance*] [**source** *ip-address*] **destination** *ip-address* **udp-port** *port-number* [**retry-count** *count*] [**time-out** *timeout*]

Context

[Tree] (oam gtp-ping)

Full Context

oam gtp-ping

Description

This command verifies whether a GTPv2 peer is reachable and correctly responds to GTPv2-C Echo Request messages. This command can be executed if no peering exists for the specified peer.

Parameters

gtp-interface

Specifies the GTP interface where the echo is sent.

Values s11, s1u, gnc, gnu, s2bc, s2bu, s2ac, s2au

router-instance

Specifies the router or VRF in which the GTP echo is sent.

Values *router-name* — Base, management

vprn-svc-id — 1 to 2147483647

Default Base

source ip-address

Specifies the source IP address to be used in the GTP ping.

Values a.b.c.d

destination ip-address

Specifies the destination IP address to be used in the GTP ping.

Values a.b.c.d

port-number

Specifies the port number to be used. Suggested port numbers are 2123 (GTP-C) or 2152 (GTP-U).

Values 1 to 65535

count

Specifies the number of echo message requests before the peer is considered unreachable.

Values 1 to 100

Default 1

timeout

Specifies the timeout, in seconds, of a single echo message.

Values 1 to 10

Default 5

Platforms

11.98 gtp-sanity-drop

gtp-sanity-drop

Syntax

gtp-sanity-drop direction *direction* [**create**]

no gtp-sanity-drop direction *direction*

Context

[Tree] (config>app-assure>group>statistics>tca gtp-sanity-drop)

Full Context

configure application-assurance group statistics threshold-crossing-alert gtp-sanity-drop

Description

This command configures a TCA for the counter capturing drops due to basic GTP header sanity checks, such as validating that the GTP-U version is 1 and that the protocol bit is set to 1 for UDP traffic destined to port 2152. A GTP sanity drop TCA can be created for traffic generated from the subscriber side of AA (**from-sub**) or for traffic generated from the network toward the AA subscriber (**to-sub**). The **create** keyword is mandatory when creating a default action TCA.

Parameters

direction

Specifies the traffic direction.

Values from-sub, to-sub

create

Keyword used to create the TCA.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

11.99 gtp-traffic

gtp-traffic

Syntax

[**no**] **gtp-traffic**

Context

[Tree] (config>app-assure>group>policer gtp-traffic)

Full Context

configure application-assurance group policer gtp-traffic

Description

This command provides a mechanism to configure a policer to function at the GTP tunnel level. GTP tunnels are defined by a TEID and destination IP address as oppose to normal flows that are defined by IP 5 tuple values. By setting this value, the policer then can be used to limit GTP traffic (SeGW GTP firewall application).

The **no** form of this command resets policer behavior to act at the normal 5 tuple flow level and not at the GTP tunnel level.

Default

no gtp-traffic

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

11.100 gtp-tunnel-database

gtp-tunnel-database

Syntax

gtp-tunnel-database

Context

[Tree] (config>app-assure>group>gtp>gtp-fltr gtp-tunnel-database)

Full Context

configure application-assurance group gtp gtp-filter gtp-tunnel-database

Description

Commands in this context configure GTP advanced firewall functions (such as validating GTP tunnels, sequence numbers, source IP addresses).

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

gtp-tunnel-database

Syntax

gtp-tunnel-database *size*

Context

[Tree] (config>isa>aa-grp>shr-res-pool gtp-tunnel-database)

Full Context

configure isa application-assurance-group shared-resources gtp-tunnel-database

Description

This command configures the allocation of memory resources required for stateful GTP firewall deployment on 3GPP S5/S8/Gn/Gp interfaces.

Default

gtp-tunnel-database 0

Parameters

size

Specifies the percentage of allocated memory resources.

Values 0 to 100

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

11.101 gtp-user

gtp-user

Syntax

gtp-user

Context

[Tree] (config>test-oam>build-packet>header gtp-user)

[Tree] (debug>oam>build-packet>packet>field-override>header gtp-user)

Full Context

configure test-oam build-packet header gtp-user

debug oam build-packet packet field-override header gtp-user

Description

This command causes the associated header to be defined as a GTP user header template and enables the context to define the GTP parameters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

11.102 gtp-user-name

gtp-user-name

Syntax

gtp-user-name {**imsi** | **imsi-apn** | **msisdn** | **msisdn-apn**}

no gtp-user-name

Context

[Tree] (config>subscr-mgmt>auth-plcy gtp-user-name)

Full Context

configure subscriber-mgmt authentication-policy gtp-user-name

Description

This command configures the username used to authenticate an FWA session. If a PAP message is present in the PCO IE of the Create Session request, the system uses that for authentication instead of the format specified for this command. If you specify a format that includes APN, the separator is an @ character; for example, msisdn@apn.

The **no** form of this command reverts to the default.

Default

gtp-user-name imsi

Parameters

imsi

Specifies to use IMSI as the username.

imsi-apn

Specifies to use IMSI and APN as the username; for example, imsi@apn.

msisdn

Specifies to use MSISDN as the username.

msisdn-apn

Specifies to use MSISDN and APN as the username; for example, msisdn@apn.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

11.103 gtpc-inspection

gtpc-inspection

Syntax

[**no**] **gtpc-inspection**

Context

[Tree] (config>app-assure>group>gtp gtpc-inspection)

Full Context

configure application-assurance group gtp gtpc-inspection

Description

This command configures the inspection of GTP-C packets. This is relevant only when AA GTP FW is deployed on S8/S5/Gp/Gn interfaces. The **gtpc-inspection** command must be enabled before configuring related features, such as APN filtering, GTP tunnel validation, message-type-v2 filtering, sequence number validation, SRC IP validation.

The **no** form of this command disables GTP-C packet inspection.

Default

no gtpc-inspection

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

11.104 gtpv1-c

gtpv1-c

Syntax

gtpv1-c *type* **direction** {**ingress** | **egress**} **script** [*script*]

no gtpv1-c *type* **direction** {**ingress** | **egress**}

Context

[Tree] (config>python>py-policy gtpv1-c)

Full Context

configure python python-policy gtpv1-c

Description

This command configures a Python script for the specified GTPv1-C message type in the specified direction.

The **no** form of this command reverts to the default.

Parameters

type

Specifies the message type.

Values echo-request, echo-response, version-not-supported, create-pdp-context-request, create-pdp-context-response, delete-pdp-context-request, delete-pdp-context-response, error-indication

direction {ingress | egress}

Specifies if the message is incoming or outgoing.

script

Specifies the name of the Python script, up to 32 characters, that is used to handle the specified message.

Platforms

All

11.105 gtpv2-c

gtpv2-c

Syntax

gtpv2-c *type* **direction** {**ingress** | **egress**} **script** [*script*]

no gtpv2-c *type* **direction** {**ingress** | **egress**}

Context

[Tree] (config>python>py-policy gtpv2-c)

Full Context

configure python python-policy gtpv2-c

Description

This command configures a Python script for the specified GTPv2-C message type in the specified direction.

The **no** form of this command reverts to the default.

Parameters

type

Specifies the message type

Values echo-request, echo-response, version-not-supported, create-session-request, create-session-response, delete-session-request, delete-session-response, delete-bearer-request, delete-bearer-response, modify-bearer-request, modify-bearer-response, release-access-bearers-request, release-access-bearers-response, downlink-data-notification, downlink-data-notification-ack, change-notification-request, change-notification-response, stop-paging-indication

direction {ingress | egress}

Specifies if the message is incoming or outgoing.

script

Specifies the name of the Python script, up to 32 characters, that is used to handle the specified message.

gw-address-range

Syntax

gw-address-range start *start* **end** *end*

no gw-address-range

Context

[Tree] (config>subscr-mgmt>isa-svc-chain>evpn>export gw-address-range)

Full Context

configure subscriber-mgmt isa-service-chaining evpn export gw-address-range

Description

This command specifies the address range to be used for the gateway IP address field in EVPN type-5 routes that are advertised for configured NAT pools, to the peer for service-chaining. The system allocates one address for each ISA in the NAT group out of the specified range.

The **no** form of this command removes the values from the configuration.

Parameters

start

Specifies the starting gateway address range (V4) for this EVPN service.

Values ipv4-address: a.b.c.d

end

Specifies the ending gateway address range (V4) for this EVPN service.

Values ipv4-address: a.b.c.d

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

11.109 gw-mac

gw-mac

Syntax

gw-mac *mac-address*

no gw-mac

Context

[Tree] (config>service>vprn>sub-if>grp-if>srrp gw-mac)

Full Context

configure service vprn subscriber-interface group-interface srrp gw-mac

Description

This command overrides the default SRRP gateway MAC address used by the SRRP instance. Unless specified, the system uses the same base MAC address for all SRRP instances with the last octet overridden by the lower 8 bits of the SRRP instance ID. The same SRRP gateway MAC address should be in-use by both the local and remote routers participating in the same SRRP context.

One reason to change the default SRRP gateway MAC address is if two SRRP instances sharing the same broadcast domain are using the same SRRP gateway MAC. The system will use the SRRP instance ID to separate the SRRP messages (by ignoring the messages that does not match the local instance ID), but a unique SRRP gateway MAC is essential to separate the routed packets for each gateway IP address.

The **no** form of this command removes the explicit SRRP gateway MAC address from the SRRP instance. The SRRP gateway MAC address can only be changed or removed when the SRRP instance is shutdown.

Parameters

mac-address

Specifies a MAC address that is used to override the default SRRP base MAC address.

Values Any MAC address except all zeros, broadcast or multicast addresses. The offset is expressed in normal Ethernet MAC address notation. The defined gw-mac cannot be 00:00:00:00:00:00, ff:ff:ff:ff:ff:ff or any multicast address.

If not specified, the system uses the default SRRP gateway MAC address with the last octet set to the 8 least significant bits of the SRRP instance ID.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

12 h Commands

12.1 half-life

half-life

Syntax

half-life *half-life* **max-suppress-time** *max-time*

Context

[Tree] (config>port>ethernet>dampening half-life)

Full Context

configure port ethernet dampening half-life

Description

This command configures the half-life decay time and the maximum period of time for which the port up state can be suppressed.

The *half-life* and *max-time* values must be set at the same time; the ratio of *max-time*/ *half-life* must be less than or equal to 49 and greater than or equal to 1.

Parameters

half-life

Specifies the required elapsed time, in seconds, before penalties decay to one-half the initial amount.

Values 1 to 2000

Default 5

max-time

Specifies the maximum suppression time, in seconds, which is the time it can take after the physical link comes up before the worst case accumulated penalties have decayed to the reuse threshold. The maximum penalty is derived from the maximum suppression time, half-life, and reuse threshold, using the following equation:

maximum penalty = (reuse threshold) X 2 expo:(max-time/half-life)

Values 1 to 43200

Default 20

Platforms

All

half-life

Syntax

half-life *minutes*

no half-life

Context

[Tree] (config>router>policy-options>damping half-life)

Full Context

configure router policy-options damping half-life

Description

This command configures the **half-life** parameter for the route damping profile.

The half-life value is the time, expressed in minutes, required for a route to remain stable in order for the Figure of Merit (FoM) value to be reduced by one half; for example, if the half-life value is 6 (minutes) and the route remains stable for 6 minutes, then the new FoM value is 3 (minutes). After another 3 minutes pass and the route remains stable, the new FoM value is 1.5 (minutes).

When the FoM value falls below the **config>router>policy-options>damping reuse** threshold, the route is once again considered valid and can be reused or included in route advertisements.

The **no** form of this command removes the half life parameter from the damping profile.

Default

no half-life

Parameters

minutes

Specifies the half-life in minutes expressed as a decimal integer.

Values 1 to 45

[Tree] (config>service>epipe>spoke-sdp hash-label)

Full Context

configure service ipipe spoke-sdp hash-label

configure service pw-template hash-label

configure service epipe spoke-sdp hash-label

Description

This command enables the use of the hash label on a VLL, VPRN or VPLS service bound to any MPLS type encapsulated SDP, as well as to a VPRN service that is using the **auto-bind-tunnel** with the **resolution-filter** set to any MPLS tunnel type. This feature is not supported on a service bound to a GRE SDP or for a VPRN service using the autobind mode with the gre option. This feature is also not supported on multicast packets forwarded using RSVP P2MP LSP or mLDP LSP in both the base router instance and

in the multicast VPN (mVPN) instance. It is, however, supported when forwarding multicast packets using an IES/VPRN spoke-interface.

When this feature is enabled, the ingress data path is modified such that the result of the hash on the packet header is communicated to the egress data path for use as the value of the label field of the hash label. The egress data path appends the hash label at the bottom of the stack (BoS) and sets the S-bit to one (1).

To allow applications where the egress LER infers the presence of the hash label implicitly from the value of the label, the Most Significant Bit (MSB) of the result of the hash is set before copying into the Hash Label. This means that the value of the hash label will always be in the range [524,288 - 1,048,575] and will not overlap with the signaled/static LSP and signaled/static service label ranges. This also guarantees that the hash label will not match a value in the reserved label range.

The (unmodified) result of the hash continues to be used for the purpose of ECMP and LAG spraying of packets locally on the ingress LER. Note, however, that for VLL services, the result of the hash is overwritten and the ECMP and LAG spraying will be based on service-id when ingress SAP shared queuing is not enabled. However, the hash label will still reflect the result of the hash such that an LSR can use it to perform fine grained load balancing of VLL pseudowire packets.

Packets generated in CPM and that are forwarded labeled within the context of a service (for example, OAM packets) must also include a Hash Label at the BoS and set the S-bit accordingly.

The TTL of the hash label is set to a value of 0.

The user enables the signaling of the hash-label capability under a VLL spoke-sdp, a VPLS spoke-sdp or mesh SDP, or an IES/VPRN spoke interface by adding the **signal-capability** option. In this case, the decision whether to insert the hash label on the user and control plane packets by the local PE is solely determined by the outcome of the signaling process and can override the local PE configuration. The following are the procedures:

- The local PE will insert the flow label interface parameters sub-TLV with F=1 in the PW ID FEC element in the label mapping message for that spoke SDP or mesh SDP.
- If the remote PE includes this sub-TLV with F=1 or F=0, then local PE must insert the hash label in the user and control plane packets.
- If remote PE does not include this sub-TLV (for example, it does not support it, or it is supported but the user did not enable the **hash-label** option or the **signal-capability** option), then the local PE establishes the PW but must not insert the hash label in the user and control packets over that spoke SDP or mesh SDP. If the remote PE does not support the **signal-capability** option, then there are a couple of possible outcomes:
  - If the **hash-label** option was enabled on the local configuration of the spoke SDP or mesh SDP at the remote PE, the PW packets received by the local PE will have the hash label included. These packets must be dropped. The only way to solve this is to disable the signaling capability option on the local node which will result in the insertion of the hash label by both PE nodes.
  - If the **hash-label** option is not supported or was not enabled on the local configuration of the spoke SDP or mesh SDP at the remote PE, the PW received by the local PE will not have the hash label included.
- The user can enable or disable the signal-capability option in CLI as needed. When doing so, the 7450 ESS or 7750 SR must withdraw the label it sent to its peer and send a new label mapping message with the new value of the F bit in the flow label interface parameters sub-TLV of the PW ID FEC element.

The **no** form of this command disables the use of the hash label.

Default

no hash-label

Parameters

signal-capability

Enables the signaling and negotiation of the use of the hash label between the local and remote PE nodes. The **signal-capability** option is not supported on a VPRN spoke-sdp.

Platforms

All

hash-label

Syntax

hash-label signal-capability

[Tree] (config>service>vpls>spoke-sdp hash-label)

Full Context

configure service vpls mesh-sdp hash-label

configure service vpls spoke-sdp hash-label

Description

This command enables the use of the hash label on a VLL, VPRN, or VPLS service bound to any MPLS type encapsulated SDP, as well as to a VPRN service using the **auto-bind-tunnel** with the **resolution-filter** set to any MPLS tunnel type. This feature is not supported on a service bound to a GRE SDP or for a VPRN service using the autobind mode with the gre option. This feature is also not supported on multicast packets forwarded using RSVP P2MP LSP or mLDP LSP in both the base router instance and in the multicast VPN (mVPN) instance. It is, however, supported when forwarding multicast packets using an IES/VPRN spoke-interface.

When this feature is enabled, the ingress data path is modified such that the result of the hash on the packet header is communicated to the egress data path for use as the value of the label field of the hash label. The egress data path appends the hash label at the bottom of the stack (BoS) and sets the S-bit to one (1).

To allow applications where the egress LER infers the presence of the hash label implicitly from the value of the label, the Most Significant Bit (MSB) of the result of the hash is set before copying into the Hash Label. This means that the value of the hash label will always be in the range [524,288 - 1,048,575] and will not overlap with the signaled/static LSP and signaled/static service label ranges. This also guarantees that the hash label will not match a value in the reserved label range.

The (unmodified) result of the hash continues to be used for the purpose of ECMP and LAG spraying of packets locally on the ingress LER. Note, however, that for VLL services, the result of the hash is overwritten and the ECMP and LAG spraying will be based on service-id when ingress SAP shared queuing is not enabled. However, the hash label will still reflect the result of the hash such that an LSR can use it to perform fine grained load balancing of VLL pseudowire packets.

Packets generated in CPM and that are forwarded labeled within the context of a service (for example, OAM packets) must also include a Hash Label at the BoS and set the S-bit accordingly.

The TTL of the hash label is set to a value of 0.

The user enables the signaling of the hash-label capability under a VLL spoke-sdp, a VPLS spoke-sdp or mesh-sdp, or an IES/VPRN spoke interface by adding the **signal-capability** option. In this case, the decision whether to insert the hash label on the user and control plane packets by the local PE is solely determined by the outcome of the signaling process and can override the local PE configuration. The following are the procedures:

- The 7450 ESS, 7750 SR, and 7950 XRS local PE will insert the flow label interface parameters sub-TLV with F=1 in the pseudowire ID FEC element in the label mapping message for that spoke-sdp or mesh-sdp.
- If the remote PE includes this sub-TLV with F=1 or F=0, then local PE must insert the hash label in the user and control plane packets.
- If remote PE does not include this sub-TLV (for example, it does not support it, or it is supported but the user did not enable the **hash-label** option or the **signal-capability** option), then the local PE establishes the pseudowire but must not insert the hash label in the user and control packets over that spoke-sdp or mesh-sdp. If the remote PE does not support the **signal-capability** option, then there are a couple of possible outcomes:
  - If the **hash-label** option was enabled on the local configuration of the spoke-sdp or mesh-sdp at the remote PE, the pseudowire packets received by the local PE will have the hash label included. These packets must be dropped. The only way to solve this is to disable the signaling capability option on the local node which will result in the insertion of the hash label by both PE nodes.
  - If the **hash-label** option is not supported or was not enabled on the local configuration of the spoke-sdp or mesh-sdp at the remote PE, the pseudowire received by the local PE will not have the hash label included.
- The user can enable or disable the signal-capability option in CLI as needed. When doing so, the 7450 ESS, 7750 SR, and 7950 XRS must withdraw the label it sent to its peer and send a new label mapping message with the new value of the F bit in the flow label interface parameters sub-TLV of the pseudowire ID FEC element.

The **no** form of this command disables the use of the hash label.

Default

no hash-label

Parameters

signal-capability

Enables the signaling and negotiation of the use of the hash label between the local and remote PE nodes. The **signal-capability** option is not supported on a VPRN spoke-sdp.

Platforms

All

hash-label

Syntax

hash-label [**signal-capability**]

no hash-label

Context

[Tree] (config>service>ies>if>spoke-sdp hash-label)

Full Context

configure service ies interface spoke-sdp hash-label

Description

This command enables the use of the hash label on a VLL, VPLS, or VPRN service bound to any MPLS-type encapsulated SDP, as well as to a VPRN service using **auto-bind-tunnel** with the **resolution-filter** configures as any MPLS tunnel type. This feature is not supported on a service bound to a GRE SDP or for a VPRN service using the autobind mode with the gre option.

When this feature is enabled, the ingress data path is modified such that the result of the hash on the packet header is communicated to the egress data path for use as the value of the label field of the hash label. The egress data path appends the hash label at the bottom of the stack (BoS) and sets the S-bit to 1 to indicate that.

In order to allow for applications whereby the egress LER infers the presence of the hash label implicitly from the value of the label, the Most Significant Bit (MSB) of the result of the hash is set before copying into the hash label. This means that the value of the hash label will always be in the range [524,288 to 1,048,575] and will not overlap with the signaled/static LSP and signaled/static service label ranges. This also guarantees that the hash label will not match a value in the reserved label range.

The (unmodified) result of the hash continues to be used for the purpose of ECMP and LAG spraying of packets locally on the ingress LER. For VLL services, the result of the hash is overwritten and the ECMP and LAG spraying will be based on service-id when ingress SAP shared queuing is not enabled. However, the hash label will still reflect the result of the hash such that an LSR can use it to perform fine grained load balancing of VLL pseudowire packets.

Packets that are generated in CPM and forwarded labeled within the context of a service (for example, OAM packets) must also include a hash label at the BoS and set the S-bit accordingly.

The TTL of the hash label is set to a value of 0.

The user enables the signaling of the hash-label capability under a VLL spoke-sdp, a VPLS spoke-sdp or mesh-sdp, or an IES/VPRN spoke interface by adding the **signal-capability** option. In this case, the decision whether to insert the hash label on the user and control plane packets by the local PE is solely determined by the outcome of the signaling process and can override the local PE configuration. The following are the procedures:

- The local PE will insert the flow label interface parameters sub-TLV with F=1 in the PW ID FEC element in the label mapping message for that spoke-sdp or mesh-sdp.

- If the remote PE includes this sub-TLV with F=1 or F=0, then local PE must insert the hash label in the user and control plane packets.
- If remote PE does not include this sub-TLV (for example, it does not support it, or it is supported but the user did not enable the **hash-label** option or the **signal-capability** option), then the local PE establishes the PW but must not insert the hash label in the user and control packets over that spoke-sdp or mesh-sdp. If the remote PE does not support the **signal-capability** option, then there are a couple of possible outcomes:
  - If the **hash-label** option was enabled on the local configuration of the spoke-sdp or mesh-sdp at the remote PE, the PW packets received by the local PE will have the hash label included. These packets must be dropped. The only way to solve this is to disable the signaling capability option on the local node which will result in the insertion of the hash label by both PE nodes.
  - If the **hash-label** option is not supported or was not enabled on the local configuration of the spoke-sdp or mesh-sdp at the remote PE, the PW received by the local PE will not have the hash label included.
- The user can enable or disable the signal-capability option in CLI as needed. When doing so, the router must withdraw the label it sent to its peer and send a new label mapping message with the new value of the F bit in the flow label interface parameters sub-TLV of the PW ID FEC element.

The **no** form of this command disables the use of the hash label.

Default

no hash-label

Parameters

configure service vprn interface spoke-sdp hash-label

configure service vprn spoke-sdp hash-label

configure service vprn hash-label

Description

This command enables the use of the hash label on a VLL, VPLS, or VPRN service bound to any MPLS-type encapsulated SDP as well as to a VPRN service using **auto-bind-tunnel** with the **resolution-filter** configured as any MPLS tunnel type. This feature is not supported on a service bound to a GRE SDP or for a VPRN service using the autobind mode with the gre option.

When this feature is enabled, the ingress data path is modified such that the result of the hash on the packet header is communicated to the egress data path for use as the value of the label field of the hash label. The egress data path appends the hash label at the bottom of the stack (BoS) and sets the S-bit to 1 to indicate that.

In order to allow for applications whereby the egress LER infers the presence of the Hash Label implicitly from the value of the label, the Most Significant Bit (MSB) of the result of the hash is set before copying into the Hash Label. This means that the value of the hash label will always be in the range [524,288 - 1,048,575] and will not overlap with the signaled/static LSP and signaled/static service label ranges. This also guarantees that the hash label will not match a value in the reserved label range.

The (unmodified) result of the hash continues to be used for the purpose of ECMP and LAG spraying of packets locally on the ingress LER. For VLL services, the result of the hash is overwritten and the ECMP and LAG spraying will be based on service-id when ingress SAP shared queuing is not enabled. However, the hash label will still reflect the result of the hash such that an LSR can use it to perform fine grained load balancing of VLL pseudowire packets.

Packets that are generated in CPM and forwarded labeled within the context of a service (for example, OAM packets) must also include a Hash Label at the BoS and set the S-bit accordingly.

The TTL of the hash label is set to a value of 0.

The **no** form of this command disables the use of the hash label.

Default

no hash-label

Parameters

signal-capability

Specifies whether the service should send the Stack Capability and check whether the capability is received from the peer via LDP interface parameters.

hash-weight-threshold

Syntax

hash-weight-threshold *weight* [**action** *action*] [**cost** *static-cost*]

no hash-weight-threshold

Context

[Tree] (config>lag hash-weight-threshold)

Full Context

configure lag hash-weight-threshold

Description

This command controls the operational status of the LAG or the IGP cost based on the sum of the **hash-weight** values for the active links in the LAG.

The **no** form of this command disables the hash weight threshold.

Parameters

weight

Specifies the value for the sum of all the active LAG ports **hash-weight** at or below which the configured action is invoked. If the sum of **hash-weight** for operational LAG links exceeds the **hash-weight-threshold** value, then no action is taken.

Values 1 to 6400000

action

Specifies the action to take if the sum of the **hash-weight** for active links in the LAG is equal or below the threshold value.

Values **down —** Specifies that the LAG is operationally DOWN. The LAG is only considered as UP once the number of **hash-weight** for the active links exceeds the configured threshold value.

dynamic-cost — Specifies that dynamic cost is activated. The LAG remains operationally UP with a link cost relative to the number of operational links. The link is only considered as operationally DOWN when all links in the LAG are down.

static-cost — Specifies that static cost is activated. The LAG remains operationally UP with the configured cost, regardless of the number of operational links. The link is only considered as operationally DOWN when all links in the LAG are down. If this parameter is used with an IGP, its **reference-bandwidth** must also be configured.

static-cost

Specifies the decimal integer static cost of the LAG.

Values 1 to 16777215

head-end

Syntax

head-end local

head-end *ipv4-address*

no head-end

Context

[Tree] (conf>router>segment-routing>sr-policies>policy head-end)

Full Context

configure router segment-routing sr-policies static-policy head-end

Description

This command associates a head-end location with a statically-defined segment-routing policy. The head-end identifies the router that is the target to install the policy. This is a mandatory parameter and configuration command for enabling the segment-routing policy; if the head-end parameter value is not configured, the execution of the **no shutdown** command on the static segment routing policy fails.

To associate a static policy with the local router as head-end, the keyword **local** must be specified. The static policy is associated with another (non-local) router, if the head-end parameter is set to any IPv4 address. When a non-local, static segment routing policy that originates as a BGP route is imported into BGP, the configured head-end address is converted to an IPv4-address specific route-target extended community that is automatically added to the route.

The **no** form of this command removes the head-end association.

Default

no head-end

Parameters

local

Keyword indicating that the policy is intended to be used by the local router and not advertised to other BGP routers.

ipv4-address

Specifies the IP address of the target head-end router.

Values ipv4-address: a.b.c.d

health-check

Syntax

[**no**] **health-check** [**interval** *interval*]

Context

[Tree] (config>system>security>password health-check)

Full Context

configure system security password health-check

Description

This command enables health check monitoring of the RADIUS, TACACS+, and LDAP servers by sending authentication requests for an unknown user at regular intervals. If a response is not received, the operational status of the server is changed to down. The operational status is changed to up when responses are received.

When RADIUS over TLS is configured, Status-Server packets are sent at 30-second intervals as specified in *RFC 3539*, regardless of whether health checks are enabled.

The **no** form of this command disables health monitoring of RADIUS, TACACS+, and LDAP servers. In this case, the operational status for the server is up if a response was received for the last user request.

Default

health-check interval 30

Parameters

interval

Specifies the polling interval for RADIUS, TACACS+, and LDAP servers.

Values 6 to 1500

Default 30

configure router ldp targeted-session peer hello

configure router ldp targeted-session peer-template hello

configure router ldp interface-parameters ipv6 hello

configure router ldp targeted-session ipv4 hello

configure router ldp interface-parameters interface ipv6 hello

Description

This command configures the time interval to wait before declaring a neighbor down. The **factor** parameter derives the Hello interval.

The **config**>**router**>**ldp**>**if-params**>**ipv6**>**hello** and **config**>**router**>**ldp**>**targ-session**>**ipv6**>**hello** commands are not supported on the 7450 ESS.

Hold time is local to the system and sent in the Hello messages to the neighbor. Hold time cannot be less than three times the Hello interval. The hold time can be configured globally (applies to all LDP interfaces) or per interface. The most specific value is used.

When LDP session is being set up, the hold down time is negotiated to the lower of the two peers. Once an operational value is agreed upon, the Hello factor is used to derive the value of the Hello interval.

The **no** form of the command at the interface-parameters and targeted-session level sets the **hello timeout** and the **hello factor** to the default values.

The **no** form of the command, at the interface level, sets the **hello timeout** and the **hello factor** to the value defined under the interface-parameters level.

The **no** form of this command, at the peer level, sets the **hello timeout** and the **hello factor** to the value defined under the targeted-session level.

The session must be flapped for the new settings to operate.

Default

Table 41: Hello Timeout Factors lists the default values.

Table 41: Hello Timeout Factors

Context	Timeout	Factor
config>router>ldp>if-params	15	3
config>router>ldp>targ-session	45	3
config>router>ldp>if-params>if	Inherits values from interface-parameters context.	
config>router>ldp>targ-session>peer	Inherits values from targeted-session context.	

Parameters

timeout

Configures the time interval, in seconds, that LDP waits before a neighbor down.

Values 1 to 65535

factor

Specifies the number of keepalive messages that should be sent on an idle LDP session in the Hello timeout interval.

Values 1 to 255

[Tree] (config>service>vprn>isis>if hello-authentication-key)

Full Context

configure service vprn isis interface level hello-authentication-key

configure service vprn isis interface hello-authentication-key

Description

This command configures the authentication key (password) for Hello PDUs. Neighboring routers use the password to verify the authenticity of Hello PDUs sent from this interface. Both the Hello authentication key and the Hello authentication type on a segment must match. The **hello-authentication-type** must be specified.

To configure the Hello authentication key in the interface context use the **hello-authentication-key** in the **config>router>isis>if** context.

To configure or override the Hello authentication key for a specific level, configure the **hello-authentication-key** in the **config>router>isis>if>level** context.

If both IS-IS and hello-authentication are configured, Hello messages are validated using Hello authentication. If only IS-IS authentication is configured, it will be used to authenticate all IS-IS (including Hello) protocol PDUs.

When the Hello authentication key is configured in the **config>router>isis>if** context, it applies to all levels configured for the interface.

The **no** form of this command removes the authentication-key from the configuration.

Default

no hello-authentication-key — No Hello authentication key is configured.

Parameters

authentication-key

The Hello authentication key (password). The key can be any combination of ASCII characters up to 254 characters in length (un-encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

hash-key

The hash key. The key can be any combination of ASCII characters up to 342 characters in length (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided.

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

custom

Specifies the custom encryption to management interface.

Platforms

[Tree] (config>router>isis>if>level hello-authentication-key)

Full Context

configure router isis interface hello-authentication-key

configure router isis interface level hello-authentication-key

Description

This command configures the authentication key (password) for Hello PDUs. Neighboring routers use the password to verify the authenticity of Hello PDUs sent from this interface. Both the Hello authentication key and the Hello authentication type on a segment must match. The **hello-authentication-type** must be specified.

To configure the Hello authentication key in the interface context, use the **hello-authentication-key** in the **config>router>isis>interface** context.

To configure or override the Hello authentication key for a specific level, configure the **hello-authentication-key** in the **config>router>isis>interface>level** context.

If both IS-IS and hello-authentication are configured, Hello messages are validated using Hello authentication. If only IS-IS authentication is configured, it will be used to authenticate all IS-IS (including Hello) protocol PDUs.

When the Hello authentication key is configured in the **config>router>isis>interface** context, it applies to all levels configured for the interface.

The **no** form of this command removes the authentication-key from the configuration.

Parameters

authentication-key

Specifies the Hello authentication key (password). The key can be any combination of ASCII characters, up to 254 characters (un-encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

hash-key

Specifies the hash key. The key can be any combination of ASCII characters, up to 342 characters (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided.

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

custom

Specifies the custom encryption to management interface.

[Tree] (config>service>vprn>isis>if hello-authentication-type)

Full Context

configure service vprn isis interface level hello-authentication-type

configure service vprn isis interface hello-authentication-type

Description

This command enables Hello authentication at either the interface or level context. Both the Hello authentication key and the Hello authentication type on a segment must match. The hello **authentication-key** statement must also be included.

To configure the Hello authentication type at the interface context, use **hello-authentication-type** in the **config>router>isis>if** context.

To configure or override the Hello authentication setting for a given level, configure the **hello-authentication-type** in the **config>router>isis>if>level** context.

The **no** form of this command disables Hello authentication.

Default

no hello-authentication-type — Hello authentication is disabled

Parameters

password

Specifies simple password (plain text) authentication is required.

message-digest

Specifies MD5 authentication in accordance with RFC2104 (HMAC: Keyed-Hashing for Message Authentication) is required.

configure router l2tp group tunnel hello-interval

configure service vprn l2tp hello-interval

configure router l2tp group hello-interval

Description

This command configures the time interval between two consecutive tunnel Hello messages. The Hello message is an L2TP control message sent by either peer of a LAC-LNS control connection. This control message is used as a keepalive for the tunnel.

The **no** form of this command removes the interval from the configuration.

Default

hello-interval 300

Parameters

hello-interval

Specifies the time interval, in seconds, between two consecutive tunnel Hello messages.

Default no hello-interval

Values 10 to 3600

infinite

Specifies that no Hello interval messages are sent.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

[Tree] (config>service>vprn>isis>if>level hello-interval)

Full Context

configure router isis interface level hello-interval

configure service vprn isis interface level hello-interval

Description

This command configures the interval between IS-IS Hello PDUs issued on the interface at this level. The **hello-interval**, along with the **hello-multiplier**, is used to calculate a hold time, which is communicated to a neighbor in a Hello PDU.

Note:
The neighbor hold time is (hello multiplier X hello interval) on non-designated intermediate system broadcast interfaces and point-to-point interfaces and is (hello multiplier X hello interval / 3) on designated intermediate system broadcast interfaces. Hello values can be adjusted for faster convergence, but the hold time should always be > 3 to reduce routing instability.

The **no** form of this command reverts to the default value.

Default

3 – for designated intermediate system interfaces

9 – for non-designated intermediate system interfaces and point-to-point interfaces

Parameters

seconds

The Hello interval in seconds expressed as a decimal integer.

Values 1 to 20000

Platforms

All

hello-interval

The **no** form of this command resets the configuration to the default value.

Default

hello-interval 30

Parameters

hello-interval

Specifies the Hello interval in seconds. A 0 (zero) value disables the sending of Hello messages (the PIM neighbor will never timeout the adjacency).

Values 0 to 255 seconds

Platforms

All

hello-interval

Syntax

hello-interval *milli-seconds*

no hello-interval

Context

[Tree] (config>router>rsvp>interface hello-interval)

Full Context

configure router rsvp interface hello-interval

Description

This command configures the time interval between RSVP Hello messages.

RSVP Hello packets are used to detect loss of RSVP connectivity with the neighboring node. Hello packets detect the loss of neighbor far quicker than it would take for the RSVP session to time out based on the refresh interval. After the loss of the of number keep-multiplier consecutive Hello packets, the neighbor is declared to be in a down state.

The **no** form of this command reverts to the default value of the hello-interval. To disable sending hello messages, set the value to zero.

Default

hello-interval 3000

Parameters

milli-seconds

Specifies the RSVP Hello interval (in ms), in multiples of 1000. A 0 (zero) value disables the sending of RSVP Hello messages.

Values 0 to 60000 ms (in multiples of 1000)

hello-multiplier *multiplier*

no hello-multiplier

Context

[Tree] (config>router>isis>if>level hello-multiplier)

Full Context

configure router isis interface level hello-multiplier

Description

This command configures a Hello multiplier. The **hello-multiplier**, along with the **hello-interval**, is used to calculate a hold time, which is communicated to a neighbor in a Hello PDU.

The hold time is the time in which the neighbor expects to receive the next Hello PDU. If the neighbor receives a Hello within this time, the hold time is reset. If the neighbor does not receive a Hello within the hold time, it brings the adjacency down.

Note:
The neighbor hold time is (hello multiplier X hello interval) on non-designated intermediate system broadcast interfaces and point-to-point interfaces and is (hello multiplier X hello interval / 3) on designated intermediate system broadcast interfaces. Hello values can be adjusted for faster convergence, but the hold time should always be > 3 to reduce routing instability.

The **no** form of this command reverts to the default value.

Default

hello-multiplier 3

Parameters

multiplier

Specifies the multiplier for the Hello interval expressed as a decimal integer.

Values 2 to 100

Platforms

All

12.23 hello-padding

hello-padding

Syntax

hello-padding {**none** | **adaptive** | **loose** | **strict**}

no hello-padding

Context

[Tree] (config>service>vprn>isis>level hello-padding)

[Tree] (config>service>vprn>isis>if hello-padding)

[Tree] (config>service>vprn>isis hello-padding)

[Tree] (config>service>vprn>isis>if>level hello-padding)

Full Context

configure service vprn isis level hello-padding

configure service vprn isis interface hello-padding

configure service vprn isis hello-padding

configure service vprn isis interface level hello-padding

Description

This command enables the IS-IS Hello (IIH) message padding to ensure that IS-IS LSPs can traverse the link. When this option is enabled, IS-IS Hello messages are padded to the maximum LSP MTU value, which can be set with the **lsp-mtu-size** command. If link MTU is greater than the maximum LSP MTU value, padding to the link MTU is applied.

The **no** form of this command disables IS-IS Hello message padding at this level. However, the router may still perform Hello padding if it was set at a higher level in the configuration. To ensure that Hello message padding is disabled, set all levels of configuration to **no hello-padding**.

Default

no hello-padding

Parameters

adaptive

Specifies the adaptive padding option; this option is able to detect MTU asymmetry from one side of the connection but uses more overhead than loose padding.

- point-to-point interface—Hello PDUs are padded until the sender declares an adjacency on the link to be in the state up. If the implementation supports RFC 3373/5303, *Three-Way Handshake for IS-IS Point-to-Point Adjacencies*, then this is when the three-way state is up. If the implementation uses the "classic" algorithm described in ISO 10589, this is when the adjacency state is up. If the neighbor does not support the adjacency state TLV, then padding continues.
- broadcast interface—Padding starts until at least one adjacency is up on the interface.

loose

Specifies the loose padding option; the loose padding may not be able to detect certain conditions such as asymmetrical MTUs between the routing devices.

- point-to-point interface—the Hello packet is padded from the initial detection of a new neighbor until the adjacency transitions to the INIT state
- broadcast interface—padding starts until at least one adjacency (broadcast only has up/down) is up on the interface

none

Specifies that the Hello message padding is not enabled at this level, even if it is configured at one of the parent levels.

strict

Specifies the strict padding option.

- point-to-point interface—padding is done for all adjacency states, and is continuous. Strict padding has the most overhead but detects MTU issues on both sides of a link
- broadcast interface—padding is done for all adjacency states, and is continuous. Strict padding has the most overhead but detects MTU issues on both sides of a link

Platforms

Full Context

configure router isis interface level hello-padding

configure router isis hello-padding

configure router isis interface hello-padding

configure router isis level hello-padding

Description

This command enables IS-IS Hello (IIH) message padding to ensure that IS-IS LSPs can traverse the link. When this option is enabled, IS-IS Hello messages are padded to the maximum LSP MTU value, which can be set with the **lsp-mtu-size** command. If link MTU is greater than the maximum LSP MTU value, padding to the link MTU is applied.

The **no** form of this command disables IS-IS Hello padding at this level. However, the router may still perform Hello padding if it was set at a higher level in the configuration. To ensure that Hello message padding is disabled, set all levels of configuration to **no hello-padding**.

Default

no hello-padding

Parameters

none

Specifies that the Hello message padding is not enabled at this level, even if it is configured at one of the parent levels.

adaptive

Specifies the adaptive padding option; this option is able to detect LSP MTU asymmetry from one side of the connection but uses more overhead than loose padding.

1. point-to-point interface—Hello PDUs are padded until the sender declares an adjacency on the link to be in state up. If the implementation supports RFC 3373/5303, "Three-Way Handshake for IS-IS Point-to- Point Adjacencies” then this is when the three-way state is Up. If the implementation use the "classic” algorithm described in ISO 10589, this is when adjacency state is Up. If the neighbor does not support the adjacency state TLV, then padding continues.
2. broadcast interface—Padding starts until at least one adjacency is up on the interface.

loose

Specifies the loose padding option; the loose padding may not be able to detect certain situations such as asymmetrical LSP MTUs between the routing devices.

1. point-to-point interface—The Hello packet is padded from the initial detection of a new neighbor until the adjacency transitions to the INIT state.
2. broadcast interface—Padding starts until there is at least one adjacency (broadcast only has up/down) is up on the interface.

strict

Specifies the strict padding option; this option is the most overhead-intensive but detects LSP MTU issues on both sides of a link.

1. point-to-point interface—Padding is done for all adjacency states, and is continuous.
2. broadcast interface—Padding is done for all adjacency states, and is continuous.

Full Context

configure router ldp targeted-session peer-template hello-reduction

configure router ldp targeted-session ipv6 hello-reduction

configure router ldp targeted-session ipv4 hello-reduction

configure router ldp targeted-session peer hello-reduction

Description

This command enables the suppression of periodic targeted Hello messages between LDP peers once the targeted LDP session is brought up.

The **config**>**router**>**ldp**>**targ-session**>**ipv6**>**hello-reduction** command is not supported on the 7450 ESS.

When this feature is enabled, the target Hello adjacency is brought up by advertising the Hold-Time value the user configured in the " **hello** timeout" parameter for the targeted session. The LSR node will then start advertising an exponentially increasing Hold-Time value in the Hello message as soon as the targeted LDP session to the peer is up. Each new incremented Hold-Time value is sent in a number of Hello messages equal to the value of the argument *factor*, which represents the dampening factor, before the next exponential value is advertised. This provides time for the two peers to settle on the new value. When the Hold-Time reaches the maximum value of 0xffff (binary 65535), the two peers will send Hello messages at a frequency of every [(65535-1)/local helloFactor] seconds for the lifetime of the targeted-LDP session (for example, if the local Hello Factor is three (3), then Hello messages will be sent every 21844 seconds.

The LSR node continues to compute the frequency of sending the Hello messages based on the minimum of its local Hold-time value and the one advertised by its peer as in RFC 5036. Thus for the targeted LDP session to suppress the periodic Hello messages, both peers must bring their advertised Hold-Time to the maximum value. If one of the LDP peers does not, the frequency of the Hello messages sent by both peers will continue to be governed by the smaller of the two Hold-Time values.

When the user enables the Hello reduction option on the LSR node while the targeted LDP session to the peer is operationally up, the change will take effect immediately. In other words, the LSR node will start advertising an exponentially increasing Hold-Time value in the Hello message, starting with the current configured Hold-Time value.

When the user disables the Hello reduction option while the targeted LDP session to the peer is operationally up, the change in the Hold-Time from 0xffff (binary 65535) to the user configured value for this peer will take effect immediately. The local LSR will immediately advertise the value of the user configured Hold-Time value and will not wait until the next scheduled time to send a Hello to make sure the peer adjusts its local hold timeout value immediately.

In general, any configuration change to the parameters of the T-LDP Hello adjacency (modifying the Hello adjacency Hello Timeout or factor, enabling/disabling Hello reduction, or modifying Hello reduction factor) will cause the LSR node to trigger immediately an updated Hello message with the updated Hold Time value without waiting for the next scheduled time to send a Hello.

The **no** form of this command disables the Hello reduction feature.

Default

no hello-reduction

Parameters

factor

Specifies the integer that specifies the Hello reduction dampening factor.

Values 3 to20

hello-time

Syntax

hello-time *hello-time*

no hello-time [*hello-time*]

Context

[Tree] (config>service>vpls>stp hello-time)

[Tree] (config>service>template>vpls-template>stp hello-time)

Full Context

configure service vpls stp hello-time

configure service template vpls-template stp hello-time

Description

This command configures the Spanning Tree Protocol (STP) Hello time for the Virtual Private LAN Service (VPLS) STP instance.

The Hello time parameter defines the default timer value that controls the sending interval between BPDU configuration messages by this bridge, on ports where this bridge assumes the designated role.

The active Hello time for the spanning tree is determined by the root bridge (except when the STP is running in RSTP mode, then the Hello time is always taken from the locally configured parameter).

The configured **hello-time** can also be used to calculate the forward delay. See **auto-edge** (**config>service>vpls>sap>stp auto-edge, config>service>template>vpls-sap-template>stp auto-edge, config>service>vpls>spoke-sdp>stp auto-edge**).

The **no** form of this command returns the Hello time to the default value.

Default

hello-time 2

Parameters

hello-time

The Hello time for the STP instance in seconds.

Values 1 to 10

Platforms

All

hello-time

Syntax

[**no**] **hello-time** *seconds*

Context

[Tree] (config>service>sdp>keep-alive hello-time)

Full Context

configure service sdp keep-alive hello-time

Description

This command configures the time period between SDP keepalive messages on the SDP-ID for the SDP connectivity monitoring messages.

The **no** form of this command reverts the **hello-time** *seconds* value to the default setting.

Default

hello-time 10

Parameters

seconds

Specifies the time period in seconds between SDP keepalive messages, expressed as a decimal integer.

help

Description

This command provides a brief description of the help system. The following information is shown:

```
Help may be requested at any point by hitting a question mark '?'.
In case of an executable node, the syntax for that node will be displayed with an
explanation of all parameters.
In case of sub-commands, a brief description is provided.
Global Commands:
Help on global commands can be observed by issuing "help globals" at any time.
Editing Commands:
Help on editing commands can be observed by issuing "help edit" at any time.
```

Parameters

help

Displays a brief description of the help system.

edit

Displays help on editing.

Available editing keystrokes:

```
Delete current character.....................Ctrl-d
Delete text up to cursor.....................Ctrl-u
Delete text after cursor.....................Ctrl-k
Move to beginning of line....................Ctrl-a
Move to end of line..........................Ctrl-e
Get prior command from history...............Ctrl-p
Get next command from history................Ctrl-n
Move cursor left.............................Ctrl-b
Move cursor right............................Ctrl-f
Move back one word...........................Esc-b
Move forward one word........................Esc-f
Convert rest of word to uppercase............Esc-c
Convert rest of word to lowercase............Esc-l
Delete remainder of word.....................Esc-d
Delete word up to cursor.....................Ctrl-w
Transpose current and previous character.....Ctrl-t
Enter command and return to root prompt......Ctrl-z
Refresh input line...........................Ctrl-l
```

global

Displays help on global commands.

Available global commands:

```
back            - Go back a level in the command tree
echo            - Echo the text that is typed in
exec            - Execute a file - use -echo to show the commands and
                  prompts on the screen
exit            - Exit to intermediate mode - use option all to exit to
                  root prompt
help            - Display help
history         - Show command history
info            - Display configuration for the present node
logout          - Log off this system
oam             + OAM Test Suite
ping            - Verify the reachability of a remote host
pwc             - Show the present working context
sleep           - Sleep for specified number of seconds
ssh             - SSH to a host
telnet          - Telnet to a host
traceroute      - Determine the route to a destination address
tree            - Display command tree structure from the context of
                  execution
write           - Write text to another user
```

special-characters

Displays help on special characters.

Use the following CLI commands to display more information about commands and command syntax:

?

Lists all commands in the current context.

string?

Lists all commands available in the current context that start with the string.

command ?

Displays command's syntax and associated keywords.

string<Tab> or string<Space>

Completes a partial command name (auto-completion) or lists available commands that match the string.

12.27 helper-disable

helper-disable

Syntax

[**no**] **helper-disable**

Context

[Tree] (config>service>vprn>isis>graceful-restart helper-disable)

Full Context

configure service vprn isis graceful-restart helper-disable

Description

This command disables helper support for IS-IS graceful restart (GR).

When **graceful-restart** is enabled, the router can be a helper (that is, the router is helping a neighbor to restart), a restarting router, or both. The router only supports the helper mode. It will not act as a restarting router, because the high availability feature set already preserves IS-IS forwarding information such that this functionality is not needed.

Note:
This command is a historical command and should not be disabled. Configuring **helper-disable** has the effect of disabling graceful restart, because the router only supports helper mode.

The **no helper-disable** command enables helper support and is the default when graceful restart is enabled.

Default

no helper-disable

configure service vprn bgp group neighbor graceful-restart long-lived helper-override-restart-time

configure service vprn bgp group graceful-restart long-lived helper-override-restart-time

Description

This command overrides the restart-time advertised by a peer (in its GR capability) with a locally-configured value. This override applies only to AFI/SAFI that were included in the GR capability of the peer. The restart-time is always zero for AFI/SAFI not included in the GR capability. This command is useful if the local router wants to force LLGR phase to begin after a set time for all protected AFI/SAFI.

By default, the restart time for all AFI/SAFI in the GR capability is the value signaled by the peer.

Default

no helper-override-restart-time

Parameters

seconds

The locally-imposed restart time for all AFI/SAFI included in the peer's GR capability.

Values 0 to 4095

12.30 hi-bw-mcast-src

hi-bw-mcast-src

Syntax

hi-bw-mcast-src [**alarm**] [**group** *group-id*] [**default-paths-only**]

no hi-bw-mcast-src

Context

[Tree] (config>card>fp hi-bw-mcast-src)

Full Context

configure card fp hi-bw-mcast-src

Description

This command designates the forwarding plane as a high-bandwidth IP multicast source, expecting the ingress traffic to include high-bandwidth IP multicast traffic. When configured, the system attempts to allocate a dedicated multicast switch fabric plane (MSFP) to the forwarding plane. If a group is specified, all FPs in the group will share the same MSFP. If the alarm parameter is specified and the system cannot allocate a dedicated MSFP to the new group or FP, the FPs will be brought online and generate an event (SYSTEM: 2052 - tmnxChassisHiBwMulticastAlarm). Similarly, if during normal operation there is a failure or removal of resources, an event will be generated if the system cannot maintain separation of MSFPs for the MDAs.

The **no** form of this command removes the high-bandwidth IP multicast source designation from the forwarding plane.

Default

no hi-bw-mcast-src

Parameters

alarm

Enables event generation if the MDA is required to share an MSFP with another MDA that is in a different group. MDAs within the same group sharing an MSFP will not cause this alarm.

group-id

Specifies the logical MSFP group for the MDA. MDAs configured with the same *group-id* will be placed on the same MSFP.

Values 0 to 32 (A value of 0 removes the MDA from the group).

Default By default, "none" is used, and the system will attempt to assign a unique MSFP to the MDA.

default-paths-only

When this parameter is specified the system will only attempt to allocate the two default paths (one high priority and one low priority) to dedicated MSFPs.

Full Context

configure subscriber-mgmt sla-profile egress qos queue high-prio-only

configure subscriber-mgmt sla-profile ingress qos queue high-prio-only

Description

This command configures the value of the percentage of buffer space for the queue, used exclusively by high priority packets. The specified value overrides the default value for the context.

The priority of a packet can only be set in the SAP ingress QoS policy and is only applicable on the ingress queues for a SAP. The **high-prio-only** parameter is used to override the default value derived from the **network-queue** command.

The defined **high-prio-only** value cannot be greater than the MBS size of the queue. Attempting to change the MBS to a value smaller than the high priority reserve will generate an error and fail execution. Attempting to set the **high-prio-only** value larger than the current MBS size will also result in an error and fail execution.

The **no** form of this command returns high-prio-only to the size as configured in the QoS policy.

Parameters

percent

The *percent* parameter is the percentage reserved for high priority traffic on the queue. If a value of 10KBytes is desired, enter the value 10. A value of 0 specifies that none of the MBS of the queue is reserved for high priority traffic. This does not affect RED slope operation for packets attempting to be queued.

Values 0 to 100, default

Context

[Tree] (config>qos>adv-config-policy>child-control>offered-measurement high-rate-hold-time)

Full Context

configure qos adv-config-policy child-control offered-measurement high-rate-hold-time

Description

This command sets a time period that the current offered rate should be maintained for a child policer or queue when it is seen that the offered rate is decreasing. The offered measurement that triggers the hold time is used when the hold timer expires, unless a higher offered rate is seen in the interim. When a higher rate is observed, the hold timer is canceled and the higher offered rate is used immediately.

A possible reason to define a hold timer for an offered rate is to allow a child queue is to dampen the effects of a child with a fluctuating rate on the virtual scheduler. This works similar to the max-decrement in that the child holds on to bandwidth from the virtual scheduler in case it may be needed in the near future.

This parameter has no effect on an increase to the child's offered rate. If the rate increase is above the change sensitivity, the new offered rate is immediately used.

When this command is not specified or removed, the virtual scheduler immediately reacts to measured decreases in offered load.

The **no** form of this command is used to remove any currently configured hold time for all child policers and queues associated with the policy. When the hold time is removed, any current hold timers for child policers are automatically canceled.

Parameters

seconds

The hold time configured must be specified in seconds. A value of 0 is equivalent to no high-rate-hold-time.

Default 0

Values 0 to 60

active-min-only

When this optional parameter is specified, the **high-rate-hold-time** command will accept the optional **active-min-only** parameter. Attempting to remove the active-min-only parameter from the **add** command, or removing the **add** command itself, will fail while **active-min-only** is enabled on the **high-rate-hold-time** command. When specified, the respective rate or percentage is treated as the minimum offered rate for a queue, only when the queue has an actual non-zero offered rate. This is intended to limit the artificial increase in offered rate to queues that are currently active. When a queue's measured offered rate drops to zero, the system stops enforcing the minimum value.

Platforms

All

12.39 high-slope

high-slope

Syntax

[**no**] **high-slope**

Context

[Tree] (config>qos>slope-policy high-slope)

Full Context

configure qos slope-policy high-slope

Description

The **high-slope** context contains the commands and parameters for defining the high Random Early Detection (RED) slope graph. Each buffer pool supports a high RED slope for managing access to the shared portion of the buffer pool for in-profile packets.

The **high-slope** parameters can be changed at any time and the affected buffer pool high RED slopes will be adjusted appropriately.

The **no** form of this command restores the high slope configuration commands to the default values. If the commands within **high-slope** are set to the default parameters, the **high-slope** node will not appear in save config and show config output unless the detail parameter is present.

Full Context

configure oam-pm session ip twamp-light loss-events hli-event

configure oam-pm session ethernet lmm loss-events hli-event

configure oam-pm session ethernet slm loss-events hli-event

Description

This command sets the high loss interval (HLI) threshold to be monitored and the associated thresholds using the counter of the specified direction. The aggregate is a function of summing forward and backward. This value is only used as a threshold mechanism and is not part of the stored statistics. If the optional **clear** *clear-threshold* parameter is not specified, the traffic crossing alarm is stateless. Stateless means the state is not carried forward to other measurement intervals. Each measurement interval is analyzed independently and regardless of any previous window. Each unique event can only be raised once within measurement interval. If the optional **clear** *clear-threshold* parameter is specified, the traffic crossing alarm uses stateful behavior. Stateful means each unique previous event state is carried forward to following measurement intervals. If a threshold crossing event is raised another is raised until a measurement interval completes and the clear threshold has not been exceeded. A clear event is raised under that condition.

The **no** form of this command removes the event threshold for frame loss ratio. The direction must be included with the **no** command.

Default

no hli-event forward

no hli-event backward

no hli-event aggregate

Parameters

forward

Specifies the threshold is applied to the forward direction count.

backward

Specifies the threshold is applied to the backward direction count.

aggregate

Specifies the threshold is applied to the aggregate count (sum of forward and backward).

raise-threshold

Specifies the rising threshold that determines when the event is to be generated, when the percentage of loss value is reached.

Values 1 to 864000

clear-threshold

Specifies an optional value used for stateful behavior that allows the operator to configure a percentage of loss value lower than the rising percentage to indicate when the clear event should be generated.

Values 0 to 863999

A value of zero means that the HLI counter must be 0.

configure vrrp policy priority-event host-unreachable hold-clear

configure vrrp policy priority-event port-down hold-clear

configure vrrp policy priority-event lag-port-down hold-clear

Description

This command configures the hold clear time for the event. The *seconds* parameter specifies the hold-clear time, the amount of time in seconds by which the effect of a cleared event on the associated virtual router instance is delayed.

The hold-clear time is used to prevent black hole conditions when a virtual router instance advertises itself as a master before other conditions associated with the cleared event have had a chance to enter a forwarding state.

Default

no hold-clear

Parameters

seconds

Specifies the amount of time in seconds by which the effect of a cleared event on the associated virtual router instance is delayed.

Values 0 to 86400

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

hold-down-time

Syntax

hold-down-time *seconds*

no hold-down-time

Context

[Tree] (config>service>sdp>keep-alive hold-down-time)

Full Context

configure service sdp keep-alive hold-down-time

Description

This command configures the minimum time period the SDP will remain in the operationally down state in response to SDP keepalive monitoring.

This parameter can be used to prevent the SDP operational state from "flapping" by rapidly transitioning between the operationally up and operationally down states based on keepalive messages.

When an SDP keepalive response is received that indicates an error condition or the **max-drop-count** keepalive messages receive no reply, the *sdp-id* will immediately be brought operationally down. If a keepalive response is received that indicates the error has cleared, the *sdp-id* will be eligible to be put into the operationally up state only after the **hold-down-time** interval has expired.

The **no** form of this command reverts the **hold-down-time seconds** *value* to the default setting.

Default

hold-down-time 10

Parameters

seconds

Specifies time, in seconds, expressed as a decimal integer. The SDP ID will remain in the operationally down state before it is eligible to enter the operationally up state. A value of 0 indicates that no **hold-down-time** will be enforced for SDP ID.

Values 0 to 3600

Platforms

All

12.50 hold-down-timer

hold-down-timer

Syntax

hold-down-timer *hold-down-timer*

no hold-down-timer

Context

[Tree] (config>router>segment-routing>maintenance-policy hold-down-timer)

Full Context

configure router segment-routing maintenance-policy hold-down-timer

Description

This command configures the hold down timer for SR policy candidate paths.

This command is intended to prevent bouncing of the SR policy path state if one or more S-BFD sessions associated with segment lists flap and therefore cause the threshold to be repeatedly crossed in a short period of time. It is started when the number of up S-BFD sessions drops below the threshold. The SR policy path is not considered to be up again until the hold down timer has expired and the number of up S-BFD sessions equals or exceeds the threshold and the internal hold timer is not running.

Note:
If the revert timer is also configured, the revert timer is not started until after the number of S-BFD sessions that are up ≥ threshold and the hold down timer for the primary candidate path has expired.

The **no** form of this command reverts to the default.

Default

hold-down-timer 0

Parameters

hold-down-timer

Specifies the hold-down timer, in deciseconds, in 10ms steps.

Values 0 to 5000

configure vrrp policy priority-event host-unreachable hold-set

configure vrrp policy priority-event mc-ipsec-non-forwarding hold-set

configure vrrp policy priority-event port-down hold-set

Description

This command specifies the amount of time that must pass before the set state for a VRRP priority control event can transition to the cleared state to dampen flapping events. A flapping event continually transitions between clear and set.

The **hold-set** command is used to dampen the effect of a flapping event. The **hold-set** value is loaded into a hold-set timer that prevents a set event from transitioning to the cleared state until it expires.

Each time an event transitions between cleared and set, the timer is loaded and begins a countdown to zero. When the timer reaches zero, the event is allowed to enter the cleared state. Entering the cleared state is dependent on the object controlling the event, conforming to the requirements defined in the event itself. It is possible, on some event types, to have another set action reload the hold-set timer. This extends the amount of time that must expire before entering the cleared state.

Once the hold-set timer expires and the event meets the cleared state requirements or is set to a lower threshold, the current set effect on the virtual router instances in-use priority can be removed. As with **lag-port-down** events, this may be a decrease in the set effect if the *clearing* amounts to a lower set threshold.

The **hold-set** command can be executed at any time. If the hold-set timer value is configured larger than the new *seconds* setting, the timer is loaded with the new **hold-set** value.

The **no** form of the command disables the hold timer so that event transitions are processed immediately.

Default

no hold-set

Parameters

seconds

The number of seconds that the hold-set timer waits after an event enters a set state or enters a higher threshold set state, depending on the event type.

The value of 0 disables the hold-set timer, preventing any delay in processing lower set thresholds or cleared events.

Values 0 to 86400

Platforms

All

12.54 hold-time

hold-time

Syntax

hold-time *seconds*

no hold-time

Context

[Tree] (config>subscr-mgmt>bgp-prng-plcy hold-time)

Full Context

configure subscriber-mgmt bgp-peering-policy hold-time

Description

This command configures the BGP hold time, expressed in seconds.

The BGP hold time specifies the maximum time BGP waits between successive messages (either keepalive or update) from its peer, before closing the connection.

Even though the router OS implementation allows setting the keepalive time separately, the configured keepalive timer is overridden by the hold-time value under the following circumstances:

If the specified hold-time is less than the configured keepalive time, then the operational keepalive time is set to a third of the hold-time; the configured keepalive time is not changed.

If the hold-time is set to zero, then the operational value of the keepalive time is set to zero; the configured keepalive time is not changed. This means that the connection with the peer is up permanently and no keepalive packets are sent to the peer.

The **no** form of this command reverts to the default.

Parameters

seconds

Specifies the hold-time, in seconds, expressed as a decimal integer. A value of 0 indicates the connection to the peer is up permanently.

Values 0, 3 to 65535

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

hold-time

Syntax

no hold-time

Context

[Tree] (config>subscr-mgmt>vrgw>brg>brg-profile hold-time)

Full Context

configure subscriber-mgmt vrgw brg brg-profile hold-time

Description

This command holds the BRG object for the specified time. This applies when the connectivity verification fails or when the last host is removed and **no connectivity-verification** is enabled. Hold time does not apply to an explicit removal via the **radius** or **clear** commands.

The **no** form of this command disables the hold time.

Parameters

seconds

Specifies the time, in seconds, to hold on to a BRG after the system considered it down.

Values 30 to 2592000

days

Specifies the hold-time in days.

Values 1 to 30

hrs

Specifies the hold-time in hours.

Values 1 to 23

min

Specifies the hold-time in minutes.

Values 1 to 59

hold-time *seconds*

no hold-time

Context

[Tree] (config>subscr-mgmt>sap-template hold-time)

Full Context

configure subscriber-mgmt sap-template hold-time

Description

This command configures the time for which an SAP is retained after the last session has been removed. Such SAPs can be forcefully removed using the **idle-saps** option in the **clear**>**subscriber-mgmt**>**sap-template** context.

The **no** form of this command reverts to the default.

Default

hold-time 30

Parameters

infinite

Keyword specifying to never automatically remove the SAP.

seconds

Specifies the time, in seconds, that the SAP is retained.

Values 30 to 2592000

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

hold-time

Syntax

hold-time *hold-time*

no hold-time

Context

[Tree] (config>port>aps hold-time)

Full Context

configure port aps hold-time

Description

This command specifies how much time can pass, in 100s of milliseconds, without receiving an advertise packet from the neighbor before the multi-chassis signaling link is considered not operational.

The **hold-time** is usually 3 times the value of the **advertise-interval**. The value of the **advertise-interval** is valid only for a multi-chassis APS as indicated by the value of neighbor IP address if it is not set to 0.0.0.0.

Parameters

hold-time

Specifies how long to wait for an APS advertisement packet before the peer in a Multi-Chassis APS group is considered operationally down.

Values 10 to 650

Platforms

7450 ESS, 7750 SR-7/12/12e, 7750 SR-a, 7750 SR-e

hold-time

Syntax

hold-time *time-value*

no hold-time

Context

[Tree] (config>port>ethernet>efm-oam hold-time)

Full Context

configure port ethernet efm-oam hold-time

Description

This command configures efm-oam operational transition dampening timers which reduce the number of efm-oam state transitions reported to upper layers.

Default

no hold-time

Parameters

time-value

Indicates the number of seconds that the efm-oam protocol will wait before going back to the operational state after leaving the operational state. Note that the hold-time does not apply if efm-oam moved from operational to link-fault.

A hold-time value of zero indicates that there should be no delay in transitioning to the operational state. A non-zero value will cause the efm-oam protocol to attempt to negotiate with a peer if possible, but it will remain in the send-local-remote-ok state until the hold time has expired if negotiation is successful.

If efm-oam is administratively shutdown while it was in the operational state and then re-enabled when a non-zero hold time is configured, efm-oam will attempt transition to the operational state immediately.

The **no** form of this command reverts the value to the default.

Values 0 to 50

Default 0

Platforms

All

hold-time

Syntax

hold-time {[**up** *hold-time- up*] [**down** *hold-time-down*] [**seconds** | **centiseconds**]}

no hold-time

Context

[Tree] (config>port>ethernet hold-time)

Full Context

configure port ethernet hold-time

Description

This command configures port link dampening timers which reduce the number of link transitions reported to upper layer protocols. The **hold-time** value dampens interface transitions.

When an interface transitions from an up state to a down state, it is immediately advertised to the rest of the system if the hold-time down interval is zero, but if the hold-time down interval is greater than zero, interface down transitions are not advertised to upper layers until the hold-time down interval has expired. Likewise, an interface is immediately advertised as up to the rest of the system if the hold-time up interval is zero, but if the hold-time up interval is greater than zero, up transitions are not advertised until the hold-time up interval has expired.

For ESM SRRP setup, MCS synchronizes subscriber information between the two chassis. After a chassis recovers from a power reset/down, MCS immediately synchronizes all subscriber information at once. The longer the host list, the longer it will take to synchronize the chassis. In a fully populated chassis, it is recommended to allow at least 45 minutes for MCS synchronization. It is also recommended to hold the port down, facing the subscriber, on the recovering chassis for 45 minutes before it is allowed to forward traffic again.

The **no** form of this command reverts to the default values.

Default

down 0 seconds — No port link down dampening is enabled; link down transitions are immediately reported to upper layer protocols.

up 0 seconds — No port link up dampening is enabled; link up transitions are immediately reported to upper layer protocols.

Parameters

hold-time-up

The delay, in seconds or centiseconds, after which to notify the upper layers when an interface transitions from a down state to an up state.

Values 0 to 36000 seconds, 0 or 10 to 3600000 centiseconds in 5 centisecond increments

The minimum non-zero *hold-time-up* interval on 10G or higher ports is 10 centiseconds with a granularity of 5 centiseconds. The granularity on 1G ports is 1 second. Centiseconds are not supported on 1G ports.

hold-time-down

The delay, in seconds or centiseconds, after which to notify the upper layers when an interface transitions from an up state to a down state.

Values 0 to 36000 seconds, 0 or 10 to 3600000 centiseconds in 5 centisecond increments

The minimum non-zero *hold-time-down* interval on 10G or higher ports is 10 centiseconds with a granularity of 5 centiseconds. The granularity on 1G ports is 1 second. Centiseconds are not supported on 1G ports.

seconds | centiseconds

Specifies the hold time units as **seconds** or **centiseconds**.

Platforms

no hold-time

Context

[Tree] (config>port>sonet-sdh hold-time)

Full Context

configure port sonet-sdh hold-time

Description

This command configures SONET link dampening timers in 100s of milliseconds. This guards against reporting excessive interface transitions. This is implemented by not advertising subsequent transitions of the interface to upper layer protocols until the configured timer has expired.

Note:
For APS configurations, the **hold-time down** and **up** default values are 100 ms and 500 ms respectively. If there is a large communication delay (time to exchange K1/K2 bytes) between the APS Controllers of the two endpoints of an APS link, it is highly suggested to increase the default hold-time down timer on the APS group port accordingly with the communication delay. See the **config>port aps** command for more information.

This command is supported by TDM satellite.

Default

no hold-time

Parameters

up *hold-time-up*

Configures the hold-timer for link up event dampening. A value of zero (0) indicates that an up transition is reported immediately.

Values 0 to 100

down *hold-time-down*

The hold-timer for link down event dampening. A value of zero (0) indicates that a down transition is reported immediately.

Values 0 to 100

hold-time down *hold-down-time*

no hold-time

Context

[Tree] (config>lag hold-time)

Full Context

configure lag hold-time

Description

This command specifies the timer, in tenths of seconds, which controls the delay between detecting that a LAG is down (all active ports are down) and reporting it to the higher levels.

A non-zero value can be configured, for example, when active/standby signaling is used in a 1:1 fashion to avoid informing higher levels during the small time interval between detecting that the LAG is down and the time needed to activate the standby link.

Default

no hold-time

Parameters

hold-down-time

Specifies the hold-time for event reporting.

Values 0 to 2000

Platforms

All

hold-time

Syntax

hold-time *value*

no hold-time

Context

[Tree] (config>service>vpls>mrp>mvrp hold-time)

Full Context

configure service vpls mrp mvrp hold-time

Description

This command enables the dampening timer and applies to both types of provisioned SAPs – end-station and UNI. When a value is configured for the timer, it controls the delay between detecting that the last provisioned SAP in VPLS goes down and reporting it to the MVRP module. The CPM will wait for the time specified in the value parameter before reporting it to the MVRP module. If the SAP comes up before the hold-timer expires, the event will not be reported to MVRP module.

The non-zero hold-time does not apply for SAP transition from down to up, This kind of transition is reported immediately to MVRP module without waiting for hold-time expiration. Also this parameter applies only to the provisioned SAPs. It does not apply to the SAPs configured with the **vpls-sap-template** command. Also when end-station QinQ SAPs are present only the "no hold-time" configuration is allowed.

The **no** form of this command disables tracking of the operational status for the last active SAP in the VPLS. MVRP will stop declaring the VLAN only when the last provisioned customer (UNI) SAP associated locally with the service is deleted. Also MVRP will declare the associated VLAN attribute as soon as the first provisioned SAP is created in the associated VPLS instance, regardless of the operational state of the SAP.

Default

no hold-time

configure service vprn bgp group neighbor hold-time

configure service vprn bgp hold-time

configure service vprn bgp group hold-time

Description

This command configures the BGP hold time, expressed in seconds.

The BGP hold time specifies the maximum time BGP waits between successive messages (either keepalive or update) from its peer, before closing the connection. This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in group) or neighbor level (only applies to specified peer). The most specific value is used.

Even though the router OS implementation allows setting the **keepalive** (**config>service>vprn>bgp keepalive**, **config>service>vprn>bgp>group keepalive**, **config>service>vprn>bgp>group>neighbor keepalive**) time separately, the configured **keepalive** timer is overridden by the **hold-time** value under the following circumstances:

- If the specified hold-time is less than the configured **keepalive** time, then the operational **keepalive** time is set to a third of the **hold-time**; the configured **keepalive** time is not changed.
- If the **hold-time** is set to zero, then the operational value of the **keepalive** time is set to zero; the configured **keepalive** time is not changed. This means that the connection with the peer is up permanently and no **keepalive** packets are sent to the peer.

The **no** form of this command used at the global level reverts to the default value.

The **no** form of this command used at the group level reverts to the value defined at the global level.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Default

hold-time 90

Parameters

seconds

Specifies the hold-time, in seconds, expressed as a decimal integer. A value of 0 indicates the connection to the peer is up permanently.

Values 0, 3 to 65535

seconds2

Specifies the minimum hold-time that is accepted for the session. If the peer proposes a hold-time lower than this value the session attempt is rejected.

12.58 hold-timer

hold-timer

Syntax

hold-timer *seconds*

no hold-timer

Context

[Tree] (config>router>mpls hold-timer)

Full Context

configure router mpls hold-timer

Description

This command specifies the amount of time that the ingress node holds before programming its data plane and declaring the LSP up to the service module. This occurs anytime the ingress node brings up an LSP path or switches traffic from a working path to another working path of the same LSP.

The **no** form of this command reverts to the default value.

Default

no hold-timer

Parameters

seconds

Specifies the time (in seconds), for which the ingress node holds before programming its data plane and declaring the LSP up to the service module.

Values 0 to 1000

Default 1

Platforms

All

12.59 holddown

holddown

Syntax

[**no**] **holddown** [**neighbor** *ip-int-name* | *ip-address*]

Context

[Tree] (debug>router>rip holddown)

Full Context

debug router rip holddown

Description

This command enables debugging for RIP holddowns.

Parameters

ip-int-name* | *ip-address

Debugs the RIP holddowns sent on the neighbor IP address or interface.

Platforms

All

holddown

Syntax

[**no**] **holddown** [**neighbor** *ip-int-name* | *ipv6-address*]

Context

[Tree] (debug>router>ripng holddown)

Full Context

debug router ripng holddown

Description

This command enables debugging for RIPng holddowns.

Parameters

ip-int-name*| *ipv6-address

Debugs the RIPng holddowns sent on the neighbor IP address or interface.

Platforms

All

12.60 holdtime

holdtime

Syntax

holdtime *holdtime*

no holdtime

Full Context

configure service vprn pim rp ipv6 rp-candidate holdtime

configure service vprn pim rp rp-candidate holdtime

Description

This command specifies the length of time a neighbor considers the sending router to be operationally up.

The **no** form of this command reverts to the default value.

Default

holdtime 150

Parameters

holdtime

Specifies the length of time, in seconds, that a neighbor should consider the sending router to be operational.

Values 5 to 255

Platforms

All

holdtime

Syntax

holdtime *holdtime*

no holdtime

Context

[Tree] (config>router>pim>rp>rp-candidate holdtime)

[Tree] (config>router>pim>rp>ipv6>rp-candidate holdtime)

Full Context

configure router pim rp rp-candidate holdtime

configure router pim rp ipv6 rp-candidate holdtime

Description

This command configures the length of time, in seconds, that neighbors should consider the sending router to be operationally up. A local RP cannot be configured on a logical router.

The **no** form of this command reverts to the default value.

Default

holdtime 150

Parameters

holdtime

Specifies the hold time, in seconds.

Values 5 to 255

Platforms

All

12.61 home

home

Syntax

home *bit* [*bit*]

no home

Context

[Tree] (config>subscr-mgmt>gtp>peer-profile>charging home)

Full Context

configure subscriber-mgmt gtp peer-profile charging-characteristics home

Description

This command configures the charging characteristics for home UE.

Default

no home

Parameters

bit

Specifies up to 16 bits to set in the Charging Characteristics Information Element (IE) for home UE, if not known by other means such as RADIUS.

Values bit0, bit1, bit2, bit3, bit4, bit5, bit6, bit7, bit8, bit9, bit10, bit11, bit12, bit13, bit14, bit15

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

12.62 home-directory

home-directory

Syntax

home-directory *url-prefix* [*directory*] [*directoryIdirectory*]

no home-directory

Context

[Tree] (config>system>security>user home-directory)

[Tree] (config>system>security>user-template home-directory)

Full Context

configure system security user home-directory

configure system security user-template home-directory

Description

This command configures the local home directory for the user for both console (file commands and '>' redirection) and FTP access.

If the URL or the specified URL/directory structure is not present, then a warning message is issued and the default is assumed.

The **no** form of this command removes the configured home directory.

Default

no home-directory

Note:
If restricted-to-home has been configured no file access is granted and no home-directory is created. If restricted-to-home is not applied then root becomes the user's home-directory.

Parameters

local-url-prefix [directory] [directory/directory]

Specifies the user's local home directory URL prefix and directory structure, up to 190 characters.

Platforms

All

12.63 hop

hop

Syntax

hop *hop-index ip-address* {**strict** | **loose**}

hop *hop-index* **sid-label** *sid-value*

no hop *hop-index*

Context

[Tree] (config>router>mpls>path hop)

Full Context

configure router mpls path hop

Description

This command specifies the hops that the LSP should traverse on its way to the egress router. When specified, the IP address can be the interface IP address, a loopback interface address, or the system IP address. If a loopback interface or the system IP address is specified then the LSP can choose the best available interface.

When an IPv6 hop is specified, the interface IP address must be a global unicast IPv6 address. A link-local address is not allowed and is rejected in the configuration if attempted.

Optionally, the LSP ingress and egress IP address can be included as the first and the last hop. A hop list can include the ingress interface IP address, the system IP address, and the egress IP address of any of the hops being specified.

When the **sid-label** parameter is specified, this command specifies an MPLS label value for a hop in the path of an SR-TE LSP. The label value implied by the SID is only used when the path is used by an SR-TE LSP.

The **no** form of this command deletes hop list entries for the path. All the LSPs currently using this path are affected. Additionally, all services actively using these LSPs are affected. The path must be shutdown first in order to delete the hop from the hop list. The **no hop** *hop-index* command will not result in any action except a warning message on the console indicating that the path is administratively up.

Parameters

hop-index

Specifies the hop index is used to order the hops specified. The LSP always traverses from the lowest hop index to the highest. The hop index does not need to be sequential.

Values 1 to 1024

ip-address

Specifies a loopback interface, the system or network interface IP address of the transit router. An interface IPv6 address must be a global unicast address.

Values ipv4-address — a.b.c.d

ipv6-address — x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x — 0 to FFFF (hexadecimal)

d — 0 to 255 (decimal)

loose

This keyword specifies that the route taken by the LSP from the previous hop to this hop can traverse through other routers. Multiple hop entries with the same IP address are flagged as errors. Either the **loose** *or* **strict** keyword must be specified.

strict

This keyword specifies that the LSP must take a direct path from the previous hop router to this router. No transit routers between the previous router and this router are allowed. If the IP address specified is the interface address, then that is the interface the LSP must use. If there are direct parallel links between the previous router and this router and if system IP address is specified, then any one of the available interfaces can be used by the LSP. The user must ensure that the previous router and this router have a direct link. Multiple hop entries with the same IP address are flagged as errors. Either the **loose** *or* **strict** keyword must be specified.

sid-value

Specifies the SID value. The *sid-value* can be any valid MPLS/SR label value. It is not restricted by any locally-defined label ranges since these may be different on the remote node or adjacency for which the SID is defined.

Values 32 to 1048575

Platforms

All

hop

Syntax

hop *hop-index ip-address*

no hop *hop-index*

Context

[Tree] (config>service>pw-routing>path hop)

Full Context

configure service pw-routing path hop

Description

This command configures each hop on an explicit path that can be used by one or more dynamic MS-PWs. It specifies the IP addresses of the hops that the MS-PE should traverse. These IP addresses can correspond to the system IP address of each S-PE, or the IP address on which the T-LDP session to a given S-PE terminates.

The **no** form of this command deletes hop list entries for the path. All the MS-PWs currently using this path are unaffected. Additionally, all services actively using these MS-PWs are unaffected. The path must be shutdown first in order to delete the hop from the hop list. The ' **no hop hop-index**' command will not result in any action, except for a warning message on the console indicating that the path is administratively up.

Default

no hop

Parameters

hop-index

Specifies a locally significant numeric identifier for the hop. The hop index is used to order the hops specified. The LSP always traverses from the lowest hop index to the highest. The hop index does not need to be sequential.

Values 1 to 1024

ip-address

Specifies the system IP address or terminating IP address for the T-LDP session to the S-PE corresponding to this hop. For a given IP address on a hop, the system will choose the appropriate SDP to use.

Platforms

12.64 hop-by-hop-opt

hop-by-hop-opt

Syntax

hop-by-hop-opt {**true** | **false**}

no hop-by-hop-opt

Context

[Tree] (config>filter>ipv6-filter>entry>match hop-by-hop-opt)

Full Context

configure filter ipv6-filter entry match hop-by-hop-opt

Description

This command enables match on existence of Hop-by-Hop Options Extension Header in the IPv6 filter policy.

The **no** form of this command ignores Hop-by-Hop Options Extension Header presence/absence in a packet when evaluating match criteria of a given filter policy entry.

Default

no hop-by-hop-opt

Parameters

true

Matches a packet with a Hop-by-Hop Options Extension header.

false

Matches a packet without a Hop-by-Hop Options Extension header.

Platforms

All

hop-by-hop-opt

Syntax

hop-by-hop-opt {**true** | **false**}

no hop-by-hop-opt

Context

[Tree] (cfg>sys>sec>cpm>ipv6-filter>entry>match hop-by-hop-opt)

Full Context

configure system security cpm-filter ipv6-filter entry match hop-by-hop-opt

Description

This command enables match on existence of Hop-by-Hop Options Extension Header in the IPv6 filter policy. This command applies to the 7750 SR and 7950 XRS.

The **no** form of this command ignores Hop-by-Hop Options Extension Header presence/absence in a packet when evaluating match criteria of a given filter policy entry.

Default

no hop-by-hop-opt

Parameters

true

Match if a packet contains Hop-by-Hop Options Extension Header.

false

Match if a packet does not contain Hop-by-Hop Options Extension Header.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

12.65 hop-limit

hop-limit

Syntax

hop-limit *limit*

no hop-limit

Context

[Tree] (config>router>mpls>lsp>fast-reroute hop-limit)

[Tree] (config>router>mpls>lsp-template>fast-reroute hop-limit)

Full Context

configure router mpls lsp fast-reroute hop-limit

configure router mpls lsp-template fast-reroute hop-limit

Description

For fast reroute, how many more routers a detour is allowed to traverse compared to the LSP itself. For example, if an LSP traverses four routers, any detour for the LSP can be no more than ten router hops, including the ingress and egress routers.

The **no** form of this command reverts to the default value.

Default

hop-limit 16

Parameters

limit

Specify the maximum number of hops.

Values 0 to 255

Platforms

All

hop-limit

Syntax

hop-limit *number*

no hop-limit

Context

[Tree] (config>router>mpls>lsp hop-limit)

[Tree] (config>router>mpls>lsp>primary-p2mp-instance hop-limit)

Full Context

configure router mpls lsp hop-limit

configure router mpls lsp primary-p2mp-instance hop-limit

Description

This command specifies the maximum number of hops that an LSP can traverse, including the ingress and egress routers. An LSP is not set up if the hop limit is exceeded. This value can be changed dynamically for an LSP that is already set up with the following implications.

If the new value is less than the current number of hops of the established LSP, the LSP is brought down. The software then tries to re-establish the LSP within the new **hop-limit** number. If the new value is equal to or greater than the current number hops of the established LSP, the LSP is not affected.

The **config**>**router**>**mpls**>**lsp**>**primary-p2mp-instance**> **hop-limit** command is not supported on the 7450 ESS.

The **no** form of this command returns the parameter to the default value.

Default

hop-limit 255

Parameters

number

Specifies the number of hops the LSP can traverse, expressed as an integer.

Values 2 to 255

Platforms

All

hop-limit

Syntax

hop-limit *number*

no hop-limit

Context

[Tree] (config>router>mpls>lsp>primary hop-limit)

[Tree] (config>router>mpls>lsp>secondary hop-limit)

Full Context

configure router mpls lsp primary hop-limit

configure router mpls lsp secondary hop-limit

Description

This optional command overrides the **config>router>mpls>lsp** *lsp-name***>hop-limit** command. This command specifies the total number of hops that an LSP traverses, including the ingress and egress routers.

This value can be changed dynamically for an LSP that is already set up with the following implications:

If the new value is less than the current hops of the established LSP, the LSP is brought down. MPLS then tries to re-establish the LSP within the new hop-limit number. If the new value is equal or more than the current hops of the established LSP then the LSP will be unaffected.

The **no** form of this command reverts the values defined under the LSP definition using the **config>router>mpls>lsp** *lsp-name***>hop-limit** command.

Default

no hop-limit

Parameters

number

Specifies the number of hops the LSP can traverse, expressed as an integer.

Values 2 to 255

Platforms

All

hop-limit

Syntax

hop-limit {**lt** | **gt** | **eq**} *hop-limit-value*

hop-limit range *hop-limit-value hop-limit-value*

no hop-limit

Context

[Tree] (config>filter>ipv6-filter>entry>match hop-limit)

Full Context

configure filter ipv6-filter entry match hop-limit

Description

This command configures the Time To Live (TTL) match criteria.

The **no** form of this command removes the configuration.

Default

no hop-limit

Parameters

lt

Specifies "less than". The **lt** parameter cannot be used with the lowest possible numerical value for the parameter.

gt

Specifies "greater than". The **gt** parameter cannot be used with the highest possible numerical value for the parameter.

eq

Specifies "equal to".

hop-limit-value

Specifies the hop limit value for the rate limit action.

Values 0 to 255

Platforms

All

12.66 host

host

Syntax

host *host-name* [**create**]

no host *host-name*

Context

[Tree] (config>subscr-mgmt>loc-user-db>ipoe host)

[Tree] (config>subscr-mgmt>loc-user-db>ppp host)

Full Context

configure subscriber-mgmt local-user-db ipoe host

configure subscriber-mgmt local-user-db ppp host

Description

This command creates an IPoE or PPP host entry in the local user database. A host entry in the local user database is matched based on the specified match-list criteria and an optional mask that is applied to the host-identification parameters.

A default host entry can be created without host-identification parameters which is used when no other host entries match. Note that creating a default host entry also requires a match-list to be specified.

The **no** form of this command removes the host entry from the local user database.

Parameters

host-name

Specifies a unique host name, up to 32 characters. The *host-name* **default** creates a special match-all host entry that should not have host-identification parameters and is used when no other host entries match.

create

Keyword used to create the host name. The **create** keyword requirement can be enabled or disabled in the **environment>create** context.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

host

Syntax

12.67 host-accounting

host-accounting

Syntax

[**no**] **host-accounting** [**interim-update**]

Context

[Tree] (config>subscr-mgmt>acct-plcy host-accounting)

Full Context

configure subscriber-mgmt radius-accounting-policy host-accounting

Description

This command enables per-host accounting. In host accounting mode, the acct-session-id is generated per host. This acct-session-id is uniformly included in all accounting messages (START/INTERIM-UPDATE/STOP) and it can be included in RADIUS Access-Request message.

Accounting counters are based on the queue counters and as such are aggregated for all host sharing the queues within an sla-profile instance. CoA and LI is supported based on the acct-session-id of the host.

The **no** form of this command reverts to the default.

Parameters

interim-update

Specifies that no interim-update messages are sent for the related subscriber hosts when the session is deleted. Without this keyword, only START and STOP accounting messages are generated when the host is established or terminated. This is equivalent to a time-based accounting where only the duration of the session is required.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

12.68 host-connectivity-verify

host-connectivity-verify

Syntax

host-connectivity-verify source-ip *ip-address* [**source-mac** *ieee-address*] [**interval** *interval*] [**action** {**remove** | **alarm**}] [**timeout** *retry-timeout*] [**retry-count** *count***]**

Context

[Tree] (config>service>vpls host-connectivity-verify)

[Tree] (config>service>vpls>sap host-connectivity-verify)

Full Context

configure service vpls host-connectivity-verify

configure service vpls sap host-connectivity-verify

Description

This command enables subscriber host connectivity verification on a given VPLS SAP or within a VPLS service.

This tool will periodically scan all known hosts (from dhcp-state) and perform a UC ARP request. The subscriber host connectivity verification will maintain state (connected vs. not-connected) for all hosts.

The **no** form of this command reverts to the default.

Parameters

ip-address

Specifies an unused IP address in the same network for generation of subscriber host connectivity verification packets.

ieee-address

Specifies the source MAC address to be used for generation of subscriber host connectivity verification packets.

interval

The interval, in minutes, which specifies the time interval in which all known sources should be verified. The actual rate is then dependent on number of known hosts and interval.

Values 1 to 6000 Note that a zero value can be used by the SNMP agent to disable host-connectivity-verify.

action {remove | alarm}

Defines the action taken on a subscriber host connectivity verification failure for a given host. The **remove** keyword raises an alarm and removes the dhcp-state and releases all allocated resources (queues, table entries, and so on). A DHCP release is signaled to corresponding DHCP server. The static host is never removed. The **alarm** keyword raises an alarm indicating that the host is disconnected.

retry-timeout

Specifies the time, in seconds, to wait before a SAP that has been disabled after exceeding the maximum relearn rate is re-enabled.

Values 0 to 120

count

Specifies the number of connectivity check retransmissions.

Values 10 to 60 seconds

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

host-connectivity-verify

[Tree] (config>service>ies>sub-if>grp-if host-connectivity-verify)

[Tree] (config>service>vprn>sub-if>grp-if host-connectivity-verify)

Full Context

configure service ies subscriber-interface group-interface host-connectivity-verify

configure service vprn subscriber-interface group-interface host-connectivity-verify

Description

This command enables subscriber host connectivity verification on a given SAP within a service. This tool periodically scans all known hosts (from dhcp-state) and perform UC ARP requests. The subscriber host connectivity verification maintains state (connected versus. not-connected) for all hosts.

The **no** form of this command reverts to the default.

Parameters

interval

Specifies the interval, in minutes, which specifies the time interval which all known sources should be verified. The actual rate is then dependent on the number of known hosts and interval.

Values 1 to 6000

A zero value can be used by the SNMP agent to disable host-connectivity-verify.

action {remove | alarm}

Defines the action taken on a subscriber host connectivity verification failure for a given host. The **remove** keyword raises an alarm and removes dhcp-state and releases all allocated resources (queues, table entries and so on). DHCP-RELEASE is signaled to corresponding DHCP server. Static hosts is never removed. The **alarm** keyword raises an alarm indicating that the host is disconnected.

retry-timeout

Specifies the retry timeout.

Values 10 to 60 seconds

count

Specifies the number of retry requests.

Values 2 to 29

family

Allows the host connectivity checks to be performed for IPv4 endpoint, IPv6 endpoint or both. With family IPv6 configured, host connectivity checks is performed on the global unicast address (assigned via SLAAC or DHCPv6 IA_NA) and link-local address of a Layer 3 RG or bridged hosts. In case of SLAAC assignment, host connectivity can only be performed if the /128 is known (via downstream ND). DHCPv6 PD assigned prefixes is removed if link-local address is determined to be unreachable via host connectivity check” Reachability checks for GUA and link-local address is done simultaneously.

Values ipv4, ipv6, both

[Tree] (config>service>vprn>if host-connectivity-verify)

[Tree] (config>service>ies>if host-connectivity-verify)

Full Context

configure service vprn interface host-connectivity-verify

configure service ies interface host-connectivity-verify

Description

This command enables subscriber host connectivity verification for all hosts on this interface. This tool periodically scans all known hosts (from dhcp-state) and perform UC ARP requests. The subscriber host connectivity verification maintains state (connected vs. not-connected) for all hosts.

The **no** form of this command reverts to the default.

Parameters

source {vrrp | interface}

Specifies the source to be used for generation of subscriber host connectivity verification packets. The **vrrp** keyword specifies that the VRRP state should be used to select proper IP and MAC (active uses VRID, back-up uses interface addresses). The **interface** keyword forces the use of the interface mac and ip addresses.

Note:
There are up to 256 possible subnets on a given interface, therefore, the subscriber host connectivity verification tool always uses an address of the subnet to which the given host is pertaining. For group-interfaces, one of the parent subscriber interface subnets (depending on host's address) is used.

action {remove | alarm}

Defines the action taken on a subscriber host connectivity verification failure for a given host. The **remove** keyword raises an alarm and removes dhcp-state and releases all allocated resources (queues, table entries, and so on). The **alarm** keyword raises an alarm indicating that the host is disconnected.

interval

Specifies the interval, expressed in minutes, which specifies when all known sources should be verified. The actual rate is then dependent on number of known hosts and interval.

Values 1 to 6000

Note:
A zero value can be used by the SNMP agent to disable host-connectivity-verification.

retry-timeout

Specifies the timeout, in seconds, before a connectivity check retransmission.

Values 10 to 60

retry-count

Specifies the number of connectivity check retransmissions.

Values 2 to 29

12.69 host-identification

host-identification

Syntax

host-identification

Context

[Tree] (config>subscr-mgmt>loc-user-db>ppp>host host-identification)

[Tree] (config>subscr-mgmt>loc-user-db>ipoe>host host-identification)

Full Context

configure subscriber-mgmt local-user-db ppp host host-identification

configure subscriber-mgmt local-user-db ipoe host host-identification

Description

Commands in this context configure host identification parameters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

12.70 host-ip

host-ip

Syntax

host-ip *prefix-list-name*

Context

[Tree] (config>router>policy-options>policy-statement>entry>from host-ip)

Full Context

configure router policy-options policy-statement entry from host-ip

Description

This command specifies a prefix list host IP address as a match criterion for the route policy-statement entry.

Default

no host-ip

Parameters

prefix-list-name

Specifies the prefix-list name. Allowed values are any string up to 64 characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

The *prefix-list-name* is defined in the **config>router>policy-options>prefix-list** context.

Platforms

All

12.71 host-key

host-key

Syntax

host-key {**mac**}

no host-key

Context

[Tree] (config>subscr-mgmt>host-lockout-plcy host-key)

Full Context

configure subscriber-mgmt host-lockout-policy host-key

Description

This command specifies the parameters used in host identification for lockout on a given SAP or capture SAP.

no host-key – include (MAC address, Circuit-Id, Remote-Id)

host-key mac – include MAC address only

"host-key mac" should be used in DHCPv4 scenarios where Circuit-Id and Remote-Id are changed with "dhcp option action replace" configuration: a host lockout context is created with the replaced Circuit-Id/Remote-Id; with the default host-key (including Circuit-Id and Remote-Id), lockout does not kick in on the original trigger packet when it is retransmitted by the client.

Changing the host-key to mac should be used with care: all hosts with the same MAC address on a given SAP or capture SAP are identified as a single host with respect to host-lockout.

This command cannot be changed when the **host-lockout-policy** is referenced (configured under a SAP context).

The **no** form of this command reverts to the default value.

Parameters

mac

Specifies to use the MAC address only for host identification for lockout.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

12.72 host-limit

host-limit

Syntax

host-limit *max-num-hosts*

no host-limit

Context

[Tree] (config>service>vprn>sub-if>grp-if>arp-host host-limit)

[Tree] (config>service>ies>sub-if>grp-if>arp-host host-limit)

[Tree] (config>subscr-mgmt>msap-policy>vpls-only>arp-host host-limit)

[Tree] (config>service>vpls>sap>arp-host host-limit)

Full Context

configure service vprn subscriber-interface group-interface arp-host host-limit

configure service ies subscriber-interface group-interface arp-host host-limit

configure subscriber-mgmt msap-policy vpls-only-sap-parameters arp-host host-limit

configure service vpls sap arp-host host-limit

Description

This command configures the maximum number of ARP hosts.

The **no** form of this command reverts to the default.

Default

host-limit 1

Parameters

max-num-hosts

Specifies the maximum number of ARP hosts allowed on this SAP.

Note:
The operational maximum value may be smaller due to equipped hardware dependencies.

Values 1 to 131071

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

host-limit

Syntax

host-limit *max-num-hosts*

no host-limit

Context

[Tree] (config>service>ies>sub-if>grp-if host-limit)

Full Context

configure service ies subscriber-interface group-interface host-limit

Description

This command configures the maximum number of ARP hosts.

Parameters

max-num-hosts

Specifies the maximum number of ARP hosts.

Values 1 to 32767

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

12.73 host-limits

host-limits

Syntax

[**no**] **no host-limits**

Context

[Tree] (config>subscr-mgmt>sla-profile host-limits)

[Tree] (config>subscr-mgmt>sub-profile host-limits)

Full Context

configure subscriber-mgmt sla-profile host-limits

configure subscriber-mgmt sub-profile host-limits

Description

Commands in this context configure host limits per SLA profile instance or per subscriber.

The **no** form of this command removes the host limit configuration.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

12.74 host-lockout-policy

host-lockout-policy

Syntax

host-lockout-policy *policy-name*

no host-lockout-policy

Context

[Tree] (config>service>vpls>sap host-lockout-policy)

[Tree] (config>service>vprn>sub-if>grp-if>sap host-lockout-policy)

Full Context

configure service vprn interface sap host-lockout-policy

configure service ies subscriber-interface group-interface sap host-lockout-policy

configure service ies interface sap host-lockout-policy

configure service vpls sap host-lockout-policy

configure service vprn subscriber-interface group-interface sap host-lockout-policy

Description

This command selects an existing host lockout policy. The **host-lockout-policy** *policy-name* is created in the **config>subscr-mgmt** context.

The **no** form of this command removes the policy name from the SAP configuration.

Parameters

policy-name

Specifies an existing host lockout policy, up to 32 characters, to associate with the SAP.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

host-lockout-policy

Syntax

host-lockout-policy *policy-name* [**create**]

no host-lockout-policy *policy-name*

Context

[Tree] (config>subscr-mgmt host-lockout-policy)

Full Context

configure subscriber-mgmt host-lockout-policy

Description

This command creates a host lockout policy. The policy contains set of host lockout configuration parameters. It is applied to SAP or MSAPs (by a MSAP-policy). Any change does not impact existing locked-out hosts, but only new incoming hosts that enter lockout.

The **no** form of this command removes the policy name from the configuration. The policy must not be associated with any entity.

Parameters

policy-name

Specifies an existing host lockout policy to associate with the SAP.

create

Specifies the keyword required to create the host lockout policy. The **create** keyword requirement can be enabled or disabled in the **environment>create** context.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

12.75 host-match

host-match

Syntax

host-match dest *destination-string* [**create**]

no host-match dest *destination-string*

Context

[Tree] (config>port>ethernet>access>egr>qgrp host-match)

Full Context

configure port ethernet access egress queue-group host-match

Description

This command configures host matching for the Ethernet port egress queue-group.

The **no** form of this command removes the destination string from the configuration.

Parameters

destination-string

Specify a host match destination string up to 32 characters.

create

Keyword used to create the host match. The **create** keyword requirement can be enabled or disabled in the **environment>create** context.

Platforms

All

host-match

Syntax

host-match dest *description-string* [**create**]

no host-match dest *destination-string*

Context

[Tree] (config>port>ethernet>access>egress>vport host-match)

Full Context

configure port ethernet access egress vport host-match

Description

This command specifies the destination and organization strings to be used for matching subscriber hosts with this Vport.

The parent Vport of a subscriber host queue, which has the port-parent option enabled, is determined by matching the destination string **dest** string associated with the subscriber and the organization string org string associated with the subscriber host with the strings defined under a Vport on the port associated with the subscriber.

If a given subscriber host queue does not have the port-parent option enabled, it will be foster-parented to the Vport used by this subscriber and which is based on matching the dest string and org string. If the subscriber could not be matched with a Vport on the egress port, the host queue will not be bandwidth controlled and will compete for bandwidth directly based on its own PIR and CIR parameters.

By default, a subscriber host queue with the port-parent option enabled is scheduled within the context of the port's port scheduler policy.

Parameters

description-string

The destination character string. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

Platforms

All

12.76 host-port

host-port

Syntax

[**no**] **host-port** *port-id*

Context

[Tree] (config>esa host-port)

Full Context

configure esa host-port

Description

This command configures an Ethernet port associated to the ESA instance.

The **no** form of this command removes the host-port.

Parameters

port-id

Specifies the port identifier of any valid Ethernet port on a supported IOM.

Values *slot*/*mda*/*port*

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s

host-port

Syntax

host-port *port-id*

no host-port

Context

12.78 host-tracking-policy

host-tracking-policy

Syntax

host-tracking-policy *policy-name* [**create**]

no host-tracking-policy *policy-name*

Context

[Tree] (config>subscr-mgmt>sub-prof host-tracking-policy)

[Tree] (config>subscr-mgmt host-tracking-policy)

Full Context

configure subscriber-mgmt sub-profile host-tracking-policy

configure subscriber-mgmt host-tracking-policy

Description

This command configures a host tracking policy. IGMP host tracking is an option in the subscriber profile that allows the factoring in of a subscriber's (multicast) video traffic by reducing the unicast operational egress aggregate rate or the rate of the scheduler specified in the ANCP policy to account for a subscriber's multicast traffic. If no ANCP policy is defined, the egress aggregate rate configured in the subscriber profile is reduced. If an ANCP policy is defined, the **rate-modify** command in the policy specifies whether the egress aggregate rate or the rate of the egress policer specified in the policy is to be reduced to account for the subscriber's multicast traffic.

The **no** form of this command reverts to the default value.

Parameters

policy-name

Specifies a host tracking policy name up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

12.79 host-unreachable

host-unreachable

Syntax

[**no**] **host-unreachable** *ip-address*

[**no**] **host-unreachable** *ipv6-address*

Context

[Tree] (config>vrrp>policy>priority-event host-unreachable)

Full Context

configure vrrp policy priority-event host-unreachable

Description

This command creates the context to configure a host unreachable priority control event to monitor the ability to receive ICMP echo reply packets from an IP host address.

A host unreachable priority event creates a continuous ICMP echo request (ping) probe to the specified *ip-address*. If a ping fails, the event is considered to be set. If a ping is successful, the event is considered to be cleared.

Multiple unique (different *ip-address*) **host-unreachable** event nodes can be configured within the **priority-event** node to a maximum of 32 events.

The **host-unreachable** command can reference any valid local or remote IP address. The ability to ARP a local IP address or find a remote IP address within a route prefix in the route table is considered part of the monitoring procedure. The **host-unreachable** priority event operational state tracks ARP or route table entries dynamically appearing and disappearing from the system. The operational state of the **host-unreachable** event are listed in Table 42: Host Unreachable Operational States.

Table 42: Host Unreachable Operational States

Host Unreachable Operational State	Description
Set – no ARP	No ARP address found for *ip-addr* for **drop-count** consecutive attempts; only applies when IP address is considered local
Set – no route	No route exists for *ip-addr* for **drop-count** consecutive attempts; only when IP address is considered remote
Set – host unreachable	ICMP host unreachable message received for **drop-count** consecutive attempts
Set – no reply	ICMP echo request timed out for **drop-count** consecutive attempts
Set – reply received	Last ICMP echo request attempt received an echo reply but historically not able to clear the event
Cleared – no ARP	No ARP address found for *ip-addr* - not enough failed attempts to set the event
Cleared – no route	No route exists for *ip-addr* - not enough failed attempts to set the event
Cleared – host unreachable	ICMP host unreachable message received - not enough failed attempts to set the event
Cleared – no reply	ICMP echo request timed out - not enough failed attempts to set the event
Cleared – reply received	Event is cleared - last ICMP echo request received an echo reply

Unlike other priority event types, the **host-unreachable** priority event monitors a repetitive task. A historical evaluation is performed on the success rate of receiving ICMP echo reply messages. The operational state takes its cleared and set orientation from the historical success rate. The informational portion of the operational state is derived from the last attempt's result. It is possible for the previous attempt to fail while the operational state is still cleared due to an insufficient number of failures to cause it to become set. It is also possible for the state to be set while the previous attempt was successful.

When an event transitions from clear to set, the set is processed immediately and must be reflected in the associated virtual router instances in-use priority value. As the event transitions from clear to set, a hold-set timer is loaded with the value configured by the events **hold-set** command. This timer prevents the event from clearing until it expires, damping the effect of event flapping. If the event clears and becomes set again before the hold-set timer expires, the timer is reset to the **hold-set** value, extending the time before another clear can take effect.

The hold-set timer be expired and the historical success rate must be met prior to the event operational state becoming cleared.

The **no** form of the command deletes the specific IP host monitoring event. The event may be deleted at any time. When the event is deleted, the in-use priority of all associated virtual router instances must be reevaluated. The event's **hold-set** timer has no effect on the removal procedure.

Default

no host-unreachable — No host unreachable priority events are created.

Parameters

ip-address

The IP address of the host for which the specific event will monitor connectivity. The *ip-addr* can only be monitored by a single event in this policy. The IP address can be monitored by multiple VRRP priority control policies. The IP address can be used in one or multiple **ping** requests. Each VRRP priority control **host-unreachable** and **ping** destined to the same *ip-addr* is uniquely identified on a per message basis. Each session originates a unique identifier value for the ICMP echo request messages it generates. This allows received ICMP echo reply messages to be directed to the appropriate sending application.

Values The following values apply to the 7450 ESS:

ipv4-address: a.b.c.d

Values The following values apply to the 7750 SR and 7950 XRS:

ipv4-address:	a.b.c.d	
ipv6-address:	x:x:x:x:x:x:x:x[-interface]	
	x:	[0..FFFF]H
	interface:	32 chars maximum, mandatory for link local addresses

The link-local IPv6 address must have an interface name specified. The global IPv6 address must not have an interface name specified.

Platforms

12.80 host-unsolicited-na-flood-evpn

host-unsolicited-na-flood-evpn

Syntax

[**no**] **host-unsolicited-na-flood-evpn**

Context

[Tree] (config>service>vpls>proxy-nd host-unsolicited-na-flood-evpn)

Full Context

configure service vpls proxy-nd host-unsolicited-na-flood-evpn

Description

This command controls whether the system floods host unsolicited Neighbor Advertisements to the EVPN. The NA messages impacted by this command are NA messages with the following flags: S=0 and R=0.

The **no** form of the command will only flood to local SAPs/binds but not to the EVPN destinations. This is only recommended in networks where CEs are routers that are directly connected to the PEs. Networks using aggregation switches between the host/routers and the PEs should flood unsolicited NA messages in the EVPN to ensure that the remote caches are updated and the BGP does not miss the advertisement of these entries.

Default

host-unsolicited-na-flood-evpn

12.82 hour

hour

Syntax

hour *hour-number* [*..hour-number*] | **all**}

no hour

Context

[Tree] (config>system>cron>sched hour)

Full Context

configure system cron schedule hour

Description

This command specifies which hour to schedule a command. Multiple hours of the day can be specified. When multiple hours are configured, each of them will cause the schedule to trigger. **Day-of-month** or **weekday** must also be specified. All days of the month or weekdays can be specified. If an hour is configured without configuring month, weekday, day-of-month, and minute, the event will not execute.

The **no** form of this command removes the specified hour from the configuration.

Default

no hour

Parameters

hour-number

Specifies the hour to schedule a command.

Values 0 to 23 (maximum 24 hour-numbers)

all

Specifies all hours.

12.83 hqos-algorithm

hqos-algorithm

Syntax

hqos-algorithm {**default** | **above-offered-allowance-control**}

no hqos-algorithm

Context

[Tree] (config>qos>port-scheduler-policy hqos-algorithm)

Full Context

configure qos port-scheduler-policy hqos-algorithm

Description

This command configures the port scheduler H-QoS algorithm used to calculate the operational rates for the children connected to the port scheduler. The algorithm can be changed on the fly.

Default

default

Parameters

default

Specifies that the default H-QoS algorithm is used by the port scheduler.

above-offered-allowance-control

Enables the control of the amount of bandwidth in excess of the offered rate to be given to a queue or scheduler. This algorithm is supported when only queues and schedulers are parented to the port scheduler on Ethernet Vports or Ethernet physical ports.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

12.84 hqos-mode

hqos-mode

Syntax

hqos-mode {**port-scheduler** | **hw-agg-shaping**}

Context

[Tree] (config>qos>fp-resource-policy>ports hqos-mode)

Full Context

configure qos fp-resource-policy ports hqos-mode

Description

This command configures the default HQoS mode for ports on the specified FP.

Default

hqos-mode port-scheduler

Parameters

port-scheduler

Specifies that the default HQoS mode is port scheduler.

hw-agg-shaping

Specifies that the default HQoS mode is hardware aggregate shaping.

Platforms

7750 SR-1, 7750 SR-s

12.85 hs-agg-rate-limit

hs-agg-rate-limit

Syntax

hs-agg-rate-limit *kilobits-per-second*

no hs-agg-rate-limit

Context

[Tree] (config>subscr-mgmt>sla-profile>egress hs-agg-rate-limit)

Full Context

configure subscriber-mgmt sla-profile egress hs-agg-rate-limit

Description

This command configures high scale (HS) aggregate rate limit of the SLA profile instance (SPI) associated with the subscriber in expanded SLA mode. The aggregate rate of the subscriber (the primary shaper) is configured in the **config>subscr-mgmt>sub-profile>egress>hs-agg-rate-limit** context.

The **no** form of this command removes the value from the configuration.

Parameters

kilobits-per-second

Specifies the HS egress aggregate rate limit.

Values 1 to 100000000

Platforms

7750 SR-7/12/12e

hs-agg-rate-limit

Syntax

hs-agg-rate-limit *kilobits-per-second* [**min-resv-bw** *min-rate*]

hs-agg-rate-limit max [**min-resv-bw** *min-rate*]

no hs-agg-rate-limit

Context

[Tree] (config>subscr-mgmt>sub-profile>egress hs-agg-rate-limit)

Full Context

configure subscriber-mgmt sub-profile egress hs-agg-rate-limit

Description

This command configures the HS aggregate rate limit for the subscriber in single SLA mode. In single SLA mode, the **hs-aggregate-rate-limit** command under the **config>subscr-mgmt>sla-profile** context should not be configured.

When both, **sub-profile>egress>hs-agg-rate-limit** and **sla-profile>egress>hs-agg-rate-limit** are configured, the system takes the minimum of the two to program the subscriber's aggregate rate.

The **no** form of this command removes the value from the configuration.

Parameters

kilobits-per-second

Specifies the HS egress aggregate rate limit.

Values 1 to 100000000

min-rate

Specifies the minimum rate of the minimum reserved bandwidth for unicast data traffic. Since minimum rate can oversubscribe subscriber bandwidth to guarantee a minimum bandwidth for unicast traffic, care must be taken in QoS provisioning to prioritize packets accordingly (downstream network elements such as the access node or aggregation nodes) when congestion occurs.

Values 0 to 100000000

max

Specifies that the egress aggregate rate limit for the subscriber is unlimited. Scheduling for the subscriber queues will only be governed by the individual queue parameters and any congestion on the port relative to each queues scheduling priority.

Platforms

7750 SR-7/12/12e

This command specifies that the HSQ queue group queues use the class buffers from the HS alternate port class buffer pools.

The **no** form of the command reverts to the HSQ queue group queues using buffers from HS standard port class pools.

Platforms

7750 SR-7/12/12e

12.87 hs-attachment-policy

hs-attachment-policy

Syntax

hs-attachment-policy *policy-name* [**create**]

no hs-attachment-policy *policy-name*

Context

[Tree] (config>qos hs-attachment-policy)

Full Context

configure qos hs-attachment-policy

Description

This command specifies how the queues within an HSQ queue group associated with the SAP egress policy instance, egress queue group instance, or egress network queue policy instance attaches to the HSQ scheduling classes managed by the port scheduler. On the HSQ IOM, eight queues are allocated per egress SAP or subscriber SLA profile instance (SPI), or per egress (access or network) queue group instance, or per egress network port, numbered 1 through 8. The port scheduler maintains six scheduling classes numbered from 1 through 6 (6 being the highest relative priority and 1 being the lowest). The set of eight queues may also be placed into one of two local Weighted Round Robin (WRR) groups which collapse the member queues into a single scheduling class while providing a weighted fair distribution of scheduling opportunities per member. The attachment policy contains the **attachment** commands that map the queue IDs and WRR groups to the scheduling classes. The attachment policy also defines the mapping of the scheduling classes to the queue's aggregate shapers low and high burst limit thresholds.

The **no** form of the command deletes the HS attachment policy from the system, which is only possible if the policy is not being referenced.

Parameters

policy-name

Specifies an existing attachment policy, up to 32 characters. Each HS attachment policy must be uniquely named within the system.

create

This keyword is required when first creating the configuration context. After the context is created, it is possible to navigate into the context without the **create** keyword.

Platforms

7750 SR-7/12/12e

hs-attachment-policy

Syntax

hs-attachment-policy *policy-name*

no hs-attachment-policy

Context

[Tree] (config>qos>network-queue hs-attachment-policy)

Full Context

configure qos network-queue hs-attachment-policy

Description

This command associates an existing HS attachment policy with the network queue QoS policy. The HS attachment policy controls how the network queues are attached to scheduler classes or WRR groups,

and how WRR groups are attached to the scheduler classes. It also defines the mapping of the scheduling classes to the queues' aggregate shaper's low and high burst limit thresholds.

Only one HS attachment policy can be associated with a network queue policy.

The **no** form of the command removes the policy name from the configuration and reapplies the default HS attachment policy.

Parameters

policy-name

Specifies an existing attachment policy up, to 32 characters. Each HSQ attachment policy must be uniquely named within the system.

Platforms

7750 SR-7/12/12e

hs-attachment-policy

Syntax

hs-attachment-policy *policy-name*

no hs-attachment-policy

Context

[Tree] (config>qos>sap-egress hs-attachment-policy)

Full Context

configure qos sap-egress hs-attachment-policy

Description

This command associates an existing HS attachment policy with the SAP egress QoS policy. The HS attachment policy controls how the SAP egress queues are attached to scheduler classes or WRR groups, and how WRR groups are attached to the scheduler classes. It also defines the mapping of the scheduling classes to the queues' aggregate shaper's low and high burst limit thresholds.

Only one HS attachment policy can be associated with a SAP egress policy.

The **no** form of the command removes the policy name from the configuration and reapplies the default HS attachment policy.

Parameters

policy-name

Specifies an existing attachment policy up, to 32 characters. Each HSQ attachment policy must be uniquely named within the system.

Platforms

7750 SR-7/12/12e

hs-attachment-policy

Syntax

hs-attachment-policy *policy-name*

no hs-attachment-policy

Context

[Tree] (config>qos>qgrps>egr>qgrp hs-attachment-policy)

Full Context

configure qos queue-group-templates egress queue-group hs-attachment-policy

Description

This command associates an existing HS attachment policy with the egress queue group template. The HS attachment policy controls how the egress queue group instance queues are attached to scheduler classes or WRR groups, and how WRR groups are attached to the scheduler classes. It also defines the mapping of the scheduling classes to the queues' aggregate shaper's low and high burst limit thresholds.

Only one HS attachment policy can be associated with an egress queue group template.

The **no** form of the command removes the policy name from the configuration and reapplies the default HS attachment policy.

Parameters

policy-name

Specifies an existing attachment policy, up to 32 characters. Each HS attachment policy must be uniquely named within the system.

Platforms

7750 SR-7/12/12e

hs-attachment-policy

Syntax

hs-attachment-policy *src-name dst-name* [**overwrite**]

Context

[Tree] (config>qos>copy hs-attachment-policy)

Full Context

configure qos copy hs-attachment-policy

Description

This command copies existing QoS policy entries for a QoS policy ID to another QoS policy ID.

The **copy** command is a configuration-level maintenance tool used to create new policies using existing policies. It also allows bulk modifications to an existing policy with the use of the **overwrite** keyword.

Parameters

src-name dst-name

Indicates that the source policy ID and the destination policy ID are HS policy IDs. Specify the source policy ID that the copy command attempts to copy from and specify the destination policy ID to which the command copies a duplicate of the policy.

overwrite

Specifies to replace the existing destination policy. Everything in the existing destination policy is overwritten with the contents of the source policy. If **overwrite** is not specified, an error occurs if the destination policy ID exists.

Example:

```
   – SR>config>qos# copy hs-pool-policy policy1 policy2
   – MINOR: CLI Destination "policy2" exists use {overwrite}.
   – SR>config>qos# copy hs-pool-policy policy1 policy2
overwrite
```

12.89 hs-fixed-high-thresh-delta

hs-fixed-high-thresh-delta

Syntax

hs-fixed-high-thresh-delta *size-in-bytes*

no hs-fixed-high-thresh-delta

Context

[Tree] (config>card>fp>egress hs-fixed-high-thresh-delta)

Full Context

configure card fp egress hs-fixed-high-thresh-delta

Description

This command specifies the egress aggregate shaper high burst limit threshold delta for this HSQ IOM FP. An aggregate rate can be applied to each egress HSQ queue group, HS secondary shaper and (for subscribers configured with HS SLA expanded mode) primary shaper which manages the maximum burst limit over a specified shaping rate. Each aggregate shaper supports two thresholds which are used in conjunction with the low burst class setting. The system utilizes the lowest value attainable for each low threshold aggregate burst limit without causing shaper under run conditions. The high burst limit threshold is determined by adding the configured value of this command to the aggregate's low burst limit threshold value. This configured value should be set to at least two times the maximum frame size to prevent lower threshold class forwarding from also affecting the higher threshold classes when forwarding larger packet sizes. An insufficient high threshold delta defeats the intended purpose of mapping classes to the higher threshold.

The configured value for this command can be changed at any time. Modifying the setting causes all aggregate shapers on this FP to reconfigure the low and high burst limit thresholds to reflect the new value.

The **no** form of this command reverts this parameter to the default.

Default

hs-fixed-high-thresh-delta 4000

Parameters

size-in-bytes

Specifies high threshold data in bytes.

Values 0 to 65536

Platforms

7750 SR-7/12/12e

12.90 hs-low-burst-max-class

hs-low-burst-max-class

Syntax

hs-low-burst-max-class *class*

no hs-low-burst-max-class

Context

[Tree] (config>subscr-mgmt>sub-prof>egress hs-low-burst-max-class)

Full Context

configure subscriber-mgmt sub-profile egress hs-low-burst-max-class

Description

This command specifies which scheduling classes map to the low burst limit threshold of an egress HS primary shaper. The HS primary shaper is used to manage aggregate bandwidth of the subscriber with multiple SLA profile instances (expanded SLA mode).

Each HS primary shaper supports two burst thresholds, a low burst limit threshold and a high burst limit threshold. The two thresholds allow separation of burstiness between low and high scheduling classes.

When the low burst threshold of the HS primary shaper is reached, the lower scheduling classes, up to the scheduling class configured by this command, stops being served. Traffic on higher scheduling classes still goes through until the high burst threshold is reached. When the high burst threshold is exceeded, all scheduling classes associated with the HS primary shaper and stops being serve, which effectively shuts off the traffic flow.

Typically, the queues associated with higher scheduling classes are individually rate-limited so that their aggregate allowed throughput is less than the configured rate of the HS primary shaper. Determining the **hs-low-burst-max-class** *class* value involves anticipating the proper dividing line between the low and high scheduling classes by evaluating the forwarding behavior and SLA enforcement of each class.

By default, all scheduling classes are mapped to the low burst limit threshold. When mapping scheduling classes to the high burst limit threshold, an adequate value for the **config>card>fp>egress>hs-fixed-high-thresh-delta** should be specified (by default, it is set to 4000 bytes). This is because the queues associated with the lower scheduling classes may burst over the lower threshold during normal operation due to the scheduler forwarding whole packets. The **hs-fixed-high-thresh-delta** value should be set to at least two times the maximum frame size to prevent lower threshold class forwarding from also affecting the higher threshold classes when forwarding larger packet sizes. An insufficient high threshold delta defeats the intended purpose of mapping classes to the higher threshold.

The system uses the lowest value attainable for each low threshold aggregate burst limit without causing shaper underrun conditions. The high burst limit threshold is determined by adding the **hs-fixed-high-thresh-delta** value to the aggregate low burst limit threshold value.

The **hs-low-burst-max-class** value for HS primary shaper can be changed at any time in the subscriber profile (sub-profile).

The **no** form of this command restores the low burst limit threshold of the scheduling classes to the default value. This causes all scheduling classes associated with the HS primary shaper to be mapped to the low burst limit threshold.

Default

hs-low-burst-max-class 6

Parameters

class

Specifies the highest scheduling class that is associated with the low burst limit threshold of the HS primary shaper. Scheduling classes that are higher than the scheduling class ID are associated with the high burst limit threshold.

Values 1 to 6

Platforms

7750 SR-7/12/12e

12.91 hs-mbs

hs-mbs

Syntax

hs-mbs *percent-of-queue-rate*

no hs-mbs

Context

[Tree] (config>qos>network-queue>queue hs-mbs)

Full Context

configure qos network-queue queue hs-mbs

Description

This command configures the queue size of an HSQ queue group network queue. Its value is calculated based on the specified percentage of one second of the queue PIR converted to bytes (the regular **mbs** parameter is ignored in the network queue policy).

The **no** form of the command reverts to the default value.

Default

hs-mbs 100

Parameters

percent-of-queue-rate

Specifies the buffer space for the queue as a percentage of its PIR (in bytes).

Values 0.00 to 100.0

Platforms

7750 SR-7/12/12e

12.92 hs-pool-policy

hs-pool-policy

Syntax

hs-pool-policy *name*

no hs-pool-policy

Context

[Tree] (config>card>fp>egress hs-pool-policy)

Full Context

configure card fp egress hs-pool-policy

Description

This command specifies the HS pool policy for this FP.

An HS pool policy contains the required parameters to create and size root and mid-tier buffer pools on an HSQ IOM, and apply a slope policy to each.

A single HS pool policy is supported per port FP. This command is only applicable to the HSQ IOM (iom4-e-hs) and will fail if configured on all other card types.

The **no** form of this command removes the policy and reapplies the default policy.

Default

hs-pool-policy default

Parameters

name

Specifies the HS pool policy name, up to 32 characters.

Platforms

7750 SR-7/12/12e

hs-pool-policy

Syntax

hs-pool-policy *policy-name* [**create**]

no hs-pool-policy *policy-name*

Context

[Tree] (config>qos hs-pool-policy)

Full Context

configure qos hs-pool-policy

Description

Commands in this context create HS pool policy parameters. The policy can be assigned to an egress forwarding plane of an HSQ IOM. The policy contains the required parameters to create and size root and mid-tier buffer pools on an HSQ IOM, and apply a slope policy to each. The HS pool policy can be applied using the **hs-pool-policy** command within the **config>card>fp** *fp-number* **egress** context.

The system supports 63 HS pool policies including the default HS pool policy.

- HSQ IOM System Reserved Buffers — The HSQ IOM maintains two types of queues; provisioned queues and system reserved queues. The HSQ IOM ensures that provisioned queues cannot consume buffers that must be available for internal system queues required for correct operating behavior. To prevent buffer starvation between the two types of queues, the system divides the available buffers into two portions. The first portion is given to system root pools and is allocated to HSQ queues reserved for internal functions. The second portion is given to the provisioned or user-defined root pools and is available for egress service queues, network queues, queue-group queues or subscriber queues. By default, 5% of the total buffers available are given to the system root pools leaving 95% for the provisioned root pools.

  The default separation between the system and the provisioned root pools can be overridden using the **system-reserve** command.

- Root Pools — Root pools are the buffer pools at the bottom of the buffer allocation hierarchy. Two sets of root pools exist: the system root pools and the provisioned root pools. The system root pools cannot be managed by the HS pool policy; only the total number of buffers given to the system root pools can be adjusted by using the **system-reserve** command.

  The HS pool policy manages sixteen provisioned root pools defined under the **root-tier** context and specified as root-pool 1 through 16. Each root pool accepts a weight command that defines the relative quantity of buffers that are allocated to each root pool. Root pools are deactivated by defining a weight equal to 0. Root pools with a non-zero weight are sized based on the pool's weight divided by the sum of all root pool weights, multiplied by the available buffer space. In this manner, all buffers not reserved for system use are distributed between the provisioned root pools without oversubscription. The lack of oversubscription prevents buffer starvation between the root pools allowing root pools, to act as protected buffer space between different types of traffic (best-effort, expedited, or real-time). Root pools allocate buffers to the FP-level mid-tier pools.

- Mid-Tier Pools — Mid-tier pools are the buffer pools that act as aggregators for port-class pools. Multiple mid-tier pools can be mapped to a single root pool and each mid-tier pool is assigned a percentage of that root pool's buffer space. The sum of the percentages may exceed 100%, allowing for oversubscription of the root pool's buffer space. Due to statistical multiplexing principles, oversubscribing the root pool's buffer allocation may allow more efficient use of the available buffers as not all mid-tier pools are expected to use their fair share simultaneously. Examples of a multiple mid-tier pool application are multiple assured forwarding (AF) or best-effort classes being grouped together in the same root pool. The HS pool policy manages the sixteen mid-tier pools on an HSQ IOM, defined under the **mid-tier** context and specified as mid-pool 1 through 16.

- Port Class Pools — The HSQ IOM maintains two sets of scheduler class pools per port: a standard (or default) set and an alternate set. Each set contains six pools, one for each scheduler class serviced by the HSQ IOM port scheduler. Each queue or WRR group is mapped to a scheduling class based on the HS attachment policy defined within the policy or template used to create the queue. Within the SAP egress policy, network queue policy and egress queue group template, an **alt-port-class-pool** command specifies whether the queues created through the policy use the standard or alternate set of port class pools on the physical port. Further, the scheduling class servicing the queue defines which port-class pool (1 through 6) within the set allocate buffers to the queue.

  Port-class pools are defined within the **hs-port-pool-policy**, which is applied to each physical port. Further information on HSQ IOM port-class pools is contained in the HS port pool policy section.

- HSQ Stable Pool Sizing Equivalency — Stable pool sizing is a feature supported on ingress and on non-HSQ egress forwarding planes. By default, the system tries to make all buffers available to active ports (provisioned and equipped). This leads to a condition where an IOM may have only a single MDA populated and the users on that MDA receive all available buffers. At a later date, the second MDA can be populated, causing the buffer space to be fragmented between the users on each MDA. The users

on the earlier populated MDA may perceive a degradation in service based on the change in available buffers. The stable pool sizing feature mitigates this potential issue by segregating the buffer space per MDA.

The HSQ IOM can be made to operate in this stable buffer allocation mechanism by utilizing per-MDA buffer pools. This is accomplished by performing the following steps:

1. Create two sets of root-pools and two sets of mid-pools in the **hs-pool-policy** applied to the IOM's FP egress CLI context. The first set of mid-pools should be parented to the first set of root-pools. The second set of mid-pools should be parented to the second set of root-pools.
2. Create two distinct HS port pool policies. One is applied to the ports on the first MDA and has the port-class pools parented to the first set of mid-tier pools from the FP level policy. The second HS port pool policy is applied to the ports on the second MDA (when it is provisioned) and has the port-class pools parented to the second set of mid-tier pools from the FP level policy. This provides deterministic pool sizing independent of MDA equipping events.
3. Configure further control at the port-class level by utilizing **explicit-percent** based port-class pool sizing, which eliminates the effect of changing port states, including bandwidth changes.

- HSQ Queue Buffer Allocation — As each packet arrives at an HSQ queue, the queue must obtain buffers to admit the packet on the queue. The queue first checks the depth of the queue relative to the packet's congestion priority (based on the in, out, or exceed profile) to determine if the packet should be discarded based on early congestion detection or based on the MBS threshold. If the packet is allowed into the queue, the HSQ IOM continues to determine buffer availability using checks to the queue's port-class pool, the port-class pool's mid-tier pool, and the mid-tier pool's root pool. The same RED slope type used at the queue (high, low, or exceed) is used within each buffer pool. If a buffer is available, the buffer can be allocated, and given to the queue.
- Default HSQ Pool Policy — An HSQ pool policy with the name **default** always exists on the system and does not need to be created. The default pool policy cannot be changed and is used by all HSQ IOMs within the system unless an explicitly created **hs-pool-policy** is associated with a forwarding plane.

  The default policy contains the following parameters:

  system-reserve: 5%

  root-pool 1

  allocation-weight: 75

  slope-policy: _tmnx_hs_default

  root-pool 2

  allocation-weight: 25

  slope-policy: _tmnx_hs_default

  root-pool 3 to **16**

  allocation-weight: 0

  slope-policy: _tmnx_hs_default

  mid-pool 1

  parent-root-pool: 1

  allocation-percent: 40%

  slope-policy: _tmnx_hs_default

  mid-pool 2

parent-root-pool: 1

allocation-percent: 35%

slope-policy: _tmnx_hs_default

mid-pool 3

parent-root-pool: 1

allocation-percent: 30%

slope-policy: _tmnx_hs_default

mid-pool 4

parent-root-pool: 1

allocation-percent: 25%

slope-policy: _tmnx_hs_default

mid-pool 5

parent-root-pool: 2

allocation-percent: 80%

slope-policy: _tmnx_hs_default

mid-pool 6

parent-root-pool: 2

allocation-percent: 20%

slope-policy: _tmnx_hs_default

mid-pool 7 to **16**

parent-root-pool: None

allocation-percent: 1%

slope-policy: _tmnx_hs_default

The **no** form of the command removes the HS pool policy from the system. If the HS pool policy is currently associated with a forwarding plane, the command fails.

Parameters

policy-name

Specifies pool policy name, up to 32 characters. Each HS pool policy must be uniquely named within the system.

create

This keyword is required when first creating the configuration context. After the context is created, it is possible to navigate into the context without the **create** keyword.

Platforms

7750 SR-7/12/12e

hs-pool-policy

Syntax

hs-pool-policy *src-name dst-name* [**overwrite**]

Context

[Tree] (config>qos>copy hs-pool-policy)

Full Context

configure qos copy hs-pool-policy

Description

This command copies existing QoS policy entries for a QoS policy ID to another QoS policy ID.

The **copy** command is a configuration-level maintenance tool used to create new policies using existing policies. It also allows bulk modifications to an existing policy with the use of the **overwrite** keyword.

Parameters

src-name dst-name

Indicates that the source policy ID and the destination policy ID are HS policy IDs. Specify the source policy ID that the copy command attempts to copy from and specify the destination policy ID to which the command copies a duplicate of the policy.

overwrite

Specifies to replace the existing destination policy. Everything in the existing destination policy is overwritten with the contents of the source policy. If **overwrite** is not specified, an error occurs if the destination policy ID exists.

Example:

```
   – SR>config>qos# copy hs-pool-policy policy1 policy2
   – MINOR: CLI Destination "policy2" exists use {overwrite}.
   – SR>config>qos# copy hs-pool-policy policy1 policy2
overwrite
```

12.93 hs-port-pool-policy

hs-port-pool-policy

Syntax

hs-port-pool-policy *policy-name*

no hs-port-pool-policy

Context

[Tree] (config>port>ethernet>egress hs-port-pool-policy)

Full Context

configure port ethernet egress hs-port-pool-policy

Description

This command specifies an HS port pool policy to associate with the port egress.

An HS port buffer pool policy defines and sizes the port-class buffer pools on an HSQ IOM egress port.

A single HS port pool policy is supported per port egress. This command is only applicable to the HSQ IOM (iom4-e-hs) and will fail if configured on all other card types.

The **no** form of this command removes the policy and reapplies the default policy.

Default

hs-port-pool-policy default

Parameters

policy-name

Specifies the HS port pool policy up to 32 characters.

Platforms

7750 SR-7/12/12e

hs-port-pool-policy

Syntax

no hs-port-pool-policy *policy-name*

Context

[Tree] (config>qos hs-port-pool-policy)

Full Context

configure qos hs-port-pool-policy

Description

This command creates an HS port buffer pool policy. The policy can be assigned to an egress port on an HSQ IOM. The policy contains the required commands to define and size port-class buffer pools on an HSQ IOM. The policy can be applied using the **hs-port-pool-policy** command within the **config>port>ethernet>egress** context.

SR OS supports 2047 HS port pool policies including the default HS port pool policy.

HSQ IOM port buffer pools provide buffer control for queues based on the queue's scheduling class. Two sets of scheduling class pools exist per port: a standard (or default) set and an alternative set. The SAP egress policy, network queue policy, and egress queue group template have a parameter (**alt-port-class-pool**) that specifies that the queues created by the policy or template uses the alternate port-class pools, as opposed to the default standard port-class pools. Each set has six pools, one for each scheduling class. Based on the **alt-port-class-pool** setting and the queue's scheduling class (based on the HS attachment policy configuration), each queue is mapped to a specific port-class pool.

The HS port pool policy defines how each of these pools are parented (mapped) to an FP level mid-pool and how each pool is sized.

The system allows two separate mechanisms to size each port-class pool:

- dynamic sizing based on port bandwidth, relative to bandwidth of other ports
- explicit sizing based on a percentage of the port-class pool's parent mid-pool

Dynamic Port-Class Pool Sizing — Dynamic port-class pool sizing is a mechanism that provides a fair share of a mid-pool's size to each of the port-class pools based on the potential bandwidth represented by each port. To understand port-class pool sizing, consider the following:

- Each port's bandwidth is the minimum of the port's line rate, the port's configured **egress-rate**, and the port's **hs-scheduler-policy** *max-rate*.
- The port's bandwidth can be further modified by the port's **egr-percentage-of-rate** command, which increases or decreases the port's bandwidth derived by the specified percent. This parameter allows the port to have a higher or lower bandwidth-derived weight based on how the port is actually being used instead of bandwidth alone.
- Because the port-class pools are user mapped to the mid-pools, not every port has a port-class pool associated with a mid-pool, requiring that the system perform the relative bandwidth calculations separately per mid-pool.
- Each port's portion of a specified mid-pool's size is calculated based on:

  Port_Portion = (Port_Adj_Bw / Sigma_Mid_Pool_Ports_Adj_Bw) * Mid_Pool_Size

  where Sigma_Mid_Pool_Ports_Adj_Bw is the sum of the adjusted bandwidths for all ports with port-class pools mapped to the mid-pool that are not sized using explicit-percent.
- A port without any port-class pools associated with a given mid-pool has a port portion of zero for that mid-pool.
- Multiple port-class pools on the same port can be mapped to the same mid-pool, requiring a mechanism to distribute the portion of the mid-pool given to the port between multiple port-class pools. Each mid-pool's **port-bw-weight** parameter is used to determine how much of the port's mid-pool portion is given to each port-class pool associated with mid-pool. Port-class pools sized using an **explicit-percent** value instead of port bandwidth are assumed to have a **port-bw-weight** equal to 0, causing those port-class pools to not participate in the port portion distribution. It is expected (but not required) that one of port bandwidth-based sizing or explicit percent-based sizing is used and any concurrent use of both mechanisms is transitory in nature.
- The port bandwidth weighting mechanism allocates 100% of the mid-pool size to the associated port-class pools. To allow the port-class pools to oversubscribe the parent mid-pool, a mid-pool **port-bw-oversub-factor** parameter is supported that allows the port-class pools sized by dynamic port bandwidth to increase in size by the specified oversubscription factor. This oversubscription factor can provide a more efficient use of the mid-pool's available buffers because it is not expected that all port-class pools are utilizing their allotted size simultaneously.

Explicit Port-Class Pool Sizing — The port-class pool's allocation **explicit-percent** *percent-of-parent-pool* command is used to override the dynamic pool sizing mechanism for a given mid-pool. The specified percentage value is applied to the port-class's parent mid-pool's size to derive the port-class pool size.

Explicit and Dynamic Sizing from the Same Mid-Pool Parent — If explicit and dynamic pool sizing are used simultaneously for port-class pools parented to the same mid-pool, unexpected contention or underutilization of the mid-pool's available buffers may result. While this is not a proscribed condition, it is expected most instances of dual-sizing mechanisms are transitory, based on moving between the two mechanisms.

Port-Class Pool Slope Policy Association — The HS port pool policy also provides the ability to specify a slope policy on each port-class pool. The slope policy is used to define the high, low, and exceed slope parameters used to manage contention within the port-class pool.

Default HS Port Pool Policy — An HS port pool policy with the name **default** always exists on the system and does not need to be created. The default port pool policy cannot be changed and is used by all HSQ IOMs within the system unless an explicitly created **hs-port-pool-policy** is associated with an HSQ egress port.

The default policy contains the following parameters:

Standard Port-Class Pools

Port-Class-Pool 1

Parent: Mid-Pool 1

Port-Class-Pool 2

Parent: Mid-Pool 2

Port-Class-Pool 3

Parent: Mid-Pool 3

Port-Class-Pool 4

Parent: Mid-Pool 4

Port-Class-Pool 5

Parent: Mid-Pool 5

Port-Class-Pool 6

Parent: Mid-Pool 6

Port-Class-Pool 1 to 6

Port-Bw-Weight: 1

Slope-Policy: _tmnx_hs_default

Alternate Port-Class Pools

Port-Class-Pool 1 to 6

Parent: None

Port-Bw-Weight: 1

Slope-Policy: _tmnx_hs_default

Parameters

policy-name

Specifies an HS port pool policy name up to 32 characters.

create

This keyword is required when first creating the configuration context. After the context is created, it is possible to navigate into the context without the **create** keyword.

hs-port-pool-policy

Syntax

hs-port-pool-policy *src-name dst-name* [**overwrite**]

Context

[Tree] (config>qos>copy hs-port-pool-policy)

Full Context

configure qos copy hs-port-pool-policy

Description

This command copies existing QoS policy entries for a QoS policy ID to another QoS policy ID.

The **copy** command is a configuration-level maintenance tool used to create new policies using existing policies. It also allows bulk modifications to an existing policy with the use of the **overwrite** keyword.

Parameters

src-name dst-name

Indicates that the source policy ID and the destination policy ID are HS policy IDs. Specify the source policy ID that the copy command attempts to copy from and specify the destination policy ID to which the command copies a duplicate of the policy.

overwrite

Specifies to replace the existing destination policy. Everything in the existing destination policy is overwritten with the contents of the source policy. If **overwrite** is not specified, an error occurs if the destination policy ID exists.

Example:

```
   – SR>config>qos# copy hs-pool-policy policy1 policy2
   – MINOR: CLI Destination "policy2" exists use {overwrite}.
   – SR>config>qos# copy hs-pool-policy policy1 policy2
overwrite
```

Syntax

hs-scheduler-policy *policy-name* [**create**]

no hs-scheduler-policy *policy-name*

Context

[Tree] (config>qos hs-scheduler-policy)

Full Context

configure qos hs-scheduler-policy

Description

This command configures an HS scheduler policy. The HS scheduler policies are applied to egress HSQ ports in the **config>port>ethernet>egress** context. The policy contains the required commands to provision the scheduling behavior of the HSQ scheduler classes. When assigned to an HSQ egress port, the policy is used to define the scheduling behavior for all queues associated with the egress port. The values defined in the policy can be overridden on each scheduler instance using the **config>port>ethernet>egress>hs-scheduler-overrides** command.

HSQ Queue Groups — A fundamental concept on an HSQ IOM is the queue group. Queue groups are not directly managed by the provisioning. Instead, they are indirectly assigned when creating SAPs or subscribers on an HSQ port. A queue group has eight queue members, numbered from 1 through 8. When creating a SAP or subscriber associated on an HSQ egress port, a queue group is allocated to the object. Within the SAP egress policy, network queue policy and egress queue group template, provisioned queue IDs 1 through 8 correspond directly to queue group queue IDs 1 through 8. Each group also allows each queue to be dynamically placed in a scheduling class or on one of two WRR groups local to the queue group.

Each queue within the group has three RED slopes (managed by associating a slope policy to the queue), an MBS defined in bytes, a packet byte offset parameter used to add or subtract bytes to or from each packet handled by the queue for accounting purposes, and a PIR shaper used to rate limit the queue. An HSQ attachment policy associated with the queue group defines how each queue maps either directly to a scheduling class or one of the WRR groups within the queue group. The attachment policy also defines the scheduling class attachments for the WRR groups.

The queue group supports an aggregate shaper used to manage an aggregate rate limit for all queues within the group. Scheduling for queues within the queue group is stopped and started based on the rate set on the shaper.

Scheduling Classes and Scheduling Priorities — HSQ supports six scheduler classes (1 through 6). The scheduler class should not be confused with a QoS policy forwarding class. Forwarding classes within the system are used between the ingress and egress forwarding complexes and help the system to map a packet to per-hop and per-domain behavior. Scheduling classes are slices of scheduling opportunity within a port-scheduling context. Each port scheduler maintains six strict priority levels, where 6 is the highest priority and 1 is the lowest. As a rule, the scheduler services all active queues associated with priority level 6 before moving to queues on priority level 5. This strict behavior continues through priority level 1. Scheduling classes are mapped either to their corresponding scheduling priority level (scheduling class 1 mapped to priority level 1 through scheduling class 6 mapped to priority level 6) or to a single port level WRR group. The WRR group allows collapsing up to 6 of the scheduling classes into a single scheduling priority. The WRR group provides a weighted fair scheduling behavior for its member scheduling classes at that strict priority level.

Strict Priority Level PIR — The scheduler supports a strict scheduling level PIR that limits the amount of bandwidth allowed for the level. The rate is defined in increments of megabits per second and can be set to **max** (the default setting) which disables the shaping function. The scheduler includes the full Ethernet frame encapsulation overhead when updating the priority level PIR, including the 12-byte inter-frame gap and the 8-byte preamble.

Scheduler Maximum Rate — A maximum scheduling rate can be defined for the scheduler. The rate is specified in megabits per second and the default rate is **max** which allows the scheduler to operate without a set limit. When the HS scheduling policy is applied to an egress port, the maximum scheduling rate can be used to define a rate less than the available line rate of the port. The scheduler includes the full Ethernet frame encapsulation overhead when updating the scheduler level PIR, including the 12-byte inter-frame gap and the 8-byte preamble.

HS Scheduler Policy Overrides — After an HS scheduler is applied to an egress port, the various parameters can be overridden, allowing an HS scheduler policy to be adapted to changing needs on a port without requiring a new policy to be created.

Default HS Scheduling Policy — An HS scheduling policy with the name **default** always exists on the system and does not need to be created. The default policy cannot be modified or deleted.

The default policy contains the following parameters:

Table 43: HS Scheduler Policy Parameter Defaults

Parameter	Sub-Parameter	Default
max-rate	—	max
scheduling-class 1 through 6	rate	max
	group	—
	weight	—
group 1	rate	max

Default

The **no** form of the command removes an HS scheduler policy from the system. If the HS scheduler policy is currently associated with an egress port, the command fails.

Parameters

policy-name

Specifies the HS scheduler policy up to 32 characters. Each HS scheduler policy must be uniquely named within the system.

create

This keyword is required when first creating the configuration context. After the context is created, it is possible to navigate into the context without the **create** keyword.

Platforms

7750 SR-7/12/12e

hs-scheduler-policy

Syntax

hs-scheduler-policy *src-name dst-name* [**overwrite**]

Context

[Tree] (config>qos>copy hs-scheduler-policy)

Full Context

configure qos copy hs-scheduler-policy

Description

This command copies existing QoS policy entries for a QoS policy ID to another QoS policy ID.

The **copy** command is a configuration-level maintenance tool used to create new policies using existing policies. It also allows bulk modifications to an existing policy with the use of the **overwrite** keyword.

Parameters

src-name dst-name

Indicates that the source policy ID and the destination policy ID are HS policy IDs. Specify the source policy ID that the copy command attempts to copy from and specify the destination policy ID to which the command copies a duplicate of the policy.

overwrite

Specifies to replace the existing destination policy. Everything in the existing destination policy is overwritten with the contents of the source policy. If **overwrite** is not specified, an error occurs if the destination policy ID exists.

Example:

```
– SR>config>qos# copy hs-pool-policy policy1 policy2
– MINOR: CLI Destination "policy2" exists use {overwrite}.
```

```
    – SR>config>qos# copy hs-pool-policy policy1 policy2
overwrite
```

hs-secondary-shaper

Syntax

hs-secondary-shaper *secondary-shaper-name* [**create**]

no hs-secondary-shaper *secondary-shaper-name*

Context

[Tree] (config>port>ethernet>egress hs-secondary-shaper)

Full Context

configure port ethernet egress hs-secondary-shaper

Description

This command specifies an HS secondary shaper on the port egress. HS secondary shapers are used to apply an aggregate rate and per-scheduling class rates to the set of SAP egress HSQ queue groups which reference them using the SAP egress queue-override **hs-secondary-shaper** command.

By default, the **hs-secondary-shaper** default is applied to each port egress on all HSQ ports and the settings under it can be modified.

Multiple HS secondary shapers are supported per port egress, up to the number supported per-HSQ FP, which is 4096 HS secondary shapers. The number of HS secondary shapers allocated on an HSQ FP can be seen using the **tools dump resource-usage card** *slot-number* **fp** *fp-number* command.

Non-default HS secondary shapers are only configurable on access or hybrid mode ports.

This command is only applicable to the HSQ IOM (iom4-e-hs) and will fail if configured on all other card types.

The **no** form of this command removes the HS secondary shaper from the port egress configuration. An HS scheduler policy cannot be removed when HS scheduler overrides exist on the port egress.

Default

hs-secondary-shaper default

Parameters

secondary-shaper-name

Specifies the secondary shaper name up to 32 characters.

Full Context

configure service ipipe sap egress queue-override hs-wrr-group

configure service epipe sap egress queue-override hs-wrr-group

Description

This command configures the egress HS WRR group override parameters.

The **no** form of this command removes the group ID from the configuration.

Parameters

group-id

Specifies the HS WRR group ID to override.

Values 1, 2

create

Keyword used to create an HSS WRR group. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

Platforms

7750 SR-7/12/12e

hs-wrr-group

Syntax

hs-wrr-group *group-id* [**create**]

no hs-wrr-group *group-id*

Context

[Tree] (config>service>vpls>sap>egress>queue-override hs-wrr-group)

Full Context

configure service vpls sap egress queue-override hs-wrr-group

Description

This command configures the egress HS WRR group override parameters.

The **no** form of this command removes the group ID from the configuration.

Parameters

group-id

Specifies the HS WRR group ID to override.

Values 1, 2

create

Keyword used to create an HSS WRR group. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

Platforms

7750 SR-7/12/12e

hs-wrr-group

Syntax

hs-wrr-group *group-id* [**create**]

hs-wrr-group *group-id*

Context

[Tree] (config>service>ies>if>sap>egress>queue-override hs-wrr-group)

Full Context

configure service ies interface sap egress queue-override hs-wrr-group

Description

This command configures the egress HS WRR group override parameters.

The **no** form of this command removes the group ID from the configuration.

Parameters

group-id

Specifies the HS WRR group ID to override.

Values 1, 2

Platforms

7750 SR-7/12/12e

hs-wrr-group

Syntax

hs-wrr-group *group-id* [**create**]

no hs-wrr-group *group-id*

Context

[Tree] (config>service>vprn>if>sap>egress>queue-override hs-wrr-group)

Full Context

configure service vprn interface sap egress queue-override hs-wrr-group

Description

This command configures the egress HS WRR group override parameters.

The **no** form of this command removes the group ID from the configuration.

Parameters

group-id

Specifies the HS WRR group ID to override.

Values 1, 2

create

Keyword used to create the HS WRR group override instance.

Platforms

7750 SR-7/12/12e

hs-wrr-group

Syntax

[**no**] **hs-wrr-group** *group-id*

Context

[Tree] (config>qos>network-queue hs-wrr-group)

Full Context

configure qos network-queue hs-wrr-group

Description

Commands in this context configure HS WRR group information in the network queue policy. This command provisions the rate and class weight of each of the two WRR scheduling groups that can be utilized by the egress queue-group instance HSQ queues.

The **no** form of the command reverts the HS WRR group parameters to their default values.

Parameters

group-id

Specifies the HS WRR group identifier. WRR group ID 1 or 2 must be specified when executing the **hs-wrr-group** command. The specified group ID identifies which WRR group context is entered for editing.

Values 1, 2

Platforms

7750 SR-7/12/12e

hs-wrr-group

Syntax

hs-wrr-group *group-id*

no hs-wrr-group

Context

[Tree] (config>qos>sap-egress hs-wrr-group)

Full Context

configure qos sap-egress hs-wrr-group

Description

Commands in this context configure HS WRR group information in the SAP egress QoS policy. The **hs-wrr-group** command is used to provision the rate and class weight of each of the two WRR scheduling groups that can be utilized by the SAP egress HSQ queues.

The **no** form of the command resets the HS WRR group parameters to their default values.

Parameters

group-id

Specifies the HS WRR group identifier. WRR group ID 1 or 2 must be specified when executing the **hs-wrr-group** command. The specified group ID identifies which WRR group context is entered for editing.

Values 1, 2

Platforms

7750 SR-7/12/12e

hs-wrr-group

Syntax

[**no**] **hs-wrr-group** *group-id*

Context

[Tree] (config>qos>qgrps>egr>qgrp hs-wrr-group)

Full Context

configure qos queue-group-templates egress queue-group hs-wrr-group

Description

Commands in this context configure HS WRR group information in the egress queue group template. The **hs-wrr-group** command is used to provision the rate and class weight of each of the two WRR scheduling groups that can be utilized by the egress queue group instance HSQ queues.

The **no** form of the command resets the HS WRR group parameters to their default values.

Parameters

group-id

Specifies the HS WRR group identifier. WRR group ID 1 or 2 must be specified when executing the **hs-wrr-group** command. The specified group ID identifies which WRR group context is entered for editing.

Values 1, 2

Platforms

7750 SR-7/12/12e

12.103 hs-wrr-weight

hs-wrr-weight

Syntax

hs-wrr-weight *weight*

no hs-wrr-weight

Context

[Tree] (config>subscr-mgmt>sla-prof>egress>qos>queue hs-wrr-weight)

Full Context

configure subscriber-mgmt sla-profile egress qos queue hs-wrr-weight

Description

This command configures the SLA profile instance WRR weight override for the HS queue. When a weight value is not specified, there is no override, meaning, the WRR weight is taken from the sap-egress policy.

The **no** form of this command removes the weight value from the configuration.

Parameters

weight

Specifies the class-weight override for expanded egress HS queues.

Values 1 to 127

Platforms

7750 SR-7/12/12e

hs-wrr-weight

Syntax

hs-wrr-weight *weight*

no hs-wrr-weight

Context

[Tree] (config>service>epipe>sap>egress>queue-override>queue hs-wrr-weight)

[Tree] (config>service>ipipe>sap>egress>queue-override>queue hs-wrr-weight)

Full Context

configure service epipe sap egress queue-override queue hs-wrr-weight

configure service ipipe sap egress queue-override queue hs-wrr-weight

Description

This command overrides the WRR relative weight as defined within the associated HS attachment policy.

The **no** form of this command removes the WRR weight override value from the configuration.

Parameters

weight

Specifies the HS WRR group queue weight.

Values 1 to 127

Platforms

7750 SR-7/12/12e

hs-wrr-weight

Syntax

hs-wrr-weight *weight*

no hs-wrr-weight

Context

[Tree] (config>service>vpls>sap>egress>queue-override>queue hs-wrr-weight)

Full Context

configure service vpls sap egress queue-override queue hs-wrr-weight

Description

This command overrides the WRR relative weight with which this queue should parent into an HSQ WRR group defined within the associated HS attachment policy.

The **no** form of this command removes the WRR weight override value from the configuration.

Parameters

weight

Specifies the HS WRR group queue weight.

Values 1 to 127

Platforms

7750 SR-7/12/12e

hs-wrr-weight

Syntax

hs-wrr-weight *weight*

no hs-wrr-weight

Context

[Tree] (config>service>ies>if>sap>egress>queue-override>queue hs-wrr-weight)

Full Context

configure service ies interface sap egress queue-override queue hs-wrr-weight

Description

This command overrides the Weighted Round Robin (WRR) relative weight with which this queue should parent into an HSQ WRR group defined within the associated HS attachment policy.

The **no** form of this command removes the WRR weight override value from the configuration.

Parameters

weight

Specifies the HS WRR group queue weight.

Values 1 to 127

Platforms

7750 SR-7/12/12e

hs-wrr-weight

Syntax

hs-wrr-weight *weight*

no hs-wrr-weight

Context

[Tree] (config>service>vprn>if>sap>egress>queue-override>queue hs-wrr-weight)

Full Context

configure service vprn interface sap egress queue-override queue hs-wrr-weight

Description

This command overrides the WRR relative weight with which this queue should parent into an HSQ Weighted Round Robin (WRR) group defined within the associated HS attachment policy.

The **no** form of this command removes the WRR weight override value from the configuration.

Parameters

weight

Specifies the HS WRR group queue weight.

Values 1 to 127

Platforms

7750 SR-7/12/12e

hs-wrr-weight

Syntax

hs-wrr-weight *weight*

no hs-wrr-weight

Context

[Tree] (config>qos>network-queue>queue hs-wrr-weight)

Full Context

configure qos network-queue queue hs-wrr-weight

Description

This command specifies the WRR relative weight, with which this queue should parent into an HSQ WRR group defined within the associated HS attachment policy. The weight of each queue determines how much bandwidth that queue gets out of the total rate for the HSQ WRR group.

The **no** form of the command reverts to the default value.

Default

hs-wrr-weight 1

Parameters

weight

Specifies the HS WRR group queue weight.

Values 1 to 127

Platforms

7750 SR-7/12/12e

hs-wrr-weight

Syntax

hs-wrr-weight *weight*

no hs-wrr-weight

Context

[Tree] (config>qos>sap-egress>queue hs-wrr-weight)

Full Context

configure qos sap-egress queue hs-wrr-weight

Description

This command specifies the WRR relative weight, with which this queue should parent into an HSQ WRR group defined within the associated HS attachment policy. The weight of each queue determines how much bandwidth that queue gets out of the total rate for the HSQ WRR group.

The **no** form of the command reverts to the default value.

Default

hs-wrr-weight 1

Parameters

weight

Specifies the HS WRR group queue weight.

Values 1 to 127

Platforms

7750 SR-7/12/12e

hs-wrr-weight

Syntax

hs-wrr-weight *weight*

no hs-wrr-weight

Context

[Tree] (config>qos>qgrps>egr>qgrp>queue hs-wrr-weight)

Full Context

configure qos queue-group-templates egress queue-group queue hs-wrr-weight

Description

This command specifies the WRR relative weight, with which this queue should parent into an HSQ WRR group defined within the associated HS attachment policy. The weight of each queue determines how much bandwidth that queue gets out of the total rate for the HSQ WRR group.

The **no** form of the command reverts to the default value.

Default

hs-wrr-weight 1

Parameters

weight

Specifies HS WRR group queue weight.

Values 1 to 127

Platforms

7750 SR-7/12/12e

12.104 http-auth

http-auth

Syntax

http-auth password *password* [**hash | hash2**]

http-auth username *user-name*

http-auth username *user-name* **password** *password* [**hash | hash2**]

no http-auth

Context

[Tree] (config>system>security>pki>est-profile http-auth)

Full Context

configure system security pki est-profile http-auth

Description

This command configures HTTP authentication parameters. HTTP authentication is used by a client when requested by the server. When disabled, there is no HTTP-level client authentication.

The **no** form of the command reverts to the default value.

Default

no http-auth

Parameters

password

Specifies a text string containing the password. Allowed values are any string up to 64 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

user-name

Specifies the name of the user to authenticate, up to 32 characters.

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

Platforms

All

12.105 http-connections

http-connections

Syntax

http-connections [*ip-address/prefix-length*]

http-connections any

http-connections [*ipv6-address/prefix-length*]

no http-connections

Context

[Tree] (debug>system http-connections)

Full Context

debug system http-connections

Description

This command displays HTTP connections debug information.

Parameters

ip-address/prefix-length

Displays information for the specified host IP address and prefix length.

Values ip-address: a.b.c.d

prefix-length: 0 to 32

any

Specifies that any address can be used.

ipv6-address/prefix-length

Displays information for the specified host IPv6 address and prefix length.

Values ipv6-address:

- x:x:x:x:x:x:x:x: (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d
- x [0 to FFFFF] H
- d [0 to 255] D

prefix-length: 0 to 128

http-enrich

Syntax

http-enrich *http-enrich-name* [**create**]

no http-enrich *http-enrich-name*

Context

[Tree] (config>app-assure>group http-enrich)

Full Context

configure application-assurance group http-enrich

Description

This command configures an HTTP enrichment policy.

The **no** form of this command removes the http enrichment policy from the configuration.

Parameters

http-enrich-name

Specifies the name of the http enrichment policy up to 32 characters.

create

Mandatory keyword used when creating an application profile. The create keyword requirement can be enabled and disabled in the **environment>create** context.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

http-enrich

Syntax

http-enrich *http-enrich-name*

no http-enrich

Context

[Tree] (config>app-assure>group>policy>aqp>entry>action http-enrich)

Full Context

configure application-assurance group policy app-qos-policy entry action http-enrich

Description

This command configures the HTTP header enrichment template name that will be applied as defined in the tmnxBsxHttpEnrichTable. An empty value specifies no HTTP header enrichment template.

Default

no http-enrich

Parameters

http-enrich-name

Specifies the HTTP header enrichment template name up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

12.107 http-enrich-max-pkt

http-enrich-max-pkt

Syntax

[**no**] **http-enrich-max-pkt** *size*

Context

[Tree] (config>isa>aa-grp http-enrich-max-pkt)

Full Context

configure isa application-assurance-group http-enrich-max-pkt

Description

This command configures the maximum HTTP enriched packet size.

Parameters

size

Specifies the maximum HTTP enriched packet size in octets.

Values 576 to 9212

Default 1500

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

12.108 http-error-redirect

http-error-redirect

Syntax

http-error-redirect *redirect-name* [**create**]

no http-error-redirect *redirect-name*

Context

[Tree] (config>app-assure>group http-error-redirect)

Full Context

configure application-assurance group http-error-redirect

Description

This command configures an HTTP error redirect policy. The policy contains important information relevant to the redirect server.

The **no** form of this command removes the redirect name from the group configuration.

Parameters

redirect-name

Specifies a string, up to 32 characters, that identifies the HTTP error redirect policy.

create

Keyword to create the HTTP error redirect policy.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

http-error-redirect

Syntax

http-error-redirect *redirect-name*

no http-error-redirect

Context

[Tree] (config>app-assure>group>policy>aqp>entry>action http-error-redirect)

Full Context

configure application-assurance group policy app-qos-policy entry action http-error-redirect

Description

This command specifies the HTTP error redirect that will be applied as defined in the redirect table. An empty value specifies no HTTP error redirect.

Default

no http-error-redirect

Parameters

redirect-name

Specifies an http-error redirect action, up to 32 characters, for flows matching this entry.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

12.109 http-host

http-host

Syntax

http-host *http-host*

no http-host

Context

[Tree] (config>app-assure>group>http-error-redirect http-host)

Full Context

configure application-assurance group http-error-redirect http-host

Description

This command refers to the http host name of the landing server (Barefruit or Xerocole). It is used in the HTTP GET operation from the client (which is being redirected) to the redirect search landing server. It must contain a valid IP address or HTTP host name / URI for the HTTP GET from the client to the landing server to work.

The **no** form of this command removes the HTTP host string from the configuration.

Default

no http-host

Parameters

http-host

Specifies a string of 255 chars max length, that refers to the HTTP host name of the landing server (barefruit or xerocole).

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

12.110 http-host-recorder

http-host-recorder

Syntax

[**no**] **http-host-recorder**

Context

[Tree] (debug>app-assure>group http-host-recorder)

Full Context

debug application-assurance group http-host-recorder

Description

This command enables the http-host-recorder feature on a particular group:partition.

The **no** form of the command disables the http-host-recorder feature.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

12.111 http-listening-port

http-listening-port

Syntax

http-listening-port *http-listening-port*

no http-listening-port

Context

[Tree] (config>service>upnp>upnp-policy http-listening-port)

Full Context

configure service upnp upnp-policy http-listening-port

Description

This command specifies the listening port of UPnP server.

The **no** form of the command reverts to the default.

Default

http-listening-port 5000

Parameters

http-listening-port

Specifies the HTTP TCP port this UPnP IGD listens to.

Values 1 to 65535

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

12.112 http-match-all-requests

http-match-all-requests

Syntax

[**no**] **http-match-all-requests**

Context

[Tree] (config>app-assure>group>policy>app-filter>entry http-match-all-requests)

[Tree] (config>app-assure>group http-match-all-requests)

Full Context

configure application-assurance group policy app-filter entry http-match-all-requests

configure application-assurance group http-match-all-requests

Description

This command enables HTTP matching for all requests for a given HTTP expression.

The **no** form of this command restores the default (removes http-match-all-request for this particular expression) by this app-filter entry.

Default

no http-match-all-requests

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

12.113 http-notification

http-notification

Syntax

http-notification *http-notification-name* [**create**]

no http-notification *http-notification-name*

Context

[Tree] (config>app-assure>group http-notification)

Full Context

configure application-assurance group http-notification

Description

This command configures an http-notification object for subscriber in browser notification.

The **no** form of this command removes the http notification policy from the configuration.

Parameters

http-notification-name

Specifies the name of the HTTP Notification policy.

create

Specifies the mandatory keyword to create the policy.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

http-notification

Syntax

http-notification *http-notification*

no http-notification

Context

[Tree] (config>app-assure>group>policy>aqp>entry>action http-notification)

Full Context

configure application-assurance group policy app-qos-policy entry action http-notification

Description

This command configures an HTTP notification action for flows matching this entry.

Default

no http-notification

Parameters

http-notification

specifies the Application-Assurance HTTP Notification that will be applied as defined in the tmnxBsxHttpNotifTable. If no string is configured then no HTTP notification will occur.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

12.114 http-port

http-port

Syntax

http-port {**eq** | **neq**} *port-num*

http-port {**eq** | **neq**} **port-list** *port-list-name*

no http-port

Context

[Tree] (config>app-assure>group>policy>app-filter>entry http-port)

Full Context

configure application-assurance group policy app-filter entry http-port

Description

This command specifies an HTTP server TCP or UDP port number or port list to use in the application definition.

The **no** form of this command restores the default by removing the HTTP port or port list from the application criteria defined by this app-filter entry.

Default

no http-port

Parameters

eq

Specifies that the value configured and the value in the flow are equal.

neq

Specifies that the value configured differs from the value in the flow.

port-list-name

Specifies the name of the port list containing a set or range of ports, up to 32 characters.

port-num

Specifies a valid server port number.

Values 0 to 65535

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

12.115 http-redirect

http-redirect

Syntax

http-redirect *redirect-name* [**create**]

no http-redirect *redirect-name*

Context

[Tree] (config>app-assure>group http-redirect)

Full Context

configure application-assurance group http-redirect

Description

This command configures an HTTP redirect.

The **no** form of this command removes the HTTP redirect policy from the configuration.

Parameters

redirect-name

Specifies the HTTP redirect that will be applied. If no redirect name is specified, then HTTP redirect is not enabled.

create

Keyword to create the HTTP redirect policy.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

http-redirect

Syntax

http-redirect *http-redirect–name* **flow-type** *flow-type*

no http-redirect

Context

[Tree] (config>app-assure>group>policy>aqp>entry>action http-redirect)

Full Context

configure application-assurance group policy app-qos-policy entry action http-redirect

Description

This command assigns an existing http redirect policy as an action on flows matching this AQP entry.

The redirect only takes effect if the matching flows are HTTP and the condition specified after the **http-redirect** command, admitted flows or dropped-flows, is met. The condition specified by "dropped-flows" means the flow is dropped due to an AQP actions such as "flow rate/count policers" or "drop" actions. HTTP Policy Redirect on admitted-flows allows the operator to redirect HTTP traffic to a web portal while allowing non-HTTP matching the same AQP rule to be forwarded.

No HTTP redirect will take place if HTTP redirect action and a "drop/flow-police" action are part of the default AQP policy, because in this case, any flow drop actions will take place before identification of the application/application-group.

The **no** form of this command removes http redirect from actions on flows matching this AQP entry.

Default

no http-redirect

Parameters

http-redirect-name

Specifies the name of the existing http policy redirect for this application assurance profile. The HTTP redirect name is configured in the **config>app-assure>group>http-redirect** context.

flow-type

Specifies the flow type.

Values **admitted-flows** — Redirect HTTP flows matching the AQP criteria.

dropped-flows — Redirects those HTTP flows that are dropped due to an AQP action.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

http-redirect

Syntax

http-redirect *http-redirect-name*

Context

[Tree] (config>app-assure>group>sess-fltr>entry>action http-redirect)

Full Context

configure application-assurance group session-filter entry action http-redirect

Description

This command configures a session filter entry action to HTTP redirect the subscriber flows. The HTTP redirect policy referenced within this session filter entry is configured for captive redirect with the appropriate VLAN id assigned.

Parameters

http-redirect-name

Specifies the name of the http-redirect-policy.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

http-redirect

Syntax

http-redirect *http-redirect-name*

no http-redirect

Context

[Tree] (config>app-assure>group>url-filter http-redirect)

Full Context

configure application-assurance group url-filter http-redirect

Description

This command specifies the HTTP redirect that will be applied when the URL filter blocks an HTTP request.

Default

no http-redirect

Parameters

http-redirect-name

Specifies the HTTP redirect name, up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

http-redirect

Syntax

http-redirect *http-redirect-name*

no http-redirect

Context

[Tree] (config>app-assure>group>url-filter>local-filtering>deny-list http-redirect)

[Tree] (config>app-assure>group>url-filter>icap http-redirect)

[Tree] (config>app-assure>group>url-filter>web-service http-redirect)

Full Context

configure application-assurance group url-filter local-filtering deny-list http-redirect

configure application-assurance group url-filter icap http-redirect

configure application-assurance group url-filter web-service http-redirect

Description

This command creates or modifies an HTTP redirect policy.

Default

no http-redirect

The **no** form of this command removes the HTTP redirect policy from the configuration.

Parameters

http-redirect-name

Specifies the name of the HTTP redirect policy, up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

http-redirect

Syntax

http-redirect *rdr-url-string* [**allow-radius-override**]

http-redirect url-from-cpf

Context

[Tree] (config>filter>ipv6-filter>entry>action http-redirect)

[Tree] (config>filter>ip-filter>entry>action http-redirect)

Full Context

configure filter ipv6-filter entry action http-redirect

configure filter ip-filter entry action http-redirect

Description

This command sets the filter entry action to **http-redirect** and specifies the redirect URL.

Parameters

rdr-url-string

Specifies the HTTP redirect URL, up to 255 characters. This option can be used for any session.

Values The following macro substitutions may be used:

$URL — request-URI in the HTTP GET request received

$MAC — a string that represents the MAC address of the subscriber host

$IP — a string that represents the IP address of the subscriber host

$SUB — a string that represents the subscriber ID

$SAP — a string that represents a SAP ID

$SAPDESC — description string configured on the SAP

$CID — a string that represents the circuit ID or interface ID of the subscriber host (hexadecimal format)

$RID — a string that represents the remote ID of the subscriber host (hexadecimal format)

allow-radius-override

Specifies that the HTTP redirect URL configured by *rdr-url-string* can be optionally overridden by a URL returned by the RADIUS server; this does not apply for the **url-from-cpf** option.

url-from-cpf

Specifies that the HTTP redirect URL is from the BNG CUPS CPF. This option can be used for BNG CUPS ESM sessions only.

Platforms

All

http-redirect

Syntax

http-redirect *url*

Context

[Tree] (config>filter>mac-filter>entry>action http-redirect)

Full Context

configure filter mac-filter entry action http-redirect

Description

This command sets the MAC filter entry action to HTTP redirect.

Parameters

url

Specifies the URL, up to 255 characters.

Platforms

All

12.116 http-redirect-policy

http-redirect-policy

Syntax

http-redirect-policy *policy-name*

no http-redirect-policy

Context

[Tree] (config>subscr-mgmt http-redirect-policy)

Full Context

configure subscriber-mgmt http-redirect-policy

Description

This command configures the redirect policy to constrain forwarding of an unauthenticated "migrant" WIFI user.

Parameters

policy-name

Specifies the HTTP redirect policy name up to 32 characters.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

http-redirect-policy

Syntax

http-redirect-policy *policy-name*

no http-redirect-policy

Context

[Tree] (config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range http-redirect-policy)

[Tree] (config>service>ies>sub-if>grp-if>wlan-gw>ranges>range http-redirect-policy)

Full Context

configure service vprn subscriber-interface group-interface wlan-gw vlan-tag-ranges range http-redirect-policy

configure service ies subscriber-interface group-interface wlan-gw vlan-tag-ranges range http-redirect-policy

Description

This command specifies http redirect policy on ISA to redirect http traffic to the URL specified in the policy.

The **no** form of this command reverts to the default.

Parameters

policy-name

Specifies the name of the http redirect policy under subscriber-management context.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

12.117 http-request-filtering

http-request-filtering

Syntax

http-request-filtering {**all** | **first**}

Context

[Tree] (config>app-assure>group>url-filter http-request-filtering)

Full Context

configure application-assurance group url-filter http-request-filtering

Description

HTTP Filtering can either be enabled for all HTTP request within a flow or limited to the first HTTP request in a flow.

Default

http-request-filtering all

Parameters

all

Specifies all HTTP Request within a flow.

first

Specifies the first HTTP Request within a flow.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

12.118 http-response-timeout

http-response-timeout

Syntax

http-response-timeout *timeout*

no http-response-timeout

Context

[Tree] (config>system>security>pki>ca-profile>cmpv2 http-response-timeout)

Full Context

configure system security pki ca-profile cmpv2 http-response-timeout

Description

This command specifies the timeout value for HTTP response that is used by CMPv2.

The **no** form of this command reverts to the default.

Default

http-response-timeout 30

Parameters

timeout

Specifies the HTTP response timeout, in seconds.

Values 1 to 3600

Platforms

All

http-response-timeout

Syntax

http-response-timeout *timeout*

no http-response-timeout

Context

[Tree] (config>system>security>pki>ca-profile>cmp2 http-response-timeout)

Full Context

configure system security pki ca-profile cmp2 http-response-timeout

Description

This command specifies the timeout value for HTTP response that is used by CMPv2.

The **no** form of this command reverts to the default.

Default

http-response-timeout 30

Parameters

timeout

Specifies the HTTP response timeout in seconds.

Values 1 to 3600

12.119 http-version

http-version

Syntax

http-version [**1.0** | **1.1**]

Context

[Tree] (config>system>security>pki>ca-profile>cmpv2 http-version)

Full Context

configure system security pki ca-profile cmpv2 http-version

Description

This command configures the HTTP version for CMPv2 messages.

Default

http-version 1.1

Platforms

All

12.120 http-x-online-host

http-x-online-host

Syntax

[**no**] **http-x-online-host**

Context

[Tree] (config>app-assure>group http-x-online-host)

Full Context

configure application-assurance group http-x-online-host

Description

This command specifies whether X-Online-Host header field is used as a replacement for the HTTP Host header field.

The **no** form of this command disables the use of X-Online-Host header field used as a replacement.

Default

no http-x-online-host

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

12.121 hw-agg-shaper-scheduler-policy

hw-agg-shaper-scheduler-policy

Syntax

hw-agg-shaper-scheduler-policy *policy-name*

no hw-agg-shaper-scheduler-policy

Context

[Tree] (config>port>ethernet>access>egress>vport hw-agg-shaper-scheduler-policy)

[Tree] (config>port>ethernet>egress hw-agg-shaper-scheduler-policy)

Full Context

configure port ethernet access egress vport hw-agg-shaper-scheduler-policy

configure port ethernet egress hw-agg-shaper-scheduler-policy

Description

This command assigns a hardware aggregate shaper scheduler policy to the specified vport.

The **no** form removes the policy from the vport.

Parameters

policy-name

Specifies the policy name.

Platforms

7750 SR-1, 7750 SR-s

hw-agg-shaper-scheduler-policy

Syntax

hw-agg-shaper-scheduler-policy *policy-name* **[create]**

no hw-agg-shaper-scheduler-policy

Context

[Tree] (config>qos hw-agg-shaper-scheduler-policy)

Full Context

configure qos hw-agg-shaper-scheduler-policy

Description

This command configures the name of the hardware aggregate shaper scheduler policy.

The **no** form removes the policy.

Parameters

policy-name

Specifies the policy name, up to 64 characters.

create

Creates a new policy.

Platforms

7750 SR-1, 7750 SR-s

12.122 hw-agg-shapers

hw-agg-shapers

Syntax

hw-agg-shapers [subscribers] [saps]

no hw-agg-shapers

Context

[Tree] (config>qos>fp-resource-policy>aggregate-shapers hw-agg-shapers)

Full Context

configure qos fp-resource-policy aggregate-shapers hw-agg-shapers

Description

This command enables the use of hardware aggregate shapers for subscribers, SAPs, or queue groups on the specified FP.

The **no** form disables the use of hardware aggregate shapers on a the specified FP.

Parameters

subscribers

Enables hardware aggregate shapers for subscribers.

saps

Enables hardware aggregate shapers for SAPs. This functionality is not currently supported.

Platforms

7750 SR-1, 7750 SR-s

12.123 hybrid-buffer-allocation

hybrid-buffer-allocation

Syntax

hybrid-buffer-allocation

Context

[Tree] (config>port hybrid-buffer-allocation)

Full Context

configure port hybrid-buffer-allocation

Description

Commands in this context configure hybrid port buffer allocation parameters.

Platforms

13 i Commands

13.1 i-counters

i-counters

Syntax

i-counters [**all**]

no i-counters

Context

[Tree] (config>subscr-mgmt>acct-plcy>cr>queue i-counters)

[Tree] (config>subscr-mgmt>acct-plcy>cr>ref-queue i-counters)

Full Context

configure subscriber-mgmt radius-accounting-policy custom-record queue i-counters

configure subscriber-mgmt radius-accounting-policy custom-record ref-queue i-counters

Description

This command configures ingress counter parameters for this custom record.

The **no** form of this command reverts to the default.

Parameters

all

Includes all counters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

i-counters

Syntax

i-counters [**all**]

no i-counters

Context

[Tree] (config>log>acct-policy>cr>ref-queue i-counters)

[Tree] (config>log>acct-policy>cr>ref-policer i-counters)

[Tree] (config>log>acct-policy>cr>policer i-counters)

[Tree] (config>log>acct-policy>cr>queue i-counters)

Full Context

configure log accounting-policy custom-record ref-queue i-counters

configure log accounting-policy custom-record ref-policer i-counters

configure log accounting-policy custom-record policer i-counters

configure log accounting-policy custom-record queue i-counters

Description

This command configures ingress counter parameters for this custom record.

The **no** form of this command reverts all ingress counters to their default value.

Default

i-counters

Parameters

all

Specifies that all ingress counters should be included.

Platforms

All

13.2 i-sid

i-sid

Syntax

i-sid *i-sid*

no i-sid

Context

[Tree] (debug>oam>build-packet>packet>field-override>header>pbb i-sid)

[Tree] (config>test-oam>build-packet>header>pbb i-sid)

Full Context

debug oam build-packet packet field-override header pbb i-sid

configure test-oam build-packet header pbb i-sid

Description

This command defines the iSID value to be used in the test PBB header.

The **no** form of this command reverts to the default value.

Default

i-sid 0

Parameters

i-sid

Specifies the iSID value to be used in the test PBB header.

Values 0 to 16777215

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

13.3 ia-na

ia-na

Syntax

ia-na

Context

[Tree] (config>service>ies>sub-if>wlan-gw>pool-manager>dhcp6-client ia-na)

[Tree] (config>service>vprn>sub-if>wlan-gw>pool-manager>dhcp6-client ia-na)

Full Context

configure service ies subscriber-interface wlan-gw pool-manager dhcpv6-client ia-na

configure service vprn subscriber-interface wlan-gw pool-manager dhcpv6-client ia-na

Description

This command configures the IA-NA for the DHCPv6 client.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

13.4 ibgp-multipath

ibgp-multipath

Syntax

[**no**] **ibgp-multipath**

Context

[Tree] (config>service>vprn>bgp ibgp-multipath)

Full Context

configure service vprn bgp ibgp-multipath

Description

This command defines the type of IBGP multipath to use when adding BGP routes to the route table if the route resolving the BGP nexthop offers multiple next-hops.

The **no** form of this command disables the IBGP multipath load balancing feature.

Platforms

All

ibgp-multipath

Syntax

[**no**] **ibgp-multipath**

Context

[Tree] (config>router>bgp ibgp-multipath)

Full Context

configure router bgp ibgp-multipath

Description

This command enables IBGP multipath load balancing when adding BGP routes to the route table if the route resolving the BGP nexthop offers multiple next-hops.

The **no** form of this command disables the IBGP multipath load balancing feature.

Default

no ibgp-multipath

13.6 icmp-code

icmp-code

Syntax

icmp-code *icmp-code*

no icmp-code

Context

[Tree] (config>filter>ipv6-filter>entry>match icmp-code)

[Tree] (config>filter>ip-exception>entry>match icmp-code)

[Tree] (config>filter>ipv6-exception>entry>match icmp-code)

[Tree] (config>filter>ip-filter>entry>match icmp-code)

Full Context

configure filter ipv6-filter entry match icmp-code

configure filter ip-exception entry match icmp-code

configure filter ipv6-exception entry match icmp-code

configure filter ip-filter entry match icmp-code

Description

Configures matching on /ICMPv6 code field in the /ICMPv6 header of an IPv4 or IPv6 packet as a filter match criterion or configures matching on the ICMP code field in the ICMP header of an IPv4 packet as an exception filter match criterion. An entry containing Layer 4 non-zero match criteria will not match non-initial (for example, 2nd, 3rd) fragments of a fragmented packet since only the first fragment contains the Layer 4 information. Similarly an entry containing " **icmp-code** 0" match criterion, may match non-initial fragments when the Layer 4 header is not present in a packet fragment and other match criteria are also met.

The **no** form of the command removes the criterion from the match entry.

Default

no icmp-code

Parameters

icmp-code

Specifies the /ICMPv6 code value that must be present to match. Value can be expressed as a decimal integer, as well as in hexadecimal or binary format, or even using keywords. The following value shows decimal integer only.

Values 0 to 255

Platforms

All

- configure filter ipv6-filter entry match icmp-code
- configure filter ip-filter entry match icmp-code

VSR

- configure filter ip-exception entry match icmp-code
- configure filter ipv6-exception entry match icmp-code

icmp-code

Syntax

icmp-code *icmp-code*

no icmp-code

Context

[Tree] (config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ip>entry>match icmp-code)

[Tree] (config>subscr-mgmt>cat-map>category>exh-lvl>ingr-ipv6>entry>match icmp-code)

[Tree] (config>subscr-mgmt>cat-map>category>exh-lvl>egr-ip>entry>match icmp-code)

Full Context

configure subscriber-mgmt category-map category exhausted-credit-service-level ingress-ip-filter-entries entry match icmp-code

configure subscriber-mgmt category-map category exhausted-credit-service-level egress-ipv6-filter-entries entry match icmp-code

configure subscriber-mgmt category-map category exhausted-credit-service-level ingress-ipv6-filter-entries entry match icmp-code

configure subscriber-mgmt category-map category exhausted-credit-service-level egress-ip-filter-entries entry match icmp-code

Description

This command configures the ICMP code match condition.

The **no** form of this command reverts to the default.

Parameters

icmp-code

Specifies the ICMP code numbers accepted in DHB.

Values [0 to 255]D, [0X0..0XFF]H, [0b0..0b11111111]B

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

icmp-code

Syntax

icmp-code *icmp-code*

no icmp-code

Context

[Tree] (cfg>sys>sec>cpm>ipv6-filter>entry>match icmp-code)

[Tree] (cfg>sys>sec>cpm>ip-filter>entry>match icmp-code)

Full Context

configure system security cpm-filter ipv6-filter entry match icmp-code

configure system security cpm-filter ip-filter entry match icmp-code

Description

This command configures matching on ICMP code field in the ICMP header of an IP packet as an IP filter match criterion.

Note:
An entry containing Layer 4 match criteria will not match non-initial (2nd, 3rd, etc) fragments of a fragmented packet since only the first fragment contains the Layer 4 information.

The behavior of the **icmp-code** value is dependent on the configured **icmp-type** value, thus a configuration with only an **icmp-code** value specified will have no effect. To match on the **icmp-code**, an associated **icmp-type** must also be specified.

The **no** form of this command removes the criterion from the match entry.

Default

no icmp-code

Parameters

icmp-code

Specifies the ICMP code values that must be present to match.

Values 0 to 255

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

13.7 icmp-echo-reply

icmp-echo-reply

Syntax

[**no**] **icmp-echo-reply**

Context

[Tree] (config>service>vprn>nat>outside>pool icmp-echo-reply)

[Tree] (config>router>nat>outside>pool icmp-echo-reply)

Full Context

configure service vprn nat outside pool icmp-echo-reply

configure router nat outside pool icmp-echo-reply

Description

IPv4 addresses in a NAT pool can be configured to respond to ICMP Echo Requests (PINGs). The configuration can be toggled online while the pool is in use.

In L2-aware NAT when **port-block-extensions** is disabled, the reply from an outside IP address is generated only when this IP address has at least one host (binding) behind it.

In L2-aware NAT when **port-block-extensions** is enabled, the reply from an outside IP address is generated regardless if a binding is present.

In LSN, the reply from an outside IP address is generated regardless if a binding is present.

The **no** form of the command disables ICMP echo replies.

Default

no icmp-echo-reply

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

13.8 icmp-generation

icmp-generation

Syntax

icmp-generation

Context

[Tree] (config>service>vprn>if>sap>ip-tunnel icmp-generation)

[Tree] (config>ipsec>tunnel-template icmp-generation)

[Tree] (config>service>ies>if>sap>ip-tunnel icmp-generation)

[Tree] (config>router>if>ipsec>ipsec-tunnel icmp-generation)

[Tree] (config>service>vprn>if>sap>ipsec-tunnel icmp-generation)

Full Context

configure service vprn interface sap ip-tunnel icmp-generation

configure ipsec tunnel-template icmp-generation

configure service ies interface sap ip-tunnel icmp-generation

configure router interface ipsec ipsec-tunnel icmp-generation

configure service vprn interface sap ipsec-tunnel icmp-generation

Description

This command enables the context to configure ICMP generation information.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

- configure service vprn interface sap ipsec-tunnel icmp-generation
- configure service vprn interface sap ip-tunnel icmp-generation
- configure service ies interface sap ip-tunnel icmp-generation
- configure ipsec tunnel-template icmp-generation

VSR

- configure router interface ipsec ipsec-tunnel icmp-generation

13.9 icmp-ping

icmp-ping

Syntax

icmp-ping {*ip-address* | *dns-name*} [{**bypass-routing** | {**interface** *interface-name*} | {**next-hop** *ip-address*}}] [**count** *requests*] [**do-not-fragment**] [**fc** *fc-name*] [**interval** { *centisecs* | *secs*}] [**pattern**

pattern] [**rapid**] [{**router** *router-or-service* | **router-instance** *router-instance* | **service-name** *service-name*}] [**size** *bytes*] [**source** *ip-address*] [**timeout** *timeout*] [**tos** *type-of-service*] [**ttl** *time-to-live*]

Context

[Tree] (config>saa>test>type icmp-ping)

Full Context

configure saa test type icmp-ping

Description

This command configures an ICMP traceroute test.

Parameters

ip-address* | *dns-name

Specifies the far-end IP address or DNS name to which to send the **svc-ping** request message in dotted decimal notation.

Values

ipv4-address:	a.b.c.d	
ipv6-address:	x:x:x:x:x:x:x:x	
	x:x:x:x:x:x:d.d.d.d	
	x:	[0 to FFFF]H
	d:	[0 to 255]D
	interface	up to 32 characters. This is mandatory for link local addresses.
dns-name	up to 128 characters	

bypass-routing

Specifies whether to send the ping request to a host on a directly attached network bypassing the routing table.

interface-name

Specifies the name used to refer to the interface, up to 32 characters. The name must already exist in the **config>router>interface** context.

next-hop *ip-address*

Displays only static routes with the specified next-hop IP address.

Values

ipv4-address:	a.b.c.d (host bits must be 0)
ipv6-address:	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x: [0 to FFFF]H

d: [0 to 255]D

requests

Specifies the number of times to perform an OAM ping probe operation. Each OAM echo message request must either time out or receive a reply before the next message request is sent.

Values 1 to 100000

Default 5

do-not-fragment

Sets the DF (Do Not Fragment) bit in the ICMP ping packet (does not apply to ICMPv6).

fc-name

Specifies the forwarding class of the SAA.

Values be, l2, af, l1, h2, ef, h1, nc

Default nc

interval {*centisecs* | *secs*}

Specifies the minimum amount of time, in seconds, that must expire before the next message request is sent. If the **rapid** parameter is configured, this value is measured in centiseconds (hundredths of a second) instead of seconds.

Values 1 to 10000

Default 1

pattern

Specifies the date portion in a ping packet is filled with the pattern value specified. If not specified, a system-generated sequential pattern is used.

Values 0 to 65535

rapid

Configures the *interval* parameter to use centiseconds (hundredths of a second) instead of seconds.

router-or-service

Specifies the numerical reference to the router instance or service. Well known router names "Base", "management", "vpm-vr-name", and " vpls-management" are allowed for convenience, but are mapped numerically.

Values {*router-name* | *vprn-svc-id*}

router-name: Base, management, cmp-vr-name, vpls-management

vprn-svc-id: 1 to 2147483647

cpm-vr-name: Up to 32 characters

The parameter *router-instance* is preferred for specifying the router or service.

Default Base

router-instance

Specifies the preferred method for entering a service name. Stored as the service name. Only the service linking function is allowed for both mixed-mode and model-driven configuration modes.

Values *router-name*, *vprn-svc-name*

router-name: Base, management, vpls-management, *cpm-vr-name*

vprn-svc-name: up to 64 characters

cpm-vr-name: up to 32 characters

service-name

Specifies the alias function that allows the service name to be used, converted and stored as a service ID, up to 64 characters.

The *router-instance* parameter is preferred for specifying the router or service.

bytes

Specifies the request packet size in bytes, expressed as a decimal integer.

Values 0 to 16384

Default 56

source *ip-address*

Specifies the IP address to be used.

Values

ipv4-address:	a.b.c.d	
ipv6-address:	x:x:x:x:x:x:x:x	
	x:x:x:x:x:x:d.d.d.d	
	x:	[0 to FFFF]H
	d:	[0 to 255]D

timeout

Specifies the override time that the router waits for a message reply after sending the last probe for a specific test. Upon the expiration of the time out, the test is marked complete and no more packets are processed for any of those request probes.

Values 1 to 10

Default 5

type-of-service

Specifies the service type.

Values 0 to 255

Default 0

time-to-live

Specifies the TTL value for the MPLS label, expressed as a decimal integer.

Values 1 to 128

Default 64

Platforms

All

13.10 icmp-query

icmp-query

Syntax

icmp-query [**min** *minutes*] [**sec** *seconds*]

no icmp-query

Context

[Tree] (config>service>nat>nat-policy>timeouts icmp-query)

[Tree] (config>service>nat>up-nat-policy>timeouts icmp-query)

Full Context

configure service nat nat-policy timeouts icmp-query

configure service nat up-nat-policy timeouts icmp-query

Description

This command configures the timeout applied to an ICMP query session.

Default

icmp-query min 1

Parameters

min *minutes*

Specifies the timeout, in minutes, applied to an ICMP query session.

Values 1 to 4

Default 1

sec *seconds*

Specifies the timeout, in seconds, applied to an ICMP query session.

Values 1 to 59

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

13.11 icmp-trace

icmp-trace

Syntax

icmp-trace [*ip-address* | *dns-name*] [**router** *router-or-service* | **router-instance** *router-instance* | **service-name** *service-name*] [**source** *ip-address*] [**tos** *type-of-service*] [**ttl** *ttl*] [**wait** *milliseconds*]

Context

[Tree] (config>saa>test>type icmp-trace)

Full Context

configure saa test type icmp-trace

Description

This command configures an ICMP traceroute test.

Parameters

ip-address

Specifies the far-end IP address to which to send the **svc-ping** request message in dotted decimal notation.

Values

ipv4-address:	a.b.c.d	
ipv6-address:	x:x:x:x:x:x:x:x	
	x:x:x:x:x:x:d.d.d.d	
	x:	[0 to FFFF]H
	d:	[0 to 255]D
dns-name	up to 63 characters	

dns-name

Specifies the DNS name of the far-end device to which to send the **svc-ping** request message, up to 63 characters.

router-instance

Specifies the preferred method for entering a service name. Stored as the service name. Only the service linking function is allowed for both mixed-mode and model-driven configuration modes.

Values {*router-name* | *vprn-svc-name*}

router-name: Base, management, vpls-management, *cpm-vr-name*

vprn-svc-name: up to 64 characters

cpm-vr-name: up to 32 characters

Default Base

router-or-service

Specifies the numerical reference to the router instance or service. Well known router names "Base", "management" and " vpls-management" are allowed for convenience, but are mapped numerically.

Values {*router-name* | *vprn-svc-id*}

router-name: Base, management, vpls-management

vprn-svc-id: 1 to 2147483647

The parameter *router-instance* is preferred for specifying the router or service.

Default Base

service-name

Specifies the alias function that allows the service name to be used, converted and stored as service ID, up to 64 characters.

The parameter *router-instance* is preferred for specifying the router or service.

source *ip-address*

Specifies the IP address to be used.

Values

ipv4-address: a.b.c.d

ipv6-address: x:x:x:x:x:x:x:x

x:x:x:x:x:x:d.d.d.d

x: [0 to FFFF]H

d: [0 to 255]D

type-of-service

Specifies the service type.

Values 0 to 255

Default 0

ttl

Specifies the TTL value for the MPLS label, expressed as a decimal integer.

Values 1 to 255

Default 30

milliseconds

Specifies the time, in milliseconds, to wait for a response to a probe, expressed as a decimal integer.

Values 10 to 60000

Default 5000

Platforms

All

13.12 icmp-tunneling

icmp-tunneling

Syntax

[**no**] **icmp-tunneling**

Context

[Tree] (config>router icmp-tunneling)

Full Context

configure router icmp-tunneling

Description

This command enables the tunneling of ICMP reply packets over MPLS LSP at a LSR node as per RFC 3032.

The LSR part of this feature consists of crafting the reply ICMP packet of type=11- 'time exceeded', with a source address set to a local address of the LSR node, and appending the IP header and leading payload octets of the original datagram. The system skips the lookup of the source address of the sender of the label TTL expiry packet, which becomes the destination address of the ICMP reply packet. Instead, CPM injects the ICMP reply packet in the forward direction of the MPLS LSP the label TTL expiry packet was received from. The TTL of pushed labels should be set to 255.

The source address of the ICMP reply packet is determined as follows. The LSR uses the address of the outgoing interface for the MPLS LSP. With LDP LSP or BGP LSP multiple ECMP next-hops can exist and in such a case the first outgoing interface is selected. If that interface does not have an address of the same family (IPv4 or IPv6) as the ICMP packet, then the system address of the same family is selected. If one is not configured, the packet is dropped.

When the packet is received by the egress LER, it performs a regular user packet lookup in the data path in the GRT context for BGP shortcut, 6PE, and BGP label route prefixes, or in VPRN context for VPRN and 6VPE prefixes. It then forwards it to the destination, which is the sender of the original packet which TTL expired at the LSR.

If the egress LER does not have a route to the destination of the ICMP packet, it drops the packets.

The rate of the tunneled ICMP replies at the LSR can be directly or indirectly controlled by the existing IOM level and CPM levels mechanisms. Specifically, the rate of the incoming UDP traceroute packets received with a label stack can be controlled at ingress IOM using the distributed CPU protection feature. The rate of the ICMP replies by CPM can also be directly controlled by configuring a system wide rate limit for packets ICMP replies to MPLS expired packets which are successfully forwarded to CPM using the command 'configure system security vprn-network-exceptions'. While this command's name refers to VPRN service, this feature rate limits ICMP replies for packets received with any label stack, including VPRN and shortcuts.

The 7450 ESS, 7750 SR, and 7950 XRS implementation supports appending to the ICMP reply of type Time Exceeded the MPLS label stack object defined in RFC 4950. It does not include it in the ICMP reply type of Destination unreachable.

The new MPLS Label Stack object permits an LSR to include label stack information including label value, EXP, and TTL field values, from the encapsulation header of the packet that expired at the LSR node. The ICMP message continues to include the IP header and leading payload octets of the original datagram.

In order to include the MPLS Label Stack object, SR OS implementation adds support of RFC 4884 which defines extensions for a multi-part ICMPv4/v6 message of type Time Exceeded.

The **no** form of command disables the tunneling of ICMP reply packets over MPLS LSP at a LSR node.

Default

Full Context

configure filter ipv6-filter entry match icmp-type

configure filter ipv6-exception entry match icmp-type

configure filter ip-exception entry match icmp-type

configure filter ip-filter entry match icmp-type

Description

This command configures matching on the /ICMPv6 type field in the /ICMPv6 header of an IPv4 or IPv6 packet as a filter match criterion or configures matching on the ICMP type field in the ICMP header of an IPv4 packet as an exception filter match criterion. An entry containing Layer 4 non-zero match criteria will not match non-initial (2nd, 3rd, etc.) fragments of a fragmented packet since only the first fragment contains the Layer 4 information. Similarly an entry containing " **icmp-type** 0" match criterion, may match non-initial fragments when the Layer 4 header is not present in a packet fragment and other match criteria are also met.

The **no** form of the command removes the criterion from the match entry.

Default

no icmp-type

Parameters

icmp-type

Specifies the /ICMPv6 type value that must be present to match. Value can be expressed as a decimal integer, as well as in hexadecimal or binary format, or even using keywords. The following value shows decimal integer only.

Values 0 to 255

debug service id

Description

This command enables debugging for the specified service ID.

The **no** form of this command disables the debugging.

Parameters

service-id

The ID that uniquely identifies a service.

Values service-id: 1 to 214748364

svc-name: A string up to 64 characters in length

Platforms

All

13.18 id-permission

id-permission

Syntax

id-permission {**chassis**}

no id-permission

Context

[Tree] (cfg>eth-cfm>domain>assoc>bridge id-permission)

Full Context

configure eth-cfm domain association bridge-identifier id-permission

Description

This command allows the operator to include the sender-id TLV information that was specified under the **config>eth>system>sender-id** configuration for service MEPs and MIPs. When this option is present under the maintenance association, the specific MPs in the association includes the **sender-id** TLV information in ETH-CFM PDUs. MEPs include the **sender-id** TLV for CCM (not sub second CCM enabled MEPs), LBM/LBR, and LTM/LTR. MIPs includes this value in the LBR and LTR PDUs.

Note:
LBR functions reflect all TLVs received in the LBM unchanged including the SenderID TLV. Transmission of the Management Domain and Management Address fields are not supported in this TLV.

Parameters

chassis

Sends the configured chassis information defined under in the **eth-cfm>system>sender-id** context.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

id-permission

Syntax

id-permission {**chassis** | **defer**}

no id-permission

Context

[Tree] (config>eth-cfm>default-domain>bridge-identifier id-permission)

Full Context

configure eth-cfm default-domain bridge-identifier id-permission

Description

This command enables the inclusion of the Sender ID TLV information specified under the **config>eth>system>sender-id** command for installed MEPs and MIPs. The inclusion of the Sender ID TLV is based on the configured value. The Sender ID TLV is supported for ETH-CC, ETH-LB, and ETH-LB PDUs.

Note: LBR functions reflect back all TLVs received in the LBM, unchanged, including the Sender ID TLV. Transmission of the Management Domain and Management Address fields are not supported in this TLV.

The **no** form of this command disables the inclusion of the Sender ID TLV.

Default

id-permission defer (config>eth-cfm>default-domain>bridge-identifier)

no id-permission (config>eth-cfm>domain>association>bridge)

Parameters

chassis

Keyword to include the Sender ID TLV with a value equal to the *sender-id* configured under the eth-cfm>system context.

defer

Keyword to specify that **id-permission** will inherit the value from the global read-only system values.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

13.19 identification-strings

identification-strings

Syntax

identification-strings *option-number* [**create**]

no identification-strings

Context

[Tree] (config>subscr-mgmt>loc-user-db>ppp>host identification-strings)

[Tree] (config>subscr-mgmt>loc-user-db>ipoe>host identification-strings)

Full Context

configure subscriber-mgmt local-user-db ppp host identification-strings

configure subscriber-mgmt local-user-db ipoe host identification-strings

Description

This command specifies identification strings for the subscriber. This is useful when the server is centralized with Enhanced Subscriber Management (ESM) in a lower level in the network. These strings are parsed by a downstream Python script or they can be used literally if the **strings-from-option** option in the **config>subscr-mgmt>sub-ident-policy** context is set to this option number. In this case, the option number may be set to any allowed number (between 224 and 254 is suggested, as these are not dedicated to specific purposes). If the option number is not given, a default value of 254 is used. For PPPoE only, if the local user database is attached to the PPPoE node under the group interface and not to a local DHCP server, the strings are used internally so the option number is not used.

The **no** form of this command returns to the default.

Parameters

option-number

Specifies identification strings for the subscriber.

Values 1 to 254

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

13.20 identifier

identifier

Syntax

identifier *identifier*

no identifier

Context

[Tree] (config>system>bluetooth>module identifier)

Full Context

configure system bluetooth module identifier

Description

This command configures an identifier string used to advertise the Bluetooth module during pairing operations.

If no identifier is specified by the user, the default is derived from the platform type, the CPM slot, and the serial number of the chassis.

For example, a device with a platform field of 7750, SR-12 chassis, and a CPM serial number of NS23456 would have a Bluetooth identifier of "7750-SR-12-CPM-A-NS23456." for the CPM in slot A.

The **no** form of this command resets the identifier back to the default.

Parameters

identifier

Specifies string, up to 32 characters, using the values in the range 0-9, a-z, or A-Z.

Platforms

7750 SR-1, 7750 SR-s

13.21 idi

idi

no idi

Context

[Tree] (config>ipsec>client-db>client>client-id idi)

Full Context

configure ipsec client-db client client-identification idi

Description

This command specifies a match criteria that uses the peer's identification initiator (IDi) as the input, only one IDi criteria can be configured for a given client entry. This command supports the following matching methods:

- **idi any**: Matches any type of IDi with any value.
- **idi ipv4-prefix**: Matches an IDi with the type ID_IPV4_ADDR. If the **any** parameter is specified, then it will match any IPv4 address. If an IPv4 prefix is specified, then it will match an IPv4 address that is within the specified prefix.
- **idi ipv6-prefix**: Matches an IDi with the type ID_IPV6_ADDR. If the **any** parameter is specified, then it will match any IPv6 address. If an IPv6 prefix is specified, then it will match an IPv6 address that is within the specified prefix.
- **idi string-type**: Supports following type of IDi:
  - FQDN: Either a full match or a suffix match
  - RFC822: Either a full match or a suffix match

The **no** form of this command reverts to the default.

Default

no idi

Parameters

any

Matches any type of IDi with any value.

ipv4-prefix/ipv4-prefix-length

Matches any IPv4 address and prefix.

ipv6-prefix/ipv6-prefix-length

Matches any IPv6 address and prefix.

string-type

Matches the type of IDi value for this IPsec client entry.

Values fqdn, fqdn-suffix, rfc822, rfc822-suffix

string-value

Matches the IDi value within the client ID for this IPsec client entry up to 256 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

idi

Syntax

[**no**] **idi**

configure router l2tp group idle-timeout

configure service vprn l2tp group idle-timeout

configure router l2tp group tunnel idle-timeout

configure service vprn l2tp idle-timeout

configure service vprn l2tp group tunnel idle-timeout

Description

This command configures the period of time that an established tunnel with no active sessions persists before being disconnected.

Enter the **no** form of this command to maintain a persistent tunnel.

The **no** form of this command removes the idle timeout from the configuration.

Default

no idle-timeout

Parameters

idle-timeout

Specifies the idle timeout value, in seconds until the group is removed.

Default no idle-timeout

Values 0 to 3600

infinite

Specifies that the tunnel is not closed when idle.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

idle-timeout

Syntax

idle-timeout *timeout*

no idle-timeout

Context

[Tree] (config>subscr-mgmt>sla-prof>cat-map>category idle-timeout)

Full Context

configure subscriber-mgmt sla-profile category-map category idle-timeout

Description

This command defines the idle-timeout value.

The **no** form of this command reverts to the default.

Parameters

timeout

Specifies the idle-timeout, in seconds.

Values 60 to 15552000

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

idle-timeout

Syntax

idle-timeout action *idle-timeout-action*

no idle-timeout

Context

[Tree] (config>service>ies>sub-if>grp-if>wlan-gw>ranges>range idle-timeout)

[Tree] (config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range idle-timeout)

Full Context

configure service ies subscriber-interface group-interface wlan-gw vlan-tag-ranges range idle-timeout

configure service vprn subscriber-interface group-interface wlan-gw vlan-tag-ranges range idle-timeout

Description

This command specifies idle-timeout behavior for DSM UEs and UEs undergoing (ISA-based) portal authentication. This knob only specifies the desired action, idle-timeout is activated by RADIUS on a per-UE basis.

The **no** form of this command resets the idle-timeout to its default.

Default

idle-timeout action remove

Parameters

action

Specifies which action to perform when the idle-timeout timer goes off.

Values remove, shcv

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

idle-timeout

Syntax

idle-timeout {*minutes* | **disable**}

no idle-timeout

Context

[Tree] (config>system>login-control idle-timeout)

Full Context

configure system login-control idle-timeout

Description

This command configures the idle timeout for console, Telnet, SSH, and FTP sessions before the session is terminated by the system.

By default, each idle console, Telnet, SSH, or FTP session times out after 30 minutes of inactivity.

The **no** form of this command reverts to the default value.

Default

idle-timeout 30

Parameters

minutes

Specifies the idle timeout in minutes. Allowed values are 1 to 1440.

Values 1 to 1440

disable

When the **disable** option is specified, a session will never timeout. To re-enable idle timeout, enter the command without the disable option.

Platforms

All

13.28 idle-timeout-action

idle-timeout-action

Syntax

idle-timeout-action {**shcv-check** | **terminate**}

no idle-timeout-action

Context

[Tree] (config>subscr-mgmt>sla-prof>cat-map>category idle-timeout-action)

Full Context

configure subscriber-mgmt sla-profile category-map category idle-timeout-action

Description

This command defines the action to be executed when the idle-timeout is reached. The action is performed for all hosts associated with the sla-profile instance.

The **no** form of this command reverts to the default.

Default

idle-timeout-action terminate

Parameters

shcv-check

Performs a subscriber host connectivity verification check (IPoE hosts only).

Note:
Host connectivity verification must be enabled on the group-interface where the host is connected.

If the check is successful, the hosts are not disconnected and the idle-timeout timer is reset.

If the check fails, the hosts are deleted, similar as for **idle-timeout-action terminate**.

terminate

Deletes the subscriber host from the system: for PPP hosts, a terminate request is send; for IPoE hosts a DHCP release is send to the DHCP server.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

13.29 ies

ies

Syntax

ies *service-id* [**customer** *customer-id*] [**create**] [**vpn** *vpn-id*] [**name** *name*]

no ies *service-id*

Context

[Tree] (config>service ies)

Full Context

configure service ies

Description

This command creates or edits an IES service instance.

The **ies** command creates or maintains an Internet Ethernet Service (IES). If the *service-id* does not exist, a context for the service is created. If the *service-id* exists, the context for editing the service is entered.

IES services allow the creation of customer facing IP interfaces in the same routing instance used for service network core routing connectivity. IES services require that the IP addressing scheme used by the subscriber must be unique between it and other addressing schemes used by the provider and potentially the entire Internet.

IP interfaces defined within the context of an IES service ID must have a SAP created as the access point to the subscriber network. This allows a combination of bridging and IP routing for redundancy purposes.

When a service is created, the **customer** keyword and *customer-id* must be specified and associates the service with a customer. The *customer-id* must already exist having been created using the **customer**

command in the service context. Once a service has been created with a customer association, it is not possible to edit the customer association. The service must be deleted and recreated with a new customer association.

Once a service is created, the use of the **customer** *customer-id* is optional for navigating into the service configuration context. Attempting to edit a service with the incorrect *customer-id* specified results in an error.

Multiple IES services are created to separate customer owned IP interfaces. More than one IES service may be created for a single customer ID. More than one IP interface may be created within a single IES service ID. All IP interfaces created within an IES service ID belongs to the same customer.

By default, no IES service instances exist until they are explicitly created.

The **no** form of this command deletes the IES service instance with the specified *service-id*. The service cannot be deleted until all the IP interfaces defined within the service ID have been shut down and deleted.

Parameters

service-id

Specifies the unique service identification number identifying the service in the service domain. This ID must be unique to this service and may not be used for any other service of any type. The *service-id* must be the same number used for every router on which this service is defined.

Values *service-id*: 1 to 214748364

svc-name: A string up to 64 characters

customer-id

Specifies the customer ID number to be associated with the service. This parameter is required on service creation and optional for service editing or deleting.

Values 1 to 2147483647

vpn-id

Specifies the VPN ID number used to identify virtual private networks (VPNs) by a VPN identification number.

Values 1 to 2147483647

Default **null** (0)

create

Keyword used to create the service ID. The **create** keyword requirement can be enabled or disabled in the **environment>create** context.

name name

This parameter configures an optional service name, up to 64 characters, which adds a name identifier to a given service to then use that service name in configuration references as well as display and use service names in show commands throughout the system. This helps the service provider or administrator to identify and manage services within the SR OS platforms.

All services are required to assign a service ID to initially create a service. However, either the service ID or the service name can be used to identify and reference a given service once it is initially created.

If a name is not specified at creation time, then SR OS assigns a string version of the service-id as the name.

Service names may not begin with an integer (0 to 9).

Values *name*: up to 64 characters

Platforms

All

ies

Syntax

[**no**] **ies** *service-id* **interface** *ip-int-name*

[**no**] **ies** *service-id* **subscriber-interface** *ip-int-name* **group-interface** *ip-int-name*

Context

[Tree] (config>cflowd>collector>exp-filter>if-list>svc ies)

Full Context

configure cflowd collector export-filter interface-list service ies

Description

This command configures which IES service interfaces' flow data is being sent to this collector.

The **no** form of the command removes the values from the configuration.

Parameters

service-id

Specifies the unique service identification number or string identifying the service in the service domain. This ID must be unique to this service and may not be used for any other service of any type. The *service-id* must be the same number used for every SR OS on which this service is defined.

Values *service-id*: 1 to 2147483647

svc-name: 64 characters maximum

interface ip-int-name

Specifies the name of the IP interface. Interface names must be unique within the group of defined IP interfaces for **config router interface** and **config service ies interface** commands. An interface name cannot be in the form of an IP address. Interface names can be from 1 to 32 alphanumeric characters and must start with a letter. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

subscriber-interface ip-int-name

Specifies the interface name of a subscriber interface. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes and must start with a letter.

group-interface ip-int-name

Specifies the interface name of a group interface. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes and must start with a letter.

configure router interface if-attribute

Description

This command creates the context to configure or apply IP interface attributes such as administrative group (admin-group) or Shared Risk Loss Group (SRLG).

Platforms

All

13.32 if-num

if-num

Syntax

if-num *if-num*

no if-num

Context

[Tree] (config>router>mpls>if>mpls-tp-mep if-num)

Full Context

configure router mpls interface mpls-tp-mep if-num

Description

This command configures the MPLS-TP interface number for the MPLS interface. This is a 32-bit unsigned integer that is node-wide unique.

Parameters

if-num

Specifies a 32-bit value that is unique to the node.

Values 1 to 4294967295

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

13.33 if-num-validation

if-num-validation

Syntax

if-num-validation {**enable** | **disable**}

no if-num-validation

Context

[Tree] (config>router>mpls>if>mpls-tp-mep if-num-validation)

Full Context

configure router mpls interface mpls-tp-mep if-num-validation

Description

The if-num-validation command is used to enable or disable validation of the if-num in LSP Trace packet against the locally configured if-num for the interface over which the LSP Trace packet was received at the egress LER. This is because some third-party implementations may not perform interface validation for unnumbered MPLS-TP interfaces and instead set the if-num in the DSMAP TLV to 0. If the value is **enable**, the node performs the validation of the ingress and egress if-nums received in the LSP echo request messages that ingress on this MPLS-interface. It validates that the message arrives on the interface as identified by the ingress if-num, and is forwarded on the interface as identified by the egress if-num.

If the value is **disable**, no validation is performed for the ingress and egress if-nums received in the LSP echo request messages that ingress on this MPLS-interface.

Default

if-num-validation enable

Parameters

enable

Enables interface number validation.

disable

Disables interface number validation.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

ifdv-avg

Syntax

[**no**] **ifdv-avg** {**forward** | **backward** | **round-trip**}

Context

[Tree] (config>oam-pm>streaming>delay-template ifdv-avg)

Full Context

configure oam-pm streaming delay-template ifdv-avg

Description

This command specifies the sending of average inter-frame delay variation for a specified direction.

The **no** form of this command deletes the specified average direction.

Note:
All directions can be specified if all directions are important for reporting. However, only enable those directions that are required.

Parameters

forward

Specifies the measurement in the forward direction.

backward

Specifies the measurement in the backward direction.

round-trip

Specifies the measurement for the round trip.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

13.36 iff-attribute-uniform-propagation

iff-attribute-uniform-propagation

Syntax

[**no**] **iff-attribute-uniform-propagation**

Context

[Tree] (config>service>system>bgp-evpn>ip-prefix-routes iff-attribute-uniform-propagation)

Full Context

configure service system bgp-evpn ip-prefix-routes iff-attribute-uniform-propagation

Description

This command enables the uniform propagation of BGP attributes for EVPN Interface-ful (EVPN-IFF) routes. EVPN-IFF is used in R-VPLS services with **bgp-evpn**>**ip-route-advertisement**. When enabled, the received EVPN-IFF routes for the R-VPLS can be propagated with the original BGP path attributes into EVPN-IFL, IPVPN, EVPN-IFF (in other R-VPLS services), or BGP IP routes advertised for the attached VPRN. This command also enables the attribute propagation in the opposite direction; for example, from EVPN-IFL, IPVPN, IP, or EVPN-IFF routes into EVPN-IFF routes.

The propagation is in accordance with the uniform mode defined in *draft-ietf-bess-evpn-ipvpn-interworking*.

The **no** form of this command re-originates the BGP path attributes when propagating EVPN-IFF routes into other inter-subnet forwarding families.

Default

no iff-attribute-uniform-propagation

Platforms

All

13.37 iff-bgp-path-selection

iff-bgp-path-selection

Syntax

iff-bgp-path-selection [**d-path-length-ignore**]

no iff-bgp-path-selection

Context

[Tree] (config>service>system>bgp-evpn>ip-prefix-routes iff-bgp-path-selection)

Full Context

configure service system bgp-evpn ip-prefix-routes iff-bgp-path-selection

Description

This command enables BGP path selection for EVPN-IFF (Interface-ful) routes.

Once the command is enabled, the EVPN-IFF routes are ordered and selected in a similar manner as IPVPN or EVPN-IFL routes, that is, based on the regular BGP path selection process.

The **no** form of this command causes the system to order EVPN-IFF routes based on their {R-VPLS Ifindex, RD, Ethernet Tag}. For example, if two EVPN-IFF routes with different Route Distinguishers (RDs) are received for the same prefix on the same R-VPLS, the route with the lowest RD is selected.

Default

no iff-bgp-path-selection

Parameters

d-path-length-ignore

Keyword used to make EVPN ignore the D-PATH length when **iff-bgp-path-selection** is enabled.

The **no** form of this command disables IGMP.

Default

no igmp

Platforms

All

igmp

Syntax

[**no**] **igmp**

Context

[Tree] (config>router igmp)

Full Context

configure router igmp

Description

This command enables the Internet Group Management Protocol (IGMP) context. When the context is created, the IGMP protocol is enabled.

The Internet Group Management Protocol (IGMP) is used by IPv4 systems (hosts and routers) to report their IP multicast group memberships to neighboring multicast routers. An IP multicast router can be a member of one or more multicast groups, in which case it performs both the "multicast router part" of the protocol which collects the membership information needed by its multicast routing protocol, and the "group member part" of the protocol which informs itself and other neighboring multicast routers of its memberships.

The **no** form of the command disables the IGMP instance. To start or suspend execution of IGMP without affecting the configuration, use the **no shutdown** command.

Platforms

All

Syntax

igmp-policy *policy-name*

no igmp-policy

Context

[Tree] (config>subscr-mgmt>sub-prof igmp-policy)

Full Context

configure subscriber-mgmt sub-profile igmp-policy

Description

This command will enable IGMP processing per subscriber host. Without this command IGMP states will not be maintained per subscriber hosts. The referenced policy is defined under the **configure>subscr-mgmt** context and can be only applied via the sub-profile.

The referenced policy contains entries such as:

- description statement
- import statement — IGMP filters
- egress-rate-modify statement—HQoS Adjustment
- mcast-redirection statement—redirection to alternate interface
- static statement—definition of static IGMP groups
- version statement —IGMP version
- fast-leave statement
- max-num-groups statement—the maximum number of multicast groups allowed

The **no** form of this command reverts to the default.

Parameters

policy-name

Specifies the name of the IGMP policy for the subscriber. The policy itself is defined under the **configure>sub-mgmt** context.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

[Tree] (config>service>vprn>l2tp ignore-avps)

Full Context

configure router l2tp ignore-avps

configure service vprn l2tp ignore-avps

Description

This command specifies the L2TP AVPs that should be ignored in L2TP session control.

The **no** form of this command reverts to the default.

Parameters

sequencing-required

Ignores the [39] Sequencing Required AVP on LNS when present in the L2TP ICCN message received from LAC. By default, the session at LNS would be disconnected, in this case with the Call Disconnect Notify (CDN) error code unknownMandatoryReceive(8). Note that when configured, to ignore the Sequencing Required AVP there is no Sequence Numbers inserted into the data channel.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

[Tree] (config>router>if>ipv6>urpf-check ignore-default)

Full Context

configure router interface urpf-check ignore-default

configure router interface ipv6 urpf-check ignore-default

Description

This command configures the uRPF check (if enabled) to ignore default routes for purposes of determining the validity of incoming packets. By default, default routes are considered eligible.

Platforms

All

13.46 ignore-df-bit

ignore-df-bit

Syntax

[**no**] **ignore-df-bit**

Context

[Tree] (config>subscr-mgmt>loc-user-db>ppp>host ignore-df-bit)

Full Context

configure subscriber-mgmt local-user-db ppp host ignore-df-bit

Description

When this command is enabled for a subscriber host, the do-not-fragment (DF) bit in the IPv4 header for frames egressing the subscriber interface is ignored, the frames are fragmented according the applicable egress MTU. The DF bit is reset for frames that are fragmented.

This command applies to PPPoE PTA and L2TP LNS frames only. It is not applicable for L2TP LAC frames.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

ignore-df-bit

Syntax

[**no**] **ignore-df-bit**

Context

[Tree] (config>service>vprn>sub-if>grp-if ignore-df-bit)

[Tree] (config>service>ies>sub-if>grp-if ignore-df-bit)

Full Context

configure service vprn subscriber-interface group-interface ignore-df-bit

configure service ies subscriber-interface group-interface ignore-df-bit

Description

This command enables the **ignore-df-bit** flag that ignores the **do-not-fragment** (DF) bit for frames egressing the WLAN-GW group interface and fragments the frame according to the applicable egress MTU. The DF bit is reset for the frames that are fragmented.

The **no** form of this command causes the router to fragment a packet larger than the MTU if the DF bit is set to 0 and drops the packet if the DF bit is set to 1.

Default

no ignore-df-bit

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

13.47 ignore-dn-bit

ignore-dn-bit

Syntax

configure service vprn dhcp6 local-dhcp-server pool failover ignore-mclt-on-takeover

configure service vprn dhcp local-dhcp-server pool failover ignore-mclt-on-takeover

Description

With this flag enabled, the remote IP address or prefix can be taken over immediately upon entering the PARTNER-DOWN state of the intercommunication link, without having to wait for the Maximum Client Lead Time (MCLT) to expire. By setting this flag, the lease times of the existing DHCP clients, while the intercommunication link is in the PARTNER-DOWN state, will still be reduced to the MCLT over time and all new lease times are set to MCLT. This behavior remains the same as originally intended for MCLT.

Some deployments require that the remote IP address/prefix range starts delegating new IP addresses and prefixes upon the failure of the intercommunication link, without waiting for the intercommunication link to transition from the COMM-INT state into the PARTNER-DOWN state and the MCLT to expire while in PARTNER-DOWN state.

This can be achieved by enabling the **ignore-mclt-on-takeover** flag and by configuring the **partner-down-delay** to 0.

Enabling this functionality must be exercised with caution. One needs to keep in mind that the partner-down-delay and MCLT timers were originally introduced to prevent IP address duplication in cases where DHCP redundant nodes transition out-of-sync due to the failure of intercommunication link. These timers (**partner-down-delay** and MCLT) would ensure that during their duration, the new IP addresses and prefixes are delegated only from one node, the one with local IP address-range/prefix. This causes the new IP address delegation to be delayed and the service is impacted.

If it can be assured that the intercommunication link is always available, then the DHCP nodes would stay in sync and the two timers would not be needed. Therefore, it is important that in this mode of operation, the intercommunication link is well protected by providing multiple paths between the two DHCP nodes. The only event that should cause intercommunication link to fail is the entire nodal failure. This failure is acceptable since in this case only one DHCP node is available to provide new IP addresses and prefixes.

The **no** form of this command reverts to the default.

Full Context

configure service vprn ignore-nh-metric

configure service vprn bgp best-path-selection ignore-nh-metric

configure router bgp best-path-selection ignore-nh-metric

Description

This command instructs BGP to disregard the resolved distance to the BGP next-hop in its decision process for selecting the best route to a destination. When configured in the config>router>bgp>best-path-selection context, this command applies to the comparison of two BGP routes with the same NLRI learned from base router BGP peers. When configured in the config>service>vprn context, this command applies to the comparison of two BGP-VPN routes for the same IP prefix imported into the VPRN from the base router BGP instance. When configured in the config>service>vprn>bgp>best-path-selection context, this command applies to the comparison of two BGP routes for the same IP prefix learned from VPRN BGP peers.

The **no** form of this command (no ignore-nh-metric) restores the default behavior whereby BGP factors distance to the next-hop into its decision process.

Default

no ignore-nh-metric

Platforms

Context

[Tree] (config>router>bgp>srv6>family ignore-received-srv6-tlvs)

Full Context

configure router bgp segment-routing-v6 family ignore-received-srv6-tlvs

Description

This command specifies that SRv6 TLVs are ignored when present in received routes of the associated family. In this case the route resolution is only based on the BGP next hop.

The **no** form of this command specifies that the SRv6 TLV is processed when a route of the family is received with a prefix SID attribute carrying an SRv6 TLV. In this case, a route is resolved only if both its BGP next hop and the locator prefix are reachable. The datapath programming and IGP cost to reach the next hop (used by the BGP decision process) is based on the route to the locator prefix.

Default

ignore-received-srv6-tlvs

Platforms

7450 ESS, 7750 SR, 7750 SR-s, 7950 XRS, VSR

13.59 ignore-router-id

ignore-router-id

ignore-router-id include-internal *family* [*family*]

[**no**] **ignore-router-id**

Context

[Tree] (config>router>bgp>best-path-selection ignore-router-id)

[Tree] (config>service>vprn>bgp>best-path-selection ignore-router-id)

Full Context

configure router bgp best-path-selection ignore-router-id

configure service vprn bgp best-path-selection ignore-router-id

Description

When the **ignore-router-id** command is present, and the current best path to a destination was learned from EBGP peer X with BGP identifier x and a new path is received from EBGP peer Y with BGP identifier y, the best path remains unchanged if the new path is equivalent to the current best path up to the BGP identifier comparison – even if y is less than x.

The **no** form of this command restores the default behavior of selecting the route with the lowest BGP identifier (y) as best.

Default

no ignore-router-id

Parameters

family

Specifies up to two internal families to be included in this configuration.

Values mvpn-ipv4, mvpn-ipv6

include-internal

Specifies to ignore the router ID value even when comparing two IGBP paths or an EBGP and an IBGP path.

[Tree] (config>router>mpls>lsp igp-shortcut)

Full Context

configure router mpls lsp-template igp-shortcut

configure router mpls lsp igp-shortcut

Description

This command enables the use of a specific RSVP LSP by IS-IS and OSPF routing protocols as a shortcut or as a forwarding adjacency for resolving IGP routes.

When the **igp-shortcut** or the **advertise-tunnel-link** option is enabled at the IGP instance level, all RSVP LSPs originating on this node are eligible by default as long as the destination address of the LSP, as configured in **config>router>mpls>lsp>to**, corresponds to a router-id of a remote node.

The **lfa-protect** option allows an LSP to be included in both the main SPF and the Loop-Free Alternate (LFA) SPF. For a given prefix, the LSP can be used either as a primary next-hop or as an LFA next-hop, but not both. If the main SPF computation selected a tunneled primary next-hop for a prefix, the LFA SPF will not select an LFA next-hop for this prefix and the protection of this prefix will rely on the RSVP LSP FRR protection. If the main SPF computation selected a direct primary next-hop, then the LFA SPF will select an LFA next-hop for this prefix but will prefer a direct LFA next-hop over a tunneled LFA next-hop.

The **lfa-only** option allows an LSP to be included in the LFA SPF only such that the introduction of IGP shortcuts does not impact the main SPF decision. For a given prefix, the main SPF always selects a direct primary next-hop. The LFA SPF selects an LFA next-hop for this prefix but will prefer a direct LFA next-hop over a tunneled LFA next-hop.

When the **relative-metric** option is enabled, IGP will apply the shortest IGP cost between the endpoints of the LSP plus the value of the offset (instead of the LSP operational metric) when computing the cost of a prefix which is resolved to the LSP. The offset value is optional and it defaults to zero. The minimum net cost for a prefix is one (1) after applying the offset. The TTM continues the show the LSP operational metric as provided by MPLS. In other words, applications such as LDP-over-RSVP (when IGP shortcut is disabled) and BGP and static route shortcuts will continue to use the LSP operational metric.

The **relative-metric** option is mutually exclusive with the **lfa-protect** or the **lfa-only** options. In other words, an LSP with the **relative-metric** option enabled cannot be included in the LFA SPF, and vice-versa, when the **igp-shortcut** option is enabled in the IGP.

Finally, the **relative-metric** option is ignored when forwarding adjacency is enabled in IS-IS or OSPF. In this case, IGP advertises the LSP as a point-to-point unnumbered link along with the LSP operational metric as returned by MPLS and capped to maximum link metric allowed in that IGP. Both the main SPF and the LFA SPFs will use the local IGP database to resolve the routes.

When the router performs local SPF, the SR-TE LSP is used as an eligible IGP shortcut for SRv4 or SRv6 only if the LSP is explicitly allowed using the **allow-sr-over-srte** option when the top SID in the SR-TE LSP is an adjacency SID.

The **no** form of this command disables the use of a specific RSVP LSP by IS-IS and OSPF routing protocols as a shortcut or a forwarding adjacency for resolving IGP routes.

Default

igp-shortcut. All RSVP LSPs originating on this node are eligible by default as long as the destination address of the LSP corresponds to a router-id of a remote node.

Parameters

lfa-protect

Specifies an LSP is included in both the main SPF and the LFA SPF.

lfa-only

Specifies an LSP is included in the LFA SPF only.

relative-metric [*offset*]

Specifies the shortest IGP cost between the endpoints of the LSP plus the configured offset, instead of the LSP operational metric returned by MPLS, is used when calculating the cost of prefix resolved to this LSP. The offset parameter is an integer and is optional. An offset value of zero is used when the relative-metric option is enabled without specifying the offset parameter value.

Values [-10, +10]

allow-sr-over-srte

Specifies that the LSP or LSP template is eligible as an IGP shortcut.

Platforms

All

igp-shortcut

Syntax

igp-shortcut

Context

[Tree] (config>router>isis igp-shortcut)

Full Context

configure router isis igp-shortcut

Description

This command enables the use of an RSVP-TE or SR-TE shortcut for resolving IGP routes by OSPF or IS-IS routing protocols.

This command instructs IGP to include RSVP LSPs and SR-TE LSPs originating on this node and terminating on the router ID of a remote node as direct links with a metric equal to the metric provided by MPLS.

During the IP reach calculation to determine the reachability of nodes and prefixes, LSPs are overlaid and the LSP metric is used to determine the subset of paths that are equal lowest cost to reach a node or a prefix. If the user enabled the **relative-metric** option for this LSP, IGP will apply the shortest IGP cost

between the endpoints of the LSP plus the value of the offset, instead of the LSP operational metric, when computing the cost of a prefix that is resolved to the LSP.

When a prefix is resolved to a tunnel next-hop, the packet is sent labeled with the label stack corresponding to the NHLFE of the RSVP-TE or SR-TE LSP, as well as the explicit-null IPv6 label at the bottom of the stack in the case of an IPv6 prefix. Any network event causing one or more IGP shortcuts to go down will trigger a full SPF computation, which may result in installing a new route over an updated set of tunnel next-hops and IP next-hops.

When **igp-shortcut** is enabled at the IGP instance level, all RSVP-TE and SR-TE LSPs originating on this node are eligible by default as long as the destination address of the LSP, as configured in **config>router>mpls>lsp>to**, corresponds to a router ID of a remote node. LSPs with a destination corresponding to an interface address or any other loopback interface address of a remote node are automatically not considered by IGP. The user can, however, exclude a specific RSVP-TE or SR-TE LSP from being used as a shortcut for resolving IGP routes by entering the **config>router>mpls>lsp>no igp-shortcut** command.

The SPF in IGP only uses RSVP LSPs as forwarding adjacencies, IGP shortcuts, or as endpoints for LDP-over-RSVP. These applications of RSVP LSPs are mutually exclusive at the IGP instance level. If two or more options are enabled in the same IGP instance, then forwarding adjacency takes precedence over the shortcut application, which takes precedence over the LDP-over-RSVP application.

The SPF in IGP uses SR-TE LSPs as IGP shortcuts only.

When ECMP is enabled on the system and multiple equal-cost paths exist for a prefix, the following selection criteria are used to pick up the set of tunnel and IP next-hops to program in the data path.

- Where a destination is a tunnel-endpoint (including external prefixes with tunnel-endpoint as the next-hop), the tunnel with lowest tunnel-index is selected (the IP next-hop is never used in this case).
- Where a destination is not a tunnel-endpoint:
  - LSPs with metric higher than underlying IGP cost between the endpoint of the LSP are excluded
  - Tunnel next-hops are preferred over IP next-hops
  - Within tunnel next-hops, the following priority applies to selection:
    1. The lowest endpoint-to-destination cost is selected
    2. If the endpoint-to-destination costs are the same, the lowest endpoint node router ID is selected
    3. If the router IDs are the same, the lowest tunnel index is selected
  - Within IP next-hops, the following priority applies to selection:
    1. The lowest downstream router ID is selected
    2. If the downstream router IDs are the same, the lowest interface-index is selected

Note:
Although ECMP is not performed across both the IP and tunnel next-hops, the tunnel endpoint may lie in one of the shortest IGP paths for that prefix. In that case, the tunnel next-hop is always selected as long as the prefix cost using the tunnel is equal to or lower than the IGP cost.

When both RSVP-TE and SR-TE IGP shortcuts are available, the IP reach calculation, in the unicast routing table, will first follow the above ECMP tunnel and IP next-hop selection rules when resolving a prefix over IGP shortcuts. After the set of ECMP tunnel and IP next-hops have been selected, the preference of tunnel type is then applied based on the user setting for prefix family resolution. If the user enabled resolution of the prefix family to both RSVP-TE and SR-TE tunnel types, the TTM tunnel

preference value is used to select one type for the prefix. In other words, an RSVP-TE LSP type is preferred to an SR-TE LSP type on a per-prefix basis.

The ingress IOM sprays the packets for this prefix over the set of tunnel next-hops and IP next-hops based on the hashing routine currently supported for IPv4 packets.

This feature provides IGP with the capability to populate the multicast RTM with the prefix IP next-hop when both the **igp-shortcut** and the **multicast-import** options are enabled in IGP. The unicast RTM can still use the tunnel next-hop for the same prefix. The SPF keeps track of both the direct first hop and the tunneled first hop of a node, which is added to the Dijkstra tree.

Description

This command enables the use of an RSVP-TE or SR-TE shortcut for resolving IGP routes by OSPF or IS-IS routing protocols.

This command instructs IGP to include RSVP LSPs and SR-TE LSPs originating on this node and terminating on the router ID of a remote node as direct links with a metric equal to the metric provided by MPLS.

During the IP reach calculation to determine the reachability of nodes and prefixes, LSPs are overlaid and the LSP metric is used to determine the subset of paths that are equal lowest cost to reach a node or a prefix. If the user enabled the **relative-metric** option for this LSP, IGP will apply the shortest IGP cost between the endpoints of the LSP plus the value of the offset, instead of the LSP operational metric, when computing the cost of a prefix that is resolved to the LSP.

When a prefix is resolved to a tunnel next hop, the packet is sent labeled with the label stack corresponding to the NHLFE of the RSVP-TE or SR-TE LSP, as well as the explicit-null IPv6 label at the bottom of the stack in the case of an IPv6 prefix. Any network event causing one or more IGP shortcuts to go down will trigger a full SPF computation, which may result in installing a new route over an updated set of tunnel next-hops and IP next-hops.

When **igp-shortcut** is enabled at the IGP instance level, all RSVP-TE and SR-TE LSPs originating on this node are eligible by default as long as the destination address of the LSP, as configured in **config>router>mpls>lsp>to**, corresponds to a router ID of a remote node. LSPs with a destination

corresponding to an interface address or any other loopback interface address of a remote node are automatically not considered by IGP. The user can, however, exclude a specific RSVP-TE or SR-TE LSP from being used as a shortcut for resolving IGP routes by entering the **config>router>mpls>lsp>no igp-shortcut** command.

The SPF in IGP only uses RSVP LSPs as forwarding adjacencies, IGP shortcuts, or as endpoints for LDP-over-RSVP. These applications of RSVP LSPs are mutually exclusive at the IGP instance level. If two or more options are enabled in the same IGP instance, then forwarding adjacency takes precedence over the shortcut application, which takes precedence over the LDP-over-RSVP application.

The SPF in IGP uses SR-TE LSPs as IGP shortcuts only.

When ECMP is enabled on the system and multiple equal-cost paths exist for a prefix, the following selection criteria are used to pick up the set of tunnel and IP next-hops to program in the data path.

- Where a destination is a tunnel-endpoint (including external prefixes with tunnel-endpoint as the next hop), the tunnel with lowest tunnel-index is selected (the IP next hop is never used in this case).
- Where a destination is not a tunnel-endpoint:
  - LSPs with metric higher than underlying IGP cost between the endpoint of the LSP are excluded
  - Tunnel next-hops are preferred over IP next-hops
  - Within tunnel next-hops:
    1. The lowest endpoint-to-destination cost is selected
    2. If the endpoint-to-destination costs are the same, the lowest endpoint node router ID is selected
    3. If the router IDs are the same, the lowest tunnel index is selected
  - Within IP next-hops:
    1. The lowest downstream router ID is selected
    2. If the downstream router IDs are the same, the lowest interface-index is selected

Note:
Although ECMP is not performed across both the IP and tunnel next-hops, the tunnel endpoint may lie in one of the shortest IGP paths for that prefix. In that case, the tunnel next hop is always selected as long as the prefix cost using the tunnel is equal or lower than the IGP cost.

When both RSVP-TE and SR-TE IGP shortcuts are available, the IP reach calculation, in the unicast routing table, will first follow the above ECMP tunnel and IP next hop selection rules when resolving a prefix over IGP shortcuts. After the set of ECMP tunnel and IP next-hops have been selected, the preference of tunnel type is then applied based on the user setting of the resolution of the family of the prefix. If the user enabled resolution of the prefix family to both RSVP-TE and SR-TE tunnel types, the TTM tunnel preference value is used to select one type for the prefix. In other words, the RSVP-TE LSP type is preferred to an SR-TE LSP type on a per-prefix basis.

The ingress IOM sprays the packets for this prefix over the set of tunnel next-hops and IP next-hops based on the hashing routine currently supported for IPv4 packets.

This feature provides IGP with the capability to populate the multicast RTM with the prefix IP next hop when both the **igp-shortcut** and the **multicast-import** options are enabled in IGP. The unicast RTM can still make use of the tunnel next hop for the same prefix. This change is made possible with the enhancement by which SPF keeps track of both the direct first hop and the tunneled first hop of a node which is added to the Dijkstra tree.

Full Context

configure ipsec ike-transform ike-auth-algorithm

Description

This command specifies the IKE authentication algorithm for the IKE transform

Default

ike-auth-algorithm sha1

Parameters

auth-algorithm

Specifies the values used to identify the hashing algorithm

Values **md5** — Configures the use of the hmac-md5 algorithm for authentication

sha1 — Configures the use of the hmac-sha1 algorithm for authentication

sha256 — Configures the use of the hmac-sha256 algorithm for authentication.

sha384 — Configures the use of the hmac-sha384 algorithm for authentication

sha512 — Configures the use of the hmac-sha512 algorithm for authentication.

aes-xcbc — Configures the use of aes-xcbc (RFC 3566, *The AES-XCBC-MAC-96 Algorithm and Its Use With IPsec*) algorithm for authentication.

ike-encryption-algorithm

Syntax

ike-encryption-algorithm {**des** | **3des** | **aes128** | **aes192** | **aes256** | **aes128-gcm8** | **aes128-gcm16** | **aes256-gcm8** | **aes256-gcm16**}

Context

[Tree] (config>ipsec>ike-transform ike-encryption-algorithm)

Full Context

configure ipsec ike-transform ike-encryption-algorithm

Description

This command specifies the IKE encryption algorithm to be used in the IKE transform instance.

Default

ike-encryption-algorithm aes128

Parameters

encryption-algorithm

Specifies the IKE encryption algorithm.

Values **des** — Configures the 56-bit des algorithm for encryption. This is an older algorithm with relatively weak security. While better than nothing, it should only be used where a strong algorithm is not available on both ends at an acceptable performance level.

3des — Configures the 3-des algorithm for encryption. This is a modified application of the des algorithm which uses multiple des operations to make information more secure.

aes128 — Configures the aes algorithm with a block size of 128 bits. This is a mandatory implementation size for aes. This is a very strong algorithm choice.

aes192 — Configures the aes algorithm with a block size of 192 bits. This is a stronger version of aes.

aes256 — Configures the aes algorithm with a block size of 256 bits. This is the strongest available version of aes.

aes128-gcm8 - Configures ESP to use aes-gcm with a 128-bit key size and an 8-byte ICV for encryption and authentication.

aes128-gcm16 - Configures ESP to use aes-gcm with a 128-bit key size and a 16-byte ICV for encryption and authentication.

aes256-gcm8 - Configures ESP to use aes-gcm with a 256-bit key size and an 8-byte ICV for encryption and authentication.

aes256-gcm16 - This parameter configures ESP to use aes-gcm with a 256-bit key size and a 16-byte ICV for encryption and authentication.

ike-mode

Syntax

ike-mode {**main** | **aggressive**}

no ike-mode

Context

[Tree] (config>ipsec>ike-policy ike-mode)

Full Context

configure ipsec ike-policy ike-mode

Description

This command specifies one of either two modes of operation. IKE version 1 can support main mode and aggressive mode. The difference lies in the number of messages used to establish the session.

The **no** form of this command reverts to the default.

Default

no ike-mode

Parameters

main

Specifies identity protection for the hosts initiating the IPsec session. This mode takes slightly longer to complete.

aggressive

Specifies that the aggressive mode provides no identity protection but is faster.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

Full Context

configure ipsec ike-transform ike-prf-algorithm

Description

This command specifies the PRF algorithm to use for IKE security association.

Note:
If an authenticated encryption algorithm like AES-GCM is used for IKE encryption algorithm, **same-as-auth** cannot be used for **ike-prf-algorithm**.

Default

ike-prf-algorithm same-as-auth

Parameters

md5

This parameter configures IKE to use the **hmac-md5** algorithm for PRF.

sha1

This parameter configures IKE to use the **hmac-sha1** algorithm for PRF.

sha256

This parameter configures IKE to use the **hmac-sha256** algorithm for PRF.

sha384

This parameter configures IKE to use the **hmac-sha384** algorithm for PRF.

sha512

This parameter configures IKE to use the **hmac-sha512** algorithm for PRF.

aes-xcbc

This parameter configures IKE to use the **aes128-xcbc** algorithm for PRF.

same-as-auth

This parameter configures the same algorithm as IKE authentication algorithm.

13.75 implicit-generation

implicit-generation

Syntax

[**no**] **implicit-generation**

Context

[Tree] (config>subscr-mgmt>auto-sub-id-key implicit-generation)

Full Context

configure subscriber-mgmt auto-sub-id-key implicit-generation

Description

By default, the system automatically generates a subscriber identifier, using the characters A to Z and 0 to 9, that is used when a subscriber ID is not provided during the authentication of a subscriber host or session and when no explicit default **def-sub-id** is configured at the SAP or in the MSAP policy.

A subscriber ID obtained from authentication sources can conflict with the format of an implicit, automatically generated subscriber ID. When this happens, the subscriber host or session setup fails and generates the following message: "Non auto-generated sub-id 4574233754 with an auto sub-id format not allowed". Therefore, when implicit subscriber ID generation is enabled (the default behavior), a 10-character string containing characters A to Z and 0 to 9 should not be returned from authentication sources.

The **no** form of this command disables the implicit automatic generation of subscriber IDs. When a subscriber ID is not provided in authentication and no explicit **def-sub-id** is configured, then the host or session setup fails and generates the following message: "Missing subscriber id". A 10-character (A to Z and 0 to 9) subscriber ID format can be returned from authentication sources without the risk of conflicts.

Disabling the implicit automatic generation of subscriber IDs fail when there are active subscribers with an implicit automatically generated subscriber ID.

Enabling the implicit automatic generation of subscriber IDs fails when there are active subscribers.

Default

implicit-generation

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

configure router ldp implicit-null-label

Description

This command enables the use of the implicit null label. Use this command to signal the implicit null option for all LDP FECs for which this node is the egress LER.

The **no** form of this command disables the signaling of the implicit null label.

Default

no implicit-null-label

Platforms

All

implicit-null-label

Syntax

[**no**] **implicit-null-label**

Context

[Tree] (config>router>rsvp implicit-null-label)

Full Context

configure router rsvp implicit-null-label

Description

This command enables the use of the implicit null label.

Signaling the IMPLICIT NULL label value for all RSVP LSPs can be enabled for which this node is the egress LER. RSVP must be shut down before being able to change this configuration option.

The egress LER does not signal the implicit null label value on P2MP RSVP LSPs. However, the Penultimate Hop Popping (PHP) node can honor a Resv message with the label value set to the implicit null.

The **no** form of this command disables the signaling of the implicit null label.

Default

no implicit-null-label

Platforms

All

implicit-null-label

Syntax

implicit-null-label [**enable** | **disable**]

no implicit-null-label

Context

[Tree] (config>router>rsvp>interface implicit-null-label)

Full Context

configure router rsvp interface implicit-null-label

Description

This command enables the use of the implicit null label over a specific RSVP interface.

All LSPs for which this node is the egress LER and for which the path message is received from the previous hop node over this RSVP interface will signal the implicit null label. This means that if the egress LER is also the merge-point (MP) node, then the incoming interface for the path refresh message over the bypass dictates if the packet will use the implicit null label or not. The same for a 1-to-1 detour LSP.

The user must shut down the RSVP interface before being able to change the implicit null configuration option.

The **no** form of this command returns the RSVP interface to use the RSVP level configuration value.

Default

no implicit-null-label

Parameters

enable

Enables the implicit null label.

disable

Disables the implicit null label.

Full Context

configure subscriber-mgmt local-user-db ipoe host mld-parameters import

configure subscriber-mgmt local-user-db ppp host mld-parameters import

Description

This command configures an MLD import policy.

The LUDB allows a list of up to 14 MLD import policies per host. The MLD policy also allows the configuration of an additional import policy, providing a total of 15 MLD import policies per host. The import policy inside the MLD policy is always applied last, which determines if the list is a black list or a white list. To configure an MLD white list, the import policies in the LUDB should all be allowed or forward entries and the import policy in the MLD policy should have a default action to deny all. To configure a black list, the import policies inside the LUDB should drop entries and the MLD policy import policy default action should be to forward all. The 15 import policies can be configured to be a mixed white and black list. Since it is difficult to control the order of the import policies within the LUDB, it is recommended to provision the import policy inside the MLD policy first for deterministic behavior.

The **no** form of this command removes the specified import policy.

Parameters

policy-name

Specifies the MLD import policy, up to 32 characters, used to control the multicast group accessible for the subscriber host.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

Description

This command specifies the import routing policy to be used for IGMP packets to be used on this SAP or SDP. Only a single policy can be imported on a SAP at any time.

The **no** form of this command removes the policy association from the SAP or SDP.

Default

no import

Parameters

policy-name

Specifies the routing policy name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters excluding double quotes. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes. Routing policies are configured in the **config>router>policy-options** context The router policy must be defined before it can be imported.

Context

[Tree] (config>subscr-mgmt>bgp-prng-plcy import)

Full Context

configure subscriber-mgmt bgp-peering-policy import

Description

This command specifies the import policies to be used to control routes advertised to BGP neighbors. Route policies are configured in the **config>router>policy-options** context. When multiple policy names are specified, the policies are evaluated in the order they are specified. The first policy that matches is applied.

The **no** form of this command removes all route policy names from the import list.

Default

no import — BGP accepts all routes from configured BGP neighbors. Import policies can be used to limit or modify the routes accepted and their corresponding parameters and metrics.

Parameters

policy

Specifies route policy statement name, up to 32 characters. Up to five policies can be specified.

configure service vprn bgp import

Description

This command is used to specify route policies that control the handling of inbound routes received from certain peers. Route policies are configured in the **config>router>policy-options** context.

This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in a peer-group) or neighbor level (only applies to the specified peer). The most specific level is used

The **import** command can reference up to 15 objects, where each object is either a policy logical expression or the name of a single policy. The objects are evaluated in the specified order to determine the modifications of each route and the final action to accept or reject the route.

Only one of the 15 objects referenced by the **import** command can be a policy logical expression consisting of policy names (enclosed in square brackets) and logical operators (AND, OR, NOT). The first of the 15 objects has a maximum length of 255 characters while the remaining 14 objects have a maximum length of 64 characters each.

When multiple **import** commands are issued, the last command entered overrides the previous command.

When an import policy is not specified, BGP routes are accepted by default.

The **no** form of this command removes the policy association.

Default

no import

Parameters

plcy-or-long-expr

Specifies the route policy name (up to 64 characters) or a policy logical expression (up to 255 characters).

plcy-or-expr

Specifies the route policy name (up to 64 characters) or a policy logical expression (up to 255 characters).

configure service vprn isis import

Description

This command applies one or more (up to five) route polices as IS-IS import policies.

When a prefix received in an IS-IS LSP is accepted by an entry in an IS-IS import policy, it is installed in the routing table, if it is the most preferred route to the destination.

When a prefix received in an IS-IS LSP is rejected by an entry in an IS-IS import policy, it is not installed in the routing table, even if it has the lowest preference value among all the routes to that destination.

The flooding of LSPs is unaffected by IS-IS import policy actions.

The **no** form of this command removes all policies from the configuration.

Default

no import

Parameters

policy-name

Identifies the export route policy name. Allowed values are any string up to 32 characters, composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed between double quotes. The specified name(s) must already be defined.

configure service vprn pim import

Description

This command specifies the import route policy to be used for determining which routes are accepted from peers. Route policies are configured in the **config>router>policy-options** context. When an import policy is not specified, BGP routes are accepted by default.

The **no** form of this command removes the policy association from the IGMP instance.

Default

no import join-policy

no import register-policy

Parameters

join-policy

Use this command to filter PIM join messages which prevents unwanted multicast streams from traversing the network.

register-policy

This keyword filters register messages. PIM register filters prevent register messages from being processed by the RP. This filter can only be defined on an RP. When a match is found, the RP immediately sends back a register-stop message.

policy-name

Specifies the route policy name. Allowed values are any string up to 32 characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed between double quotes. Route policies are configured in the **config>router>policy-options** context.

import

Syntax

import {**join-policy** | **register-policy**} [*policy-name* [*policy-name*]]

no import {**join-policy** | **register-policy**}

Context

[Tree] (config>router>pim import)

Full Context

configure router pim import

Description

This command specifies the import route policy to be used. Route policies are configured in the **config>router>policy-options** context.

When an import policy is not specified, BGP routes are accepted by default. Up to five import policy names can be specified.

The **no** form of this command removes the policy association from the instance.

Default

no import

Parameters

join-policy

Filters PIM join messages which prevents unwanted multicast streams from traversing the network.

register-policy

Filters register messages. PIM register filters prevent register messages from being processed by the RP. This filter can only be defined on an RP. When a match is found, the RP immediately sends back a register-stop message.

policy-name

Specifies the route policy name, up to 32 characters. Route policies are configured in the **config>router>policy-options** context.

Platforms

All

import

Syntax

import *policy-name*

no import

Context

[Tree] (config>service>pw-template>igmp-snooping import)

Full Context

configure service pw-template igmp-snooping import

Description

This command specifies the import routing policy to be used for IGMP packets. Only a single policy can be imported at a time.

The **no** form of the command removes the policy association.

Default

no import

Parameters

policy-name

Specifies the import policy name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes. Routing policies are configured in the config>router>policy-options context The router policy must be defined before it can be imported.

Platforms

import

Syntax

import type {**cert** | **key** | **crl**} **input** *url-string* **output** *filename* **format** *input-format* [**password** [*32 chars max*]]

Context

[Tree] (admin>certificate import)

Full Context

admin certificate import

Description

This command converts an input file (key/certificate/CRL) to a system format file. The following list summarizes the formats supported by this command:

- Certificate
  - PKCS #12
  - PKCS #7 PEM encoded

  - PKCS #7 DER encoded
  - PEM
  - DER
- Key
  - PKCS #12
  - PEM
  - DER
- CRL
  - PKCS #7 PEM encoded
  - PKCS #7 DER encoded
  - PEM
  - DER

Note:
If there are multiple objects with the same type in the input file, only the first object is extracted and converted.

Parameters

input *url-string*

Specifies the URL for the input file. This URL could be either a local CF card URL file or a FP URL to download the input file.

Values		
	url-string	<local-url> up to 99 characters
	local-url	<cflash-id>/<file-path>
	cflash-id	cf1:| cf2:| cf3:

output *filename*

Specifies the name of output file up to 95 characters. The output directory depends on the file type like following:

- Key: cf3:\system-pki\key
- Cert: cf3:\system-pki\cert
- CRL: cf3:\system-pki\CRL

type

The type of input file.

Values cert, key, crl

format

Specifies the format of input file.

Values pkcs12, pkcs7-der, pkcs7-pem, pem, der

password

Specifies the password to decrypt the input file in case that it is an encrypted PKCS#12 file.

[Tree] (config>router>bgp import)

[Tree] (config>router>bgp>group import)

Full Context

configure router bgp group neighbor import

configure router bgp import

configure router bgp group import

Description

This command specifies route policies that control the handling of inbound routes received from certain peers. Route policies are configured in the **config>router>policy-options** context.

This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). The most specific level is used.

The **import** command can reference up to 15 objects, where each object is either a policy logical expression or the name of a single policy. The objects are evaluated in the specified order to determine the modifications of each route and the final action to accept or reject the route.

Only one of the 15 objects referenced by the **import** command is allowed to be a policy logical expression consisting of policy names (enclosed in square brackets) and logical operators (AND, OR, NOT). The first of the 15 objects has a maximum length of 255 characters; the remaining 14 objects have a maximum length of 64 characters each.

When multiple **import** commands are issued, the last command entered overrides the previous command.

When an import policy is not specified, BGP routes are accepted by default.

The **no** form of this command removes the policy association.

Default

no import

Parameters

plcy-or-long-expr

Specifies the route policy name (up to 64 characters long) or a policy logical expression (up to 255 characters long). Allowed values are any string up to 255 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

plcy-or-expr

Specifies the route policy name (up to 64 characters long) or a policy logical expression (up to 64 characters long). Allowed values are any string up to 64 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

Syntax

import *policy-name* [*policy-name*]

no import

Context

[Tree] (config>router>isis import)

Full Context

configure router isis import

Description

This command specifies up to five route polices as IS-IS import policies.

When a prefix received in an IS-IS LSP is accepted by an entry in an IS-IS import policy, it is installed in the routing table, if it is the most preferred route to the destination.

When a prefix received in an IS-IS LSP is rejected by an entry in an IS-IS import policy, it is not installed in the routing table, even if it has the lowest preference value among all the routes to that destination.

The flooding of LSPs is unaffected by IS-IS import policy actions.

The **no** form of this command removes all policies from the configuration.

Default

no import

Parameters

policy-name

Specifies the import route policy name. Allowed values are any string up to 32 characters, composed of printable, 7-bit ASCII characters. If the string contains special characters

(#, $, spaces, and so on), the entire string must be enclosed within double quotes. The specified names must already be defined.

Context

[Tree] (config>router>ospf3 import)

[Tree] (config>router>ospf import)

Full Context

configure router ospf3 import

configure router ospf import

Description

This command applies one or more (up to 5) route polices as OSPF import policies. When a prefix received in an OSPF LSA is accepted by an entry in an OSPF import policy, it is installed in the routing table if it is the most preferred route to the destination. When a prefix received in an OSPF LSA is rejected by an entry in an OSPF import policy, it is not installed in the routing table, even if it has the lowest preference value among all the routes to that destination. The flooding of LSAs is unaffected by OSPF import policy actions. The **no** form of this command removes all policies from the configuration.

Default

no import

Parameters

policy-name

Specifies up to 5 export route policy names. Allowed values are any string up to 32 characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes. The specified names must already be defined.

configure router ripng group neighbor import

configure router rip group neighbor import

configure router rip import

configure router ripng import

configure router rip group import

configure router ripng group import

Description

This command configures import route policies to determine which routes are accepted from RIP neighbors. If no import policy is specified, RIP accepts all routes from configured RIP neighbors. Import policies can be used to limit or modify the routes accepted and their corresponding parameters and metrics.

If multiple policy names are specified, the policies are evaluated in the order they are specified. The first policy that matches is applied. If multiple import commands are issued, the last command entered will override the previous command. A maximum of five policy names can be specified.

The **no** form of the command removes all policies from the configuration.

Default

no import

Parameters

policy-name

Specifies up to five import route policy names. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

The specified names must already be defined.

Platforms

13.78 import-grt

import-grt

Syntax

import-grt *plcy-or-long-expr* [*plcy-or-expr*]

no import-grt

Context

[Tree] (config>service>vprn>grt import-grt)

Full Context

configure service vprn grt-lookup import-grt

Description

This command associates policies to control the leaking of GRT routes into the associated VPRN.

The GRT route must have first been leaked by a **leak-export** policy defined under the **config>router** context. Then the route must match a route entry in the specified **import-grt** policy with an accept action. Refer to the *IP Router Configuration Command Reference* section in the *7750 SR Extensible Routing System Virtualized Service Router*.

The **no** form of this command removes route leaking policy associations and disables the leaking of GRT routes into the local VPRN.

Parameters

plcy-or-long-expr

Specifies route policy names, up to 64 characters, or a policy logical expression, up to 255 characters.

Values *plcy-or-long-expr*: *policy-name* | *long-expr*

policy-name: up to 64 characters

long-expr: up to 255 characters

plcy-or-expr

Specifies up to four route policy names, up to 64 characters, or a policy logical expression, up to 64 characters.

Values *plcy-or-expr*: *policy-name* | *expr*

policy-name: up to 64 characters

expr: up to 64 characters

import-mcast-policy *policy-name* [*policy-name*]

no import-mcast-policy

Context

[Tree] (config>router>ldp import-mcast-policy)

Full Context

configure router ldp import-mcast-policy

Description

This command configures an import policy for mLDP FECs arriving on the node. This command does not work for self-generated mLDP FECs. The action of the policy will accept or reject the FEC. If the FEC is rejected, it will be kept but is not resolved.

The **no** form of this command removes all policies from the configuration.

Default

no import-mcast-policy

Parameters

policy-name

Specifies up to five import route policy names, up to 32 characters, to be assigned to mLDP. The specified name(s) must already be defined.

Platforms

All

13.80 import-pmsi-routes

import-pmsi-routes

Syntax

import-pmsi-routes

Context

[Tree] (config>router>ldp import-pmsi-routes)

Full Context

configure router ldp import-pmsi-routes

Description

Commands in this context configure import-pmsi-routes.

For option B, the leafs or ABR/ASBR that are not directly connected to the root have no visibility of the root. As such, for LDP to build the recursive FEC it needs to cache the MVPN PMSI AD routes, this command gives the user the ability to manually enable caching of MVPN PMSI AD routes internally in LDP for EVPN or MVPN inter-as or **mvpn_no_export_community** intra-as.

Platforms

All

13.81 import-prefixes

import-prefixes

Syntax

[**no**] **import-prefixes** *policy-name*

Context

[Tree] (config>router>ldp>session-params>peer import-prefixes)

Full Context

configure router ldp session-parameters peer import-prefixes

Description

This command configures the import FEC prefix policy to determine which prefixes received from this LDP peer are imported and installed by LDP on this node. If resolved these FEC prefixes are then re-distributed to other LDP and T-LDP peers. A FEC prefix that is filtered out (deny) will not be imported. A FEC prefix that is filtered in (accept) will be imported.

If no import policy is specified, the node will import all prefixes received from this LDP/T-LDP peer. This policy is applied in addition to the global LDP policy and targeted session policy.

Policies are configured in the **config>router>policy-options** context. A maximum of five policy names can be specified. Peer address has to be the peer LSR-ID address.

The **no** form of the command removes the policy from the configuration.

Default

no import-prefixes - no import route policy is specified

Parameters

policy-name

Specifies up to five import-prefix route policy names. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters excluding double quotes. If the string contains spaces, use double quotes to delimit the start and end of the string. The specified name(s) must already be defined.

Syntax

import-prefixes *policy-name* [*policy-name*]

no import-prefixes

Context

[Tree] (config>router>ldp>targeted-session import-prefixes)

Full Context

configure router ldp targeted-session import-prefixes

Description

This command configures the import route policy to determine which FEC prefix label bindings are accepted from targeted LDP neighbors into this node. A label binding that is filtered out (deny) will not be imported. A route that is filtered in (accept) will be imported.

If no import policy is specified, this node session will accept all bindings from configured targeted LDP neighbors. This policy is applied in addition to the global LDP policy.

Policies are configured in the **config>router>policy-option**s context. A maximum of five policy names can be specified.

The **no** form of this command removes the policy from the configuration.

Parameters

policy-name

Specifies up to five import policy names. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

13.82 import-tunnel-table

import-tunnel-table

Syntax

import-tunnel-table *policy-name* [*policy-name*]

no import-tunnel-table

Context

[Tree] (config>router>ldp import-tunnel-table)

Full Context

configure router ldp import-tunnel-table

Description

This command controls the import, in the tunnel table, of LDP tunnels to non-host prefixes. This command is only intended for importing tunnels; it cannot be used for preventing the import of any specific prefix and only non-host prefixes will be considered when evaluating this policy in this context. The LDP tunnels to these non-host prefixes must be created before they can be imported.

This command does not affect the automatic import of LDP tunnels to host prefixes.

The **no** version of this command removes all of the import policies and, by consequence, any tunnels to non-host prefixes from the tunnel table. If a non-host prefix tunnel is currently being used for forwarding, disabling this command may be service-impacting.

Default

no import-tunnel-table

Parameters

policy-name

Specifies up to five import route policy names. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

The specified policy names must already be defined.

Description

This command enables improved assert procedure on the PIM inclusive provider tunnel.

The **no** form of this command disables improved assert procedure.

Default

enabled

Platforms

All

improved-assert

Syntax

[**no**] **improved-assert**

Context

[Tree] (config>service>vprn>pim>if improved-assert)

Full Context

configure service vprn pim interface improved-assert

Description

This command enables improved assert processing on this interface. The PIM assert process establishes a forwarder for a LAN and requires interaction between the control and forwarding planes.

The assert process is started when data is received on an outgoing interface. This could impact performance if data is continuously received on an outgoing interface.

When enabled, the PIM assert process is done entirely on the control-plane with no interaction between the control and forwarding plane.

Default

improved-assert

Platforms

All

improved-assert

Syntax

[**no**] **improved-assert**

Context

[Tree] (config>router>pim>interface improved-assert)

Full Context

configure router pim interface improved-assert

Description

This command enables improved assert processing. The PIM assert process establishes a forwarder for a LAN and requires interaction between the control and forwarding planes. The assert process is started when data is received on an outgoing interface meaning that duplicate traffic is forwarded to the LAN until the forwarder is negotiated among the routers.

When the **improved-assert** command is enabled, the PIM assert process is done entirely in the control plane. The advantages are that it eliminates duplicate traffic forwarding to the LAN. It also improves performance since it removes the required interaction between the control and data planes.

Note:
improved-assert is still fully interoperable with the RFC 4601, *Protocol Independent Multicast - Sparse Mode (PIM-SM): Protocol Specification (Revised)* and RFC 2362, *Protocol Independent Multicast-Sparse Mode (PIM-SM)*, implementations. However, there may be conformance tests that may fail if the tests expect control-data plane interaction in determining the assert winner. Disabling the **improved-assert** command when performing conformance tests is recommended.

Default

improved-assert

configure router mpls mpls-tp transit-path reverse-path in-label

configure router mpls mpls-tp transit-path forward-path in-label

Description

This command configures the label mapping associated with a forward path or reverse path of an MPLS-TP transit path to be configured.

The incoming label, outgoing label and outgoing interface must be configured, using the **in-label**, **out-label** and **out-link** parameters. If the out-link refers to a numbered IP interface, the user may optionally configure the **next-hop** parameter and the system will determine the interface to use to reach the configured next-hop, but will check that the user-entered value for the *out-link* corresponds to the link returned by the system. If they do not correspond, then the path will not come up.

Default

no in-label

Parameters

in-label

Specifies the in label.

Values 32 to 16415

out-label

Specifies the out label.

Values 32 to 16415

if-name

Specifies the name of the outgoing interface use for the path.

next-hop

Specifies the next-hop.

Values a.b.c.d

13.101 in-remark

in-remark

Syntax

in-remark {**dscp** *dscp-name* | **prec** *ip-prec-value*}

no in-remark

Context

[Tree] (config>qos>sap-ingress>fc in-remark)

Full Context

configure qos sap-ingress fc in-remark

Description

This command is used in a SAP ingress QoS policy to define an explicit in-profile remark action for a forwarding class or subclass. While the SAP ingress QoS policy may be applied to any SAP, the remarking functions are only enforced when the SAP is associated with an IP or subscriber interface (in an IES or VPRN). When the policy is applied to a Layer 2 SAP (i.e., Epipe or VPLS), the remarking definitions are silently ignored.

In the case where the policy is applied to a Layer 3 SAP, the in-profile remarking definition will be applied to packets that have been classified to the forwarding class or subclass. It is possible for a packet to match a classification command that maps the packet to a particular forwarding class or subclass, only to have a more explicit (higher priority match) override the association. Only the highest priority match forwarding class or subclass association will drive the in-profile marking.

The in-remark command is only applicable to ingress IP routed packets that are considered in-profile. The profile of a SAP ingress packet is affected by either the explicit in-profile/out-of-profile definitions or the ingress policing function applied to the packet. Table 44: Effect of In-Remark Command on Received SAP Ingress Packets shows the effect of the in-remark command on received SAP ingress packets. Within the in-profile IP packet's ToS field, either the six DSCP bits or the three precedence bits are remarked.

Table 44: Effect of In-Remark Command on Received SAP Ingress Packets

SAP Ingress Packet State	in-remark Command Effect
Non-Routed, Policed In-Profile	No Effect (non-routed packet)
Non-Routed, Policed Out-of-Profile	No Effect (non-routed packet)
Non-Routed, Explicit In-Profile	No Effect (non-routed packet)
Non-Routed, Explicit Out-of-Profile	No Effect (non-routed packet)
IP Routed, Policed In-Profile	in-remark value applied to IP header ToS field
IP Routed, Policed Out-of-Profile	No Effect (out-of-profile packet)
IP Routed, Explicit In-Profile	in-remark value applied to IP header ToS field
IP Routed, Explicit Out-of-Profile	No Effect (out-of-profile packet)

The **no** form of this command disables ingress remarking of in-profile packets classified to the forwarding class or subclass.

Parameters

dscp *dscp-name*

Specifies that the matching packet's DSCP bits should be overridden with the value represented by dscp-name.

The *dscp-name* parameter is a 6-bit value. It must be one of the predefined DSCP names defined on the system.

Values be, cp1, cp2, cp3, cp4, cp5, cp6, cp7, cs1, cp9, af11, cp11, af12, cp13, af13, cp15, cs2, cp17, af21, cp19, af22, cp21, af23, cp23, cs3, cp25,

af31, cp27, af32, cp29, af33, cp31, cs4, cp33, af41, c p35, af42, cp37, af43, cp39, cs5, cp41, cp42, cp43, cp44, cp45, ef, cp47, nc1, cp49, cp50, cp51, cp52, cp53, cp54, cp55, nc2, cp57, cp58, cp59, cp60, cp61, cp62, cp63

prec ***ip-prec-value***

Specifies that the matching packet's precedence bits should be overridden with the value represented by *ip-prec-value*.

Values 0 to 7

Platforms

13.102 inactive-flow-timeout

inactive-flow-timeout

Syntax

inactive-flow-timeout *seconds*

no inactive-flow-timeout

Context

[Tree] (config>cflowd inactive-flow-timeout)

Full Context

configure cflowd inactive-flow-timeout

Description

This command specifies the length of time, in seconds, that must elapse without a packet matching a flow before the flow is considered inactive.

The **no** form of this command resets the inactive flow timeout back to the default of 15 seconds.

Existing flows do not inherit the new **inactive-flow-timeout** value if this parameter is changed while **cflowd** is active. The **inactive-flow-timeout** value for a flow is set when the flow is first created in the active cache table and does not change dynamically.

Default

inactive-flow-timeout 15

Parameters

seconds

Specifies the length of time, in seconds, without a packet matching a flow before the flow is considered inactive.

Values 10 to 600

Platforms

All

13.103 inactivity-mon

inactivity-mon

Syntax

inactivity-timeout *seconds*

no inactivity-timeout

Context

[Tree] (config>test-oam>twamp>twamp-light inactivity-timeout)

Full Context

configure test-oam twamp twamp-light inactivity-timeout

Description

This command configures the length of time to maintain stale state on the session reflector. Stale state is test data that has not been refreshed or updated by newly arriving probes for that specific test in a predetermined length of time. Any single reflector can maintain up state for a maximum of 12000 tests. If the maximum value is exceeded, the session reflector lacks memory to allocate to new tests.

The **no** form of this command returns the value to the default.

Default

inactivity-timeout 100

Parameters

seconds

Specifies the value in seconds for maintaining stale state.

Values 10 to 100

Default 100

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

inactivity-timer

Syntax

inactivity-timer *timer*

no inactivity-timer

Context

[Tree] (config>eth-cfm>slm inactivity-timer)

Full Context

configure eth-cfm slm inactivity-timer

Description

The time the responder keeps a test active. Should the time between packets exceed this values within a test the responder will mark the previous test as complete. It will treat any new packets from a peer with the same test-id, source-mac and MEP-ID as a new test responding with the sequence number one.

The **no** form of the command reverts the timeout to the default value.

Default

inactivity-timer 100

Parameters

timer

Specifies the amount of time in seconds.

Values 10 100

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

[Tree] (config>cflowd inband-collector-export-only)

Full Context

configure cflowd inband-collector-export-only

Description

This command, when the **inband-collector-export-only** command is enabled, allows only collectors that are reachable through inband interfaces and enables a higher flow export rate.

The **no** form of this command, the default, re-enables the use of the out-of-band management Ethernet port.

inbound-max-sessions

Syntax

inbound-max-sessions *number-of-sessions*

no inbound-max-sessions

Context

[Tree] (config>system>login-control>ftp inbound-max-sessions)

Full Context

configure system login-control ftp inbound-max-sessions

Description

This command configures the maximum number of concurrent inbound FTP sessions.

This value is the combined total of inbound and outbound sessions.

The **no** form of this command reverts to the default value.

Default

inbound-max-sessions 3

Parameters

value

Specifies the maximum number of concurrent FTP sessions on the node.

Values 0 to 5

Platforms

All

inbound-max-sessions

Syntax

inbound-max-sessions *number-of-sessions*

no inbound-max-sessions

Context

[Tree] (config>system>login-control>ssh inbound-max-sessions)

[Tree] (config>system>login-control>telnet inbound-max-sessions)

Full Context

configure system login-control ssh inbound-max-sessions

configure system login-control telnet inbound-max-sessions

Description

This parameter limits the number of inbound Telnet and SSH sessions. A maximum of 30 telnet and ssh connections can be established to the router. The local serial port cannot be disabled.

Telnet and SSH maximum sessions can also use the combined total of both inbound sessions (SSH +Telnet). While it is acceptable to continue to internally limit the combined total of SSH and Telnet sessions to N, either SSH or Telnet sessions can use the inbound maximum sessions, if so required by the Operator.

The **no** form of this command reverts to the default value.

Default

inbound-max-sessions 5

Parameters

number-of-sessions

The maximum number of concurrent inbound Telnet sessions, expressed as an integer.

Values 0 **to** 50 (default = 5) or 0 **to** N where N is the new total number of SSH +Telnet sessions if they are scaled

incl-mcast-l2-attributes-advertisement

Syntax

[**no**] **incl-mcast-l2-attributes-advertisement**

Context

[Tree] (config>service>vpls>bgp-evpn incl-mcast-l2-attributes-advertisement)

Full Context

configure service vpls bgp-evpn incl-mcast-l2-attributes-advertisement

Description

This command triggers the advertisement of the Layer-2 Attributes extended community including:

- Service-MTU in the layer-2 MTU field
- C bit, which is set based on the configuration of the **control-word** command (when enabled, sets the C bit, otherwise it is unset)

Upon reception, the Layer-2 MTU for a peer is compared with the local service MTU. If there is a mismatch, the EVPN destination is operational state is down, unless the **bgp-evpn ignore-mtu-mismatch** command is enabled.

The received C bit from a peer is compared with the local **control-word** setting. In case of a mismatch the EVPN destination becomes operationally down.

The **no** form of this command prevents the router from advertising the Layer-2 Attributes extended community along with the Inclusive Multicast Ethernet Tag route for the service.

Default

no incl-mcast-l2-attributes-advertisement

Platforms

incl-mcast-orig-ip

Syntax

incl-mcast-orig-ip *ip-address*

no incl-mcast-orig-ip

Context

[Tree] (config>service>vpls>bgp-evpn>mpls incl-mcast-orig-ip)

Full Context

configure service vpls bgp-evpn mpls incl-mcast-orig-ip

Description

The IP address configured by the user in the **incl-mcast-orig-ip** command is encoded in the **originating-ip** field of EVPN Inclusive Multicast Routes with tunnel type Ingress Replication (value 6), mLDP (2), and Composite IR and mLDP (130).

The configured address does not need to be reachable in the base router or have an interface in the base router. The originating-ip address is used solely for BGP route-key selection.

The originating-ip is never changed for Inclusive Multicast Routes with tunnel type AR (Assisted Replication, value 10).

The **no** version of the command withdraws the affected Inclusive Multicast Routes and re-advertises it with the default system-ip address in the originating-ip field.

Default

incl-mcast-orig-ip 1

Parameters

ip-address

Specifies the IPv4 address value.

Values a.b.c.d

Full Context

configure router mpls lsp-template include

configure router mpls lsp primary include

configure router mpls lsp include

configure router mpls lsp secondary include

configure router mpls lsp primary-p2mp-instance include

Description

This command specifies the admin groups to be included when an LSP is set up. Up to five groups per operation can be specified, up to 32 maximum. The **include** statement instructs the CSPF algorithm to pick TE links among the links which belong to one or more of the specified admin groups. A link that does not belong to at least one of the specified admin groups is excluded and thus pruned from the TE database before the CSPF computation. However, a link can still be selected if it belongs to one of the groups in a **include** statement but also belongs to other groups which are not part of any **include** statement in the LSP or primary/secondary path configuration. In other words, the **include** statements implements the "include-any" behavior.

The **config**>**router**>**mpls**>**lsp**>**primary-p2mp-instance**> **include** command is not supported on the 7450 ESS.

The **no** form of this command deletes the specified groups in the specified context.

Default

no include

Parameters

group-name

Specifies admin groups to be included when an LSP is set up.

13.116 include-group

include-group

Syntax

include-group *ip-admin-group-name* [**pref** *preference*]

no include-group *ip-admin-group-name*

Context

[Tree] (config>router>route-next-hop-policy>template include-group)

Full Context

configure router route-next-hop-policy template include-group

Description

This command configures the admin group constraint into the route next-hop policy template.

Each group is entered individually. The **include-group** statement instructs the LFA SPF selection algorithm to pick up a subset of LFA next-hops among the links which belong to one or more of the specified admin groups. A link which does not belong to at least one of the admin-groups is excluded. However, a link can still be selected if it belongs to one of the groups in a include-group statement but also belongs to other groups which are not part of any include-group statement in the route next-hop policy.

The **pref** option is used to provide a relative preference for the admin group to select. A lower preference value means that LFA SPF will first attempt to select a LFA backup next-hop which is a member of the corresponding admin group. If none is found, then the admin group with the next higher preference value is evaluated. If no preference is configured for a given admin group name, then it is supposed to be the least preferred, that is, numerically the highest preference value.

When evaluating multiple **include-group** statements within the same preference, any link which belongs to one or more of the included admin groups can be selected as an LFA next-hop. There is no relative preference based on how many of those included admin groups the link is a member of.

The **exclude-group** statement simply prunes all links belonging to the specified admin group before making the LFA backup next-hop selection for a prefix.

If the same group name is part of both include and exclude statements, the exclude statement will win. It other words, the exclude statement can be viewed as having an implicit preference value of 0.

The admin-group criteria are applied before running the LFA next-hop selection algorithm.

The **no** form deletes the admin group constraint from the route next-hop policy template.

Parameters

ip-admin-group-name

Specifies the name of the group, up to 32 characters.

preference

An integer specifying the relative preference of a group.

Values 1 to 255

Default 255

13.120 inclusive

inclusive

Syntax

inclusive

Context

[Tree] (config>service>vpls>provider-tunnel inclusive)

Full Context

configure service vpls provider-tunnel inclusive

Description

Commands in this context configure the use of a P2MP LSP as the default tree for forwarding Broadcast, Unknown unicast, and Multicast (BUM) packets of a VPLS or B-VPLS instance. The P2MP LSP is referred to, in this case, as the Inclusive Provider Multicast Service Interface (I-PMSI).

When enabled, this feature relies on BGP Auto-Discovery (BGP-AD), BGP-VPLS or BGP-EVPN to discover the PE nodes participating in a specified VPLS/B-VPLS instance. In the case of BGP-AD or BGP-VPLS, the BGP route contains the information required to signal both point-to-point (P2P) PWs used to forward unicast known Ethernet frames, and the RSVP or mLDP P2MP LSP used to forward the BUM frames. In the case of BGP-EVPN, the EVPN IMET route contains the information to set up the mLDP P2MP LSP and may also contain the information that enables the remote leaf-only nodes to setup an EVPN destination to the sending PE.

Note:
The provider-tunnel for a specified service must be configured with an owner protocol (BGP-AD, BGP-VPLS or BGP-EVPN); only one owner must be configured. Use the **owner {bgp-ad|bgp-vpls|bgp-evpn-mpls}** command to configure an owner.

With an mLDP I-PMSI, each leaf node will initiate the signaling of the mLDP P2MP LSP upstream using the P2MP FEC information in the I-PMSI tunnel information discovered through the BGP.

If IGMP or PIM snooping are configured on the VPLS/B-VPLS instance, multicast packets matching an L2 multicast Forwarding Information Base (FIB) record will also be forwarded over the P2MP LSP.

Use the **mldp** command to enable the use of an LDP P2MP LSP as the I-PMSI for forwarding Ethernet BUM and IP multicast packets in a VPLS instance:

config>service>vpls [b-vpls]>provider-tunnel>inclusive>mldp

When a **no shutdown** is performed under the context of the inclusive node and the expiration of a delay timer, BUM packets will be forwarded over an automatically signaled mLDP P2MP LSP.

Use the **root-and-leaf** command to configure the node to operate as both root and leaf in the VPLS instance:

config>service>vpls [b-vpls]>provider-tunnel>inclusive>root-and-leaf

The node behaves as a leaf-only node by default. For the I-PMSI of type mLDP, the leaf-only node will join I-PMSI rooted at other nodes it discovered but will not include a PMSI Tunnel Attribute in BGP route update messages. This way a leaf-only node will forward packets to other nodes in the VPLS/B-VPLS using the point-to-point spoke-SDPs in the case of BGP-AD or BGP-VPLS, or using EVPN destinations in the case of BGP-EVPN.

Note:
Either BGP-AD/VPLS or BGP-EVPN must be enabled in the VPLS/B-VPLS instance otherwise the execution of the **no shutdown** command under the context of the inclusive node will fail and the I-PMSI will not come up.

If the P2MP LSP instance goes down, the VPLS/B-VPLS immediately reverts the forwarding of BUM packets to the P2P PWs or EVPN destinations (in the case of BGP-EVPN). Performing a shutdown under the context of the inclusive node will allow the user to restore BUM packet forwarding over the P2P PWs or EVPN destinations.

This feature is supported with VPLS and B-VPLS; it is not supported with I-VPLS. Although Routed VPLS is supported, routed traffic cannot be sent over the I-PMSI tree.

[Tree] (config>router>ospf3>timers incremental-spf-wait)

Full Context

configure router ospf timers incremental-spf-wait

configure router ospf3 timers incremental-spf-wait

Description

This command sets the delay before an incremental SPF calculation is performed when LSA types 3, 4, 5, or 7 are received. This allows multiple updates to be processed in the same SPF calculation. Type 1 or type 2 LSAs are considered a topology change and will always trigger a full SPF calculation.

The **no** form of this command resets the timer value back to the default value.

Note:
The timer granularity is 10 ms if the value is less than 500 ms, and 100 ms if the value is ≥ 500 ms. Timer values are rounded down to the nearest granularity, for example a configured value of 550 ms is internally rounded down to 500 ms.

Default

incremental-spf-wait 1000

Parameters

incremental-spf-wait

Specifies the OSPF incremental SPF calculation delay, in milliseconds.

Values 0 to 1000

Platforms

All

info

Syntax

info [**detail**] [**objective**]

info [**detail**] [**objective**] **operational**

Context

[Tree] (info)

Full Context

info

Description

This command displays the running configuration for the configuration context where it is entered and all branches below that context level. It can be used in any branch under configure, but not with **configure** itself.

By default, the command only enters the configuration parameters that vary from the default values.

The **detail** keyword causes all configuration parameters to be displayed. The **include-dynamic** objective keyword includes configuration parameters from dynamic sources such as dynamic data services Python scripts. These dynamic configuration parameters are not saved in the configuration file.

The **operational** keyword is available in edit-cfg mode only, in which case the keyword is mandatory when using the **info** command.

Example:

```
A:ALA-48>config>router>if-attr# info
----------------------------------
            admin-group "green" value 15
            admin-group "red" value 25
            admin-group "yellow" value 20
A:ALA-48>config>router>mpls# info
----------------------------------
            interface "system"

13.127 info-notification

info-notification

Syntax

info-notification

Context

[Tree] (config>port>ethernet>efm-oam>link-mon>local-sf-action info-notification)

Full Context

configure port ethernet efm-oam link-monitoring local-sf-action info-notification

Description

The context allows the operator to set different flags in the Information OAM PDU. The flags can be used to notify the peer that a local signal failure threshold has been exceeded within the configured window. This is useful when the local node supports the link monitoring function, but the remote peer does not support this capability. Information OAM PDUs are sent on the interval where the Event Notification OAM PDU is typically only sent on the initial sf-threshold crossing event. It is strongly suggested one of the Information OAM PDU Flag fields used to continually communicate current monitor state to the peer.

Interactions: The signal failure threshold will trigger these actions.

Platforms

All

13.128 ing-percentage-of-rate

ing-percentage-of-rate

Syntax

ing-percentage-of-rate *ing-rate-percentage*

no ing-percentage-of-rate

Context

[Tree] (config>port>modify-buffer-allocation-rate ing-percentage-of-rate)

Full Context

configure port modify-buffer-allocation-rate ing-percentage-of-rate

Description

This command increases or decreases the active bandwidth associated with the ingress port that affects the amount of ingress buffer space managed by the port. Changing a port's active bandwidth using the **ing-percentage-of-rate** command is an effective means of artificially lowering the buffers managed by one ingress port and giving them to other ingress ports on the same MDA.

The **ing-percentage-of-rate** command accepts a percentage value that increases or decreases the active bandwidth based on the defined percentage. A value of 50% causes the active bandwidth to be reduced by 50%. A value of 150% causes the active bandwidth to be increased by 50%. Values from 1 to 1000 percent are supported.

A value of 100 (the default value) is equivalent to executing the **no ing-percentage-of-rate** command and restores the ingress active rate to the normal value.

The **no** form of this command removes any artificial increase or decrease of the ingress active bandwidth used for ingress buffer space allocation to the port. The **no ing-percentage-of-rate** command sets the ingress rate percentage to 100%.

Parameters

ing-rate-percentage

The *ing-rate-percentage* parameter is required and specifies the percentage value used to modify the current ingress active bandwidth of the port. This does not actually change the bandwidth available on the port in any way. The defined *ing-rate-percentage* parameter is multiplied by the ingress active bandwidth of the port. A value of 150 results in an increase of 50% (1.5 x Rate).

Values 1 to 1000

Default 100 (no change to active rate)

ing-weight

Syntax

ing-weight access *access-weight* **network** *network-weight*

no ing-weight

Context

[Tree] (config>port>hybrid-buffer-allocation ing-weight)

Full Context

configure port hybrid-buffer-allocation ing-weight

Description

This command configures the sharing of the ingress buffers allocated to a hybrid port among the access and network contexts. By default, it is split equally between network and access.

The **no** form of this command reverts to the default values for the ingress access and network weights.

Parameters

access-weight

Specifies the access weight as an integer.

Values 0 to 100

Default 50

network-weight

Specifies the network weight as an integer.

Values 0 to 100

Default 50

ingress

Syntax

ingress

Context

[Tree] (config>qos>network ingress)

Full Context

configure qos network ingress

Description

This command is used to enter the CLI node that creates or edits policy entries that specify the DiffServ code points-to-forwarding class mapping for all IP packets and define the MPLS EXP bits-to-forwarding class mapping for all labeled packets.

When premarked IP or MPLS packets ingress on a network port, they get a Per Hop Behavior (that is, the QoS treatment through the router, based on the mapping defined under the current node).

Platforms

All

ingress

Syntax

ingress

Context

[Tree] (config>qos>queue-group-templates ingress)

Full Context

configure qos queue-group-templates ingress

Description

Commands in this context create ingress queue group templates. Ingress queue group templates can be applied to ingress ports to create an ingress queue group of the same name.

An ingress template must be created for a group-name prior to creating a queue group with the same name on an ingress port.

Platforms

All

ingress

Syntax

ingress

Context

13.131 ingress-buffer-allocation

ingress-buffer-allocation

Syntax

ingress-buffer-allocation *percentage*

no ingress-buffer-allocation

Context

[Tree] (config>card>fp ingress-buffer-allocation)

Full Context

configure card fp ingress-buffer-allocation

Description

This command allows the user to configure an ingress buffer allocation percentage per forwarding plane from 20.00% to 80.00%. Ingress buffer allocation applies to user-accessible buffers (total buffers less those reserved for system use).

The ingress buffer allocation percentage determines how much of the user-accessible buffers will be available for ingress purposes. The remaining buffers will be available for egress purposes.

This command is supported on all 50G FP2-based and 100G/200G FP3-based hardware. It is not supported on other FP2 or FP3-based hardware, nor on FP4-based hardware.

The **no** form of this command reverts the ingress buffer allocation to the default value.

Default

ingress-buffer-allocation 50.00

Parameters

percentage

Specifies the buffer allocation percentage.

Values 20.00 to 80.00

Platforms

7450 ESS, 7750 SR-7/12/12e, 7750 SR-a, 7750 SR-e, 7950 XRS

13.132 ingress-counter-map

ingress-counter-map

Syntax

ingress-counter-map policer *policer-id* **traffic-type** { **unicast** | **multicast** | **broadcast**} [**create**]

ingress-counter-map queue *queue-id* **traffic-type** { **unicast** | **multicast** | **broadcast**} [**create**]

no ingress-counter-map policer *policer-id*

no ingress-counter-map queue *queue-id*

Context

[Tree] (config>sflow ingress-counter-map)

Full Context

configure sflow ingress-counter-map

Description

This command configures the ingress counter map for sFlow. The map must be configured so sFlow agent understands how to interpret data collected against SAP queues and policers. Multiple queues/policers can be mapped to the same **traffic-type** using separate line entries.

The **no** form of this command deletes a SAP policy queue/policer from the map.

Parameters

policer-id

Specifies the policer ID in a SAP ingress QoS policy. If the SAP policy does not have a policer with the specified ID, the map entry will be ignored for this SAP.

Values 1 to 32

queue-id

Specifies the queue ID in a SAP ingress QoS policy. If the SAP policy does not have a queue with the specified ID, the map entry will be ignored for this SAP.

Values 1 to 32

Platforms

7750 SR, 7750 SR-s, 7950 XRS

13.133 ingress-ip-filter-entries

Full Context

configure subscriber-mgmt category-map category exhausted-credit-service-level ingress-ipv6-filter-entries

Description

Commands in this context configure the ingress IPv6 filter parameters.

The **no** form of this command reverts to the default.

Default

ingress-ipv6-filter-entries

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

13.135 ingress-label

ingress-label

Syntax

ingress-label *label* [*label*]

no ingress-label [*label*]

Context

[Tree] (debug>mirror-source ingress-label)

Full Context

debug mirror-source ingress-label

Description

This command enables ingress mirroring based on MPLS labels with the following limitations.

- The ingress label provisioned must be a MPLS transport label and can be at any label stack as long as it is known by the system. Transport label distributed by LDP, RSVP, and segment routing are supported. For BGP-specific label distribution mirroring, the following are supported.
  - BGP label-unicast (RFC 8277, *Using BGP to Bind MPLS Labels to Address Prefixes*)
  - VPN service labels distributed by BGP for Carrier Supporting Carrier (CSC) VPNs (RFC 4364, *BGP/MPLS IP Virtual Private Networks (VPNs)*)
  - VPN service labels distributed by BGP in an ASBR (inter-as-option-B)
  - VPN service labels distributed by BGP in a route reflector with next-hop-self (RR + NHS)
- VPN service label mirroring is not supported in a provider edge (PE) router.
- The ingress label can only be mirrored to a single mirror destination. If the same label is defined with multiple mirror destinations, an error is generated and the original mirror destination remains unchanged.

The ingress label mirror source overrides all other mirror source definitions. The MPLS frame is mirrored to the mirror destination as it is received on the ingress network port. The router MPLS label space is global for the system. A specific label is mirrored to a mirror destination regardless of the ingress interface. In addition to mirroring known labels, debug also allows pre-provisioning label values which are yet to be known by the system. Be aware that debug mirroring requires provisioning of static label values while labels distributed by label distribution protocols are dynamic in nature. Therefore, when label values change due to network changes, labels provisioned in debug mirroring must be changed or deleted manually.

By default, no ingress MPLS frames are mirrored. The **ingress-label** command must be executed to start mirroring on a specific MPLS label.

Parameters

label

Specifies up to eight transport labels received on ingress to be mirrored. Each label can only be mirrored to a single mirror destination.

If the label does not exist on any ingress network ports, no packets are mirrored for that label. An error will not occur. Once the label exists on a network port, ingress mirroring begins for that label.

Values 0 to 1048575

The local MPLS stack may not support portions of this range.

Platforms

All

13.136 ingress-percent-of-total

ingress-percent-of-total

Syntax

ingress-percent-of-total *percent-of-total-queues*

no ingress-percent-of-total

Context

[Tree] (config>qos>fp-resource-policy>queues ingress-percent-of-total)

Full Context

configure qos fp-resource-policy queues ingress-percent-of-total

Description

This command configures the percentage of the total number of queues on the FP on which the policy is applied that are allocated to ingress, with the remainder allocated to egress. The ingress and egress buffer pool sizes are not affected by the queue allocation.

The allocation is performed in sets of 8192 queues, with a minimum of 8192 queues at ingress and 8192 queues at egress. If the percentage configured results in the queue allocation not being a multiple of 8192, the number of queues at ingress is rounded down to the next 8192 boundary, and consequently the number of queues at egress is rounded up to the next 8192 boundary, both while respecting the minimum at ingress and egress.

If the FP resources policy being applied to any FP and the updated allocation is not achievable with the current ingress or egress queue consumption on any of the related FPs, then the command fails.

The configuration of **ingress-percent-of-total** command, including removing this parameter to return to its default configuration, causes the router to immediately reset the associated cards, XIOMs, and MDAs,

except on the 7750 SR-1 where the configuration must be saved, and the router rebooted, immediately after committing the configuration transaction.

The **no** form of this command reverts the percentage of ingress queues, and consequently egress queues, to their default allocation.

Default

ingress-percent-of-total 50.00

Parameters

percent-of-total-queues

Specifies the percentage of total ingress queues as two fraction digits.

Values 4.00 to 97.00

Platforms

7450 ESS, 7750 SR, 7750 SR-s, 7950 XRS

13.137 ingress-policer

ingress-policer

Syntax

ingress-policer *policer-name*

no ingress-policer

Context

[Tree] (config>service>ies>sub-if>grp-if>wlan-gw>ranges>range>dsm ingress-policer)

[Tree] (config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range>dsm ingress-policer)

Full Context

configure service ies subscriber-interface group-interface wlan-gw vlan-tag-ranges range distributed-sub-mgmt ingress-policer

configure service vprn subscriber-interface group-interface wlan-gw vlan-tag-ranges range distributed-sub-mgmt ingress-policer

Description

This command specifies the ingress policer applied to all UEs corresponding to default vlan-range (such as group-interface) or the specified vlan-range. The policer can be created in the **config>subscr-mgmt>isa-policer** context. The ingress policer can be overridden per UE from RADIUS via access-accept or COA.

The **no** form of this command reverts to the default.

Parameters

policer-name

Specifies the identifier of the distributed-sub-mgmt policer for ingress traffic.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

13.138 ingress-rate

ingress-rate

Syntax

ingress-rate *sub-rate*

no ingress-rate

Context

[Tree] (config>port>ethernet ingress-rate)

Full Context

configure port ethernet ingress-rate

Description

This command configures the maximum amount of ingress bandwidth that this port can receive with the configured sub-rate using packet-based accounting.

The **no** form of this command returns the value to the default.

Default

no ingress-rate

Parameters

sub-rate

Specifies the ingress rate, in Mb/s.

Values 1 to 400000

Platforms

All

13.139 ingress-repl-inc-mcast-advertisement

ingress-repl-inc-mcast-advertisement

Syntax

[**no**] **ingress-repl-inc-mcast-advertisement**

Context

[Tree] (config>service>vpls>bgp-evpn ingress-repl-inc-mcast-advertisement)

Full Context

configure service vpls bgp-evpn ingress-repl-inc-mcast-advertisement

Description

This command enables and disables the advertisement of the Inclusive Multicast Ethernet Tag route (IMET route) with tunnel-type Ingress-Replication in the PMSI Tunnel Attribute, or with the tunnel-type Composite Point-to-Multipoint and Ingress-Replication (P2MP+IR) in the root-and-leaf nodes. The following must be considered:

- When **no ingress-repl-inc-mcast-advertisement** is configured, no IMET routes will be sent for the service unless the **provider-tunnel** is configured with **owner bgp-evpn-mpls** and **root-and-leaf**, in which case, an IMET-P2MP route is sent.
- When **ingress-repl-inc-mcast-advertisement** and **provider-tunnel** are configured for **bgp-evpn-mpls** with **root-and-leaf**, the system will send an IMET-P2MP-IR route, that is, an IMET route with a composite P2MP+IR tunnel type.
- When **no ingress-repl-inc-mcast-advertisement** and **assisted-replication replicator** are configured, the system will send IMET-AR routes, but IMET-IR routes will not be sent.

Default

ingress-repl-inc-mcast-advertisement

Platforms

All

13.140 ingress-replication-bum-label

ingress-replication-bum-label

Syntax

[**no**] **no-ingress-replication-bum-label**

Context

[Tree] (config>service>vpls>bgp-evpn>mpls ingress-replication-bum-label)

Full Context

configure service vpls bgp-evpn mpls ingress-replication-bum-label

Description

This command allows the user to configure the system so that a separate label is sent for BUM (Broadcast, Unknown unicast and Multicast) traffic in a specified service. By default (**no ingress-replication-bum-label**), the same label is used for unicast and flooded BUM packets when for-warding traffic to remote PEs.

When saving labels, this might cause transient traffic duplication for all-active multi-homing. By enabling **ingress-replication-bum-label**, the system will advertise two labels per EVPN VPLS instance, one for unicast and one for BUM traffic. The ingress PE will use the BUM label for flooded traffic to the advertising egress PE, so that the egress PE can determine if the unicast traffic has been flooded by the ingress PE. Depending on the scale required in the network, the user may choose between saving label space or avoiding transient packet duplication sent to an all-active multi-homed CE for certain macs.

Default

no ingress-replication-bum-label

13.146 init-extract-prio-mode

init-extract-prio-mode

Syntax

init-extract-prio-mode {**uniform** | **l3-classify**}

Context

[Tree] (config>card>fp init-extract-prio-mode)

Full Context

configure card fp init-extract-prio-mode

Description

This command determines the scheme used to select the initial drop priority of extracted control plane traffic. The initial drop priority of extracted packets can be either low or high priority. The drop priority of the extracted packets can be subsequently altered by mechanisms such as CPU protection. High-priority traffic receives preferential treatment in control plane congestion situations over low-priority traffic.

Default

init-extract-prio-mode uniform

Parameters

uniform

Initializes the drop priority of all extracted control traffic as high priority. Drop priority can then be altered (marked low priority) by distributed CPU protection (DCP) or centralized CPU protection rate-limiting functions in order to achieve protocol and interface isolation.

l3-classify

Initializes the drop priority of Layer 3 extracted control traffic (BGP and OSPF) based on the QoS classification of the packets. This is useful in networks where the DSCP and EXP markings can be trusted as the primary method to distinguish, protect, and isolate good terminating protocol traffic from unknown or potentially harmful protocol traffic instead of using the rate-based DCP and centralized CPU protection traffic marking/coloring mechanisms (for example, **out-profile-rate** and **exceed-action low-priority**).

For network interfaces, the QoS classification profile result selects the drop priority (in = high priority, out = low priority) for extracted control traffic, and the default QoS classification maps different DSCP and EXP values to different in/out profile states.

For access interfaces, the QoS classification priority result typically selects the drop priority for extracted control traffic. The default access QoS classification (**default-priority**) maps all traffic to **low**. If the queues in the access QoS policy are configured as **profile-mode** queues (rather than the default **priority-mode**) extracted traffic will use the QoS classification profile value configured against the associated FC (rather than the priority result) to select the drop priority.

Layer 2 extracted control traffic (ARP or ETH-CFM) and protocols that cannot always be QoS-classified, such as IS-IS, are initialized as low drop priority in order to protect Layer 2 protocol traffic on uniform interfaces (which would typically be subject to centralized CPU protection). Alternately, DCP can be used (by configuring a non-zero rate with **exceed-action** of **low-priority** for the **all-unspecified** protocol) to mark some of this traffic as high priority.

13.147 init-ss-threshold

init-ss-threshold

Syntax

init-ss-threshold *init-ss-threshold*

Context

[Tree] (config>app-assure>group>tcp-optimizer init-ss-threshold)

Full Context

configure application-assurance group tcp-optimizer init-ss-threshold

Description

This command configures the initial Slow Start (SS) threshold for a given TCP optimizer policy. Nokia recommends to set the threshold close to the access network Bandwidth Delay Product (BDP).

Default

1000000

Parameters

init-ss-threshold

Specifies the initial SS threshold value in kilobytes.

Values auto, 0 to 1000000

The auto value instructs the system to use an intelligent mechanism to set the optimum value for the initial SS threshold to dynamically track the BDP of the access network.

Platforms

configure service ies subscriber-interface group-interface wpp initial-app-profile

configure service vprn subscriber-interface group-interface wpp initial-app-profile

configure subscriber-mgmt local-user-db ipoe host wpp initial-app-profile

Description

This command specifies the initial app-profile for the hosts created on the group-interface. This initial app-profile is replaced after hosts pass web portal authentication.

The **no** form of this command reverts to the default.

Default

no initial-app-profile

Parameters

app-profile-name

Specifies the initial application profile, up to 32 characters, to be used during the WPP authentication phase of the IPoE hosts.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

13.149 initial-hold-time

initial-hold-time

Syntax

initial-hold-time *seconds*

initial-hold-time [**min** *min*] [**sec** *sec*]

no initial-hold-time

Context

[Tree] (config>subscr-mgmt>vrgw>brg>brg-profile initial-hold-time)

Full Context

configure subscriber-mgmt vrgw brg brg-profile initial-hold-time

Description

This hold time applies to BRG instances that are created without any hosts; for example, triggered due to proxy authentication. During this initial hold-time the BRG is not deleted and no connectivity-verification is started. When this timer expires, connectivity verification is started. If connectivity verification is disabled and no hosts are associated with the BRG upon expiry, the regular hold time is started and the BRG instance will be removed.

This command allows an operator to have fast BRG removal (no connectivity-verification and **no hold-time**) but still use BRG proxy authentication. Without an initial hold time the BRG would be removed immediately after creation.

This command does not apply to BRG instances that are created through host setup.

The **no** form of this command reverts to the default.

Default

initial-hold-time min 5

Parameters

seconds

Specifies the initial time, in seconds, to hold on to a BRG after the system considered it down.

Values 0 to 900

min

Specifies the initial time in minutes.

Values 1 to 15

sec

Specifies the initial time in seconds.

Values 1 to 59

Context

[Tree] (admin>certificate>cmpv2 initial-registration)

Full Context

admin certificate cmpv2 initial-registration

Description

This command request initial certificate from CA by using CMPv2 initial registration procedure.

The **ca** parameter specifies a CA-profile which includes CMP server information.

The **key-to-certify** is an imported key file to be certified by the CA.

The protection-key is an imported key file used to for message protection if protection-alg is signature.

The request is authenticated either of following methods:

- A password and a reference number that pre-distributed by CA via out-of-band means.
- The specified password and reference number are not necessarily in the cmp-keylist configured in the corresponding CA-Profile
- A signature signed by the protection-key or key-to-certify, optionally along with the corresponding certificate. If the protection-key is not specified, system will use the key-to-certify for message protection. The hash algorithm used for signature is depends on key type:
- DSA key: SHA1
- RSA key: MD5/SHA1/SHA224 | SHA256 | SHA384 | SHA512, by default is SHA1

Optionally, the system could also send a certificate or a chain of certificates in extraCerts field. Certificate is specified by the "cert" parameter, it must include the public key of the key used for message protection.

Sending a chain is enabled by specify the **send-chain** parameter.

subject-dn specifies the subject of the requesting certificate.

save-as specifies full path name of saving the result certificate.

In some cases, CA may not return certificate immediately, due to reason like request processing need manual intervention. In such cases, the **admin certificate cmpv2** poll command could be used to poll the status of the request. If key-list is not configured in the corresponding **ca-profile**, then the system will use the existing password to authenticate the CMPv2 packets from server if it is in password protection.

If key-list is configured in the corresponding **ca-profile** and server does not send SenderKID, then the system will use lexicographical first key in the key-list to authenticate the CMPv2 packets from server in case it is in password protection.

Parameters

ca-profile-name

Specifies a ca-profile name which includes CMP server information up to 32 characters.

key-filename

Specifies the file name of the key to certify up to 95 characters.

password

Specifies an ASCII string up to 64 characters.

ref-number

Specifies the reference number for this CA initial authentication key up to 64 characters.

cert-file-name

specifies the certificate file up to 95 characters.

ca-profile-name

Specifies to send the chain.

key-file-name

Specifies the protection key associated with the action on the CA profile.

hash-algorithm

Specifies the hash algorithm for RSA key.

Values md5,sha1,sha224,sha256,sha384,sha512

dn

Specifies the subject of the requesting certificate up to 256 characters.

Values attr1 equals val1

attr2 equals val2 where: attrN equals {C | ST | O | OU | CN}

save-path-of-result-cert

Specifies the save full path name of saving the result certificate up to 200 characters.

domain-name *domain-names*

Specifies FQDNs for SubjectAltName of the requesting certificate, separated by commas, up to 512 characters.

ip-address* | *ipv6-address

Specifies an IPv4 or IPv6 address for SubjectAtName of the requesting certificate.

13.157 initiation-message

initiation-message

Syntax

initiation-message [*initiation-message*]

no initiation-message

Context

[Tree] (config>bmp>station initiation-message)

Full Context

configure bmp station initiation-message

Description

This command configures a free-form initiation message for a type 0 TLV to be sent to the BMP monitoring station. The message is transmitted when a BMP monitoring station establishes a connection to the device. Information can be provided to the BMP station system administrator (for example, a contact phone number). The initiation message includes a type 1 TLV containing the SNMP sysDescr value specified in RFC 1213, *Management Information Base for Network Management of TCP/IP-based internets: MIB-II*, and a type 2 TLV containing the SNMP sysName value also from RFC 1213. The string in the initiation-message is UTF-8 encoded.

The **no** form of this command removes initiation message from the configuration and causes a free-form message to be included in the type 0 information TLV and the corresponding tlv-length is made 0.

Parameters

initiation-message

Specifies an initiation message up to 256 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

Platforms

All

13.158 inner-tag

inner-tag

Syntax

inner-tag *value* [*vid-mask*]

no inner-tag

Context

[Tree] (config>qos>sap-ingress>mac-criteria>entry>match inner-tag)

Full Context

configure qos sap-ingress mac-criteria entry match inner-tag

Description

This command configures the matching of the second tag that is carried transparently through the service. The inner tag on ingress is the second tag on the frame if there are no service delimiting tags. The inner tag is the second tag before any service delimiting tags on egress but is dependent in the ingress configuration and may be set to 0 even in cases where additional tags are on the frame. This allows matching VLAN tags for explicit filtering or QoS setting when using default or null encapsulations.

The inner tag is not applicable in ingress on dot1Q SAPs. The inner tag may be populated on egress depending on the ingress SAP type.

On QinQ SAPs of null and default that do not strip tags, the inner-tag will contain the second tag (which is still the second tag carried transparently through the service.) On ingress SAPs that strip any tags, the inner tag will contain 0 even if there are more than two tags on the frame.

The optional vid_mask is defaulted to 4095 (exact match) but may be specified to allow pattern matching. The masking operation is ((value and vid-mask) = = (tag and vid-mask)). A value of 6 and a mask of 7 would match all VIDs with the lower 3 bits set to 6.

For QoS, the VID type cannot be specified on the default QoS policy.

The default vid-mask is set to 4095 for exact match.

Platforms

All

inner-tag

Syntax

inner-tag *value* [*vid-mask*]

configure system power-management peq input-power-mode

Description

This command sets the input-power-mode of the APEQ for the designated APEQ slot.

Parameters

amperage

Sets the APEQ input power mode.

Values 60, 80

Default 60

Platforms

7750 SR-12e, 7950 XRS

13.161 insert

insert

Syntax

insert [*line*]

Context

[Tree] (candidate insert)

Full Context

candidate insert

Description

This command inserts the contents of the temporary buffer (populated by a previous copy or delete command) into the candidate configuration. The contents are inserted by default after the current edit point. Optional parameters allow the insertion after some other point of the candidate. The contents of the temporary buffer are deleted when the operator exits candidate edit mode.

Insertions are context-aware. The temporary buffer always stores the CLI context (such as the current CLI branch) for each line deleted or copied. If the lines to be inserted are supported at the context of the insertion point then the lines are simply inserted into the configuration. If the lines to be inserted are not supported at the context of the insertion point, then the context at the insertion point is first closed using multiple exit statements, the context of the lines to be inserted is built (added) into the candidate at the insertion point, then the lines themselves are added, the context of the inserted lines is closed using exit statements and finally the context from the original insertion point is built again leaving the context at the same point as it was before the insertion.

Parameters

line

Indicates where to insert the line starting at the point indicated by the following options.

Values line, offset, **first**, **edit-point**, **last**

line	absolute line number
offset	relative line number to current edit point. Prefixed with '+' or '-'
first	keyword - first line
edit-point	keyword - current edit point
last	keyword - last line that is not 'exit'

Full Context

configure aaa isa-radius-policy acct-include-attributes inside-service-id

Description

This command enables the inclusion of the NAT inside service ID attributes.

The **no** form of the command excludes NAT inside service ID attributes.

Default

no inside-service-id

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

13.167 install-backup-path

install-backup-path

Syntax

install-backup-path

no install-backup-path

Context

[Tree] (config>router>policy-options>policy-statement>entry>action install-backup-path)

[Tree] (config>router>policy-options>policy-statement>default-action install-backup-path)

Full Context

configure router policy-options policy-statement entry action install-backup-path

configure router policy-options policy-statement default-action install-backup-path

Description

When the best BGP route for an IPv4 or IPv6 prefix is matched by a policy entry or policy default action with this command, BGP attempts to find and install a preprogrammed backup path for the prefix in order to provide BGP fast reroute protection.

The **install-backup-path** command overrides and has no dependency on commands such as the BGP instance **backup-path** command or the VPRN-level **enable-bgp-vpn-backup** command, which enable BGP fast reroute for an entire address family. The **install-backup-path** command provides more precise control over which IP prefixes are supported with preprogrammed backup paths.

In VPRN, if the best path for an IP prefix is provided by a VPRN BGP route, the backup path can be provided by another VPRN BGP route or an imported VPN-IP route. If the best path for an IP prefix is provided by an imported VPN-IP route, the backup path can be provided by another VPN-IP route.

The **install-backup-path** command is supported only in BGP and VRF import policies and has no effect on other types. The **install-backup-path** command applies only to the following types of matched routes: IPv4, IPv6, label-IPv4, label-IPv6, VPN-IPv4, and VPN-IPv6.

The **no** form of this command disables the install-backup-path functionality.

Default

no install-backup-path

Syntax

[**no**] **interactive-authentication**

Context

[Tree] (config>service>vprn>aaa>remote-servers>tacplus interactive-authentication)

Full Context

configure service vprn aaa remote-servers tacplus interactive-authentication

Description

This configuration instructs the SR OS to send no username nor password in the TACACS+ start message, and to display the *server_msg* in the GETUSER and GETPASS response from the TACACS+ server. Interactive authentication can be used to support a One Time Password scheme (such as an S/Key). An example flow (such as with a telnet connection) is as follows:

- The SR OS sends an authentication start request to the TACACS+ server with no username nor password.
- TACACS+ server replies with TAC_PLUS_AUTHEN_STATUS_GETUSER and a *server_msg*.

- The SR OS displays the *server_msg*, and collects the username.
- The SR OS sends a continue message with the username.
- TACACS+ server replies with TAC_PLUS_AUTHEN_STATUS_GETPASS and a *server_msg*.
- The SR OS displays the *server_msg* (which may contain, for example, an S/Key for One Time Password operation), and collects the password.
- The SR OS sends a continue message with the password.
- TACACS+ server replies with PASS or FAIL.

When interactive-authentication is disabled the SR OS will send the username and password in the *tacplus* start message. An example flow (e.g. with a telnet connection) is as follows:

- TAC_PLUS_AUTHEN_TYPE_ASCII.
  - the login username in the "user" field.
  - the password in the *user_msg* field (while this is non-standard, it does not cause interoperability problems).
- TACACS+ server ignores the password and replies with TAC_PLUS_AUTHEN_STATUS_GETPASS.
- The SR OS sends a continue packet with the password in the *user_msg* field.
- TACACS+ server replies with PASS or FAIL.

When interactive-authentication is enabled, tacplus must be the first method specified in the authentication-order configuration.

[Tree] (config>li>li-source>nat>nat64-lsn-sub intercept-id)

Full Context

configure li li-source nat ethernet-header intercept-id

configure li li-source nat dslite-lsn-sub intercept-id

configure li li-source nat classic-lsn-sub intercept-id

configure li li-source nat l2-aware-sub intercept-id

configure li li-source nat nat64-lsn-sub intercept-id

Description

This command configures the intercept-id that is inserted into the packet header for all mirrored packets of the associated **li-source** entry. This **intercept-id** can be used (for example by a downstream LI gateway) to identify the particular LI session to which the packet belongs.

For nat mirroring (a **nat li-source** entry type), when the mirror service is not configured with any routable encap (for example, no ip-udp-shim or ip-gre configured under **config>mirror>mirror-dest>encap**), the presence of a configured intercept-id against an li-source (nat) entry will cause the insertion of the intercept-id after a configurable mac-da, mac-sa and etype (configured under **li-source>nat>ethernet-header**), at the front of each packet mirrored for that particular li-source entry. If there is no **intercept-id**

configured (for a **nat** entry using a mirror service without routable encap), then a configurable mac-da and mac-sa are added to the front of the packets (but no intercept-id). In both cases a non-configurable etype is also added immediately before the mirrored customer packet. Note that routable encapsulation configured in the mirror-dest takes precedence over the ethernet-header configuration in the li-source nat entries. If routable encapsulation is configured, then the ethernet-header config is ignored and no mac header is added to the packet (the encap is determined by the mirror-dest in this case).

For all types of **li-source** entries (filter, nat, sap, subscriber), when the mirror service is configured with **ip-udp-shim** routable encap, an intercept-id field (as part of the routable encap) is always present in the mirrored packets. If there is no intercept ID configured for an li-source entry, then the default value will be inserted. When the mirror service is configured with ip-gre routable encap, no intercept-id is inserted and none should be specified against the **li-source** entries.

The **no** form of this command removes the value from the configuration.

Default

no intercept-id (an id of 0, or no id)

Parameters

id

Specifies the intercept ID value to insert into the header of the mirrored packets.

Values 1 to 4294967295 (32b) For nat li-source entries that are using a mirror service that is not configured with routable encap

Values 1 to 1,073,741,824 (30b) For all types of li-source entries that are using a mirror service with routable ip-udp-shim encap and no direction-bit.

Values 1 to 536,870,912 (29b) For all types of li-source entries that are using a mirror service with routable ip-udp-shim encap and with the direction-bit enabled.

Platforms

interconnect

Syntax

interconnect {**ring-id** *ring-index* | **vpls**}

no interconnect

Context

[Tree] (config>eth-ring>sub-ring interconnect)

Full Context

configure eth-ring sub-ring interconnect

Description

This command links the G.8032 sub-ring to a ring instance or to a VPLS instance. The ring instance must be a complete ring with two paths but may itself be a sub-ring or a major ring (declared by its configuration on another node).

When the interconnection is to another node, the sub-ring may have a virtual link or a non-virtual-link.

When the sub-ring is configured with a non-virtual link, the sub ring may be alternatively connected to a VPLS service.

This command is only valid on the interconnection node where a single sub-ring port connects to a major ring or terminates on a VPLS service.

The **no** form of this command removes the interconnect node.

Default

no interconnect

Parameters

ring-id

Specifies the identifier for the ring instance of the connection ring for this sub-ring on this node.

Values 0 to 128

vpls

Specifies that the sub-ring is connected to the VPLS instance that contains the sub-ring SAP.

Platforms

[Tree] (config>service>ies interface)

[Tree] (config>service>vprn interface)

Full Context

configure service ies interface

configure service vprn interface

Description

This command creates a logical IP routing interface. Once created, attributes like an IP address and service access point (SAP) can be associated with the IP interface.

The **interface** command, under the context of services, is used to create and maintain IP routing interfaces within service IDs. The **interface** command can be executed in the context of a service ID. The IP interface created is associated with the service core network routing instance and default routing table. The typical use for IP interfaces created in this manner is for subscriber Internet access. An IP address cannot be assigned to an IES interface. Multiple SAPs can be assigned to a single group interface.

Interface names are case sensitive and must be unique within the group of defined IP interfaces defined for **config>router>interface**, **config>service>ies>interface** and **config>service>vprn>interface** (that is, the network core router instance). Interface names must not be in the dotted decimal notation of an IP address. For example, the name "1.1.1.1” is not allowed, but "int-1.1.1.1” is allowed. Show commands for

router interfaces use either interface names or the IP addresses. Use unique IP address values and IP address names to maintain clarity. It could be unclear to the user if the same IP address and IP address name values are used. Although not recommended, duplicate interface names can exist in different router instances.

When a new name is entered, a new logical router interface is created. When an existing interface name is entered, the user enters the router interface context for editing and configuration.

By default, there are no default IP interface names defined within the system. All IP interfaces must be explicitly defined. Interfaces are created in an enabled state.

The **no** form of this command removes IP the interface and all the associated configuration. The interface must be administratively shut down before issuing the **no interface** command.

The IP interface must be shut down before the SAP on that interface may be removed. IES and VPRN services do not have the **shutdown** command in the SAP CLI context. The service SAPs rely on the interface status to enable and disable them.

Parameters

ip-int-name

Specifies the name of the IP interface. Interface names must be unique within the group of defined IP interfaces for **config router interface** and config service vprn interface commands. An interface name cannot be in the form of an IP address. Interface names can be from 1 to 32 alphanumeric characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed between double quotes.

If *ip-int-name* already exists within the service ID, the context will be changed to maintain that IP interface. If *ip-int-name* already exists within another service ID or is an IP interface defined within the **config router** commands, an error will occur and context will not be changed to that IP interface. If *ip-int-name* does not exist, the interface is created and context is changed to that interface for further command processing.

tunnel

Specifies that the interface is configured as tunnel interface, which could be used to terminate IPsec or GRE runnels in the private service.

create

Creates the IPsec interface instance. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

Platforms

All

interface

Syntax

[**no**] **interface** *ip-int-name*

Context

[Tree] (config>router>igmp interface)

Full Context

configure router igmp interface

Description

Commands in this context configure an IGMP interface. The interface is a local identifier of the network interface on which reception of the specified multicast address is to be enabled or disabled.

The **no** form of the command deletes the IGMP interface. The **shutdown** command in the **config>router>igmp>interface** context can be used to disable an interface without removing the configuration for the interface.

Default

no interface

Parameters

ip-int-name

The IP interface name. Interface names must be unique within the group of defined IP interfaces for **config router interface** and **config service ies interface** commands. An interface name cannot be in the form of an IP address. Interface names can be any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

If the IP interface name does not exist or does not have an IP address configured an error message will be returned.

If the IP interface exists in a different area it will be moved to this area.

Platforms

interface

Syntax

[**no**] **interface** *ip-int-name*

Context

[Tree] (config>service>vpls interface)

Full Context

configure service vpls interface

Description

This command creates a logical IP routing interface for a VPLS service. Once created, attributes such as IP address and service access points (SAP) can be associated with the IP interface.

The interface command, under the context of services, is used to create and maintain IP routing interfaces within the VPLS service IDs. The IP interface created is associated with the VPLS management routing instance. This instance does not support routing.

Interface names are case-sensitive and must be unique within the group of defined IP interfaces defined for the network core router instance. Interface names in the dotted decimal notation of an IP address are not allowed. For example, the name "1.1.1.1” is not allowed, but "int-1.1.1.1” is allowed. Show commands for router interfaces use either interface names or the IP addresses. Use unique IP address values and IP address names to maintain clarity. Duplicate interface names can exist in different router instances.

Enter a new name to create a logical router interface. When an existing interface name is entered, the user enters the router interface context for editing and configuration.

By default, no default IP interface names are defined within the system. All VPLS IP interfaces must be explicitly defined in an enabled state.

The no form of this command removes the IP interface and the entire associated configuration. The interface must be administratively shut down before issuing the no interface command.

For VPLS services, the IP interface must be shut down before the SAP on that interface is removed.

For VPLS service, ping and traceroute are the only applications supported.

Parameters

ip-int-name

Specifies the name of the IP interface. Interface names must be unique within the group of defined IP.

An interface name:

- Should not be in the form of an IP address.
- Can be from 1 to 32 alphanumeric characters.
- If the string contains special characters (such as #,$,spaces), the entire string must be enclosed within double quotes.

If ip-int-name already exists within the service ID, the context changes to maintain that IP interface. If ip-int-name already exists within another service ID, an error occurs and the context does not change to that IP interface. If ip-int-name does not exist, the interface is created and the context is changed to that interface for further command processing.

Context

[Tree] (config>service>vprn>isis interface)

Full Context

configure service vprn isis interface

Description

This command creates the context to configure an IS-IS interface.

When an area is defined, the interfaces belong to that area. Interfaces cannot belong to separate areas.

When the interface is a POS channel, the OSI Network Layer Control Protocol (OSINLCP) is enabled when the interface is created and removed when the interface is deleted.

The **no** form of this command removes IS-IS from the interface.

The **shutdown** command in the **config>router>isis>if** context administratively disables IS-IS on the interface without affecting the IS-IS configuration.

Default

no interface — No IS-IS interfaces are defined.

Parameters

ip-int-name

Identify the IP interface name created in the **config>router>if** context. The IP interface name must already exist.

Platforms

All

interface

Syntax

[**no**] **interface** *ip-int-name*

[Tree] (config>service>vprn>ospf3>area interface)

[Tree] (config>service>vprn>ospf>area interface)

Full Context

configure service vprn ospf3 area interface

configure service vprn ospf area interface

Description

This command creates a context to configure an OSPF interface.

By default interfaces are not activated in any interior gateway protocol, such as OSPF, unless explicitly configured.

The **no** form of this command deletes the OSPF interface configuration for this interface. The **shutdown** command in the **config>router>ospf>if** context can be used to disable an interface without removing the configuration for the interface.

Default

no interface

Parameters

ip-int-name

Specifies the IP interface name. Interface names must be unique within the group of defined IP interfaces for **config router interface** and **config service vprn interface** commands. An interface name cannot be in the form of an IP address. Interface names can be any string up to 32 characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed between double quotes.

If the IP interface name does not exist or does not have an IP address configured an error message will be returned.

If the IP interface exists in a different area it will be moved to this area.

secondary

Keyword used to allow multiple secondary adjacencies, in addition to the primary adjacency, to be established over a single IP interface. This keyword can also be applied

to the system interface and to loopback interfaces to allow them to participate in multiple areas, although no adjacencies are formed over these types of interfaces.

Platforms

All

interface

Syntax

[**no**] **interface** *ip-int-name*

Context

[Tree] (config>service>vprn>pim interface)

Full Context

configure service vprn pim interface

Description

This command enables PIM on an interface and enables the context to configure interface-specific parameters. By default interfaces are activated in PIM based on the **apply-to** command, and do not have to be configured on an individual basis unless the default values must be changed.

The **no** form of this command deletes the PIM interface configuration for this interface. If the **apply-to** command parameter is configured, then the **no interface** form must be saved in the configuration to avoid automatic (re)creation after the next **apply-to** is executed as part of a reboot.

The **shutdown** command can be used to disable an interface without removing the configuration for the interface.

Default

Interfaces are activated in PIM based on the apply-to command.

Parameters

ip-int-name

Specifies the interface name. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed between double quotes.

Platforms

[Tree] (config>service>vprn>router-advertisement interface)

Full Context

configure service vprn router-advertisement interface

Description

This command configures router advertisement properties on a specific interface. The interface must already exist in the **config>router>if** context.

Default

No interfaces are configured by default.

Parameters

ip-int-name

Specifies the interface name. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed between double quotes.

Platforms

All

interface

Syntax

[**no**] **interface** *ip-int-name* [**dual-stack**]

Context

[Tree] (config>router>ldp>interface-parameters interface)

Full Context

configure router ldp interface-parameters interface

Description

This command enables LDP on the specified IP interface.

The **no** form of the command deletes the LDP interface and all configuration information associated with the LDP interface.

The LDP interface must be disabled using the **shutdown** command before it can be deleted.

The user can configure different parameters for IPv4 and IPv6 LDP interfaces by entering **ipv4** or **ipv6** as the next command.

Parameters

ip-int-name

Specifies the name of an existing interface. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

dual-stack

This optional keyword allows the user to explicitly indicate if this interface should create the IPv4 context automatically or not. With the introduction of LDP IPv6, the creation of the interface does not automatically mean it is to be used for IPv4 like with legacy IPv4 only LDP interface. Thus the dual-stack keyword is an indication to the system that user will manually enable the IPv4, IPv6, or the dual-stack IPv4/IPv6 contexts manually.

The following are some of the key points for this keyword:

- If the keyword is provided, then IPv4 interface context will not be created automatically. If it is not provided, the IPv4 interface context will be created like in the legacy single stack LDP IPv4 interface behavior.
- This new keyword will always show in a configuration.
- When entering an already configured interface, there is no need to provide the keyword, but it will be ignored if provided.
- When deleting a configured interface, the keyword will not be accepted in the **no** version of the **interface** command.

interface

Syntax

interface *ip-address* **srlg-group** *group-name* [*group-name*]

no interface *ip-address* [**srlg-group** *group-name*]

Context

[Tree] (config>router>mpls>srlg-database>router-id interface)

Full Context

configure router mpls srlg-database router-id interface

Description

This command allows the operator to manually enter the SRLG membership information for any link in the network, including links on this node, into the user SRLG database.

An interface can be associated with up to five SRLG groups for each execution of this command. The operator can associate an interface with up to 64 SRLG groups by executing the command multiple times.

CSPF will not use entered SRLG membership if an interface is not validated as part of a router ID in the routing table.

The **no** form of this command deletes a specific interface entry in this user SRLG database. The *group-name* must already exist in the config>router>if-attribute>srlg-group context.

Parameters

ip-address

Specifies the IPv4 address in a.b.c.d

srlg-group group-name

Specifies the SRLG group name. Up to 1024 group names can be defined in the config>router>if-attribute context. The SRLG group names must be identical across all routers in a single domain.

Platforms

All

interface

Syntax

[**no**] **interface** *ip-int-name*

Context

[Tree] (config>router>mpls interface)

Full Context

configure router mpls interface

Description

This command specifies MPLS protocol support on an IP interface. No MPLS commands are executed on an IP interface where MPLS is not enabled. An MPLS interface must be explicitly enabled (**no shutdown**).

The **no** form of this command deletes all MPLS commands such as **label-map** which are defined under the interface. The MPLS interface must be shutdown first in order to delete the interface definition. If the interface is not shutdown, the **no interface** *ip-int-name* command does nothing except issue a warning message on the console indicating that the interface is administratively up.

Default

shutdown

Parameters

ip-int-name

Specifies the name of the network IP interface. An interface name cannot be in the form of an IP address. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

Values 1 to 32 alphanumeric characters.

Syntax

[**no**] **interface** *ip-int-name*

Context

[Tree] (config>router>pim interface)

Full Context

configure router pim interface

Description

This command creates a PIM interface.

Interface names are case-sensitive and must be unique within the group of defined IP interfaces defined for **config>router>interface**, **config>service>ies>interface**, and **config>service>ies>subscriber-interface>group-interface**. Interface names must not be in the dotted decimal notation of an IP address. For example, the name "1.1.1.1" is not allowed, but "int-1.1.1.1" is allowed. Show commands for router interfaces use either the interface names or the IP addresses. Ambiguity can exist if an IP address is used as an IP address and an interface name. Duplicate interface names can exist in different router instances, although this is not recommended because it may be confusing.

By default, no interfaces or names are defined within PIM.

The **no** form of this command removes the IP interface and all the associated configurations.

Parameters

ip-int-name

Specifies the name of the IP interface, up to 32 characters. Interface names must be unique within the group of defined IP interfaces for **config router interface**, **config service ies interface**, and **config service ies subscriber-interface group-interface** commands. An interface name cannot be in the form of an IP address. If the string contains special characters (#, $, spaces, and so on.), the entire string must be enclosed within double quotes.

If the *ip-int-name* already exists, the context is changed to maintain that IP interface. If *ip-int-name* does not exist, the interface is created and the context is changed to that interface for further command processing.

Platforms

All

interface

Syntax

interface *interface-name* [**unnumbered-mpls-tp**]

interface *interface-name* **pdn**

no interface *interface-name*

Context

[Tree] (config>router interface)

Full Context

configure router interface

Description

This command creates a logical IP routing or unnumbered MPLS-TP interface. Once created, attributes like IP address, port, or system can be associated with the IP interface.

Interface names are case-sensitive and must be unique within the group of IP interfaces defined for **config router interface** and **config service ies interface**. Interface names must not be in the dotted decimal notation of an IP address.; for example, the name "1.1.1.1" is not allowed, but "int-1.1.1.1" is allowed. Show commands for router interfaces use either the interface names or the IP addresses. Ambiguity can exist if an IP address is used as an IP address and an interface name. Duplicate interface names can exist in different router instances, although this is not recommended because it is confusing. Nokia recommends that names are meaningful and unique to remove ambiguity when displaying the state associated with IP interfaces through show commands.

When a new name is entered, a new logical router interface is created. When an existing interface name is entered, the user enters the router interface context for editing and configuration.

Although not a keyword, the ip-int-name "**system**" is associated with the network entity (such as a specific router), not a specific interface. The system interface is also referred to as the loopback address.

An unnumbered MPLS-TP interface is a special type of interface that is only intended for MPLS-TP LSPs. IP routing protocols are blocked on interfaces of this type. If an interface is configured as unnumbered-mpls-tp, then it can only be associated with an Ethernet port or VLAN, using the port command, then either a unicast, multicast, or broadcast remote MAC address may be configured. Only static ARP is supported.

The control-tunnel parameter creates a loopback interface representing a GRE tunnel. One IP tunnel can be created in this interface.

Only the primary IPv4 interface address and only one IP tunnel per interface are allowed. Multiple tunnels can be configured using up to four controlTunnel loopback interfaces. A static route can take the new controlTunnel interface as a next hop.

The **no** form of this command removes the IP interface and all the associated configurations. The interface must be administratively shut down before issuing the **no interface** command.

Parameters

interface-name

Specifies the name of the IP interface. Interface names must be unique within the group of defined IP interfaces for **config router interface** and **config service ies interface** commands. An interface name cannot be in the form of an IP address. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

Values 1 to 32 alphanumeric characters

If the *ip-int-name* already exists, the context is changed to maintain that IP interface. If *ip-int-name* already exists within another service ID or is an IP interface defined within the **config router** commands, an error will occur and the context will not be changed to that IP interface. If *ip-int-name* does not exist, the interface is created and the context is changed to that interface for further command processing.

unnumbered-mpls-tp

Specifies that an interface is an unnumbered MPLS-TP. An unnumbered MPLS-TP interface is a special type of interface that is only intended for MPLS-TP LSPs. IP routing protocols are blocked on interfaces of this type. If an interface is configured as **unnumbered-mpls-tp**, then it can only be associated with an Ethernet port or VLAN, using the **port** command. A unicast, multicast, or broadcast remote MAC address can be configured using the **static-arp** command. Only static ARP is supported.

pdn

Specifies that the interface is a PDN.

debug router ip interface

Description

This command displays the router IP interface table sorted by interface index.

Parameters

ip-int-name

Only displays the interface information associated with the specified IP interface name.

Values 32 characters maximum

ip-address

Only displays the interface information associated with the specified IP address.

Values The following values apply to the 7750 SR and 7950 XRS:

ipv4-address	a.b.c.d (host bits must be 0)
ipv6-address	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x: [0 to FFFF]H
	d: [0 to 255]D

Values The following values apply to the 7450 ESS:
ipv4-address: a.b.c.d (host bits must be 0)

Platforms

All

interface

Syntax

[**no**] **interface** *ip-int-name*

Context

[Tree] (config>router>isis interface)

Full Context

configure router isis interface

Description

This command creates the context to configure an IS-IS interface.

When an area is defined, the interfaces belong to that area. Interfaces cannot belong to separate areas.

When the interface is a POS channel, the OSINLCP is enabled when the interface is created and removed when the interface is deleted.

The **no** form of this command removes IS-IS from the interface.

The **shutdown** command in the **config>router>isis>interface** context administratively disables IS-IS on the interface without affecting the IS-IS configuration.

Parameters

ip-int-name

Identify the IP interface name created in the **config>router>interface** context. The IP interface name must already exist.

Platforms

All

interface

Syntax

interface [*ip-int-name* | *ip-address*]

no interface

Context

[Tree] (config>router>ospf3>area interface)

[Tree] (config>router>ospf>area interface)

Full Context

configure router ospf3 area interface

configure router ospf area interface

Description

This command configures an OSPF interface.

Unless they are explicitly configured, interfaces are not activated, by default, in any interior gateway protocol, such as OSPF.

The **no** form of this command deletes the OSPF interface configuration for this interface. Use the **shutdown** command in the **config**>**router**>**ospf**>**interface** context to disable an interface without removing the configuration for the interface.

Default

no interface

Parameters

ip-int-name

Specifies the IP interface name. Interface names must be unique within the group of defined IP interfaces for the **configure router interface** and **configure service ies interface** commands. An interface name cannot be in the form of an IP address. Interface names can be any string, up to 32 characters, composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

If the IP interface name does not exist or does not have an IP address configured, an error message is returned.

If the IP interface exists in a different area it is moved to this area.

secondary

Keyword used to allow multiple secondary adjacencies, in addition to the primary adjacency, to be established over a single IP interface. This keyword can also be applied to the system interface and to loopback interfaces to allow them to participate in multiple areas, although no adjacencies are formed over these types of interfaces.

interface

Syntax

[**no**] **interface** *ip-int-name*

Context

[Tree] (config>router>bgp>group>dynamic-neighbor interface)

Full Context

configure router bgp group dynamic-neighbor interface

Description

Commands in this context configure an unnumbered base router network interface for dynamic neighbors.

If this interface connects to a network with other BGP routers, sessions with the other routers can be set up automatically without explicitly configuring them as BGP neighbors. The interface must be IPv6 enabled, but because the interface is considered unnumbered, it does not require an IPv4 address or a global-unicast IPv6 address. The sessions are set up using IPv6 link-local addresses.

The BGP unnumbered feature supports all address families that allow IPv6 link-local BGP next-hop addresses. This includes IPv4 with the use of RFC 8950 extensions.

When an interface is added to the list of dynamic-neighbor interfaces, an outgoing connection attempt is initiated toward any directly connected router on the interface that announces itself using an ICMPv6 router advertisement message. The session attempt is unsuccessful if the peer type is not EBGP, the reported AS number of the peer does not match one of the allowed values, or the maximum session limit of the interface would be exceeded.

The **no** form of this command removes the interface from the list of dynamic-neighbor interfaces.

Parameters

ip-int-name

Specifies the name of a base router IP interface, up to 32 characters.

Platforms

All

interface

Syntax

[**no**] **interface** *ip-int-name*

Context

[Tree] (config>service>vprn>bgp>group>dynamic-neighbor interface)

Full Context

configure service vprn bgp group dynamic-neighbor interface

Description

Commands in this context configure an unnumbered VPRN access IP interface for dynamic neighbors.

If this interface connects to a network with other BGP routers, sessions with the other routers can be set up automatically without explicitly configuring them as BGP neighbors. The interface must be IPv6 enabled, but because the interface is considered unnumbered, it does not require an IPv4 address or a global-unicast IPv6 address. The sessions are set up using IPv6 link-local addresses.

The BGP unnumbered feature supports all address families that allow IPv6 link-local BGP next-hop addresses. This includes IPv4 with the use of RFC 8950 extensions.

When an interface is added to the list of dynamic-neighbor interfaces, an outgoing connection attempt is initiated toward any directly connected router on the interface that announces itself using an ICMPv6 router advertisement message. The session attempt is unsuccessful if the peer type is not EBGP, the reported AS number of the peer does not match one of the allowed values, or the maximum session limit of the interface would be exceeded.

The **no** form of this command removes the interface from the list of dynamic-neighbor interfaces.

interface-subnets

Syntax

interface-subnets [**service** *service-id*] *interface-name*

no interface-subnets

Context

[Tree] (config>router>policy-options>policy-statement>entry>from interface-subnets)

Full Context

configure router policy-options policy-statement entry from interface-subnets

Description

This command configures the applied router instance and interfaces that are used as matching condition within each policy-statement entry. A maximum of 10 *interface-name* entries is supported, and all entries must belong to the same routing context (either **base** or **service**). The interface subnet policy-statement match criterion is applied to the following unicast use case contexts:

- **export**, when used with OSPFv2, OSPFv3, IS-IS, RIP, RIPng, and BGP
- **route-table-import**, when used with BGP
- **vrf-export**, when used with MP-BGP

The **no** form of this command removes all policies from the configuration.

Default

no interface-subnets

Parameters

service

Specifies the context in which the configured interface exists. By default, the base routing instance is assumed. However, the configured service context is used only when the service is configured.

service-id

Specifies the service ID of the service to match.

Values *service-id* — 1 to 2147483647

svc-name — 64 characters maximum

interface-name

Specifies the interface name, up to 32 characters, to match when exporting the IP address of the associated interface to a routing protocol.

configure service vpls spoke-sdp eth-cfm mep ais-enable interface-support-enable

configure service vpls mesh-sdp eth-cfm mep ais-enable interface-support-enable

Description

This command enables the AIS function to consider the operational state of the entity on which it is configured. With this command, ETH-AIS on DOWN MEPs are triggered and cleared based on the operational status of the entity on which it is configured. If CCM is also enabled, then transmission of the AIS PDU is based on either the non-operational state of the entity or on any CCM defect condition. AIS generation ceases if both the operational state is UP and the CCM has no defect conditions. If the MEP is not CCM-enabled then the operational state of the entity is the only consideration, assuming this command is present for the MEP. By default, AIS is not generated or stopped based on the state of the entity on which the DOWN MEP is configured.

The **no** form of this command disables the AIS function to consider the operational state of the entity on which it is configured.

Default

no interface-support-enabled

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

interface-type {**broadcast** | **point-to-point**}

no interface-type

Context

[Tree] (config>service>vprn>isis>if interface-type)

Full Context

configure service vprn isis interface interface-type

Description

This command configures the IS-IS interface type as either broadcast or point-to-point.

Use this command to set the interface type of an Ethernet link to point-to-point to avoid having to carry the designated IS-IS overhead if the link is used as a point-to-point.

If the interface type is not known at the time the interface is added to IS-IS and subsequently the IP interface is bound (or moved) to a different interface type, then this command must be entered manually.

The **no** form of this command reverts to the default value.

Default

point-to-point — For IP interfaces on SONET channels.

broadcast — For IP interfaces on Ethernet or unknown type physical interfaces.

Parameters

broadcast

Configures the interface to maintain this link as a broadcast network.

point-to-point

Configures the interface to maintain this link as a point-to-point link.

Platforms

All

interface-type

Syntax

interface-type {**broadcast** | **point-to-point** | **non-broadcast** | **p2mp-nbma**}

[Tree] (config>service>vprn>ospf>area>if interface-type)

Full Context

configure service vprn ospf3 area interface interface-type

configure service vprn ospf area interface interface-type

Description

This command configures the interface type to:

- broadcast

- non-broadcast
- point-to-point
- point-to-multipoint on a link without broadcast or multicast support

Use this command to set the interface type of an Ethernet link to point-to-point to avoid having to carry the broadcast adjacency maintenance overhead if the Ethernet link provided the link is used as a point-to-point.

For subscriber interfaces, configure the adjacent interface (CPE) with interface type point-to-point. For subscriber interfaces, when the interface is configured as P2MP-NBMA, the subscriber interface becomes an active OPSF interface, allowing it to both send and receive OSPF LSAs. For all other interface types, subscriber interfaces remain as passive OSPF interfaces by default.

The **no** form of this command reverts to the default value.

Default

point-to-point — If the physical interface is SONET.

broadcast — If the physical interface is Ethernet or unknown.

Parameters

broadcast

Specifies the interface as a broadcast network. To significantly improve adjacency forming and network convergence, configure the network as point-to-point if only two routers are connected, even if the network is a broadcast media such as Ethernet.

point-to-point

Specifies the interface as a point-to-point link. Set the interface type of an Ethernet link to point-to-point to avoid having to carry the broadcast adjacency maintenance overhead if the Ethernet link provided is used as a point-to-point.

non-broadcast

Specifies the interface as a non-broadcast network.

p2mp-nbma

Specifies the interface as a point-to-multipoint on a link without broadcast or multicast support. No designated router or backup designated router is elected on this type of interface and all OSPF neighbors connect through individual point-to-point links. Only VPRN and IES services interfaces support this interface type.

Full Context

configure system sync-if-timing bits interface-type

Description

This command configures the Building Integrated Timing Source (BITS) timing reference.

The **no** form of the command reverts to the default configuration.

Default

interface-type ds1 esf

Parameters

ds1 esf

Specifies Extended Super Frame (ESF). This is a framing type used on DS1 circuits that consists of 24 192-bit frames, The 193rd bit provides timing and other functions.

ds1 sf

Specifies Super Frame (SF), also called D4 framing. This is a common framing type used on DS1 circuits. SF consists of 12 192-bit frames. The 193rd bit provides error checking and other functions. ESF supersedes SF.

e1 pcm30crc

Specifies the pulse code modulation (PCM) type. PCM30CRC uses PCM to separate the signal into 30 user channels with CRC protection.

e1 pcm31crc

Specifies the pulse code modulation (PCM) type. PCM31CRC uses PCM to separate the signal into 31 user channels with CRC protection.

configure router ospf3 area interface interface-type

configure router ospf area interface interface-type

Description

This command configures the interface type to:

- broadcast
- non-broadcast
- point-to-point

- point-to-multipoint on a link without broadcast or multicast support

Use this command to set the interface type of an Ethernet link to point-to-point to avoid having to carry the broadcast adjacency maintenance overhead of the Ethernet link provided the link is used as point-to-point.

For subscriber interfaces, configure the adjacent interface (CPE) with interface type point-to-point. For subscriber interfaces, when the interface is configured as P2MP-NBMA, the subscriber interface becomes an active OPSF interface, allowing it to both send and receive OSPF LSAs. For all other interface types, subscriber interfaces remain as passive OSPF interfaces by default.

The **no** form of this command returns the setting to the default value.

Default

interface-type point-to-point (if the physical interface is SONET)

interface-type broadcast (if the physical interface is Ethernet or unknown)

Parameters

broadcast

Specifies the interface as a broadcast network. To significantly improve adjacency forming and network convergence, configure a network as point-to-point if only two routers are connected, even if the network is a broadcast media such as Ethernet.

point-to-point

Specifies the interface as a point-to-point link. Set the interface type of an Ethernet link to point-to-point to avoid having to carry the broadcast adjacency maintenance overhead if the Ethernet link provided is used as a point-to-point.

non-broadcast

Specifies the interface as a non-broadcast network.

p2mp-nbma

Specifies the interface as a point-to-multipoint on a link without broadcast or multicast support. No designated router or backup designated router is elected on this type of interface and all OSPF neighbors connect through individual point-to-point links. Only VPRN and IES services interfaces support this interface type.

Full Context

configure service vprn wlan-gw mobility-triggered-acct interim-update

configure router wlan-gw mobility-triggered-acct interim-update

Description

This command enables the inclusion of counters with a **hold-down** time option in mobility-triggered interim updates. When enabled, to disable the inclusion of counters, interim updates must be disabled and then re-enabled without the **include-counters** keyword. By default, the **hold-down** time is not imposed.

The **no** form of this command disables generation of flash interim accounting updates to RADIUS when change in location of the UE is detected.

Default

no interim-update

Parameters

include-counters

Specifies the inclusion of counters in mobility-triggered interim updates.

seconds

Specifies the time, in seconds, that must elapse after a mobility-triggered interim with counters sent for the next mobility-triggered interim with counters to be sent.

Values 60 to 864000

Platforms

[Tree] (config>router>l2tp>group>mlppp interleave)

Full Context

configure service vprn l2tp group mlppp interleave

configure router l2tp group mlppp interleave

Description

This command is applicable only to LNS. Interleaving is supported only on MLPPPoX bundles that contain a single member link. If more than one link is present in the MLPPPoX bundle, interleaving is automatically disabled and a TRAP/log (tmnxMlpppBundleIndicatorsChange) is generated.

The minimum supported rate of the link on which interleaving is performed is 1 kb/s.

If configured at this level, interleaving is enabled on all tunnels within the group, unless it is explicitly disable per tunnel.

The **no** form of this command reverts to the default.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s

interleave

Syntax

interleave {**always** | **never**}

no interleave

Context

[Tree] (config>router>l2tp>group>tunnel>mlppp interleave)

[Tree] (config>service>vprn>l2tp>group>tunnel>mlppp interleave)

Full Context

configure router l2tp group tunnel mlppp interleave

configure service vprn l2tp group tunnel mlppp interleave

Description

This command configures the user of link fragmentation and interleaving and is applicable only to LNS. Interleaving is supported only on MLPPPoX bundles that contain a single member link. If more than one link is present in the MLPPPoX bundle, interleaving is automatically disabled and a TRAP/log (tmnxMlpppBundleIndicatorsChange) is generated.

The minimum supported rate of the link on which interleaving is performed is 1 kb/s.

Interleaving configured on this level overwrites the configuration option under the group hierarchy. If the **no** form of this command is configured for interleaving at this level, the interleaving configuration inherits the configuration option configured under the L2TP group.

The **no** form of this command reverts to the default.

Parameters

always

Always perform interleaving on single linked MLPPPoX sessions within this tunnel, regardless of the configuration option for interleaving under the group level.

never

Never perform interleaving on single linked MLPPPoX sessions within this tunnel, regardless of the configuration option for interleaving under the group level.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s

interleave

Syntax

[**no**] **interleave**

Context

[Tree] (config>service>vprn>if>sap>frame-relay>frf.12 interleave)

Full Context

configure service vprn interface sap frame-relay frf.12 interleave

Description

This command enables interleaving of high priority frames and low-priority frame fragments within a FR SAP using FRF.12 end-to-end fragmentation.

When this option is enabled, only frames of the FR SAP non expedited forwarding class queues are subject to fragmentation. The frames of the FR SAP expedited queues are interleaved, with no fragmentation header, among the fragmented frames. In effect, this provides a behavior like in MLPPP Link Fragment Interleaving (LFI).

When this option is disabled, frames of all the FR SAP forwarding class queues are subject to fragmentation. The fragmentation header is however not included when the frame size is smaller than the user configured fragmentation size. In this mode, the SAP transmits all fragments of a frame before sending the next full or fragmented frame.

The receive direction of the FR SAP supports both modes of operation concurrently, with and without fragment interleaving.

The **no** form of this command restores the default mode of operation.

Default

no interleave

13.201 intersite-shared

intersite-shared

Syntax

intersite-shared [**persistent-type5-adv**] [**kat-type5-adv-withdraw**]

no intersite-shared

Context

[Tree] (config>service>vprn>mvpn intersite-shared)

Full Context

configure service vprn mvpn intersite-shared

Description

This command specifies whether to use inter-site shared C-trees or not. Optional parameters allow enabling additional inter-site shared functionality. Not specifying an optional parameter when executing the command disables that parameter.

Default

n/a

Parameters

persistent-type5-adv

When specified for inter-site shared trees enabled, this parameter ensures that Type 5 SA routes are generated for the multicast source even if no joins are present for that source. When the parameter is not specified, the Type 5 SA routes are withdrawn where the prune from the last receiver is received for the multicast source.

kat-type5-adv-withdraw

When specified for inter-site shared trees, this parameter allows operators to enable KeepAlive Timers (KAT) on source PEs for ng-MVPN inter-site shared deployments. On a multicast source failure, a KAT expiry on source PEs will trigger a withdrawal of Type-5 Source-Active (S-A) route and switch from (C-S,C-G) to (C-*,C-G). When receiver PEs process reflected Type-5 S-A route withdrawals, they will withdraw their Type-7 ng-MVPN routes to the failed multicast source. The following conditions apply:

- KAT must only be enabled on source PEs.
- Functionality is supported with mLDP and RSVP-TE in the P-instance.
- Local receiver per (C-S, C-G) must be configured on source PEs running KAT.

Full Context

configure subscriber-mgmt diameter-application-policy gx ccrt-replay interval

configure subscriber-mgmt diameter-application-policy gy ccrt-replay interval

Description

This command specifies the interval at which CCR-T messages for Diameter Gx or Gy sessions that belong to the Diameter application policy are replayed, until a valid CCA-t response is received or until the configured **max-lifetime** period expires.

The **no** form of this command resets the interval to the default setting.

Default

interval 3600

Parameters

seconds

Specifies the interval at which the CCR-T messages are replayed for a gx session. The messages are replayed until a valid CCA-t response is received or until a 24 hour period expires, whichever comes first.

Values 60 to 86400

Default 3600

Platforms

configure service vprn static-route-entry indirect cpe-check interval

configure service vprn static-route-entry next-hop cpe-check interval

Description

This optional parameter specifies the interval between ICMP pings to the target IP address.

Default

interval 1

Parameters

seconds

An integer interval value.

Values 1 to 255

Platforms

All

interval

Syntax

interval *seconds*

no interval

Context

[Tree] (config>router>mpls>lsp-self-ping interval)

Full Context

configure router mpls lsp-self-ping interval

Description

This command configures the interval at which LSP Self Ping packets are periodically sent on a candidate path of an RSVP LSP. This value is used for all LSPs that have LSP Self Ping enabled.

The **no** form of this command reverts to the default value.

Default

interval 1

Parameters

seconds

Specifies the value, in seconds, used as the fast retry timer for a secondary path.

Values 1 to 10

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

interval

Syntax

interval {**one-time** | *minimum-interval*}

Context

[Tree] (config>app-assure>group>http-notif interval)

Full Context

configure application-assurance group http-notification interval

Description

This command configures the minimum interval in between notification messages. It can be set to **one-time** or a value in minutes from 1 to 1440.

The **no** form of this command removes the interval from the http-notification policy.

Default

interval one-time

Parameters

minimum-interval

Represents the minimum interval value in minutes in between two http notifications.

Values 1 to 1440

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

interval

Context

[Tree] (config>test-oam>ldp-treetrace>path-discovery interval)

Full Context

configure test-oam ldp-treetrace path-discovery interval

Description

This command configures the frequency of the LDP ECMP OAM path discovery. Every interval, the node sends LSP trace messages to attempt to discover the entire ECMP path tree for a given destination FEC.

The **no** form of this command removes the value from the configuration.

Default

no interval

Parameters

minutes

Specifies the number of minutes to wait before repeating the LDP tree auto discovery process.

Values 60 to 1440

Platforms

All

interval

Syntax

interval *seconds*

no interval

Context

[Tree] (config>test-oam>icmp>ping-template interval)

Full Context

configure test-oam icmp ping-template interval

Description

This command configures the packet transmit interval used when the interface is operational and possibly transitioning from up to down, but not down to up, because of the ping-template function.

The **no** form of this command reverts to the default value.

Default

interval 60

Parameters

seconds

Sets the packet transmit interval, in seconds, when the interface is operational.

Values 1 to 60

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

configure saa test type-multi-line lsp-trace sr-policy interval

configure saa test type-multi-line lsp-ping interval

Description

This command configures the number of seconds to override the default request message send interval and defines the minimum amount of time that must expire before the next message request is sent.

The **no** form of this command reverts to the default value.

Default

interval 1

Parameters

interval

Specifies the number of seconds to wait before the next message request is sent.

Values 1 to 10

Default 1

Platforms

All

interval

Syntax

interval *milliseconds*

no interval

Context

[Tree] (config>oam-pm>session>ethernet>dmm interval)

[Tree] (config>oam-pm>session>ethernet>lmm interval)

Full Context

configure oam-pm session ethernet dmm interval

configure oam-pm session ethernet lmm interval

Description

This command defines the message period or probe spacing for the transmission of the DMM or LMM frame.

The **no** form of this command sets the interval to the default. If an LMM test is in **no shutdown** state, it always has timing parameters, whether default or operator configured.

Parameters

milliseconds

Specifies the number of milliseconds between the transmission of the DMM or LMM frames. The default value for the DMM or LMM interval is different than the default interval for SLM. This is intentional.

Values 100, 1000, 10000

Default 1000

Platforms

All

interval

Syntax

interval *milliseconds*

no interval

Context

[Tree] (config>oam-pm>session>ip>twamp-light interval)

Full Context

configure oam-pm session ip twamp-light interval

Description

This command defines the message period, or probe spacing, for transmitting a TWAMP Light frame.

The **no** form of this command sets the interval to the default value.

Default

interval 1000

Parameters

milliseconds

Specifies the number of milliseconds between TWAMP Light frame transmission.

Values 100, 1000, 10000

Default 1000

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

interval

Syntax

Description

This command configures the interval between ICMP pings to the target CPE IP address.

Default

interval 1

Parameters

seconds

Specifies the interval value, in seconds.

Values 1 to 255

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

13.203 intervals-stored

intervals-stored

Syntax

intervals-stored *intervals*

no intervals-stored

Context

[Tree] (config>oam-pm>session>meas-interval intervals-stored)

Full Context

configure oam-pm session meas-interval intervals-stored

Description

This command defines the number of completed measurement intervals per session to be stored in volatile system memory. The entire block of memory is allocated for the measurement interval when the test is active (**no shutdown**) to ensure memory is available. The numbers are increasing from 1 to the configured value + 1. The active pm data is stored in the interval number 1 and older runs are stored, in order, to the upper most number with the oldest rolling off when the number of completed measurement intervals exceeds the configured value+1. As new test measurement intervals complete for the session, the stored intervals are renumbered to maintain the described order. Use caution when setting this value. There must be a balance between completed runs stored in volatile memory and the use of the write-to-flash function of the accounting policy.

The **5-mins** and **15-mins** measurement intervals share the same (1 to 96) retention pool. In the event that both intervals are required, the sum total of both intervals cannot exceed 96. The **1-hour** and **1-day** measurement intervals utilize their own ranges.

If this command is omitted when configuring the measurement interval, the default value is used.

The **no** form of the command reverts to the default.

Default

intervals-stored 1

Parameters

intervals

Specifies the number of measurement intervals.

Values **5-mins**: 1 to 96
15-mins: 1 to 96
1-hour: 1 to 24
1-day: 1

Default **5-mins**: 32
15-mins: 32
1-hour: 8
1-day: 1

Syntax

iom *slot-number* **type** {[**load-balancer**] [**ue-anchor**]}

no iom *slot-number*

Context

[Tree] (config>isa>wlan-gw-group iom)

Full Context

configure isa wlan-gw-group iom

Description

This command designates the specified IOM as a WLAN-GW IOM. Each WLAN-GW IOM must be provisioned with two ISA-BB modules on a hardware chassis and with an ISA-BB module in the first MDA slot in the VSR.

The **no** form of this command removes the IOM from the configuration.

Parameters

slot-number

Indicates the IOM slot to be used in the WLAN-GW group.

Values 1 to 10

type {[load-balancer] [ue-anchor]}

This parameter is supported on the VSR only. It determines if an IOM slot is used for load-balancing or UE anchoring and processing, or both. When the **wlan-gw-group** has only a single IOM, it is required to put this IOM in both modes at the same time.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

iom

Syntax

iom [**detail**]

no iom

Context

[Tree] (debug>router>mpls>event iom)

Full Context

debug router mpls event iom

Description

This command reports MPLS debug events originating from the XMA.

The **no** form of the command disables the debugging.

Parameters

detail

Displays detailed information about MPLS events originating from the XMA.

Platforms

All

13.207 ip

ip

Syntax

ip *address*

no ip

Context

[Tree] (config>service>vpls>mcr-default-gtw ip)

Full Context

configure service vpls mcr-default-gtw ip

Description

This command relates to a system configured for Dual Homing in L2-TPSDA. It defines the IP address used when the system sends out a gratuitous ARP on an active SAP after a ring heals or fails in order to attract traffic from subscribers on the ring with connectivity to that SAP.

The **no** form of this command reverts to the default.

Default

no ip

Parameters

address

Specifies the IP address in a.b.c.d. format.

Platforms

All

ip

Syntax

ip *ip-filter-id*

no ip

Context

[Tree] (config>service>template>epipe-sap-template>egress>filter ip)

[Tree] (config>service>template>epipe-sap-template>ingress>filter ip)

Full Context

configure service template epipe-sap-template egress filter ip

configure service template epipe-sap-template ingress filter ip

Description

This command associates an existing IP filter policy with the template.

This command is only supported in 'classic' configuration-mode (**configure system management-interface configuration-mode classic**).

Parameters

ip-filter-id

Specifies the IP filter policy ID. The filter ID must already exist within the created IP filters.

Values 1 to 65535

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

ip

Syntax

configure service template vpls-sap-template ingress filter-name ip

configure service template vpls-sap-template egress filter-name ip

Description

This command associates an existing IP filter policy with the template.

Parameters

name

Specifies the IP filter policy name, up to 64 characters.

Platforms

All

ip

Syntax

[**no**] **ip** *ip-address*

Context

[Tree] (debug>service>id>arp-host ip)

Full Context

debug service id arp-host ip

Description

This command displays ARP host events for a particular IP address.

Parameters

ip-address

The IP address of the IP interface. The *ip-address* portion of the **address** command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).

Values a.b.c.d

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

ip

Syntax

[**no**] **ip** *ip-address*

Context

[Tree] (debug>service>id>host-connectivity-verify ip)

Full Context

debug service id host-connectivity-verify ip

Description

This command displays Subscriber Host Connectivity Verification (SHCV) events for a particular IP address.

Parameters

ip-address

The IP address of the IP interface. The *ip-address* portion of the **address** command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).

Values ipv4-prefix: a.b.c.d (host bits must be 0)

ipv6-prefix:

- x:x:x:x:x:x:x:x (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d
- x: [0 to FFFF] H
- d: [0 to 255] D

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

ip

Syntax

[**no**] **ip** *ip-address*[/*mask*]

Context

[Tree] (config>app-assure>group>policy>transit-ip-policy>static-aa-sub ip)

Full Context

configure application-assurance group policy transit-ip-policy static-aa-sub ip

Description

This command configures the /32 IP address for a static transit aa-sub.

The **no** form of this command deletes the ip address assigned to the static transit aa-sub from the configuration.

Parameters

ip-address

Specifies the IP address in a.b.c.d form.

Values

ipv6-address/ prefix:	ipv6-address x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x [0 to FFFF]H
	d [0 to 255]D
	prefix-length /32 to /64

ip

Syntax

configure oam-pm session ip

Description

Commands in this context configure the IP-specific source and destination information, the priority, and the IP test tools on the launch point.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

ip

Syntax

[**no**] **ip** *ip-filter-id*

Context

[Tree] (config>filter>system-filter ip)

Full Context

configure filter system-filter ip

Description

This command activates an IPv4 system filter policy. Once activated, all IPv4 ACL filter policies that chain to the system filter (**config>filter>ip-filter>chain-to-system-filter**) will automatically execute system filter policy rules first.

The **no** form of the command deactivates the system filter policy.

Parameters

ip-filter-id

Specifies the existing IPv4 filter policy with scope **system**. This parameter can either be expressed as a decimal integer, or as an ASCII string of up to 64 characters.

Values 1 to 65535 or the filter policy name (*filter-name*, 64 char max)

Platforms

13.208 ip-addr-backup

ip-addr-backup

Syntax

ip-addr-backup *ip-address*[*:port*]

no ip-addr-backup

Context

[Tree] (config>sflow>receiver ip-addr-backup)

Full Context

configure sflow receiver ip-addr-backup

Description

This command configures back-up IPv4 or IPv6 destination address for the sFlow agent to send sFlow datagrams to. Optionally a destination port can also be configured (by default port 6343 is used).

The **no** form of this command deletes backup sFlow receiver destination.

Parameters

ip-address

Specifies the IPv4 or IPv6 address to send the sFlow datagrams to.

Values

a.b.c.d	(IPv4)
x:x:x:x:x:x:x:x	(IPv6)
[x:x:x:x:x:x:x:x]	(IPv6)
x - [0 to FFFF]H	

port

Specifies the UDP destination port to send the sFlow datagrams to.

Values 1 to 65535

Platforms

7750 SR, 7750 SR-s, 7950 XRS

13.209 ip-addr-primary

ip-addr-primary

Syntax

ip-addr-primary *ip-address*[:*port*]

no ip-addr-primary

Context

[Tree] (config>sflow>receiver ip-addr-primary)

Full Context

configure sflow receiver ip-addr-primary

Description

This command configures primary IPv4 or IPv6 destination address for the sFlow agent to send sFlow datagrams to. Optionally a destination port can also be configured (by default port 6343 is used).

The **no** form of this command deletes primary sFlow receiver destination.

Parameters

ip-address

Specifies the IPv4 or IPv6 address to send the sFlow datagrams.

Values

a.b.c.d	(IPv4)
x:x:x:x:x:x:x:x	(IPv6)
[x:x:x:x:x:x:x:x]	(IPv6)
x - [0..FFFF]H	

port

Specifies the UDP destination port to send the sFlow datagrams.

Values 1 to 65535

Platforms

7750 SR, 7750 SR-s, 7950 XRS

13.212 ip-address

ip-address

Syntax

ip-address *ipv6-address*

no ip-address

Context

[Tree] (conf>router>segment-routing>sr-policies>policy>srv6>binding-sid ip-address)

Full Context

configure router segment-routing sr-policies static-policy segment-routing-v6 binding-sid ip-address

Description

This command configures an SRv6 binding SID for a remote SRv6 policy. It cannot be used with a local head end location (defined with the **head-end local** command in the **conf>router>segment-routing>sr-policies>policy**). This command and the **locator** command in the **conf>router>segment-routing>sr-policies>policy>srv6>binding-sid** context for a local SRv6 policy are mutually exclusive.

The **no** form of this command removes the configuration.

Parameters

ipv6-address

Specifies the SRv6 binding SID as a 128 bit IPv6 address.

Values x:x:x:x:x:x:x:x (16 eight-bit pieces) or x:x:x:x:x:x:d:d:d:d

x — [0 to FFFF]H

d — [0 to 255]D

Platforms

7450 ESS, 7750 SR, 7750 SR-s, 7950 XRS, VSR

ip-address

Syntax

ip-address *unicast-ip-address*

no ip-address

Context

[Tree] (config>aaa>isa-radius-plcy>servers>server ip-address)

Full Context

configure aaa isa-radius-policy servers server ip-address

Description

This command configures the IP address of the RADIUS server.

The **no** form of this command removes the IP address.

Default

no ip-address

Parameters

unicast-ip-address

Specifies the unicast IPv4 or IPv6 address of the RADIUS server.

Values

ipv4-address:	a.b.c.d
ipv6-address:	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x: [0 to FFFF]H
	d: [0 to 255]D

13.214 ip-assigned

ip-assigned

Syntax

[**no**] **ip-assigned**

Context

[Tree] (config>subscr-mgmt>wlan-gw>ue-query>state ip-assigned)

Full Context

configure subscriber-mgmt wlan-gw ue-query state ip-assigned

Description

This command enables matching on UEs in an IP-assigned state, meaning that the UE already has an IP assigned but it is not yet authorized. This usually only applies when **auth-on-dhcp** is not configured.

The **no** form of this command disables matching on UEs in an IP-assigned state, unless all state matching is disabled.

Default

no ip-assigned

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

13.215 ip-assigned-authorized

ip-assigned-authorized

Syntax

[**no**] **ip-assigned-authorized**

Context

[Tree] (config>subscr-mgmt>wlan-gw>ue-query>state ip-assigned-authorized)

Full Context

configure subscriber-mgmt wlan-gw ue-query state ip-assigned-authorized

Description

This command enables matching on UEs in an IP-assigned and authorized state, meaning that the UE already has an IP assigned and is authorized, but is not yet promoted to a final state such as ESM or DSM. This applies to UEs authenticated by distributed RADIUS proxy without **auth-on-dhcp** configured. UEs move to this state upon DHCP completion and continue to a more final state (such as DSM, ESM, or portal) upon receiving the first data packet.

The **no** form of this command disables matching on UEs in an IP-assigned and authorized state, unless all state matching is disabled.

Default

no ip-assigned-authorized

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

[Tree] (config>subscr-mgmt>diam-appl-plcy>gx>include-avp ip-can-type)

Full Context

configure subscriber-mgmt diameter-application-policy gx include-avp ip-can-type

Description

This command includes the ip-can-type.

The **no** form of this command reverts to the default.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

13.218 ip-criteria

ip-criteria

Syntax

[**no**] **ip-criteria**

Context

[Tree] (config>qos>sap-ingress ip-criteria)

[Tree] (config>qos>sap-egress ip-criteria)

Full Context

configure qos sap-ingress ip-criteria

configure qos sap-egress ip-criteria

Description

IP criteria-based SAP ingress or egress policies are used to select the appropriate ingress or egress queue or policer and corresponding forwarding class and packet profile for matched traffic.

This command is used to enter the context to create or edit policy entries that specify IP criteria such as IP quintuple lookup or DiffServ code point.

The software implementation will exit on the first match found and execute the actions in accordance with the accompanying action command. For this reason, entries must be sequenced correctly from most to least explicit.

The **no** form of this command deletes all the entries specified under this node. When IP criteria entries are removed from a SAP ingress or egress policy, the IP criteria is removed from all services where that policy is applied.

Platforms

All

ip-criteria

Syntax

[**no**] **ip-criteria**

Context

[Tree] (config>qos>network>egress ip-criteria)

[Tree] (config>qos>network>ingress ip-criteria)

Full Context

configure qos network egress ip-criteria

configure qos network ingress ip-criteria

Description

IP criteria-based network ingress and egress policies are used to select the appropriate ingress or egress queue or policer, and the corresponding forwarding class and packet profile for matched traffic. This command is used to enter the context to create or edit policy entries that specify IP criteria such as IP quintuple lookup or DSCP.

The 7750 SR OS implementation will exit on the first match found and execute the actions in accordance with the accompanying action command. Entries must be sequenced correctly from most to least explicit.

The ingress classification only applies to the outer IP header of non-tunneled traffic. The only exception is for traffic received on a Draft Rosen tunnel, for which only classification on the outer IP header is supported.

Attempting to apply a network QoS policy containing an **ip-criteria** statement to any object except a network IP interface will result in an error.

The **no** form of this command deletes all entries specified under this node. When IP criteria entries are removed from a network policy, the IP criteria are removed from all network interfaces to which that policy is applied.

Platforms

All

Full Context

configure filter ip-exception

Description

Commands in this context configure the specified IPv4 exception filter.

The **no** form of the command deletes the IPv4 exception filter.

Parameters

filter-id

Specifies the IPv4 filter policy ID expressed as a decimal integer.

Values 1 to 65535

create

This keyword is required to create the configuration context. Once it is created, the context can be enabled with or without the **create** keyword.

Platforms

VSR

ip-exception

Syntax

ip-exception *filter-id* **direction** {**inbound** | **outbound**}

no ip-exception direction {**inbound** | **outbound**}

Context

[Tree] (config>router>if>group-encryption ip-exception)

Full Context

configure router interface group-encryption ip-exception

Description

This command associates an IP exception filter policy with an NGE-enabled router interface to allow packets matching the exception criteria to transit the NGE domain as clear text.

When an exception filter is added for inbound traffic, packets matching the criteria in the IP exception filter policy are allowed to be received in clear text even if an inbound key group is configured. If no inbound key group is configured, then associated inbound IP exception filter policies will be ignored.

When an exception filter is added for outbound traffic, packets matching the criteria in the IP exception filter policy are not encrypted when sent out of the router interface even if an outbound key group is configured. If no outbound key group is configured, then associated outbound IP exception filter policies will be ignored.

The **no** form of this command removes the IP exception filter policy from the specified direction.

Default

no ip-exception direction inbound

no ip-exception direction outbound

Parameters

filter-id

Specifies the IP exception filter policy. The IP exception ID or exception name must have already been created.

Values 1 to 6553, *filter-name* (64 characters maximum)

inbound

Binds the exception filter policy in the inbound direction.

outbound

Binds the exception filter policy in the outbound direction.

Platforms

VSR

13.220 ip-fast-reroute

ip-fast-reroute

Syntax

[**no**] **ip-fast-reroute**

Context

[Tree] (config>router ip-fast-reroute)

Full Context

configure router ip-fast-reroute

Description

This command enables IP Fast-Reroute (FRR) feature on the system.

This feature provides for the use of a Loop-Free Alternate (LFA) backup next-hop for forwarding in-transit and CPM generated IP packets when the primary next-hop is not available. IP FRR is supported on IPv4 and IPv6 OSPF/IS-IS prefixes forwarded in the base router instance to a network IP interface or to an IES SAP interface or spoke interface. It is also supported for VPRN VPN-IPv4 OSPF prefixes and VPN-IPv6 OSPF prefixes forwarded to a VPRN SAP interface or spoke interface.

IP FRR also provides a LFA backup next-hop for the destination prefix of a GRE tunnel used in an SDP or in VPRN auto-bind.

When any of the following events occurs, IGP instructs in the fast path on the XMAs to enable the LFA backup next-hop:

- OSPF/IS-IS interface goes operationally down: physical or local admin shutdown.
- Timeout of a BFD session to a next-hop when BFD is enabled on the OSPF/IS-IS interface

When the SPF computation determines there is more than one primary next-hop for a prefix, it will not program any LFA next-hop in RTM. Therefore, the IP prefix will resolve to the multiple equal-cost primary next-hops that provide the required protection.

The **no** form of this command disables the IP FRR feature on the system

Default

no ip-fast-reroute

ip-filter

Syntax

ip-filter *ip-filter-id* **entry** *entry-id* [*entry-id*]

no ip-filter *ip-filter-id* [**entry** *entry-id*]

Context

[Tree] (config>mirror>mirror-source ip-filter)

Full Context

configure mirror mirror-source ip-filter

Description

This command enables mirroring of packets that match specific entries in an existing IP filter.

The **ip-filter** command directs packets which match the defined list of entry IDs to be mirrored to the mirror destination referenced by the *mirror-dest-service-id* of the **mirror-source**.

The IP filter must already exist in order for the command to execute. Filters are configured in the **config>filter** context. If the IP filter does not exist, an error will occur. If the filter exists but has not been associated with a SAP or IP interface, an error is not generated but mirroring will not be enabled (there are no packets to mirror). Once the IP filter is defined to a SAP or IP interface, mirroring is enabled.

If the IP filter is defined as ingress, only ingress packets are mirrored. Ingress mirrored packets are mirrored to the mirror destination prior to any ingress packet modifications.

If the IP filter is defined as egress, only egress packets are mirrored. Egress mirrored packets are mirrored to the mirror destination after all egress packet modifications.

An *entry-id* within an IP filter can only be mirrored to a single mirror destination. If the same *entry-id* is defined multiple times, an error occurs and only the first **mirror-source** definition is in effect.

By default, no packets matching any IP filters are mirrored. Mirroring of IP filter entries must be explicitly defined.

The **no ip-filter** command, without the **entry** keyword, removes mirroring on all *entry-id*'s within the *ip-filter-id*.

When the **no** command is executed with the **entry** keyword and one or more *entry-id*'s, mirroring of that list of *entry-id*'s is terminated within the *ip-filter-id*. If an *entry-id* is listed that does not exist, an error will occur and the command will not execute. If an *entry-id* is listed that is not currently being mirrored, no error will occur for that *entry-id* and the command will execute normally.

Parameters

ip-filter-id

Specifies the IP filter ID whose entries are mirrored. If the *ip-filter-id* does not exist, an error will occur and the command will not execute. Mirroring of packets will commence once the *ip-filter-id* is defined on a SAP or IP interface.

Values 1 to 65535

name, up to 64 characters

entry-id

Specifies the IP filter entries to use as match criteria for packet mirroring. The **entry** keyword begins a list of *entry-id*'s for mirroring. Multiple *entry-id* entries may be specified with a single command. Each *entry-id* must be separated by a space.

If an *entry-id* does not exist within the IP filter, an error occurs and the command will not execute.

If the filter's *entry-id* is renumbered within the IP filter definition, the old *entry-id* is removed but the new *entry-id* must be manually added to the configuration to include the new (renumbered) entry's criteria.

Values 1 to 2097151

Platforms

All

ip-filter

Syntax

Context

[Tree] (config>li>li-filter-block-reservation>li-reserved-block ip-filter)

Full Context

configure li li-filter-block-reservation li-reserved-block ip-filter

Description

This command configures to which normal IPv4 address filters the entry reservation is applied.

This command is only supported in 'classic' configuration-mode (**configure system management-interface configuration-mode classic**).

The **no** form of this command removes the IPv4 filter ID from the configuration.

Parameters

ip-filter-id

Specifies the filter identification identifies the normal IPv4 address filters.

Values {*filter-id* | *filter-name*}

filter-id: 1 to 65535

filter-name: up to 64 characters (*filter-name* is an alias for input only. The *filter-name* gets replaced with an id automatically by SR OS in the configuration).

Context

[Tree] (config>li>li-filter-assoc>li-ip-fltr ip-filter)

Full Context

configure li li-filter-associations li-ip-filter ip-filter

Description

This command specifies the IP filter(s) into which the entries from the specified li-ip-filter are to be inserted. The **li-ip-filter** and **ip-filter** must already exist before the association is made. If the normal IP filter is deleted then the association is also removed (and not re-created if the IP filter comes into existence in the future).

The **no** form of this command removes the IP filter name from the configuration.

Parameters

ip-filter-id

Specifies an existing IP filter policy.

Values *filter-id* — 1 to 65535

filter-name — up to 64 characters

Platforms

All

ip-filter

Syntax

ip-filter *ip-filter-id* **entry** *entry-id* [*entry-id*] [**intercept-id** *intercept-id* [*intercept-id*]] [**session-id** *session-id* [*session-id*]]

no ip-filter *ip-filter-id* [**entry** *entry-id* [*entry-id*]]

Context

[Tree] (config>li>li-source ip-filter)

Full Context

configure li li-source ip-filter

Description

This command enables lawful interception (LI) of packets that match specific entries in an existing IP filter.

The **ip-filter** command directs packets which match the defined list of entry IDs to be intercepted to the destination referenced by the *mirror-dest-service-id* of the **mirror-source**.

The IP filter must already exist in order for the command to execute. Filters are configured in the **config>filter** context. If the IP filter does not exist, an error occurs. If the filter exists but has not been associated with a SAP or IP interface, an error is not generated but mirroring will not be enabled (there are no packets to mirror). Once the IP filter is defined to a SAP, IP interface or subscriber, mirroring is enabled.

If the IP filter is defined as ingress, only ingress packets are intercepted. Ingress packets are sent to the destination prior to any ingress packet modifications.

If the IP filter is defined as egress, only egress packets are intercepted. Egress packets are sent to the destination after all egress packet modifications.

An *entry-id* within an IP filter can only be intercepted to a single destination. If the same *entry-id* is defined multiple times, an error occurs and only the first definition is in effect.

By default, no packets matching any IP filters are intercepted. Interception of IP filter entries must be explicitly defined.

When the **no** command is executed with the **entry** keyword and one or more *entry-id*'s, interception of that list of *entry-id*'s is terminated within the *ip-filter-id*. If an *entry-id* is listed that does not exist, an error will occur and the command will not execute. If an *entry-id* is listed that is not currently being intercepted, no error will occur for that *entry-id* and the command will execute normally.

Parameters

ip-filter-id

Specifies the IP filter ID whose entries are to be intercepted. If the *ip-filter-id* does not exist, an error will occur and the command will not execute. Intercepting packets will commence when the *ip-filter-id* is defined on a SAP or IP interface.

entry-id

Specifies the IP filter entries to use as match criteria for lawful intercept (LI). The **entry** keyword begins a list of *entry-id*'s for interception. Multiple *entry-id* entries can be specified with a single command. Each *entry-id* must be separated by a space. Up to <N><n> 8 entry IDs may be specified in a single command.

If an *entry-id* does not exist within the IP filter, an error occurs and the command will not execute.

If the filter's *entry-id* is renumbered within the IP filter definition, the old *entry-id* is removed but the new *entry-id* must be manually added to the configuration to include the new (renumbered) entry's criteria.

intercept-id

Specifies the intercept ID that is inserted into the packet header for all mirrored packets of the associated **li-source** entry. This intercept ID can be used (for example by a downstream LI gateway) to identify the particular LI session to which the packet belongs. For all types of **li-source** entries (filter, nat, sap, subscriber), when the mirror service is configured with **ip-udp-shim** routable encap, an *intercept-id* field (as part of the routable

encap) is always present in the mirrored packets. If there is no *intercept-id* configured for an **li-source** entry, then the default value is inserted. When the mirror service is configured with **ip-gre** routable encapsulation, no *intercept-id* is inserted and none should be specified against the **li-source** entries.

Values 1 to 4294967295 (32b) for **nat li-source** entries that are using a mirror service that is not configured with routable encap

1 to 1073741824 (30b) for all types of **li-source** entries that are using a mirror service with routable ip-udp-shim encap and no direction-bit.

1 to 536870912 (29b) for all types of **li-source** entries that are using a mirror service with routable **ip-udp-shim** encapsulation and with the **direction-bit** enabled.

session-id

Specifies the *session-id* that is inserted into the packet header for all mirrored packets of the associated **li-source** entry. This *session-id* can be used (for example by a downstream LI Gateway) to identify the particular LI session to which the packet belongs. The *session-id* is only valid and used for mirror services that are configured with **ip-udp-shim** routable encap (**config>mirror>mirror-dest>encap>ip-udp-shim**). For all types of **li-source** entries (filter, nat, sap, subscriber), when the mirror service is configured with **ip-udp-shim** routable encap, a *session-id* field (as part of the routable encap) is always present in the mirrored packets. If there is no *session-id* configured for an **li-source** entry, then the default value is inserted. When a mirror service is configured with **ip-gre** routable encap, no *session-id* is inserted and none should be specified against the **li-source** entries.

Context

[Tree] (debug>mirror-source ip-filter)

Full Context

debug mirror-source ip-filter

Description

This command enables mirroring of packets that match specific entries in an existing IP filter.

The **ip-filter** command directs packets which match the defined list of entry IDs to be mirrored to the mirror destination referenced by the *mirror-dest-service-id* of the **mirror-source**.

The IP filter must already exist in order for the command to execute. Filters are configured in the **config>filter** context. If the IP filter does not exist, an error will occur. If the filter exists but has not been associated with a SAP or IP interface, an error is not generated but mirroring will not be enabled (there are no packets to mirror). Once the IP filter is defined to a SAP or IP interface, mirroring is enabled.

If the IP filter is defined as ingress, only ingress packets are mirrored. Ingress mirrored packets are mirrored to the mirror destination prior to any ingress packet modifications.

If the IP filter is defined as egress, only egress packets are mirrored. Egress mirrored packets are mirrored to the mirror destination after all egress packet modifications.

An *entry-id* within an IP filter can only be mirrored to a single mirror destination. If the same *entry-id* is defined multiple times, an error occurs and only the first **mirror-source** definition is in effect.

By default, no packets matching any IP filters are mirrored. Mirroring of IP filter entries must be explicitly defined.

The **no ip-filter** command, without the **entry** keyword, removes mirroring on all *entry-id*'s within the *ip-filter-id*.

When the **no** command is executed with the **entry** keyword and one or more *entry-id*'s, mirroring of that list of *entry-id*'s is terminated within the *ip-filter-id*. If an *entry-id* is listed that does not exist, an error will occur and the command will not execute. If an *entry-id* is listed that is not currently being mirrored, no error will occur for that *entry-id* and the command will execute normally.

Parameters

ip-filter-id

The IP filter ID whose entries are mirrored. If the *ip-filter-id* does not exist, an error will occur and the command will not execute. Mirroring of packets will commence once the *ip-filter-id* is defined on a SAP or IP interface.

entry-id

The IP filter entries to use as match criteria for packet mirroring. The **entry** keyword begins a list of *entry-id*'s for mirroring. A maximum of eight *entry-id* entries may be specified with a single command. Each *entry-id* must be separated by a space.

If an *entry-id* does not exist within the IP filter, an error occurs and the command will not execute.

If the filter's *entry-id* is renumbered within the IP filter definition, the old *entry-id* is removed but the new *entry-id* must be manually added to the configuration to include the new (renumbered) entry's criteria.

Syntax

ip-filter *filter-id* [**name**] [**create**]

no ip-filter {*filter-id* | *filter-name*}

Context

[Tree] (config>filter ip-filter)

Full Context

configure filter ip-filter

Description

Commands in this context configure the specified IPv4 filter policy.

The **no** form of the command deletes the IPv4 filter policy. A filter policy cannot be deleted until it is removed from all objects where it is applied.

Parameters

filter-id

Specifies the IPv4 filter policy ID expressed as a decimal integer.

Values 1 to 65535

name

Configures an optional filter name, up to 64 characters in length, to a given filter. This filter name can then be used in configuration references, display, and show commands throughout the system. A defined filter name can help the service provider or administrator to identify and manage filters within the SR OS platforms.

To create a filter, you must assign a filter ID, however, after it is created, either the filter ID or filter name can be used to identify and reference a filter.

If a name is not specified at creation time, then SR OS assigns a string version of the *filter-id* as the name.

Filter names may not begin with an integer (0 to 9).

filter-name

Specifies a string, up to 64 characters, uniquely identifying this IPv4 filter policy.

create

This keyword is required to create the configuration context. Once it is created, the context can be enabled with or without the **create** keyword.

ip-filter

Syntax

ip-filter *src-filter-id* [**src-entry** *src-entry-id*] **to** *dst-filter-id* [**dst-entry** *dst-entry-id*] [**overwrite**]

Context

[Tree] (config>filter>copy ip-filter)

Full Context

configure filter copy ip-filter

Description

This command copies an existing filter entry for a specific filter ID to another filter ID. The command is a configuration level maintenance tool used to create new entries using an existing filter policy. If **overwrite** is not specified, an error will occur if the destination filter entry exists.

Parameters

src-filter-id

Identifies the source filter policy from which the copy command will attempt to copy. The filter policy must exist within the context of the preceding keyword (**ip-filter**).

dst-filter-id

Identifies the destination filter policy to which the copy command will attempt to copy. If the **overwrite** keyword is not specified, the filter entry ID cannot already exist in the destination filter policy. If the **overwrite** keyword is present, the destination entry ID may or may not exist.

overwrite

Specifies that the destination filter entry may exist. If it does, everything in the existing destination filter entry will be completely overwritten with the contents of the source filter entry. If the destination filter entry exists, either **overwrite** must be specified or an error message will be returned. If **overwrite** is specified, the function of copying from source to destination occurs in a "break before make" manner and therefore should be handled with care.

All

13.222 ip-filter-max-size

ip-filter-max-size

Syntax

ip-filter-max-size {*value* | **default**}

Context

[Tree] (config>service>vprn>flowspec ip-filter-max-size)

Full Context

configure service vprn flowspec ip-filter-max-size

Description

This command configures the maximum number of FlowSpec routes or rules that can be embedded into an ingress IP filter policy for a specified routing instance. FlowSpec filter entries embedded in a filter policy in this routing instance will use filter entries from the range between the embedding offset and "offset + ip-filter-max-size – 1".

The sum of the **ip-filter-max-size** *value* parameter and the highest offset in any IPv4 filter that embeds IPv4 FlowSpec rules from this routing instance (excluding filters that embed at offset 262143) must not exceed 262143.

The **ip-filter-max-size** configuration can be adjusted up or down at any time. If the number of IPv4 FlowSpec rules that are currently installed is *M*, and the new limit is *N*, where *N*<*M*, then the last set of rules from *N* to *M* (by FlowSpec order) are immediately removed, but are retained in the BGP RIB. If the limit is increased, new rules are programmed only as they are received again in new BGP updates.

Default

ip-filter-max-size default

Parameters

value

The maximum number of FlowSpec routes or rules that can be embedded into an ingress IP filter policy.

Values 0 to 262143

default

Configures the maximum size as 512.

Platforms

All

ip-filter-max-size

Syntax

ip-filter-max-size {*value* | **default**}

Context

[Tree] (config>router>flowspec ip-filter-max-size)

Full Context

configure router flowspec ip-filter-max-size

Description

This command configures the maximum number of FlowSpec routes or rules that can be embedded into the auto-created embedded filter (fSpec- *X*). FlowSpec filter entries embedded in a filter policy in this routing instance will use filter entries from the range between "embedding offset + 1" and "embedding offset + ip-filter-max-size".

The sum of the **ip-filter-max-size** *value* parameter and the highest offset in any IPv4 filter that embeds IPv4 FlowSpec rules from this routing instance (excluding filters that embed at offset 262143) must not exceed 262143.

The **ip-filter-max-size** configuration can be adjusted up or down at any time. If the number of IPv4 FlowSpec rules that are currently installed is *M*, and the new limit is *N*, where *N*<*M*, then the last set of rules from *N* to *M* (by FlowSpec order) are immediately removed, but are retained in the BGP RIB. If the limit is increased, new rules are programmed only as they are received again in new BGP updates.

Default

ip-filter-max-size 512

Parameters

value

Specifies the maximum number of FlowSpec routes or rules that can be embedded into an ingress IP filter policy.

Values 0 to 262143

default

Keyword to configure the maximum size as 512.

Full Context

configure service vprn nat inside nat64 ip-fragmentation

configure service vprn nat inside dslite addressip-fragmentation ip-fragmentation

configure router nat inside dual-stack-lite address ip-fragmentation

configure router nat inside nat64 ip-fragmentation

Description

This command configures downstream IPv6 fragmentation behavior in DS-Lite and NAT64. IPv6 fragmentation is performed in the ISA. IPv4 fragmentation is not affected by this command. If desired, downstream IPv4 packet can be fragmented in the carrier IOM before the packet reaches ISA (and the NAT function). The IPv4 fragmentation in the downstream direction can be set by the **config>router/vprn>nat>outside>mtu** command.

DS-Lite IPv6 Fragmentation in Downstream Direction (IPv4 to IPv6)

In case that the length of the received IPv4 packet is larger than the configured tunnel-mtu value while fragmentation is allowed, the resulting IPv6 packet will be fragmented (IPv4 is tunneled within IPv6). The maximum size of the of the fragmented IPv6 packet will be 48bytes larger than the configured tunnel-mtu value. This is due to the size of the tunneling IPv6 header: 40bytes basic IPv6 header + 8 bytes of extended fragmentation IPv6 header.

In case that fragmentation is not allowed while the IPv4 packet size is larger than configured tunnel-mtu size, the IPv4 packet will be dropped and an ICMPv4 Datagram Too Big message will be generated towards the source. The advertised mtu size in that ICMP message will be set to configured tunnel-mtu value.

NAT64 IPv6 Fragmentation in Downstream Direction (IPv4to IPv6)

In contrast to DS-Lite, NAT64 transport is not based on tunneling. Instead, IP headers are translated between IPv4 and IPv6. Consequently, NAT64 fragmentation operates based on the ipv6-mtu, as opposed to tunnel-mtu in DS-Lite which represents the size of the tunnel payload (IPv4 packet).

In case that the length of the translated IPv6 packet exceeds the size of the configured ipv6-mtu value while fragmentation is allowed, the resulting IPv6 packet will be fragmented. The maximum size of the of the fragmented IPv6 packet will be the configured ipv6-mtu value.

In case that fragmentation is not allowed while the translated IPv6 packet size is larger than configured ipv6-mtu size, the IPv4 packet (that is supposed to be translated into IPv6) will be dropped and an ICMPv4 Datagram Too Big message will be generated towards the source. The advertised mtu size in that ICMP message will be set to the ipv6-mtu value minus 28bytes. The 28bytes comes from the size of the IPv6 overhead of the translated packet (20bytes difference between the IP header sizes 40bytes in IPv6 vs 20bytes in IPv4; 8 bytes for extended IPv6 fragmentation header).

Default

disabled

Parameters

disabled

IPv6 Fragmentation is disabled. In case that the packet size is larger

than what is set by the mtu value (tunnel-mtu or ipv6-mtu) the IPv4 packet will be dropped and ICPMv4 Datagram Too Big messages will be sent back to the source.

fragment-ipv6

IPv6 fragmentation will be performed in all cases, regardless of the DF bit setting in the tunneled/translated IPv4 packet.

fragment-ipv6-unless-ipv4-df-set

IPv6 Fragmentation will be performed only in cases when DF bit in tunneled/translated IPv4 packet is cleared.

Context

[Tree] (config>service>vprn ip-mirror-interface)

Full Context

configure service vprn ip-mirror-interface

Description

This command is used for remote mirroring, where the mirror source is a separate system then the mirror destination. The mirror source can only be of IP type and is only supported for the following services: IES, VPRN, VPLS and Ipipe. The mirror destination on a remote system will configure an interface on a VPRN as **ip-mirror-interface**. This interface only supports spoke sdp termination. The IP mirror interface requires PBR to determine the next outgoing interface for the mirror packet to be delivered to.

The **no** form of this command removes the interface name from the configuration.

Parameters

ip-int-name

Specifies the name of the IP interface, up to 32 characters. An interface name cannot be in the form of an IP address.

create

Keyword used to create an IP mirror interface.

Platforms

All

13.230 ip-mtu

ip-mtu

Syntax

ip-mtu *octets*

no ip-mtu

Context

[Tree] (config>service>ies>sub-if>grp-if ip-mtu)

ip-mtu

Syntax

ip-mtu *octets*

no ip-mtu

Context

[Tree] (config>service>vprn>if ip-mtu)

Full Context

configure service vprn interface ip-mtu

Description

This command specifies the maximum size of IP packets on this group interface. Packets larger than this are fragmented.

The **ip-mtu** applies to all IPoE host types (DHCP, ARP, or static). For PPP/L2TP sessions, the **ip-mtu** is not considered for the MTU negotiation. The **ppp-mtu** in the PPP policy should be used instead.

The **no** form of this command reverts to the default.

Default

no ip-mtu

Parameters

octets

Specifies the largest frame size (in octets) that this interface can handle.

Values 512 to 9000

Platforms

All

ip-mtu

Syntax

ip-mtu *octets*

no ip-mtu

Context

[Tree] (config>service>ies>if ip-mtu)

[Tree] (config>service>ies>if>sap>ip-tunnel ip-mtu)

Full Context

configure service ies interface ip-mtu

configure service ies interface sap ip-tunnel ip-mtu

Description

This command configures the IP maximum transmit unit (packet) for this interface.

Because this connects a Layer 2 to a Layer 3 service, this parameter can be adjusted under the IES interface.

The MTU that is advertised from the IES size is:

MINIMUM((SdpOperPathMtu - EtherHeaderSize), (Configured ip-mtu))

By default (for Ethernet network interface) if no ip-mtu is configured it is (1568 - 14) = 1554.

The **no** form of this command returns the default value.

Default

no ip-mtu

Parameters

octets

Specifies the maximum number of octets that can be transmitted.

Values 512 to 9786 (for IES interface)
512 to 9000 (for ip-tunnel interface)

Platforms

All

- configure service ies interface ip-mtu

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

configure service ies interface ipsec ipsec-tunnel ip-mtu

configure router interface ipsec ipsec-tunnel ip-mtu

configure service vprn interface sap ipsec-tunnel ip-mtu

configure service vprn interface ipsec ipsec-tunnel ip-mtu

Description

This command configures the IP maximum transmit unit (packet) for this interface.

Because this connects a Layer 2 to a Layer 3 service, this parameter can be adjusted under the IES interface.

The MTU that is advertised from the IES size is:

MINIMUM((SdpOperPathMtu - EtherHeaderSize), (Configured ip-mtu))

By default (for the Ethernet network interface), if no ip-mtu is configured it is (1568 - 14) equals 1554.

The **ip-mtu** command instructs the MS-ISA to perform IP packet fragmentation, prior to IPsec encryption and encapsulation, based on the configured MTU value. In particular:

If the length of a payload IP packet (including its header) exceeds the configured MTU value and the DF flag is clear (due to the presence of the clear-df-bit command or because the original DF value was 0) then the MS-ISA fragments the payload packet as efficiently as possible (i.e. it creates the minimum number of fragments each less than or equal to the configured MTU size); in each created fragment the DF bit shall be 0.

If the length of a payload IP packet (including its header) exceeds the configured MTU value and the DF flag is set (because the original DF value was 1 and the tunnel has no clear-df-bit in its configuration) then the MS-ISA discards the payload packet without sending an ICMP type 3/code 4 message back to the packet's source address.

The effective MTU for packets entering a tunnel is the minimum of the private tunnel SAP interface IP MTU value (used by the IOM) and the tunnel IP MTU value (configured using the above command and used by the MS-ISA). To fragment IP packets larger than X bytes with DF set, rather than discarding them, the tunnel IP MTU should be set to X and the private tunnel SAP interface IP MTU should be set to a value larger than X.

The **no ip-mtu** command, corresponding to the default behavior, disables fragmentation of IP packets by the MS-ISA; all IP packets, regardless of size or DF bit setting, are allowed into the tunnel.

Default

no ip-mtu

Parameters

bytes

Specifies the IP maximum transmit unit (packet) for this interface.

Values 512 to 9000

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

Description

This command configures the IP-MTU size that is used to transport flow synchronization records between the ISAs. Multiple flow synchronization events can be packed into a single frame up to the IP-MTU size.

Default

ip-mtu 1500

Parameters

bytes

Specifies the IP-MTU size in bytes.

Values 512 to 9000

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

ip-mtu

Syntax

ip-mtu *octets*

no ip-mtu

Context

[Tree] (config>router>if ip-mtu)

Full Context

configure router interface ip-mtu

Description

This command configures the IP maximum transmit unit (packet) for the associated router IP interface.

The operational IP MTU that is used for the interface is determined based on both the configured IP MTU and the port MTU of the port bound to this interface.

The MTU that is used is:

MINIMUM((Port_MTU - EthernetHeaderSize), (configured ip-mtu))

The **no** form of this command returns the associated IP interfaces MTU to its default value, which is calculated based on the port MTU setting. (For Ethernet ports the default IP MTU is 1500 octets.)

Default

no ip-mtu

Parameters

octets

Specifies the IP MTU value associated with the IP interface, specified in octets. If the interface supports IPv6 packets, the IP-MTU must be set to a value greater than or equal to (≥) 1280 in accordance with RFC 2460 *Internet Protocol, Version 6 (IPv6) Specification*.

Values 512 to 9786

Platforms

All

ip-mtu

Syntax

ip-mtu *octets*

no ip-mtu

Context

[Tree] (bof ip-mtu)

Full Context

bof ip-mtu

Description

This command configures the IP maximum transmit unit (packet) for the management router instance.

The operational IP MTU that is used for the interface is determined based on both the configured IP MTU and the port MTU of the port bound to this interface.

The MTU that is used is:

MINIMUM((Port_MTU - EthernetHeaderSize), (configured ip-mtu))

For the management port, the port MTU is fixed at 1514 and the EthernetHeaderSize is 14 so the first element of the equation above is 1500 octets.

The **no** form of this command returns the associated IP interfaces MTU to its default value, which is calculated based on the port MTU setting. (For the management port the default IP MTU is 1500 octets.)

Default

ip-mtu 1500

Parameters

octets

Specifies the IP MTU value associated with the IP interface, specified in octets. If the interface supports IPv6 packets, the IP-MTU must be set to a value greater than or equal to (≥) 1280 in accordance with RFC 2460 *Internet Protocol, Version 6 (IPv6) Specification*.

ip-option *ip-option-value* [*ip-option-mask*]

no ip-option

Context

[Tree] (config>filter>ip-filter>entry>match ip-option)

Full Context

configure filter ip-filter entry match ip-option

Description

This command configures matching packets with a specific IP option or a range of IP options in the first option of the IP header as an IP filter match criterion.

The option-type octet contains 3 fields:

- 1 bit copied flag (copy options in all fragments)
- 2 bits option class
- 5 bits option number

The **no** form of the command removes the match criterion.

Default

no ip-option

Parameters

ip-option-value

Specifies the 8 bit option-type as a decimal integer, binary, or hexadecimal format. The mask is applied as an AND to the option byte, the result is compared with the option-value.

The decimal value entered for the match should be a combined value of the eight bit option type field and not just the option number. Therefore, to match on IP packets that contain the Router Alert option (option number = 20), enter the option type of 148 (10010100).

Values 0 to 255

ip-option-mask

Specifies an optional parameter that can be used when specifying a range of option numbers to use as the match criteria.

This 8 bit mask can be configured using the following formats:

Table 46: ip-option-mask Formats

Format Style	Format Syntax	Example
Decimal	DDD	20
Hexadecimal	0xHH	0x14
Binary	0bBBBBBBBB	0b0010100

Default 255 (decimal) (exact match)

Values 1 to 255 (decimal)

13.232 ip-prefix

ip-prefix

Syntax

ip-prefix *ip-prefix/ip-prefix-length*

no ip-prefix

Context

[Tree] (config>subscr-mgmt>loc-user-db>ipoe>host>host-ident ip-prefix)

Full Context

configure subscriber-mgmt local-user-db ipoe host host-identification ip-prefix

Description

This command specifies the source IPv4/IPv6 address/prefix of the data trigger packet as the host identification.

Note:
This command is only used when **ip** is configured as one of the **match-list** parameters.

The **no** form of this command removes the IP prefix from the configuration.

Parameters

ip-prefix/ip-prefix-length

Specifies the IPv4 address, IPv6 address, or IPv6 prefix.

Values ipv4-prefix a.b.c.d
ipv4-prefix-length 0 to 32
ipv6-prefix x:x:x:x:x:x:x:x (eight 16-bit pieces)
x:x:x:x:x:x:d.d.d.d
x to [0 to FFFF]H
d to [0 to 255]D
ipv6-prefix-length 0 to 128

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

ip-prefix

Syntax

ip-prefix *ipv6-prefix*/*prefix-length*

no ip-prefix

Context

[Tree] (conf>router>segment-routing>srv6>loc>prefix ip-prefix)

Full Context

configure router segment-routing segment-routing-v6 locator prefix ip-prefix

Description

This command configures the IPv6 prefix and prefix length for an SRv6 locator.

The locator prefix length is the sum of the lengths of the block field and that of the node ID field.

The **no** form of this command deletes the IPv6 prefix from this locator.

Default

no ip-prefix

Parameters

ipv6-prefix/prefix-length

Specifies an IPv6 address prefix written as hexadecimal numbers separated by colons with host bits set to 0.

Values

ipv6-prefix	x:x:x:x:x:x:x:x (eight 16-bit pieces)
ipv6-prefix-length	4 to 96

Platforms

7450 ESS, 7750 SR, 7750 SR-s, 7950 XRS, VSR

ip-prefix

Syntax

ip-prefix *ipv6-prefix/prefix-length*

no ip-prefix

Context

[Tree] (conf>router>sr>srv6>ms>block>prefix ip-prefix)

Full Context

configure router segment-routing segment-routing-v6 micro-segment block prefix ip-prefix

Description

This command configures the IPv6 prefix and prefix length for an SRv6 micro-segment locator.

For micro-segment SRv6, the locator prefix length must be equal to the micro-segment block length.

The **no** form of this command deletes the IPv6 prefix from this micro-segment locator.

Default

no ip-prefix

Parameters

ipv6-prefix/prefix-length

Specifies an IPv6 address prefix written as hexadecimal numbers separated by colons with host bits set to 0.

Values		
	ipv6-prefix	x:x:x:x:x:x:x:x (eight 4-hexadecimal pieces)
	ipv6-prefix-length	8 to 64

Platforms

7450 ESS, 7750 SR, 7750 SR-s, 7950 XRS, VSR

configure qos match-list ip-prefix-list

Description

This command creates a list of IPv4 prefixes for match criteria in QoS policies.

An IP prefix list must contain only IPv4 address prefixes created using the prefix command and cannot be deleted if it is referenced by a QoS policy.

The **no** form of this command deletes the specified list.

Parameters

ip-prefix-list-name

A string of up to 32 characters of printable ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes. The name **default** (case insensitive) is reserved by the system.

Platforms

All

ip-prefix-list

Syntax

ip-prefix-list *ip-prefix-list-name* [**create**]

no ip-prefix-list *ip-prefix-list-name*

Context

[Tree] (config>filter>match-list ip-prefix-list)

Full Context

configure filter match-list ip-prefix-list

Description

This command creates a list of IPv4 prefixes for match criteria in IPv4 ACL and CPM filter policies.

The **no** form of this command deletes the specified list.

Operational Notes:

An **ip-prefix-list** must contain only IPv4 address prefixes.

An IPv4 prefix match list cannot be deleted if it is referenced by a filter policy.

See general description related to match-list usage in filter policies.

Parameters

ip-prefix-list-name

Specifies a string of up to 32 printable ASCII characters. If special characters are used, the string must be enclosed within double quotes.

configure application-assurance group policy app-filter entry ip-protocol-num

Description

This command configures the IP protocol to use in the application definition.

The **no** form of this command restores the default (removes IP protocol number from application criteria defined by this app-filter entry).

Default

no ip-protocol-num

Parameters

eq

Specifies that the value configured and the value in the flow must be equal.

neq

Specifies that the value configured differs from the value in the flow.

protocol-id

Specifies the decimal value representing the IP protocol to be used as an IP filter match criterion. Well known protocol numbers include ICMP (1), TCP (6), UDP (17).

The **no** form the command removes the protocol from the match criteria.

Values 1 to 255 (Decimal, Hexadecimal, or Binary representation).

Supported IANA IP protocol names:

none, crtp, crudp, egp, eigrp, encap, ether-ip, gre, icmp, idrp, igmp, igp, ip, ipv6, ipv6-frag, ipv6-icmp, ipv6-no-nxt, ipv6-opts, ipv6-route, isis, iso-ip, l2tp, ospf-igp, pim, pnni, ptp, rdp, rsvp, sctp, stp, tcp, udp, vrrp

* - udp/tcp wildcard

ip-route-advertisement

Syntax

ip-route-advertisement [**incl-host**] [**domain-id** *global-field*:*local-field*]

no ip-route-advertisement

Context

[Tree] (config>service>vpls>bgp-evpn ip-route-advertisement)

Full Context

configure service vpls bgp-evpn ip-route-advertisement

Description

This command enables and disables the advertisement of IP prefixes in EVPN. If enabled, any active route in the R-VPLS VPRN route table are advertised in EVPN using the VPLS BGP configuration. The interface host addresses are not advertised in EVPN unless the **ip-route-advertisement incl-host** command is enabled.

The **no** form of this command disables IP prefixes advertisement in EVPN.

Default

no ip-route-advertisement

Parameters

incl-host

Specifies to advertise the interface host addresses in EVPN.

global-field:local-field

Specifies the domain ID.

Values	*4byte-GlobalAdminValue:2byte-LocalAdminValue*	
	4byte-GlobalAdminValue:	0 to 4294967295
	2byte-LocalAdminValue	0 to 65535

Syntax
ip-src *ip-address*

no ip-src

Context
[Tree] (config>li>mirror-dest-template>layer-3-encap ip-src)

Full Context

configure li mirror-dest-template layer-3-encap ip-src

Description

This command configures the source IPv4 address to use in the IPv4 header part of the routable LI encapsulation.

Parameters

ip-address

Specifies the source IPv4 address.

Values a.b.c.d

Platforms

All

13.239 ip-ttl

ip-ttl

Syntax

ip-ttl *hops*

no ip-ttl

Context

[Tree] (config>subscr-mgmt>gtp>peer-profile ip-ttl)

Full Context

configure subscriber-mgmt gtp peer-profile ip-ttl

Description

This command configures the value to put in the IP header's TTL field for GTP control messages.

The **no** form of this command reverts to the default value.

Default

ip-ttl 255

Parameters

hops

Specifies the IP TTL.

Values 1 to 255

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

13.240 ip-tunnel

ip-tunnel

Syntax

ip-tunnel *name* [**create**]

no ip-tunnel *name*

Context

[Tree] (config>service>vprn>if>sap ip-tunnel)

[Tree] (config>service>ies>if>sap ip-tunnel)

Full Context

configure service vprn interface sap ip-tunnel

configure service ies interface sap ip-tunnel

Description

This command is used to configure an IP-GRE or IP-IP tunnel and associate it with a private tunnel SAP within an IES or VPRN service.

The **no** form of this command deletes the specified IP/GRE or IP-IP tunnel from the configuration. The tunnel must be administratively shutdown before issuing the **no ip-tunnel** command.

Default

no-ip tunnel *name*

Parameters

name

Specifies the name of the IP tunnel. Tunnel names can be from 1 to 32 alphanumeric characters. If the string contains special characters (for example, #, $, spaces), the entire string must be enclosed within double quotes.

Platforms

All

13.241 ipcp-subnet-negotiation

ipcp-subnet-negotiation

Syntax

no ipcp-subnet-negotiation

Context

[Tree] (config>service>vprn>l2tp>group>tunnel>ppp ipcp-subnet-negotiation)

[Tree] (config>service>vprn>l2tp>group>ppp ipcp-subnet-negotiation)

[Tree] (config>router>l2tp>group>ppp ipcp-subnet-negotiation)

[Tree] (config>router>l2tp>group>tunnel>ppp ipcp-subnet-negotiation)

Full Context

configure service vprn l2tp group tunnel ppp ipcp-subnet-negotiation

configure service vprn l2tp group ppp ipcp-subnet-negotiation

configure router l2tp group ppp ipcp-subnet-negotiation

configure router l2tp group tunnel ppp ipcp-subnet-negotiation

Description

This command configures the IPCP subnet negotiation using PPP IPCP Subnet-Mask option (0x90) if requested by the client. The subnet can be obtained from RADIUS (Framed-IP-Netmask attribute) or local user database. The subnet is installed as a managed route of the PPP session. This requires the anti-spoof type on the SAP to be configured to nh-mac.

By default, an IPCP Config Request with IPCP Subnet-Mask option (0x90) is rejected.

The **no** form of this command reverts to the default value.

Default

no ipcp-subnet-negotiation

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

ipcp-subnet-negotiation

Syntax

[**no**] **ipcp-subnet-negotiation**

Context

[Tree] (config>subscr-mgmt>ppp-policy ipcp-subnet-negotiation)

Full Context

configure subscriber-mgmt ppp-policy ipcp-subnet-negotiation

Description

This command enables subnet negotiation using PPP IPCP Subnet-Mask option (0x90) if requested by the client. The subnet can be obtained from RADIUS (Framed-IP-Netmask attribute) or local user database. The subnet is installed as a managed route of the PPP session. This requires the anti-spoof type on the SAP to be configured to nh-mac.

By default, an IPCP Config Request with IPCP Subnet-Mask option (0x90) is rejected.

ipfix-export-policy

Syntax

ipfix-export-policy *policy-name*

no ipfix-export-policy

Context

[Tree] (config>service>nat>nat-policy ipfix-export-policy)

[Tree] (config>service>nat>up-nat-policy ipfix-export-policy)

Full Context

configure service nat nat-policy ipfix-export-policy

configure service nat up-nat-policy ipfix-export-policy

Description

This command configures the IP flow information export policy.

The **no** form of the command removes the IP flow information export policy.

Default

no ipfix-export-policy

Parameters

policy-name

Specifies the name of the policy, up to 32 characters. The specified policy must be created in the **config**>**service**>**ipfix ipfix-export-policy** context.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

ipfix-export-policy

Syntax

ipfix-export-policy *policy-name* [**create**]

no ipfix-export-policy *policy-name*

Context

[Tree] (config>service>ipfix ipfix-export-policy)

Full Context

configure service ipfix ipfix-export-policy

Description

This command creates an IPFIX export policy with a set of transport parameters that will be used to transmit IPFIX records generated by an application within 7750 SR node to an external collector node. This policy name can be referenced from each application within 7750 SR that requires flow logging.

Parameters

policy-name

Specifies the name of the policy that can be referenced within an application in 7750 SR node that requires flow logging.

create

Keyword used to create the policy.

Platforms

All

13.244 ipipe

ipipe

Syntax

ipipe *service-id* [**customer** *customer-id*] [**create**] [**vpn** *vpn-id*] [**vc-switching**] [**name** *name*]

no ipipe *service-id*

Context

[Tree] (config>service ipipe)

Full Context

configure service ipipe

Description

This command configures an IP-Pipe service.

Parameters

service-id

The unique service identification number or string identifying the service in the service domain. This ID must be unique to this service and may not be used for any other service of any type. The *service-id* must be the same number used for every 7450 ESS or 7750 SR on which this service is defined.

Values *service-id*: 1 to 2147483647

svc-name: up to 64 characters

customer-id

Specifies the customer ID number to be associated with the service. This parameter is required on service creation and optional for service editing or deleting.

Values 1 to 2147483647

vpn vpn-id

Specifies the VPN ID number which allows you to identify virtual private networks (VPNs) by a VPN identification number.

Values 1 to 2147483647

Default null (0)

vc-switching

Specifies if the pseudowire switching signaling is used for the spoke SDPs configured in this service.

create

Keyword used to create the Ipipe service instance. The **create** keyword requirement can be enabled/disabled in the **environment**>**create** context.

name name

Configures an optional service name identifier, up to 64 characters, to a given service. This service name can then be used in configuration references, display, and show commands throughout the system. A defined service name can help the service provider or administrator to identify and manage services within the SR OS platforms.

To create a service, you must assign a service ID; however, after it is created, either the service ID or the service name can be used to identify and reference a service.

If a name is not specified at creation time, then SR OS assigns a string version of the *service-id* as the name.

Values *name*: up to 64 characters

Platforms

Description

This command specifies the IPoE session policy applicable for this group interface or capture SAP.

On WLAN GW group interfaces, it is not possible to change this value.

The **no** form of this command reverts to the default.

Default

no ipoe-session-policy ipoe-session-policy default on WLAN GW group interfaces

Parameters

policy-name

Specifies the IPoE session policy name up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

13.250 ipoe-sub-id-key

ipoe-sub-id-key

Syntax

ipoe-sub-id-key *sub-id-key* [*sub-id-key*]

no ipoe-sub-id-key

Context

[Tree] (config>subscr-mgmt>auto-sub-id-key ipoe-sub-id-key)

Full Context

configure subscriber-mgmt auto-sub-id-key ipoe-sub-id-key

Description

This command enables certain fields to become the base for auto-generation of the default sub-id name. The sub-id name is auto generated if there is not a more specific method available. Such more specific methods would be a default sub-id name as a sap-id, a preconfigured static string or explicit mappings based on RADIUS/LUDB returned strings.

In case that a more specific sub-id name generation method is not available and the auto-id keyword is defined under the def-sub-id hierarchy, the sub-id name is generated by concatenating fields defined in this command separated by a "|" character.

The maximum length of the auto-generated sub-id name is 64 characters while the concatenation of subscriber identification fields can exceed 64 characters. Subscriber host instantiation fails if the sub-id name is based on subscriber identification fields whose concatenated length exceeds 64 characters. Failing the host creation rather than truncating the sub-id name on a 64 character boundary prevents collision of sub-ids (subscriber name duplication).

If the more specific sub-id name generation method is not available and the **auto-id** keyword is not defined under the **def-sub-id** hierarchy, the sub-id name is a random 10 character encoded string based on the fields defined under this command.

There is only one set of identification fields allowed per host type (IPoE or PPP) per chassis.

The **no** form of this command reverts to the default.

Default

ipoe-sub-id-key mac sap-id

Parameters

sub-id-key

Specifies the auto-generated sub-id keys for IPoE hosts.

Values **mac** — Specifies that the MAC address can be combined with other subscriber host identification fields (circuit-id, remote-id, session-id, sap-id, or service-name) to form a sub-id name in a user readable format or as a random 10 character encoded value.

In case that the mac address is used as a concatenation field in the sub-id name, then its format becomes a string xx:xx:xx:xx:xx:xx with the length 17B.

The MAC address as the subscriber host identification field is not applicable to static hosts.

circuit-id — Specifies that the circuit-id can be combined with other subscriber host identification fields (mac, remote-id, session-id, sap-id, or service-name) to form a sub-id name in a user readable format or as a random 10 character encoded value.

In case that the circuit-id is used as a concatenation field in the sub-id name, then its format becomes access-node-id eth slot/port:[vlan-id] or access-node-id atm slot/port:vpi.vci with a variable length.

Note:
If circuit-id contains any non-printable ASCII characters, the entire circuit-id string is formatted in hex in the sub-id name output. Otherwise all characters in circuit-id is converted to ASCII. ASCII printable characters contain bytes in range 0x20 to 0x7E.

The circuit-id as the subscriber identification field is not applicable to ARP hosts or static hosts.

remote-id — Specifies that the remote-id can be combined with other subscriber host identification fields (mac, circuit-id, session-id, sap-id, or service-name) to form a sub-id name in a user readable format or as a random 10 character encoded value.

In case that the remote-id is used as a concatenation field in the sub-id name, then its format becomes a remote-id string with a variable length.

Note:
If remote-id contains any non-printable ASCII characters, the entire remote-id string is formatted in hex in the sub-id name output. Otherwise all characters in remote-id is converted to ASCII. ASCII printable characters contain bytes in range 0x20 to 0x7E.

The remote-id as the subscriber identification field is not applicable to ARP hosts or static hosts.

sap-id — Specifies that the sap-id can be combined with other subscriber host identification fields (mac, circuit-id, remote-id, session-id, or service-name) to form a sub-id name in a user readable format or as a random 10 character encoded value.

If a circuit-id is used as a concatenation field in the sub-id name, then its format becomes: slot/mda:[outer-vlan].[inner-vlan] with a variable length.

The sap-id as the subscriber identification field is applicable to all hosts types with exception of static hosts.

dual-stack-remote-id — Specifies that the dual stack remote ID is used as the base for the auto-generated subscriber identification

service-name — Specifies that the service name that terminates the subscriber is used as the base for auto-generated subscriber identification.

ipsec-gw

Syntax

ipsec-gw *name*

no ipsec-gw

Context

[Tree] (config>service>ies>if>sap ipsec-gw)

[Tree] (config>service>vprn>if>sap ipsec-gw)

Full Context

configure service ies interface sap ipsec-gw

configure service vprn interface sap ipsec-gw

Description

This command configures an IPsec gateway.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

13.255 ipsec-lifetime

ipsec-lifetime

Syntax

ipsec-lifetime *ipsec-lifetime*

no ipsec-lifetime

Context

[Tree] (config>ipsec>ike-policy ipsec-lifetime)

Full Context

configure ipsec ike-policy ipsec-lifetime

Description

This command specifies the lifetime of the Phase 2 IKE key.

The **no** form of this command reverts to the default, which is 3600 seconds.

Default

no ipsec-lifetime

Parameters

ipsec-lifetime

Specifies the Phase 2 lifetime for this IKE policy in seconds.

Values 1200 to 31536000

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

ipsec-lifetime

Syntax

ipsec-lifetime *seconds*

ipsec-lifetime inherit

Context

[Tree] (config>ipsec>ipsec-transform ipsec-lifetime)

Full Context

configure ipsec ipsec-transform ipsec-lifetime

Description

This command specifies the CHILD_SA. If the **inherit** parameter is specified, then the system uses the IPsec lifetime configuration in the corresponding IKE policy configured in the same IPsec gateway or IPsec tunnel.

Default

ipsec-lifetime inherit

Parameters

seconds

Specifies the lifetime of the Phase 2 IKE key in seconds.

Values 1200 to 31536000

inherit

Specifies that the system uses the **ipsec-lifetime** configuration in the corresponding IKE policy that is configured for the same IPsec gateway or IPsec tunnel.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

13.256 ipsec-responder-only

ipsec-responder-only

Syntax

[**no**] **ipsec-responder-only**

Context

[Tree] (config>isa>tunnel-group ipsec-responder-only)

Full Context

configure isa tunnel-group ipsec-responder-only

Description

With this command configured, system will only act as IKE responder except for the automatic CHILD_SA re-key upon MC-IPsec switchover.

Default

no ipsec-responder-only

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

13.257 ipsec-transform

ipsec-transform

Syntax

ipsec-transform *transform-id* [**create**]

no ipsec-transform *transform-id*

Context

[Tree] (config>ipsec ipsec-transform)

Full Context

configure ipsec ipsec-transform

Description

Commands in this context create an **ipsec-transform** policy. IPsec transforms policies can be shared. A change to the ipsec-transform is allowed at any time. The change will not impact tunnels that have been established until they are renegotiated. If the change is required immediately the tunnel must be cleared (reset) for force renegotiation.

IPsec transform policy assignments to a tunnel require the tunnel to be shutdown.

The **no** form of this command removes the ID from the configuration.

Parameters

transform-id

Specifies a policy ID value to identify the IPsec transform policy.

Values 1 to 2048

create

This keyword is mandatory when creating an ipsec-transform policy. The **create** keyword requirement can be enabled or disabled in the **environment>create** context.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

13.258 ipsec-transport-mode-profile

ipsec-transport-mode-profile

Syntax

ipsec-transport-mode-profile *name* [**create**]

no ipsec-transport-mode-profile *name*

Context

[Tree] (config ipsec ipsec-transport-mode-profile)

Full Context

configure ipsec ipsec-transport-mode-profile

Description

Commands in this context configure an IPsec transport mode profile.

The **no** form of this command removes the name from the configuration.

Parameters

name

Specifies the name of the IPsec transport mode profile, up to 32 characters.

create

Keyword used to create the IPsec transport mode profile instance.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

ipsec-transport-mode-profile

Syntax

ipsec-transport-mode-profile *name*

no ipsec-transport-mode-profile

Context

[Tree] (config service ies if sap ip-tunnel ipsec-transport-mode-profile)

[Tree] (config service vprn if sap ip-tunnel ipsec-transport-mode-profile)

Full Context

configure service ies interface sap ip-tunnel ipsec-transport-mode-profile

configure service vprn interface sap ip-tunnel ipsec-transport-mode-profile

Description

This command specifies an IPsec transport mode profile name to the SAP.

The **no** form of this command removes the profile name from the service configuration.

Parameters

name

Specifies the name of an existing IPsec transport mode profile, up to 32 characters

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

13.259 ipsec-tunnel

ipsec-tunnel

Syntax

ipsec-tunnel *ipsec-tunnel-name*

no ipsec-tunnel [*ipsec-tunnel-name*]

Context

[Tree] (config>service>vprn>static-route-entry ipsec-tunnel)

Full Context

configure service vprn static-route-entry ipsec-tunnel

Description

This command creates a static route in a VPRN service context that points to the global routing context (base router). This is primarily used to allow traffic that ingress through a VPRN service to be routed out of the global routing context.

This **next-hop** type cannot be used in conjunction with any other next-hop types.

Default

no ipsec-tunnel

Parameters

ipsec-tunnel-name

IPsec tunnel name; maximum length up to 32 characters.

Platforms

All

ipsec-tunnel

Syntax

ipsec-tunnel *name* [**private-sap** [*0..4094*]] [**private-service-name** *private-service-name*] [**create**]

no ipsec-tunnel *ipsec-tunnel-name*

Context

[Tree] (config>service>ies>if>ipsec ipsec-tunnel)

[Tree] (config>service>vprn>if>sap ipsec-tunnel)

[Tree] (config>router>if>ipsec ipsec-tunnel)

Full Context

configure service ies interface ipsec ipsec-tunnel

configure service vprn interface sap ipsec-tunnel

configure router interface ipsec ipsec-tunnel

Description

This command configures a secured interface IPsec tunnel. If the **private-service-name** is not specified, the private service is the secured interface service.

The **no** form of this command removes the IPsec tunnel from the configuration.

Parameters

name

Specifies the name of the IPsec tunnel.

private-sap

Specifies the private SAP ID.

Values 0 to 4094

private-service-name

Specifies the private service name.

create

Keyword used to create the IPsec tunnel instance. The **create** keyword requirement can be enabled or disabled in the **environment>create** context.

Platforms

VSR

- configure service ies interface ipsec ipsec-tunnel
- configure router interface ipsec ipsec-tunnel

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

- configure service vprn interface sap ipsec-tunnel

no ipv4

Context

[Tree] (config>service>vprn>bgp>multi-path ipv4)

Full Context

configure service vprn bgp multi-path ipv4

Description

This command sets ECMP multipath parameters that apply only to the (unlabeled) IPv4 unicast address family. These settings override the values set by the **maximum-paths** command.

When multipath is enabled, traffic to the destination is load-shared across a set of paths (BGP routes) that the BGP decision process considers equal to the best path. The actual distribution of traffic over the multiple paths may be equal or unequal (that is, based on weights derived from the Link Bandwidth Extended Community).

To qualify as a multipath, a non-best route must meet the following criteria (some criteria are controlled by this command):

- The multi-path route must be the same type of route as the best path (same AFI/SAFI and, in some cases, same next-hop resolution method).
- The multi-path route must be tied with the best path for all criteria of greater significance than next-hop cost, except for criteria that are configured to be ignored.
- If the best path selection reaches the next-hop cost comparison, the multi-path route must have the same next-hop cost as the best route unless the **unequal-cost** option is configured.
- The multi-path route must not have the same BGP next-hop as the best path or any other multi-path route.
- The multi-path route must not cause the ECMP limit of the routing instance to be exceeded (configured using the **ecmp** command with a value in the range 1 to 64).
- The multi-path route must not cause the applicable *max-paths* limit to be exceeded. If the best path is an EBGP learned route and the **ebgp** option is used, the *ebgp-max-paths* limit overrides the *max-paths* limit. If the best path is an IBGP-learned route and the **ibgp** option is used, the *ibgp-max-paths* limit overrides the *max-paths* limit. All path limits are configurable up to a maximum of 64. Multi-path is effectively disabled if a value is set to 1.
- The multi-path route must have the same neighbor AS in its AS path as the best path if the **restrict same-neighbor-as** option is configured. By default, any path with the same AS path length as the best path (regardless of neighbor AS) is eligible for multi-path.

- The route must have the same AS path as the best path if the **restrict exact-as-path** option is configured. By default, any path with the same AS path length as the best path (regardless of the actual AS numbers) is eligible for multi-path.

The **no** form of this command removes IPv4-specific overrides.

Default

no ipv4

Parameters

max-paths

Specifies the maximum number of multipaths per prefix/NLRI if *ebgp-max-paths* or *ibgp-max-paths* does not apply.

Values 1 to 64

egp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an EBGP learned route.

Values 1 to 64

ibgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an IBGP learned route.

Values 1 to 64

restrict same-neighbor-as

Specifies that the non-best path must have the same neighbor AS in its AS path as the best path.

restrict exact-as-path-as

Specifies that the non-best path must have the same AS path as the best path.

unequal-cost

Instructs BGP to ignore differences in the next-hop cost only when determining eligible multipaths.

Full Context

configure system network-element-discovery profile neip ipv4

Description

This command configures the IPv4 NEIP for this profile. The NEIP can be configured manually or set to be automatically generated using the NEID. If the NEID option is set, the first most significant byte of the IPv4 NEIP is set to 140 and the remaining 3 bytes are set to the NEID value. The NEID can be configured with a vendor ID value, in which case the first most significant byte of the IPv4 NEIP is set to this vendor ID value.

The **no** form of this command removes the IPv4 address association for this profile.

Default

no ipv4

Parameters

ip-address

Specifies the IPv4 address of the NEIP.

auto-generate

Specifies that the NEIP is automatically generated using the NEID.

vendor-id-value

Specifies the vendor ID value.

Values 1 to 255

Platforms

All

ipv4

Syntax

ipv4 send *send-limit* **receive** [**none**]

[Tree] (config>router>bgp>group>add-paths ipv4)

[Tree] (config>router>bgp>add-paths ipv4)

Full Context

configure router bgp group neighbor add-paths ipv4

configure router bgp group add-paths ipv4

configure router bgp add-paths ipv4

Description

This command configures the add-paths capability for unlabeled IPv4 unicast routes. By default, add-paths is not enabled for unlabeled IPv4 unicast routes.

The maximum number of unlabeled unicast paths per IPv4 prefix to send is the configured send limit, which is a mandatory parameter. The capability to receive multiple unlabeled IPv4 unicast paths per prefix from a peer is configurable using the **receive** keyword, which is optional. If the **receive** keyword is not included in the command the receive capability is enabled by default.

The **no** form of this command disables add-paths support for unlabeled IPv4 unicast routes, causing sessions established using add-paths for unlabeled IPv4 unicast to go down and come back up without the add-paths capability.

Default

no ipv4

Parameters

send-limit

Specifies the maximum number of paths per unlabeled IPv4 unicast prefix that are allowed to be advertised to add-paths peers, the actual number of advertised routes may be less. If the value is **none**, the router does not negotiate the send capability with respect to IPv4 AFI/SAFI. If the value is **multipaths**, then BGP advertises all of the used BGP multipaths for each IPv4 NLRI if the peer has signaled support to receive multiple add-paths.

Values 1 to 16, none, multipaths

receive

Specifies that the router negotiates to receive multiple unlabeled unicast routes per IPv4 prefix.

none

Specifies that the router does not negotiate to receive multiple unlabeled unicast routes per IPv4 prefix.

Platforms

All

ipv4

Syntax

ipv4 *max-paths* [**ebgp** *ebgp-max-paths*] [**ibgp** *ibgp-max-paths*] [**restrict** { **same-neighbor-as** | **exact-as-path**}] [**unequal-cost**]

no ipv4

Context

[Tree] (config>router>bgp>multi-path ipv4)

Full Context

configure router bgp multi-path ipv4

Description

This command sets ECMP multipath parameters that apply only to the (unlabeled) IPv4 unicast address family. These settings override the values set by the **maximum-paths** command.

When multipath is enabled, traffic to the destination is load-shared across a set of paths (BGP routes) that the BGP decision process considers equal to the best path. The actual distribution of traffic over the multiple paths may be equal or unequal (that is, based on weights derived from the Link Bandwidth Extended Community).

The **no** form of this command removes IPv4-specific overrides.

Default

no ipv4

Parameters

max-paths

Specifies the maximum number of multipaths per prefix/NLRI if *ebgp-max-paths* or *ibgp-max-paths* does not apply.

Values 1 to 64

ebgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an EBGP learned route.

Values 1 to 64

ibgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an IBGP learned route.

Values 1 to 64

restrict same-neighbor-as

Specifies that the non-best path must have the same neighbor AS in its AS path as the best path.

restrict exact-as-path

Specifies that the non-best path must have the same AS path as the best path.

unequal-cost

Instructs BGP to ignore differences in the next-hop cost only when determining eligible multipaths.

no ipv4-address

Context

[Tree] (config>subscr-mgmt>wlan-gw>ue-query ipv4-address)

Full Context

configure subscriber-mgmt wlan-gw ue-query ipv4-address

Description

This command enables matching on UEs with the specified IPv4 address.

The **no** form of this command disables matching on the IPv4 address.

Default

no ipv4-address

Parameters

ip-address

Specifies the IPv4 address.

Values a.b.c.d

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

13.262 ipv4-adjacency-sid

ipv4-adjacency-sid

Syntax

ipv4-adjacency-sid label *value*

no ipv4-adjacency-sid

Context

[Tree] (config>router>isis>interface ipv4-adjacency-sid)

Full Context

configure router isis interface ipv4-adjacency-sid

Description

This command allows a static value to be assigned to an IPv4 adjacency SID in IS-IS segment routing.

The **label** option specifies that the value is assigned to an MPLS label.

The **no** form of this command removes the adjacency SID.

Parameters

value

Specifies the adjacency SID label.

Values 18432 to 5248 | 1048575 (FP4 or FP5 only)

Platforms

All

13.263 ipv4-arp

ipv4-arp

Syntax

ipv4-arp *max-nr-of-hosts*

no ipv4-arp

Full Context

configure subscriber-mgmt sub-profile host-limits ipv4-dhcp

configure subscriber-mgmt sla-profile host-limits ipv4-dhcp

Description

This command limits the number of IPv4 DHCP hosts per SLA profile instance or per subscriber.

The **no** form of this command removes the maximum number of IPv4 DHCP hosts limit.

Parameters

max-nr-of-hosts

Specifies the maximum number of IPv4 DHCP hosts.

Note:
The operational maximum value may be smaller due to equipped hardware dependencies.

Values 0 to 131071

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

13.265 ipv4-mtu

ipv4-mtu

Syntax

ipv4-mtu *bytes*

no ipv4-mtu

Context

[Tree] (config>subscr-mgmt>gtp>peer-profile ipv4-mtu)

Full Context

configure subscriber-mgmt gtp peer-profile ipv4-mtu

Description

This command configures the value of the IPv4-MTU PCO sent in S11 GTP messages. This is the MTU a device should honor when sending data toward the SGW/PGW. For IPv6, this value is signaled in the RA message and which can be configured in the **grp-if> ipv6>rtr-adv>mtu** context.

The **no** form of this command resets the signaled IPv4 MTU to the default.

Default

ipv4-mtu 1400

Parameters

bytes

Specifies the MTU value in bytes.

Values 512 to 9000

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

13.266 ipv4-multicast

ipv4-multicast-routing

Syntax

ipv4-multicast-routing {**native** | **mt**}

[**no**] **ipv4-multicast-routing**

Context

[Tree] (config>service>vprn>isis ipv4-multicast-routing)

Full Context

configure service vprn isis ipv4-multicast-routing

Description

The multicast RTM is used for Reverse Path Forwarding checks. This command controls which IS-IS topology is used to populate the IPv4 multicast RTM.

The **no** ipv4-multicast-routing form of this command results in none of the IS-IS routes being populated in the IPv4 multicast RTM and would be used if multicast is configured to use the unicast RTM for the RPF check.

Default

ipv4-multicast-routing native

Parameters

native

Causes IPv4 routes from the MT0 topology to be added to the multicast RTM for RPF checks.

mt

Causes IPv4 routes from the MT3 topology to be added to the multicast RTM for RPF checks.

Platforms

All

ipv4-multicast-routing

Syntax

ipv4-multicast-routing {**native** | **mt**}

[**no**] **ipv4-multicast-routing**

Context

[Tree] (config>router>isis ipv4-multicast-routing)

Full Context

configure router isis ipv4-multicast-routing

Description

The multicast RTM is used for Reverse Path Forwarding checks. This command controls which IS-IS topology is used to populate the IPv4 multicast RTM.

The **no** form of this command results in none of the IS-IS routes being populated in the IPv4 multicast RTM and would be used if multicast is configured to use the unicast RTM for the RPF check.

Default

ipv4-multicast-routing native

Parameters

native

Causes IPv4 routes from the MT0 topology to be added to the multicast RTM for RPF checks.

mt

Causes IPv4 routes from the MT3 topology to be added to the multicast RTM for RPF checks.

Platforms

13.271 ipv4-node-sid

ipv4-node-sid

Syntax

ipv4-node-sid index *index-value* [**clear-n-flag**]

ipv4-node-sid label *label-value* [**clear-n-flag**]

no ipv4-node-sid

Context

[Tree] (config>router>isis>interface ipv4-node-sid)

Full Context

configure router isis interface ipv4-node-sid

Description

This command assigns a node SID index or label value to the prefix representing the primary address of an IPv4 network interface of **type loopback**. Only a single node SID can be assigned to an interface. The secondary address of an IPv4 interface cannot be assigned a node SID index and does not inherit the SID of the primary IPv4 address.

The command fails if the network interface is not of **type loopback** or if the interface is defined in an IES or a VPRN context. Also, assigning the same SID index or label value to the same interface in two different IGP instances is not allowed within the same node.

The value of the label or index SID is taken from the range configured for this IGP instance. When using the global mode of operation, a new segment routing module checks that the same index or label value

cannot be assigned to more than one loopback interface address. When using the per-instance mode of operation, this check is not required since the index and thus label ranges of the various IGP instance are not allowed to overlap.

The **clear-n-flag** option allows the user to clear the N-flag (node-sid flag) in an IS-IS prefix SID sub-TLV originated for the IPv4 prefix of a loopback interface on the system.

By default, the prefix SID sub-TLV for the prefix of a loopback interface is tagged as a node SID, meaning that it belongs to this node only. However, when the user wants to configure and advertise an anycast SID using the same loopback interface prefix on multiple nodes, you must clear the N-flag to assure interoperability with third party implementations, which may perform a strict check on the receiving end and drop duplicate prefix SID sub-TLVs when the N-flag is set.

The SR OS implementation is relaxed on the receiving end and accepts duplicate prefix SIDs with the N-flag set or cleared. SR OS will resolve to the closest owner, or owners if ECMP is configured, of the prefix SID according to its cost.

Default

no ipv4-node-sid

Parameters

index index-value

Specifies the index value.

Values 0 to 4294967295

label label-value

Specifies the label value.

Values 0 to 4294967295

clear-n-flag

Clears the node SID flag.

Default no clear-n-flag

no ipv4-overall

Context

[Tree] (config>subscr-mgmt>sla-profile>host-limits ipv4-overall)

[Tree] (config>subscr-mgmt>sub-profile>host-limits ipv4-overall)

Full Context

configure subscriber-mgmt sla-profile host-limits ipv4-overall

configure subscriber-mgmt sub-profile host-limits ipv4-overall

Description

This command configures the maximum number of IPv4 hosts per SLA profile instance or per subscriber.

The **no** form of this command removes the maximum number of IPv4 hosts limit.

Parameters

max-nr-of-hosts

Specifies the maximum number of IPv4 hosts.

Note:
The operational maximum value may be smaller due to equipped hardware dependencies.

Values 0 to 131071

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

13.273 ipv4-ppp

ipv4-ppp

Syntax

no ipv4-sid

Context

[Tree] (config>router>segment-routing>sr-mpls>prefix-sids ipv4-sid)

Full Context

configure router segment-routing sr-mpls prefix-sids ipv4-sid

Description

This command is used to configure the IPv4 segment routing SID associated with the primary IPv4 address of the loopback or system interface.

The **no** form of this command removes the configuration of the IPv4 segment routing SID associated with the primary IPv4 interface address.

Default

no ipv4-sid

Parameters

index *index-id*

Specifies the node SID index for this interface.

Values 0 to 4294967295

label *label-id*

Specifies the label value for the node SID.

Values 32 to 1048575

Platforms

All

13.277 ipv4-source-address

ipv4-source-address

Syntax

ipv4-source-address *ipv4-address*

no ipv4-source-address

Context

[Tree] (config>service>vprn>dns ipv4-source-address)

Full Context

configure service vprn dns ipv4-source-address

Description

This command configures the IPv4 address of the default secondary DNS server for the subscribers using this interface. Subscribers that cannot obtain an IPv4 DNS server address by other means, can use this for DNS name resolution.

The ipv4-address value can only be set to a nonzero value if the value of VPRN type is set to **subscriber-split-horizon**.

The **no** form of this command reverts to the default.

Parameters

ipv4-address

Specifies the IPv4 address of the default secondary DNS server.

Values ipv4-address - a.b.c.d

Platforms

All

ipv4-source-address

Syntax

ipv4-source-address *ip-address*

no ipv4-source-address

Context

[Tree] (config>system>file-trans-prof ipv4-source-address)

Full Context

configure system file-transmission-profile ipv4-source-address

Description

This command specifies the IPv4 source address used for transport protocol.

The **no** form of this command uses the default source address which typically is the address of the egress interface.

Default

no ipv4-source-address

Parameters

ip-address

Specifies a unicast v4 address. This should be a local interface address.

Platforms

All

ipv4-source-address

Syntax

ipv4-source-address *ip-address*

no ipv4-source-address

Context

[Tree] (config>service>nat>syslog>syslog-export-policy>collector ipv4-source-address)

Full Context

configure service nat syslog syslog-export-policy collector ipv4-source-address

Description

This command configures the IPv4 source address from which the UDP streams containing syslog flow records are sourced.

The **no** form of the command removes the IPv4 address from the configuration.

Parameters

ip-address

Specifies the source IPv4 address from which UDP streams are sent.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

13.278 ipv4-unicast-metric-offset

ipv4-unicast-metric-offset

Syntax

ipv4-unicast-metric-offset *offset-value*

Context

[Tree] (config>service>vprn>isis>link-group>level ipv4-unicast-metric-offset)

Full Context

configure service vprn isis link-group level ipv4-unicast-metric-offset

Description

This command sets the offset value for the IPv4 unicast address family. If the number of operational links drops below the oper-members threshold, the configured offset is applied to the interface metric.

The **no** form of this command reverts the offset value to 0.

Default

no ipv4-unicast-metric-offset

Parameters

offset-value

Specifies the amount the interface metric for the associated address family is to be increased if the number of operational members in the associated link-group drops below the oper-members threshold.

Values 0 to 6777215

Platforms

All

ipv4-unicast-metric-offset

Syntax

ipv4-unicast-metric-offset *offset-value*

no ipv4-unicast-metric-offset

Context

[Tree] (config>router>isis>link-group>level ipv4-unicast-metric-offset)

Full Context

configure router isis link-group level ipv4-unicast-metric-offset

Description

This command sets the offset value for the IPv4 unicast address family. If the number of operational links drops below the oper-members threshold, the configured offset is applied to the interface metric.

The **no** form of this command reverts the offset value to 0.

Default

no ipv4-unicast-metric-offset

Parameters

offset-value

Specifies the amount the interface metric for the associated address family is to be increased if the number of operational members in the associated link-group drops below the oper-members threshold.

Values 0 to 6777215

ipv6

Syntax

ipv6 max-paths [**ebgp** *ebgp-max-paths*] [**ibgp** *ibgp-max-paths*] [**restrict** { **same-neighbor-as** | **exact-as-path**}] [**unequal-cost**]

no ipv6

Context

[Tree] (config>service>vprn>bgp>multi-path ipv6)

Full Context

configure service vprn bgp multi-path ipv6

Description

This command sets ECMP multipath parameters that apply only to the (unlabeled) IPv6 unicast address family. These settings override the values set by the **maximum-paths** command.

When multipath is enabled, traffic to the destination is load-shared across a set of paths (BGP routes) that the BGP decision process considers equal to the best path. The actual distribution of traffic over the multiple paths may be equal or unequal (that is, based on weights derived from the Link Bandwidth Extended Community).

To qualify as a multipath, a non-best route must meet the following criteria (some criteria are controlled by this command):

- The multi-path route must be the same type of route as the best path (same AFI/SAFI and, in some cases, same next-hop resolution method).
- The multi-path route must be tied with the best path for all criteria of greater significance than next-hop cost, except for criteria that are configured to be ignored.
- If the best path selection reaches the next-hop cost comparison, the multi-path route must have the same next-hop cost as the best route unless the **unequal-cost** option is configured.
- The multi-path route must not have the same BGP next-hop as the best path or any other multi-path route.
- The multi-path route must not cause the ECMP limit of the routing instance to be exceeded (configured using the **ecmp** command with a value in the range 1 to 64)
- The multi-path route must not cause the applicable *max-paths* limit to be exceeded. If the best path is an EBGP learned route and the **ebgp** option is used, the *ebgp-max-paths* limit overrides the *max-paths* limit. If the best path is an IBGP-learned route and the **ibgp** option is used, the *ibgp-max-paths* limit overrides the *max-paths* limit. All path limits are configurable up to a maximum of 64. Multi-path is effectively disabled if a value is set to 1.
- The multi-path route must have the same neighbor AS in its AS path as the best path if the **restrict same-neighbor-as** option is configured. By default, any path with the same AS path length as the best path (regardless of neighbor AS) is eligible for multi-path.
- The route must have the same AS path as the best path if the **restrict exact-as-path** option is configured. By default, any path with the same AS path length as the best path (regardless of the actual AS numbers) is eligible for multi-path.

The **no** form of this command removes IPv6-specific overrides.

Default

no ipv6

Parameters

max-paths

Specifies the maximum number of multipaths per prefix/NLRI if *ebgp-max-paths* or *ibgp-max-paths* does not apply.

Values 1 to 64

egp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an EBGP learned route.

Values 1 to 64

ibgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an IBGP learned route.

Values 1 to 64

restrict same-neighbor-as

Specifies that the non-best path must have the same neighbor AS in its AS path as the best path.

restrict exact-as-path-as

Specifies that the non-best path must have the same AS path as the best path.

unequal-cost

Instructs BGP to ignore differences in the next-hop cost only when determining eligible multipaths.

When enabled, the Alc-App-Prof-Str VSA is ignored in a radius Accept that enables portal redirection using this redirect policy. AA functionality will be disabled during portal authentication.

The **no** version of this command allows an Alc-App-Prof-Str to be present and will enable Application Assurance during portal authentication. In this case redirection rules defined in this policy are bypassed and it is assumed the AA function is configured for portal redirection.

Description

This command enables context to configure list of redundant IPv6 source prefixes for preferred source selection.

Platforms

All

ipv6

Syntax

ipv6

Context

[Tree] (config>service>vprn>pim>rp ipv6)

Full Context

configure service vprn pim rp ipv6

Description

This command enables access to the context to configure the rendezvous point (RP) of a PIM IPv6 protocol instance.

A Nokia IPv6 PIM router acting as an RP must respond to an IPv6 PIM register message specifying an SSM multicast group address by sending to the first hop router stop register message(s). It does not build an (S, G) shortest path tree toward the first hop router. An SSM multicast group address can be either from the SSM default range or from a multicast group address range that was explicitly configured for SSM.

Default

ipv6 RP enabled when IPv6 PIM is enabled.

configure system network-element-discovery profile neip ipv6

Description

This command configures the IPv6 NEIP for this profile. The NEIP can be configured manually or set to be automatically generated. If the NEIP is set to be automatically generated, the NEID is used for the subnet and host portion of the IPv6 address and the vendor ID value is set to 140 by default. The vendor ID value can be configured.

The **no** form of this command removes the IPv6 address association for this profile.

Default

no ipv6

Parameters

ipv6-address

Specifies the IPv6 address of the NEIP.

Values

ipv6-address	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x: [0..FFFF]H
	d: [0..255]D

auto-generate

Specifies that the NEIP is automatically generated using the NEID.

vendor-id-value

Specifies the vendor ID value.

Values 1 to 255

Context

[Tree] (config>router>bgp>group>add-paths ipv6)

[Tree] (config>router>bgp>add-paths ipv6)

[Tree] (config>router>bgp>group>neighbor>add-paths ipv6)

Full Context

configure router bgp group add-paths ipv6

configure router bgp add-paths ipv6

configure router bgp group neighbor add-paths ipv6

Description

This command configures the add-paths capability for unlabeled IPv6 unicast routes. By default, add-paths is not enabled for unlabeled IPv6 unicast routes.

The maximum number of unlabeled unicast paths per IPv6 prefix to send is the configured send limit, which is a mandatory parameter. The capability to receive multiple unlabeled IPv6 unicast paths per prefix from a peer is configurable using the **receive** keyword, which is optional. If the **receive** keyword is not included in the command the receive capability is enabled by default.

The **no** form of this command disables add-paths support for unlabeled IPv6 unicast routes, causing sessions established using add-paths for unlabeled IPv6 unicast to go down and come back up without the add-paths capability.

Default

no ipv6

Parameters

send *send-limit*

Specifies the maximum number of paths per unlabeled IPv6 unicast prefix that are allowed to be advertised to add-paths peers. (The actual number of advertised routes may be less.) If the value is **none**, the router does not negotiate the send capability with respect to IPv6 AFI/SAFI. If the value is **multipaths**, then BGP advertises all the used BGP multipaths for each IPv6 NLRI if the peer has signaled support to receive multiple add-paths.

Values 1 to 16, none, multipaths

receive

Specifies the router negotiates to receive multiple unlabeled unicast routes per IPv6 prefix.

none

Specifies the router does not negotiate to receive multiple unlabeled unicast routes per IPv6 prefix.

Platforms

All

ipv6

Syntax

ipv6 *max-paths* [**ebgp** *ebgp-max-paths*] [**ibgp** *ibgp-max-paths*] [**restrict** { **same-neighbor-as** | **exact-as-path**}] [**unequal-cost**]

no ipv6

Context

[Tree] (config>router>bgp>multi-path ipv6)

Full Context

configure router bgp multi-path ipv6

Description

This command sets ECMP multipath parameters that apply only to the (unlabeled) IPv6 unicast address family. These settings override the values set by the **maximum-paths** command.

When multipath is enabled, traffic to the destination is load-shared across a set of paths (BGP routes) that the BGP decision process considers equal to the best path. The actual distribution of traffic over the multiple paths may be equal or unequal (that is, based on weights derived from the Link Bandwidth Extended Community).

The **no** form of this command removes IPv6-specific overrides.

Default

no ipv6

Parameters

max-paths

Specifies the maximum number of multipaths per prefix/NLRI if *ebgp-max-paths* or *ibgp-max-paths* does not apply.

Values 1 to 64

ebgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an EBGP learned route.

Values 1 to 64

ibgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an IBGP learned route.

Values 1 to 64

restrict same-neighbor-as

Specifies that the non-best path must have the same neighbor AS in its AS path as the best path.

restrict exact-as-path

Specifies that the non-best path must have the same AS path as the best path.

unequal-cost

Instructs BGP to ignore differences in the next-hop cost only when determining eligible multipaths.

Full Context

configure subscriber-mgmt local-user-db ipoe host ipv6-address

configure subscriber-mgmt local-user-db ppp host ipv6-address

Description

This command configures static DHCPv6 IA-NA address for the host. This address is delegated to the client as /128 via DHCPv6 proxy function within the router. This IP address must not be part of any DHCP pool within internal DHCP server.

The **no** form of this command removes the IPv6 address from the host configuration.

Parameters

ipv6-address

Specifies the IPv6 address.

Values

ipv6-address: ipv6-prefix x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x [0 to FFFF]H

13.283 ipv6-criteria

ipv6-criteria

Syntax

[**no**] **ipv6-criteria**

Context

[Tree] (config>qos>sap-egress ipv6-criteria)

[Tree] (config>qos>sap-ingress ipv6-criteria)

Full Context

configure qos sap-egress ipv6-criteria

configure qos sap-ingress ipv6-criteria

Description

IPv6 criteria-based SAP egress or ingress policies are used to select the appropriate ingress or egress queue or policer and corresponding forwarding class and packet profile for matched traffic.

This command is used to enter the node to create or edit policy entries that specify IPv6 criteria such as IP quintuple lookup or DiffServ code point.

The OS implementation will exit on the first match found and execute the actions in accordance with the accompanying action command. For this reason, entries must be sequenced correctly from most to least explicit.

The **no** form of this command deletes all the entries specified under this node. When ipv6-criteria entries are removed from a SAP ingress policy, the ipv6-criteria is removed from all services where that policy is applied.

Platforms

All

ipv6-criteria

Syntax

[**no**] **ipv6-criteria**

Context

[Tree] (config>qos>network>egress ipv6-criteria)

[Tree] (config>qos>network>ingress ipv6-criteria)

Full Context

configure qos network egress ipv6-criteria

configure qos network ingress ipv6-criteria

Description

IPv6 criteria-based network ingress and egress policies are used to select the appropriate ingress or egress queue or policer, and the corresponding forwarding class and packet profile for matched traffic. This command is used to enter the context to create or edit policy entries that specify IPv6 criteria such as IP quintuple lookup or DSCP.

The 7750 SR OS implementation will exit on the first match found and execute the actions in accordance with the accompanying action command. Entries must be sequenced correctly from most to least explicit.

The ingress classification only applies to the outer IPv6 header of non-tunneled traffic.

Attempting to apply a network QoS policy containing an **ipv6-criteria** statement to any object except a network IP interface will result in an error.

The **no** form of this command deletes all entries specified under this node. When IP criteria entries are removed from a network policy, the IPv6 criteria are removed from all network interfaces to which that policy is applied.

13.288 ipv6-eh

ipv6-eh

Syntax

ipv6-eh {**max** | **limited**}

no ipv6-eh

Context

[Tree] (config>system>ip ipv6-eh)

Full Context

configure system ip ipv6-eh

Description

This command defines the maximum number of IPv6 extension headers parsed in the line cards. The system parses up to six extension headers when **ipv6-eh max** is configured.

When the **ipv6-eh limited** command is configured, the system does not parse IPv6 extension headers and provides consistent ipv6-filter matches for the next-header value found in the IPv6 packet header. LAG and ECMP hashing of IPv6 packets with extension headers is limited to Layer 3 IP addresses. Layer 4 ports, TEID, and SPI values are not available for hashing. MLD snooping on Layer 2 services is also not supported in this mode.

The **no** form of this command reverts to the default value.

Default

ipv6-eh max

Parameters

max

Specifies that the maximum number of IPv6 extension headers is parsed in the line cards.

limited

Specifies that the system does not parse IPv6 extension headers and provides consistent ipv6-filter matches for the next-header value found in the IPv6 packet header.

Platforms

ipv6-filter

Syntax

ipv6-filter *ipv6-filter-id* **entry** *entry-id* [*entry-id*]

no ipv6-filter *ipv6-filter-id* [**entry** *entry-id*]

Context

[Tree] (config>mirror>mirror-source ipv6-filter)

Full Context

configure mirror mirror-source ipv6-filter

Description

This command enables mirroring of packets that match specific entries in an existing IPv6 filter.

The **ipv6-filter** command directs packets which match the defined list of entry IDs to be mirrored to the mirror destination referenced by the *mirror-dest-service-id* of the **mirror-source**.

The IPv6 filter must already exist in order for the command to execute. Filters are configured in the **config>filter** context. If the IPv6 filter does not exist, an error will occur. If the filter exists but has not been associated with a SAP or IPv6 interface, an error is not generated but mirroring will not be enabled (there are no packets to mirror). Once the IPv6 filter is defined to a SAP or IPv6 interface, mirroring is enabled.

If the IPv6 filter is defined as ingress, only ingress packets are mirrored. Ingress mirrored packets are mirrored to the mirror destination prior to any ingress packet modifications.

If the IPv6 filter is defined as egress, only egress packets are mirrored. Egress mirrored packets are mirrored to the mirror destination after all egress packet modifications.

An *entry-id* within an IPv6 filter can only be mirrored to a single mirror destination. If the same *entry-id* is defined multiple times, an error occurs and only the first **mirror-source** definition is in effect.

By default, no packets matching any IPv6 filters are mirrored. Mirroring of IPv6 filter entries must be explicitly defined.

The **no ipv6-filter** command, without the **entry** keyword, removes mirroring on all *entry-id*'s within the *ip-filter-id*.

When the **no** form of this command is executed with the **entry** keyword and one or more *entry-id*'s, mirroring that *entry-id* list is terminated within the *ip-filter-id*. If an *entry-id* is listed that does not exist, an error will occur and the command will not execute. If an *entry-id* is listed that is not currently being mirrored, no error will occur for that *entry-id* and the command will execute normally.

Parameters

ipv6-filter-id

Specifies the IPv6 filter ID whose entries are mirrored. If the *ipv6-filter-id* does not exist, an error will occur and the command will not execute. Mirroring of packets will commence once the *ipv6-filter-id* is defined on a SAP or IPv6 interface.

entry-id

Specifies the IP filter entries to use as match criteria for packet mirroring. The **entry** keyword begins a list of *entry-id*'s for mirroring. Multiple *entry-id* entries may be specified with a single command. Each *entry-id* must be separated by a space.

If an *entry-id* does not exist within the IP filter, an error occurs and the command will not execute.

If the filter's *entry-id* is renumbered within the IP filter definition, the old *entry-id* is removed but the new *entry-id* must be manually added to the configuration to include the new (renumbered) entry's criteria.

Platforms

All

ipv6-filter

Syntax

[**no**] **ipv6-filter** *ipv6-filter-id*

Context

[Tree] (config>li>li-filter-block-reservation>li-reserved-block ipv6-filter)

Full Context

configure li li-filter-block-reservation li-reserved-block ipv6-filter

Description

This command configures to which normal IPv6 address filters the entry reservation is applied.

This command is only supported in 'classic' configuration-mode (**configure system management-interface configuration-mode classic**).

The **no** form of this command removes the IPv6 filter ID from the configuration.

Parameters

ipv6-filter-id

Specifies the filter identification identifies the normal IPv6 address filters.

Values {*filter-id* | *filter-name*}

filter-id:	1 to 65535
filter-name:	up to 64 characters (*filter-name* is an alias for input only. The *filter-name* gets replaced with an id automatically by SR OS in the configuration).

Platforms

All

Context

[Tree] (config>li>li-fltr-assoc>li-ipv6-fltr ipv6-filter)

Full Context

configure li li-filter-associations li-ipv6-filter ipv6-filter

Description

This command specifies the IP filter(s) into which the entries from the specified **li-ipv6-filter** are to be inserted. The **li-ipv6-filter** and **ipv6-filter** must already exist before the association is made. If the normal IPv6 filter is deleted then the association is also removed (and not re-created if the IPv6 filter comes into existence in the future).

The **no** form of this command removes the IPv6 filter ID from the configuration.

Parameters

ipv6-filter-id

Specifies an existing IPv6 filter policy.

Values *filter-id* — 1 to 65535

filter-name — up to 64 characters

Platforms

All

ipv6-filter

Syntax

ipv6-filter *ipv6-filter-id* **entry** *entry-id* [*entry-id*] [**intercept-id** *intercept-id* [*intercept-id*]] [**session-id** *session-id* [*session-id*]]

no ipv6-filter *ipv6-filter-id* [**entry** *entry-id* [*entry-id*]]

Context

[Tree] (config>li>li-source ipv6-filter)

Full Context

configure li li-source ipv6-filter

Description

This command enables lawful interception (LI) of packets that match specific entries in an existing IPv6 filter.

The **ipv6-filter** command directs packets which match the defined list of entry IDs to be intercepted to the destination referenced by the *mirror-dest-service-id* of the **mirror-source**.

The IPv6 filter must already exist in order for the command to execute. Filters are configured in the **config>filter** context. If the IPv6 filter does not exist, an error will occur. If the filter exists but has not been associated with a SAP or IPv6 interface, an error is not generated but mirroring will not be enabled (there are no packets to mirror). Once the IPv6 filter is defined to a SAP, IPv6 interface or subscriber, mirroring is enabled (subscriber mirroring applies only to the 7750 SR).

If the IPv6 filter is defined as ingress, only ingress packets are intercepted. Ingress packets are sent to the destination prior to any ingress packet modifications.

If the IPv6 filter is defined as egress, only egress packets are intercepted. Egress packets are sent to the destination after all egress packet modifications.

An *entry-id* within an IPv6 filter can only be intercepted to a single destination. If the same *entry-id* is defined multiple times, an error occurs and only the first definition is in effect.

By default, no packets matching any IPv6 filters are intercepted. Interception of IPv6 filter entries must be explicitly defined.

When the **no** command is executed with the **entry** keyword and one or more *entry-id*'s, interception of that list of *entry-id*'s is terminated within the *ipv6-filter-id*. If an *entry-id* is listed that does not exist, an error will occur and the command will not execute. If an *entry-id* is listed that is not currently being intercepted, no error will occur for that *entry-id* and the command will execute normally.

Parameters

ipv6-filter-id

Specifies the IPv6 filter ID whose entries are to be intercepted. If the *ipv6-filter-id* does not exist, an error will occur and the command will not execute. Intercepting packets will commence when the *ipv6-filter-id* is defined on a SAP or IPv6 interface.

entry-id

Specifies the IPv6 filter entries to use as match criteria for lawful intercept (LI). The **entry** keyword begins a list of *entry-id*'s for interception. Multiple *entry-id* entries can be specified with a single command. Each *entry-id* must be separated by a space. Up to <N><n> 8 entry IDs may be specified in a single command.

If an *entry-id* does not exist within the IPv6 filter, an error occurs and the command will not execute.

If the filter's *entry-id* is renumbered within the IPv6 filter definition, the old *entry-id* is removed but the new *entry-id* must be manually added to the configuration to include the new (renumbered) entry's criteria.

intercept-id

Specifies the intercept ID that is inserted into the packet header for all mirrored packets of the associated **li-source** entry. This intercept ID can be used (for example by a downstream LI Gateway) to identify the particular LI session to which the packet belongs. For all types of **li-source** entries (**filter**, **nat**, **sap**, **subscriber**), when the mirror service is configured with **ip-udp-shim** routable encap, an *intercept-id* field (as part of the routable encap) is always present in the mirrored packets. If there is no intercept ID configured for an **li-source** entry, then the default value will be inserted. When the mirror service is configured with **ip-gre** routable encapsulation, no *intercept-id* is inserted and none should be specified against the **li-source** entries.

Values 1 to 4294967295 (32b) For nat li-source entries that are using a mirror service that is not configured with routable encap

Values 1 to 1,073,741,824 (30b) For all types of li-source entries that are using a mirror service with routable ip-udp-shim encap and no direction-bit.

Values 1 to 536,870,912 (29b) For all types of li-source entries that are using a mirror service with routable ip-udp-shim encap and with the direction-bit enabled.

session-id

Specifies the *session-id* that is inserted into the packet header for all mirrored packets of the associated **li-source** entry. This *session-id* can be used (for example by a downstream LI Gateway) to identify the particular LI session to which the packet belongs. The *session-id* is only valid and used for mirror services that are configured with **ip-udp-shim** routable encap (**config>mirror>mirror-dest>encap>ip-udp-shim**). For all types of **li-source** entries (filter, nat, sap, subscriber), when the mirror service is configured with **ip-udp-shim** routable encapsulation, a *session-id* field (as part of the routable encapsulation) is always present in the mirrored packets. If there is no *session-id* configured for an **li-source** entry, then the default value will be inserted. When a mirror service is configured with **ip-gre** routable encap, no *session-id* is inserted and none should be specified against the **li-source** entries.

Values 1 to 4,294,967,295 (32b)

Platforms

ipv6-filter

Syntax

ipv6-filter *filter-id* [**name** *filter-name*] [**create**]

no ipv6-filter {*filter-id* | *filter-name*}

Context

[Tree] (config>filter ipv6-filter)

Full Context

configure filter ipv6-filter

Description

Commands in this context configure the specified IPv6 filter policy.

The **no** form of the command deletes the IPv6 filter policy. A filter policy cannot be deleted until it is removed from all objects where it is applied.

Parameters

filter-id

Specifies the IPv6 filter policy ID expressed as a decimal integer.

Values 1 to 65535

name

Configures an optional filter name, up to 64 characters in length, to a given filter. This filter name can then be used in configuration references, display, and show commands throughout the system. A defined filter name can help the service provider or administrator to identify and manage filters within the SR OS platforms.

To create a filter, you must assign a filter ID, however, after it is created, either the filter ID or filter name can be used to identify and reference a filter.

If a name is not specified at creation time, then SR OS assigns a string version of the *filter-id* as the name.

Filter names may not begin with an integer (0 to 9).

Values *name*: 64 characters maximum

filter-name

Specifies a string of up to 64 characters uniquely identifying this IPv6 filter policy.

create

This keyword is required to create the configuration context. Once it is created, the context can be enabled with or without the **create** keyword.

configure system security cpm-filter ipv6-filter

Description

Commands in this context configure CPM IPv6 filter parameters. This command applies only to the 7750 SR and 7950 XRS.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

ipv6-filter

Syntax

ipv6-filter *src-filter-id* [**src-entry** *src-entry-id*] **to** *dst-filter-id* [**dst-entry** *dst-entry-id*] [**overwrite**]

Context

[Tree] (config>filter>copy ipv6-filter)

Full Context

configure filter copy ipv6-filter

Description

This command copies an existing filter entry for a specific filter ID to another filter ID. The command is a configuration level maintenance tool used to create new entries using an existing filter policy. If **overwrite** is not specified, an error will occur if the destination filter entry exists.

Parameters

src-filter-id

Identifies the source filter policy from which the copy command will attempt to copy. The filter policy must exist within the context of the preceding keyword (**ipv6-filter**).

dst-filter-id

Identifies the destination filter policy to which the copy command will attempt to copy. If the **overwrite** keyword is not specified, the filter entry ID cannot already exist in the destination filter policy. If the **overwrite** keyword is present, the destination entry ID may or may not exist.

overwrite

Specifies that the destination filter entry may exist. If it does, everything in the existing destination filter entry will be completely overwritten with the contents of the source filter entry. If the destination filter entry exists, either **overwrite** must be specified or an error message will be returned. If **overwrite** is specified, the function of copying from source to

destination occurs in a "break before make” manner and therefore should be handled with care.

Platforms

All

13.292 ipv6-filter-max-size

ipv6-filter-max-size

Syntax

ipv6-filter-max-size {*value* | **default**}

Context

[Tree] (config>service>vprn>flowspec ipv6-filter-max-size)

Full Context

configure service vprn flowspec ipv6-filter-max-size

Description

This command configures the maximum number of IPv6 FlowSpec routes or rules that can be embedded into an ingress IPv6 filter policy for a specified routing instance. Flowspec filter entries embedded in a filter policy in this routing instance will use filter entries from the range between the embedding offset and "offset + ip-filter-max-size – 1”.

The sum of the **ip-filter-max-size** *value* parameter and the highest offset in any IPv6 filter that embeds IPv6 FlowSpec rules from this routing instance (excluding filters that embed at offset 262143) must not exceed 262143.

The **ip-filter-max-size** configuration can be adjusted up or down at any time. If the number of IPv6 FlowSpec rules that are currently installed is *M*, and the new limit is *N*, where *N*<*M*, then the last set of rules from *N* to *M* (by FlowSpec order) are immediately removed, but are retained in the BGP RIB. If the limit is increased, new rules are programmed only as they are received again in new BGP updates.

Default

ipv6-filter-max-size default

Parameters

value

The maximum number of FlowSpec routes or rules that can be embedded into an ingress IP filter policy.

Values 0 to 262143

default

Configures the maximum size as 512.

Platforms

All

ipv6-filter-max-size

Syntax

ipv6-filter-max-size {*value* | **default**}

Context

[Tree] (config>router>flowspec ipv6-filter-max-size)

Full Context

configure router flowspec ipv6-filter-max-size

Description

This command configures the maximum number of IPv6 FlowSpec routes or rules that can be embedded into the auto-created embedded filter (fSpec- *X*). FlowSpec filter entries embedded in a filter policy in this routing instance will use filter entries from the range between "embedding offset + 1" and "embedding offset + ip-filter-max-size".

The sum of the **ipv6-filter-max-size** *value* parameter and the highest offset in any IPv6 filter that embeds IPv6 FlowSpec rules from this routing instance (excluding filters that embed at offset 262143) must not exceed 262143.

The **ipv6-filter-max-size** configuration can be adjusted up or down at any time. If the number of IPv6 FlowSpec rules that are currently installed is *M*, and the new limit is *N*, where *N*<*M*, then the last set of rules from *N* to *M* (by FlowSpec order) are immediately removed, but are retained in the BGP RIB. If the limit is increased, new rules are programmed only as they are received again in new BGP updates.

Default

ipv6-filter-max-size 512

Parameters

value

Specifies the maximum number of FlowSpec routes or rules that can be embedded into an ingress IP filter policy.

Values 0 to 262143

default

Keyword to configure the maximum size as 512.

no ipv6-multicast-metric-offset

Context

[Tree] (config>router>isis>link-group>level ipv6-multicast-metric-offset)

Full Context

configure router isis link-group level ipv6-multicast-metric-offset

Description

This command sets the offset value for the IPv6 multicast address family. If the number of operational links drops below the oper-members threshold, the configured offset is applied to the interface metric for the IPv6 multicast topology.

The **no** form of this command reverts the offset value to 0.

Default

no ipv6-multicast-metric-offset

Parameters

offset-value

Specifies the amount the interface metric for the associated address family is to be increased if the number of operational members in the associated link-group drops below the oper-members threshold

Values 0 to 6777215

Platforms

All

13.301 ipv6-multicast-routing

ipv6-multicast-routing

Syntax

ipv6-multicast-routing {**native** | **mt**}

[**no**] **ipv6-multicast-routing**

Context

[Tree] (config>router>isis ipv6-multicast-routing)

Full Context

configure router isis ipv6-multicast-routing

Description

The multicast RTM is used for Reverse Path Forwarding checks. This command controls which IS-IS topology is used to populate the IPv6 multicast RTM.

The **no** form of this command results in none of the IS-IS routes being populated in the IPv4 multicast RTM and would be used if multicast is configured to use the unicast RTM for the RPF check.

Default

ipv6-multicast-routing native

Parameters

native

Causes IPv6 routes from the MT0 topology to be added to the multicast RTM for RPF checks.

mt

Causes IPv6 routes from the MT3 topology to be added to the multicast RTM for RPF checks.

Platforms

All

13.302 ipv6-node-sid

ipv6-node-sid

Syntax

ipv6-node-sid index *index-value* [**clear-n-flag**]

ipv6-node-sid label *label-value* [**clear-n-flag**]

no ipv6-node-sid

Context

[Tree] (config>router>isis>interface ipv6-node-sid)

Full Context

configure router isis interface ipv6-node-sid

Description

This command assigns a node SID index or label value to the prefix representing the primary address of an IPv6 network interface of type loopback. Only a single node SID can be assigned to an IPv6 interface. When an IPv6 interface has multiple global addresses, the primary address is always the first one in the list, as displayed by the **interface info** command.

The command fails if the network interface is not of loopback type or if the interface is defined in an IES or a VPRN context. Assigning the same SID index/label value to the same interface in two different IGP instances is not allowed within the same node.

The value of the label or index SID is taken from the range configured for this IGP instance. When using the global mode of operation, a new segment routing module checks that the same index or label value cannot be assigned to more than one loopback interface address. When using the per-instance mode of operation, this check is not required since the index and thus label ranges of the various IGP instance are not allowed to overlap.

The **clear-n-flag** option allows the user to clear the N-flag (node-sid flag) in an IS-IS prefix SID sub-TLV originated for the IPv6 prefix of a loopback interface on the system.

By default, the prefix SID sub-TLV for the prefix of a loopback interface is tagged as a node SID, meaning that it belongs to this node only. However, when the user wants to configure and advertise an anycast SID using the same loopback interface prefix on multiple nodes, you must clear the N-flag to assure interoperability with third-party implementations, which may perform a strict check on the receiving end and drop duplicate prefix SID sub-TLVs when the N-flag is set.

The SR OS implementation is relaxed on the receiving end and accepts duplicate prefix SIDs with the N-flag set or cleared. SR OS will resolve to the closest owner, or owners if ECMP is configured, of the prefix SID according to its cost.

Default

no ipv6-node-sid

Parameters

index-value

Specifies the index value.

Values 0 to 4294967295

label-value

Specifies the label value.

Values 0 to 4294967295

clear-n-flag

Clears the node SID flag.

Default no clear-n-flag

configure router isis ipv6-routing

Description

This command enables IPv6 routing.

The **no** form of this command disables support for IS-IS IPv6 TLVs for IPv6 routing.

Default

no ipv6-routing

Parameters

native

Enables IS-IS IPv6 TLVs for IPv6 routing and enables support for native IPv6 TLVs.

mt

Enables IS-IS multi-topology TLVs for IPv6 routing. When this parameter is specified, the support for native IPv6 TLVs is disabled.

Platforms

All

13.310 ipv6-sid

ipv6-sid

Syntax

ipv6-sid index *index-id*

ipv6-sid label *label-id*

no ipv6-sid

Context

[Tree] (config>router>segment-routing>sr-mpls>prefix-sids ipv6-sid)

Full Context

configure router segment-routing sr-mpls prefix-sids ipv6-sid

Description

This command is used to configure the IPv6 segment routing SID associated with the primary IPv6 address of the loopback or system interface.

The **no** form of this command removes the configuration of the IPv6 segment routing SID associated with the primary IPv6 interface address.

Default

no ipv6-sid

Parameters

index *index-id*

Specifies the node SID index for this interface.

Values 0 to 4294967295

label *label-id*

Specifies the label value for the node SID.

Values 32 to 1048575

Platforms

All

13.311 ipv6-slaac-prefix

ipv6-slaac-prefix

Syntax

ipv6-slaac-prefix *ipv6-prefix/prefix-length*

no ipv6-slaac-prefix

Context

[Tree] (config>subscr-mgmt>loc-user-db>ipoe>host ipv6-slaac-prefix)

[Tree] (config>subscr-mgmt>loc-user-db>ppp>host ipv6-slaac-prefix)

Full Context

configure subscriber-mgmt local-user-db ipoe host ipv6-slaac-prefix

configure subscriber-mgmt local-user-db ppp host ipv6-slaac-prefix

Description

This command configures static IPv6 SLAAC prefix (PIO) for the host. The host will assign an IPv6 address to itself based on this prefix. The prefix length is 64 bits.

The **no** form of this command removes the static IPv6 SLAAC prefix (PIO) for the host from the configuration.

Default

no ipv6-slaac-prefix

Parameters

ipv6-prefix/prefix-length

Specifies the IPv6 address and prefix length.

Values	ipv6-prefix/prefix-length	ipv6-prefix x:x:x:x:x:x:x:x (eight 16-bit pieces)
		x:x:x:x:x:x:d.d.d.d
		x [0 to FFFF]H
		d [0 to 255]D
	prefix-length	64

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

13.312 ipv6-slaac-prefix-pool

ipv6-slaac-prefix-pool

Syntax

ipv6-slaac-prefix-pool *pool*

no ipv6-slaac-prefix-pool

Context

[Tree] (config>subscr-mgmt>loc-user-db>ipoe>host ipv6-slaac-prefix-pool)

[Tree] (config>subscr-mgmt>loc-user-db>ppp>host ipv6-slaac-prefix-pool)

Full Context

configure subscriber-mgmt local-user-db ipoe host ipv6-slaac-prefix-pool

configure subscriber-mgmt local-user-db ppp host ipv6-slaac-prefix-pool

Description

This command configures the IPv6 SLAAC prefix pool of this host.

The **no** form of this command reverts to the default.

Parameters

pool

Specifies the pool name, up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

13.313 ipv6-source-address

ipv6-source-address

Syntax

ipv6-source-address *ipv6-address* [**allow-connections**]

no ipv6-source-address

Context

[Tree] (config>aaa>diam>node ipv6-source-address)

Full Context

configure aaa diameter node ipv6-source-address

Description

This command configures IPv6 source address that the SR OS node will use for its peering connection.

The **no** form of this command removes the IPv6 source address from the configuration.

Parameters

ipv6-address

Specifies the source IPv6 address to use for outgoing diameter messages to an IPv6-reachable peer.

Values *ipv6-address*: x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x - [0 to FFFF]H

d - [0 to 255]D

allow-connections

Specifies to accept peering connections on the configured source IPv6 address. The peer initiating the connection can only be an inter-chassis peer.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

ipv6-source-address

Syntax

ipv6-source-address *ipv6-address*

no ipv6-source-address

Context

[Tree] (config>aaa>radius-srv-plcy>servers ipv6-source-address)

Full Context

configure aaa radius-server-policy servers ipv6-source-address

Description

This command configures the source address of an IPv6 RADIUS packet.

When no ipv6-source-address is configured, the system IPv6 address (inband RADIUS server connection) or Boot Option File (BOF) IPv6 address (outband RADIUS server connection) must be configured in order for the RADIUS client to work with an IPv6 RADIUS server.

This address is also used in the NAS-IPv6-Address attribute.

The **no** form of this command reverts to the default value.

Parameters

ipv6-address

Specifies the source address of an IPv6 RADIUS packet.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

ipv6-source-address

Syntax

ipv6-source-address *ipv6-address*

no ipv6-source-address

Context

[Tree] (config>service>vprn>dns ipv6-source-address)

Full Context

configure service vprn dns ipv6-source-address

Description

This command configures the IPv6 address of the default secondary DNS server for the subscribers using this interface. Subscribers that cannot obtain an IPv6 DNS server address by other means, can use this for DNS name resolution.

The ipv6-address value can only be set to a nonzero value if the value of VPRN type is set to **subscriber-split-horizon**.

The **no** form of this command reverts to the default.

Parameters

ipv6-address

Specifies the IPv6 address of the default secondary DNS server.

Values ipv6-address - a.b.c.d

Platforms

All

ipv6-source-address

Syntax

ipv6-source-address *ipv6-address*

no ipv6-source-address

Context

[Tree] (config>system>file-trans-prof ipv6-source-address)

Full Context

configure system file-transmission-profile ipv6-source-address

Description

This command specifies the IPv6 source address used for transport protocol.

The **no** form of this command uses the default source address which typically is the address of egress interface.

Default

no ipv6-source-address

Parameters

Ipv6-address

Specifies a unicast v6 address. This should be a local interface address.

Platforms

All

13.314 ipv6-tcp-mss-adjust

ipv6-tcp-mss-adjust

Syntax

ipv6-tcp-mss-adjust *segment-size*

no ipv6-tcp-mss-adjust

Context

[Tree] (config>service>vprn>wlan-gw>dsm ipv6-tcp-mss-adjust)

[Tree] (config>router>wlan-gw>dsm ipv6-tcp-mss-adjust)

Full Context

configure service vprn wlan-gw distributed-sub-mgmt ipv6-tcp-mss-adjust

configure router wlan-gw distributed-sub-mgmt ipv6-tcp-mss-adjust

Description

This command specifies the value used for TCP-MSS-adjust in the IPv6 upstream direction for DSM. The downstream direction for both IPv4 and IPv6 are both configured under the group-interface. The upstream direction for IPv4 NAT hosts is configured under the NAT policy.

The defined segment size is inserted in a TCP SYN message if there is no existing MSS option or the value in the MSS option is bigger than the configured value.

The **no** form of this command disables upstream TCP MSS adjust for IPv6 DSM.

Default

no ipv6-tcp-mss-adjust

Parameters

segment-size

Specifies the segment size to be inserted.

Values 160 to 10240

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

13.315 ipv6-te-router-id

ipv6-te-router-id

Syntax

ipv6-te-router-id interface *interface-name*

no ipv6-te-router-id

Context

[Tree] (config>router ipv6-te-router-id)

Full Context

configure router ipv6-te-router-id

Description

This command configures the IPv6 TE Router ID. The IPv6 TE Router ID, when configured, uniquely identifies the router as being IPv6 TE capable to other routers in an IGP TE domain.

IS-IS advertises this information using the IPv6 TE Router ID TLV.

If this command is not configured, the IPv6 TE Router ID will use the global unicast address of the system interface by default. The user can specify the system interface using this command to achieve the same result. If a different interface is specified, the preferred primary global unicast address of that interface is used instead

The **no** form of this command reverts the IPv6 TE Router ID to the default value.

Parameters

interface interface-name

Specifies the name of the interface to be added or removed. Only system and loopback interfaces are accepted.

Platforms

All

13.316 ipv6-unicast

ipv6-unicast

Syntax

[**no**] **ipv6-unicast**

Context

[Tree] (config>service>vprn>isis>multi-topology ipv6-unicast)

Full Context

configure service vprn isis multi-topology ipv6-unicast

Description

This command enables multi-topology TLVs.

The **no** form of this command disables multi-topology TLVs.

Platforms

All

ipv6-unicast

Syntax

[**no**] **ipv6-unicast**

Context

[Tree] (config>router>isis>multi-topology ipv6-unicast)

Full Context

configure router isis multi-topology ipv6-unicast

Description

This command enables multi-topology TLVs.

The **no** form of this command disables multi-topology TLVs.

Default

no ipv6-unicast

Platforms

All

13.317 ipv6-unicast-disable

ipv6-unicast-disable

Syntax

[**no**] **ipv6-unicast-disable**

Context

[Tree] (config>service>vprn>isis>if ipv6-unicast-disable)

[Tree] (config>router>isis>if ipv6-unicast-disable)

Full Context

configure service vprn isis interface ipv6-unicast-disable

configure router isis interface ipv6-unicast-disable

Description

This command disables IS-IS IPv6 unicast routing for the interface.

By default IPv6 unicast on all interfaces is enabled. However, IPv6 unicast routing on IS-IS is in effect when the **config>router>isis>ipv6-routing mt** command is configured.

The **no** form of this command enables IS-IS IPv6 unicast routing for the interface.

Platforms

All

13.318 ipv6-unicast-metric

ipv6-unicast-metric

Syntax

ipv6-unicast-metric *metric*

no ipv6-unicast-metric

Context

[Tree] (config>service>vprn>isis>if>level ipv6-unicast-metric)

Full Context

configure service vprn isis interface level ipv6-unicast-metric

Description

This command configures IS-IS interface metric for IPv6 unicast.

The **no** form of this command removes the metric from the configuration.

Parameters

metric

Specifies the IS-IS interface metric for IPv6 unicast.

Values 1 to 16777215

Platforms

All

ipv6-unicast-metric

Syntax

ipv6-unicast-metric *metric*

no ipv6-unicast-metric

Context

[Tree] (config>router>isis>if>level ipv6-unicast-metric)

Full Context

configure router isis interface level ipv6-unicast-metric

Description

This command configures the IS-IS interface metric for IPv6 unicast.

The **no** form of this command removes the metric from the configuration.

Default

no ipv6-unicast-metric

Parameters

metric

Specifies the IS-IS interface metric for IPv6 unicast.

Values 1 to 16777215

Platforms

All

13.319 ipv6-unicast-metric-offset

ipv6-unicast-metric-offset

Syntax

ipv6-unicast-metric-offset *offset-value*

no ipv6-unicast-metric-offset

Context

[Tree] (config>service>vprn>isis>link-group>level ipv6-unicast-metric-offset)

Full Context

configure service vprn isis link-group level ipv6-unicast-metric-offset

Description

This command sets the offset value for the IPv6 unicast address family. If the number of operational links drops below the **oper-members** threshold, the configured offset is applied to the interface metric for the IPv6 topology.

The **no** form of this command reverts the offset value to 0.

Default

no ipv6-unicast-metric-offset

Parameters

offset-value

Specifies the amount the interface metric for the associated address family is to be increased if the number of operational members in the associated link-group drops below the oper-members threshold.

Values 0 to 6777215

Platforms

All

ipv6-unicast-metric-offset

Syntax

ipv6-unicast-metric-offset *offset-value*

no ipv6-unicast-metric-offset

Context

[Tree] (config>router>isis>link-group>level ipv6-unicast-metric-offset)

Full Context

configure router isis link-group level ipv6-unicast-metric-offset

Description

This command sets the offset value for the IPv6 unicast address family. If the number of operational links drops below the **oper-members** threshold, the configured offset is applied to the interface metric for the IPv6 topology.

The **no** form of this command reverts the offset value to 0.

Default

no ipv6-unicast-metric-offset

Parameters

offset-value

Specifies the amount the interface metric for the associated address family is to be increased if the number of operational members in the associated link-group drops below the oper-members threshold.

Values 0 to 6777215

Platforms

All

13.320 ipv6-wan-address-pool

ipv6-wan-address-pool

Syntax

ipv6-wan-address-pool *pool-name*

no ipv6-wan-address-pool

Context

[Tree] (config>subscr-mgmt>loc-user-db>ppp>host ipv6-wan-address-pool)

[Tree] (config>subscr-mgmt>loc-user-db>ipoe>host ipv6-wan-address-pool)

Full Context

configure subscriber-mgmt local-user-db ppp host ipv6-wan-address-pool

configure subscriber-mgmt local-user-db ipoe host ipv6-wan-address-pool

Description

This command configures the pool name that is used in the DHCPv6 server for DHCPv6 IA-PA address selection.

The **no** form of this command removes the pool name from the configuration.

Parameters

pool-name

Specifies the WAN address pool, up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

13.321 ipv6-wan-ipoe-dhcp

Full Context

configure subscriber-mgmt sla-profile host-limits ipv6-wan-ipoe-dhcp

configure subscriber-mgmt sub-profile host-limits ipv6-wan-ipoe-dhcp

Description

This command configures the maximum number of IPv6 IPoE DHCP WAN hosts (IA-NA) per SLA profile instance or per subscriber.

The **no** form of this command removes the maximum number of IPv6 IPoE DHCP WAN hosts (IA-NA) limit.

Parameters

max-nr-of-hosts

Specifies the maximum number of IPv6 IPoE DHCP WAN hosts.

Note:
The operational maximum value may be smaller due to equipped hardware dependencies.

Values 0 to 131071

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

13.322 ipv6-wan-ipoe-slaac

Full Context

configure subscriber-mgmt sub-profile host-limits ipv6-wan-overall

configure subscriber-mgmt sla-profile host-limits ipv6-wan-overall

Description

This command configures the maximum number of IPv6 WAN hosts per SLA profile instance or per subscriber.

The **no** form of this command removes the maximum number of IPV6 WAN hosts limit.

Parameters

max-nr-of-hosts

Specifies the maximum number of IPv6 WAN hosts.

Note:
The operational maximum value may be smaller due to equipped hardware dependencies.

Values 0 to 131071

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

13.326 isa

isa

Syntax

isa

Context

[Tree] (config isa)

Full Context

configure isa

Description

Commands in this context configure Integrated Services Adapter (ISA) parameters.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

13.327 isa-aa-group

isa-aa-group

Syntax

isa-aa-group *aa-group-id*

no isa-aa-group

Context

[Tree] (config>isa>wlan-gw-group>distributed-sub-mgmt isa-aa-group)

Full Context

configure isa wlan-gw-group distributed-sub-mgmt isa-aa-group

Description

This command configures an ISA application assurance group for WLAN gateway DSM subscribers.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

isa-aa-group

Syntax

isa-aa-group *isa-aa-group-id* {**all** | **unknown**}

no isa-aa-group *isa-aa-group-id*

Context

[Tree] (debug>mirror-source isa-aa-group)

Full Context

debug mirror-source isa-aa-group

Description

This command configures AA ISA group as a mirror source for this mirror service. Traffic is mirrored after AA processing takes place on AA ISAs of the group, therefore, any packets dropped as part of that AA processing are not mirrored.

Parameters

isa-aa-group-id

Specifies the ISA ISA-AA group ID.

Values 1 to 255

all

Specifies that all traffic after AA processing will be mirrored.

unknown

Specifies that all traffic during the identification phase (may match policy entry or entries that have mirror action configured) and traffic that had been identified as unknown_tcp or unknown_udp after AA processing will be mirrored.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

13.328 isa-aa-oversubscription-factor

isa-aa-oversubscription-factor

Syntax

isa-aa-oversubscription-factor *factor*

no isa-aa-oversubscription-factor

Context

[Tree] (config>isa>wlan-gw-group>distributed-sub-mgmt isa-aa-oversubscription-factor)

Full Context

configure isa wlan-gw-group distributed-sub-mgmt isa-aa-oversubscription-factor

Description

This command specifies by how much an AA ISA is oversubscribed when linked to a WLAN-GW group. A factor of 1 indicates that each AA ISA is linked to a single WLAN-GW ISA, while a factor of 10 indicates that each AA ISA is linked to up to 10 WLAN-GW ISAs. The factor must be an integer but poses an oversubscription limit, not an exact ratio. For example, for 2 AA ISAs and 5 WLAN-GW ISAs, a factor of 3 or higher is valid. Additional standby ISAs can be added until the oversubscription limit is reached.

The **no** form of this command resets the configuration to the default value.

Default

isa-aa-oversubscription-factor 1

Parameters

factor

The number of WLAN GW ISAs that can be served by a single AA ISA.

Values 1 to 10

Platforms

7750 SR, 7750 SR-e, 7750 SR-s

13.329 isa-capacity-cost-high-threshold

isa-capacity-cost-high-threshold

Syntax

isa-capacity-cost-high-threshold *threshold*

no isa-capacity-cost-high-threshold

Context

[Tree] (config>isa>aa-grp isa-capacity-cost-high-threshold)

Full Context

configure isa application-assurance-group isa-capacity-cost-high-threshold

Description

This command configures the ISA-AA capacity cost high threshold.

The **no** form of this command reverts the threshold to the default value.

Default

isa-capacity-cost-high-threshold 4294967295

Parameters

threshold

Specifies the capacity cost high threshold for the ISA-AA group.

Values 0 to 4294967295

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

13.330 isa-capacity-cost-low-threshold

isa-capacity-cost-low-threshold

Syntax

isa-capacity-cost-low-threshold *threshold*

no isa-capacity-cost-low-threshold

Context

[Tree] (config>isa>aa-grp isa-capacity-cost-low-threshold)

Full Context

configure isa application-assurance-group isa-capacity-cost-low-threshold

Description

This command configures the ISA-AA capacity cost low threshold.

The **no** form of this command reverts the threshold to the default value.

Default

isa-capacity-cost-low-threshold 0

Parameters

threshold

Specifies the capacity cost low threshold for the ISA-AA group.

Values 0 to 4294967295

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

13.331 isa-dp-cpu-usage

isa-dp-cpu-usage

Syntax

[**no**] **isa-dp-cpu-usage**

Context

[Tree] (config>isa>tunnel-grp>stats-collection isa-dp-cpu-usage)

Full Context

configure isa tunnel-group stats-collection isa-dp-cpu-usage

Description

This command enables the system to collect statistics used to derive ISA CPU data plane usage. When enabled, this command impacts the ISA performance.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

13.332 isa-filter

isa-filter

Syntax

isa-filter *name* [**type** {**dsm**}] [**create**]

no isa-filter *name*

Context

[Tree] (config>subscr-mgmt isa-filter)

Full Context

configure subscriber-mgmt isa-filter

Description

Commands in this context configure ISA filter parameters.

Parameters

name

Specifies the name of the filter.

type dsm

Selects DSM as the type.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

13.333 isa-overload-cut-through

isa-overload-cut-through

Syntax

[**no**] **isa-overload-cut-through**

Context

[Tree] (config>isa>aa-grp isa-overload-cut-through)

Full Context

configure isa application-assurance-group isa-overload-cut-through

Description

This command configures the ISA group to enable cut-through of traffic if an overload event occurs, triggered when the IOM weighted average queues depth exceeds the **wa-shared-high-wmark**. In this ISA state, packets are cut-through from application analysis but retain subscriber context with default subscriber policy applied.

The **no** form of this command disables cut-through processing on overload.

Default

no isa-overload-cut-through

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

13.334 isa-policer

isa-policer

Syntax

isa-policer *policer-name* [**type** *policer-type*] [**create**]

no isa-policer *policer-name*

Context

[Tree] (config>subscr-mgmt isa-policer)

Full Context

configure subscriber-mgmt isa-policer

Description

This command creates the context to configure an ISA policer. When creating a policer for the first time, both the **create** and **type** parameters are required.

The **no** form of this command reverts to the default.

Parameters

policer-name

Specifies the name by which this policer is referenced up to 32 characters.

policer-type

Specifies the policer type. The dual-bucket-bandwidth policer applies both a CIR and PIR.

Values single-bucket-bandwidth, dual-bucket-bandwidth

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

13.335 isa-radius-policy

isa-radius-policy

Syntax

isa-radius-policy *name* [**create**]

no isa-radius-policy *name*

Context

[Tree] (config>aaa isa-radius-policy)

Full Context

configure aaa isa-radius-policy

Description

This command creates a policy template related to transport of accounting messages from the BB-ISA card to the accounting server. It also defines accounting attributes that will be included in accounting messages. The policy template will be instantiated once it is applied to the BB-ISA cards in the nat-group.

The **no** form of the command removes the policy name from the configuration.

Parameters

name

Specifies the name of the ISA RADIUS policy that can be referenced by a NAT application.

create

Keyword used to create the policy.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

13.336 isa-service-chaining

configure ipsec ike-transform isakmp-lifetime

Description

This command specifies the lifetime of the IKE SA.

Default

isakmp-lifetime 86400

Parameters

seconds

Specifies the Phase 1 life time for this IKE transform.

Values 1200 to 31536000

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

13.338 isid

isid

Syntax

isid *start* [**to** *to*]

no isid *start*

Context

[Tree] (config>service>system>bgp-evpn>eth-seg>service-carving>manual isid)

Full Context

configure service system bgp-evpn ethernet-segment service-carving manual isid

Description

This command configures the ISID ranges for which the PE is primary, or uses the lowest preference algorithm.

Note:
Multiple individual ISID values and ranges are allowed.

The following service-carving manual algorithms are supported for DF election:

- Manual non-preference

  A **preference** command is not configured for this algorithm. The primary PE for the configured ISIDs is determined by the ISID range. The manual non-preference algorithm only supports two PEs in the Ethernet Segment

- Manual preference-based

  If a **preference** command is configured, the algorithm uses the configured value to determine the DF election. For ISIDs not defined in the range, the highest-preference algorithm is used. For configured ISIDs, the lowest-preference algorithm is used.

Parameters

start

Specifies the initial **isid** value of the range.

Values 1 to 16777215

to

Specifies the end **isid** value of the range. If not configured, only the individual start value is considered.

Values 1 to 16777215

Platforms

All

isid

Syntax

isid *value* [**to** *higher-value*]

no isid

Context

[Tree] (config>filter>mac-filter>entry>match isid)

Full Context

configure filter mac-filter entry match isid

Description

This command configures an ISID value or a range of ISID values to be matched by the mac-filter parent. The pbb-etype value for the related SAP (inherited from the ethernet port configuration) or for the related SDP binding (inherited from SDP configuration) will be used to identify the ISID tag.

The **no** form of this command removes the ISID match criterion.

Default

no isid

Parameters

value

Specifies the ISID value, 24 bits as a decimal integer. When just one present identifies a specific ISID to be used for matching.

Values 0 to 16777215

higher-value

Identifies a range of ISIDs to be used as matching criteria.

Platforms

All

isid

Syntax

isid *value* [**to** *higher-value*]

no isid

no isid *value* [**to** *higher-value*]

Context

[Tree] (config>serv>mrp>mrp-policy>entry>match isid)

Full Context

configure service mrp mrp-policy entry match isid

Description

This command configures an ISID value or a range of ISID values to be matched by the mrp-policy parent when looking at the related MMRP attributes (Group B-MACs). The pbb-etype value for the related SAP (inherited from the ethernet port configuration) or for the related SDP binding (inherited from SDP configuration) will be used to identify the ISID tag.

Multiple ISID statements are allowed under a match node. The following rules govern the usage of multiple ISID statements:

- Overlapping values are allowed:
  - isid from 1 to 10
  - isid from 5 to 15
  - isid 16
- The minimum and maximum values from overlapping ranges are considered and displayed. The above entries will be equivalent with the "isid from 1 to 16” statement.
- There is no consistency check with the content of ISID statements from other entries. The entries are evaluated in the order of their IDs and the first match causes the implementation to execute the associated action for that entry and then to exit the mrp-policy.
- If there are no ISID statements under a match criteria but the **mac-filter** type is **isid** the following behaviors apply for different actions:
  - For **end-station**, it treats any ISID value as no match and goes to next entry or default action which must be "block” in this case
  - For **allow**, it treats any ISID value as a match and allows it
  - For **block**, it treats any ISID value as a match and blocks it

The **no** form of the command can be used in two ways:

no isid removes all the previous statements under one match node.

no isid *value* | **from** *value* **to** *higher-value* removes a specific ISID value or range. It must match a previously used positive statement: for example if the command **isid 16 to 100** was used using **no isid 16 to 50** will not work but **no isid 16 to 100** will be successful.

Default

no isid

Parameters

value or higher-value

Specifies the ISID value in 24 bits. When just one value is present, it identifies a particular ISID to be used for matching.

Values 0 to 16777215

from value to higher-value

Identifies a range of ISIDs to be used as matching criteria.

Platforms

All

13.339 isid-policy

isid-policy

Syntax

isid-policy

Context

[Tree] (config>service>vpls isid-policy)

Full Context

configure service vpls isid-policy

Description

This command configures ISID policies for individual ISIDs or ISID ranges in a B-VPLS using SPBM. The ISIDs may belong to I-VPLS services or may be static-isids defined on this node. Multiple entry statements are allowed under a **isid-policy**. ISIDs that are declared as static do not require and **isid-policy** unless the ISIDs are not to be advertised.

isid-policy allows finer control of ISID multicast but is not typically required for SPBM operation. Use of ISID policies can cause additional flooding of multicast traffic.

Platforms

All

13.340 isid-range

isid-range

Syntax

isid-range *from* [**to** *to*] {**auto-rt** | **route-target** *rt*}

no isid-range *from*

Context

[Tree] (config>service>vpls>bgp-evpn>isid-route-target isid-range)

Full Context

configure service vpls bgp-evpn isid-route-target isid-range

Description

This command creates a range of ISIDs associated with a specified route-target that is advertised with BMAC-ISID and IMET-ISID routes for the ISID. The route-target can be explicitly configured or automatically assigned by the system if the **auto-rt** option is configured. Auto routes assignment is based on RFC 7623 as follows:

<2-byte-as-number>:<4-byte-value>, where 4-byte-value = 0x30+ISID

The **no** form of the command deletes the **isid-range** and its association with the **route-target**.

The **no** form is the default action, which advertises the BMAC-ISID and IMET-ISID routes with the B-VPLS configured route-target.

Default

no isid-range

Parameters

from

Specifies the start of the ISID range.

Values 1 to 16777215

to

Specifies the end of the ISID range. If it is not configured, the range is comprised of (only) the ISID specified in the *to* option.

Values 1 to 16777215

auto-rt

Automatically generates an ISID-derived **route-target** in the format: AS_number:0x30+ISID.

route-target

Specifies an explicit route target.

Values rt - target:{<ip-addr:comm-val>| <2byte-as-number:extcomm-val>| <4byte-asnumber:comm-val>}

ip-addr: a.b.c.d

comm-val: [0 to 65535]

2byte-as-number: [0 to 65535]

ext-comm-val: [0 to 4294967295]

4byte-asnumber: [0 to 4294967295]

isis

Syntax

[**no**] **isis** *isis-instance*

Context

[Tree] (config>service>vprn isis)

Full Context

configure service vprn isis

Description

Commands in this context configure the Intermediate-System-to-Intermediate-System (IS-IS) protocol instance in the VPRN.

The IS-IS protocol instance is enabled with the **no shutdown** command in the **config>service>vprn>isis** context. Alternatively, the IS-IS protocol instance is disabled with the **shutdown** command in the **config>service>vprn>isis** context.

IS-IS instances are **shutdown** when created, so that all parameters can be configured prior to the instance being enabled.

The **no** form of this command disables the ISIS protocol instance from the given VPRN service.

Default

0

Parameters

isis-instance

Specifies the instance ID for an IS-IS instance.

Values 0 to 127

Platforms

All

isis

Syntax

[**no**] **isis** [*isis-instance*]

Context

[Tree] (config>router isis)

Full Context

configure router isis

Description

Commands in this context configure the Intermediate-System-to-Intermediate-System (IS-IS) protocol instance.

The IS-IS protocol instance is enabled with the **no shutdown** command in the **config>router>isis** context. Alternatively, the IS-IS protocol instance is disabled with the **shutdown** command in the **config>router>isis** context.

IS-IS instances are shutdown when created, so that all parameters can be configured prior to the instance being enabled.

The **no** form of this command deletes the IS-IS protocol instance. Deleting the protocol instance removes all configuration parameters for this IS-IS instance.

Parameters

isis-instance

Specifies the instance ID for an IS-IS instance.

Values 0 to 127

Platforms

All

isis

Syntax

isis [*isis-instance*]

14 j Commands

14.1 jitter-event

jitter-event

Syntax

jitter-event rising-threshold *threshold* [**falling-threshold** *threshold*] [*direction*]

no jitter-event

Context

[Tree] (config>saa>test jitter-event)

Full Context

configure saa test jitter-event

Description

This command specifies that at the termination of an SAA test probe, the calculated jitter value is evaluated against the configured rising and falling jitter thresholds. SAA threshold events are generated as required.

Once the threshold (rising/falling) is crossed, it is disabled from generating additional events until the opposite threshold is crossed. If a **falling-threshold** is not supplied, the **rising- threshold** is re-enabled when it falls below the threshold after the initial crossing that generated the event.

The configuration of jitter event thresholds is optional.

The **no** form of the command disables the jitter event.

Parameters

rising-threshold *threshold*

Specifies a rising threshold jitter value, in milliseconds. When the test run is completed, the calculated jitter value is compared to the configured jitter rising threshold. If the test run jitter value is greater than the configured rising threshold value then an SAA threshold event is generated. The SAA threshold event is tmnxOamSaaThreshold, logger application OAM, event #2101.

Values 0 to 2147483

Default 0

falling-threshold *threshold*

Specifies a falling threshold jitter value, in milliseconds. When the test run is completed, the calculated jitter value is compared to the configured jitter falling threshold. If the test

run jitter value is greater than the configured falling threshold value then an SAA threshold event is generated. The SAA threshold event is tmnxOamSaaThreshold, logger application OAM, event #2101.

Values 0 to 2147483

Default 0

direction

Specifies the direction for OAM ping responses received for an OAM ping test run.

Values **inbound** — Monitor the value of jitter calculated for the inbound, one-way, OAM ping responses received for an OAM ping test run.

outbound — Monitor the value of jitter calculated for the outbound, one-way, OAM ping requests sent for an OAM ping test run.

roundtrip — Monitor the value of jitter calculated for the round trip, two-way, OAM ping requests and replies for an OAM ping test run.

Default roundtrip

kb-memory-use-alarm

Syntax

kb-memory-use-alarm rising-threshold *threshold* [**falling-threshold** *threshold*] **interval** *seconds* [*rmon-event-type*] [**startup-alarm** *alarm-type*]

no kb-memory-use-warn

Context

[Tree] (config>system>thresholds kb-memory-use-alarm)

Full Context

configure system thresholds kb-memory-use-alarm

Description

This command configures memory use, in kilobytes, alarm thresholds.

The **no** form of the command removes the parameters from the configuration.

Parameters

rising-threshold *threshold*

Specifies a threshold for the sampled statistic. When the current sampled value is greater than or equal to this threshold, and the value at the last sampling interval was less than this threshold, a single threshold crossing event will be generated. A single threshold crossing event will also be generated if the first sample taken is greater than or equal to this threshold and the associated startup-alarm is equal to rising or either.

After a rising threshold crossing event is generated, another such event will not be generated until the sampled value falls below this threshold and reaches less than or equal the falling-threshold value.

The threshold value represents units of kilobytes.

Values -2147483648 to 2147483647

Default 0

falling-threshold *threshold*

Specifies a threshold for the sampled statistic. When the current sampled value is less than or equal to this threshold, and the value at the last sampling interval was greater

than this threshold, a single threshold crossing event will be generated. A single threshold crossing event will also be generated if the first sample taken is less than or equal to this threshold and the associated startup-alarm is equal to falling or either.

After a falling threshold crossing event is generated, another such event will not be generated until the sampled value rises above this threshold and reaches greater than or equal the rising-threshold value.

The threshold value represents units of kilobytes.

Values -2147483648 to 2147483647

Default 0

seconds

Specifies the polling period over which the data is sampled and compared with the rising and falling thresholds.

Values 1 to 2147483647

rmon-event-type

Specifies the type of notification action to be taken when this event occurs.

Values log — In the case of log, an entry is made in the RMON-MIB log table for each event occurrence. This does not create an SR OS logger entry. The RMON-MIB log table entries can be viewed using the **show>system>thresholds** CLI command.

trap — An SR OS logger event is generated. The SR OS logger utility then distributes the notification of this event to its configured log destinations which may be CONSOLE, telnet session, memory log, cflash file, syslog, or SNMP trap destinations logs.

both — Both an entry in the RMON-MIB logTable and an SR OS logger event are generated.

none — No action is taken.

Default both

startup-alarm *alarm-type*

Specifies the alarm that may be sent when this alarm is first created. If the first sample is greater than or equal to the rising threshold value and startup-alarm is equal to rising or either, then a single rising threshold crossing event is generated. If the first sample is less than or equal to the falling threshold value and startup-alarm is equal to falling or either, a single falling threshold crossing event is generated.

Values rising, falling, either

Default either

configure system thresholds kb-memory-use-warn

Description

This command configures memory usage, in kilobytes, for warning thresholds

Parameters

rising-threshold *threshold*

Specifies a threshold for the sampled statistic. When the current sampled value is greater than or equal to this threshold, and the value at the last sampling interval was less than this threshold, a single threshold crossing event will be generated. A single threshold crossing event will also be generated if the first sample taken is greater than or equal to this threshold and the associated startup-alarm is equal to rising or either.

After a rising threshold crossing event is generated, another such event will not be generated until the sampled value falls below this threshold and reaches less than or equal the falling-threshold value.

The threshold value represents units of kilobytes.

Values -2147483648 to 2147483647

Default 0

falling-threshold *threshold*

Specifies a threshold for the sampled statistic. When the current sampled value is less than or equal to this threshold, and the value at the last sampling interval was greater than this threshold, a single threshold crossing event will be generated. A single threshold crossing event will also be generated if the first sample taken is less than or equal to this threshold and the associated startup-alarm is equal to falling or either.

After a falling threshold crossing event is generated, another such event will not be generated until the sampled value rises above this threshold and reaches greater than or equal the rising-threshold value.

The threshold value represents units of kilobytes.

Values -2147483648 to 2147483647

Default 0

seconds

Specifies the polling period over which the data is sampled and compared with the rising and falling thresholds.

Values 1 to 2147483647

rmon-event-type

Specifies the type of notification action to be taken when this event occurs.

Values log — An entry is made in the RMON-MIB log table for each event occurrence. This does not create an SR OS logger entry. The RMON-MIB log table entries can be viewed using the show>system>thresholds CLI command.

trap — An SR OSS logger event is generated. The SR OS logger utility then distributes the notification of this event to its configured log destinations which may be CONSOLE, telnet session, memory log, cflash file, syslog, or SNMP trap destinations logs.

both — Both an entry in the RMON-MIB logTable and an SR OS logger event are generated.

none — No action is taken.

Default both

alarm-type

Specifies the alarm that may be sent when this alarm is first created. If the first sample is greater than or equal to the rising threshold value and startup-alarm is equal to rising or either, then a single rising threshold crossing event is generated. If the first sample is less than or equal to the falling threshold value and startup-alarm is equal to falling or either, a single falling threshold crossing event is generated.

keep-alive

Syntax

keep-alive

Context

[Tree] (config>service>sdp keep-alive)

Full Context

configure service sdp keep-alive

Description

This command enables the context to configure SDP connectivity monitoring keepalive messages for the SDP ID.

SDP ID keepalive messages use SDP Echo Request and Reply messages to monitor SDP connectivity. The operating state of the SDP is affected by the keepalive state on the SDP ID. SDP Echo Request messages are only sent when the SDP ID is completely configured and administratively up. If the SDP ID is administratively down, keepalives for that SDP ID are disabled. SDP Echo Requests (when sent for keepalive messages) are always sent with the *originator-sdp-id*. All SDP ID keepalive SDP Echo Replies are sent using generic IP/GRE OAM encapsulation.

When a keepalive response is received that indicates an error condition, the SDP ID will immediately be brought operationally down. Once a response is received that indicates the error has cleared and the **hold-down-time** interval has expired, the SDP ID will be eligible to be put into the operationally up state. If no other condition prevents the operational change, the SDP ID will enter the operational state.

A set of event counters track the number of keepalive requests sent, the size of the message sent, non-error replies received and error replies received. A keepalive state value is kept indicating the last response event. A keepalive state timestamp value is kept indicating the time of the last event. With each keepalive event change, a log message is generated indicating the event type and the timestamp value.

Table 48: Keepalive Interpretation and Effect of SDP Echo Reply describes the keepalive interpretation of SDP echo reply response conditions and the effect on the SDP ID operational status.

Table 48: Keepalive Interpretation and Effect of SDP Echo Reply

Result of Request	Stored Response State	Operational State
keepalive request timeout without reply	Request Timeout	Down
keepalive request not sent due to non-existent *orig-sdp-id* (This condition should not occur)	Orig-SDP Non-Existent	Down
keepalive request not sent due to administratively down *orig-sdp-id*	Orig-SDP Admin-Down	Down
keepalive reply received, invalid origination-id	Far End: Originator-ID Invalid	Down
keepalive reply received, invalid responder-id	Far End: Responder-ID Error	Down
keepalive reply received, No Error	Success	Up (If no other condition prevents)

Full Context

configure service vprn subscriber-interface group-interface srrp keep-alive-interval

configure service ies subscriber-interface group-interface srrp keep-alive-interval

Description

This command defines the interval between SRRP advertisement messages sent when operating in the master state. The interval is also the basis for setting the master-down timer used to determine when the master is no longer sending. The system uses three times the keep-alive interval to set the timer. Every time an SRRP advertisement is seen that is better than the local priority, the timer is reset. If the timer expires, the SRRP instance assumes that a master does not exist and initiates the attempt to become master.

When in backup state, the SRRP instance takes the keep-alive interval of the master as represented in the masters SRRP advertisement message. Once in master state, the SRRP instance uses its own configured keep-alive interval.

The keep-alive-interval may be changed at any time, but will have no effect until the SRRP instance is in the master state.

The **no** form of this command restores the default interval.

Default

keep-alive-interval 10

Parameters

interval

Specifies the interval, in deciseconds, between SRRP advertisement messages sent when operating in the master state.

Values 1 to 100

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

no keepalive

Context

[Tree] (config>subscr-mgmt>loc-user-db>ppp>host>plcy-parms keepalive)

Full Context

configure subscriber-mgmt local-user-db ppp host ppp-policy-parameters keepalive

Description

This command configures the keepalive time interval in seconds at which LCP echo requests are transmitted for the PPP session and the number of LCP echo replies that can be missed before the PPP session is brought down. Overrides the values configured in **subscriber-mgmt ppp-policy** for PPPoE PTA sessions or in the Base router or VPRN service **l2tp group** context for L2TP LNS sessions.

The **no** form of this command removes the LCP keepalive parmeter overrides.

Default

no keepalive

Parameters

seconds

Specifies the keepalive interval in seconds.

Values 4 to 300

hold-up-multiplier *multiplier*

Specifies the number of keepalives that can be missed.

Values 1 to 5

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

keepalive

Syntax

keepalive *seconds*

no keepalive

Context

[Tree] (config>subscr-mgmt>bgp-prng-plcy keepalive)

Full Context

configure subscriber-mgmt bgp-peering-policy keepalive

Description

This command configures the BGP keepalive timer. A keepalive message is sent every time this timer expires.

The keepalive value is generally one-third of the hold-time interval. Even though the OS implementation allows the keepalive value and the hold-time interval to be independently set, under the following circumstances, the configured keepalive value is overridden by the hold-time value:

If the specified keepalive value is greater than the configured hold-time, then the specified value is ignored, and the keepalive is set to one third of the current hold-time value.

If the specified hold-time interval is less than the configured keepalive value, then the keepalive value is reset to one third of the specified hold-time interval.

If the hold-time interval is set to zero, then the configured value of the keepalive value is ignored. This means that the connection with the peer is up permanently and no keepalive packets are sent to the peer.

The **no** form of this command used at the global level reverts to the default value.

Default

keepalive 30

Parameters

seconds

Specifies the keepalive timer in seconds, expressed as a decimal integer.

Values 0 to 21845

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

Full Context

configure service vprn bgp group neighbor keepalive

configure service vprn bgp group keepalive

configure service vprn bgp keepalive

Description

This command configures the BGP keepalive timer. A keepalive message is sent every time this timer expires. The **seconds** parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). The most specific value is used.

The **keepalive** value is generally one-third of the **hold-time** interval. Even though the OS implementation allows the **keepalive** value and the **hold-time** interval to be independently set, under the following circumstances, the configured **keepalive** value is overridden by the **hold-time** value:

If the specified **keepalive** value is greater than the configured **hold-time**, then the specified value is ignored, and the **keepalive** is set to one third of the current **hold-time** value.

If the specified **hold-time** interval is less than the configured **hold-time** value, then the **keepalive** value is reset to one third of the specified **hold-time** interval.

If the **hold-time** interval is set to zero, then the configured value of the **keepalive** value is ignored. This means that the connection with the peer is up permanently and no **keepalive** packets are sent to the peer.

The **no** form of this command used at the global level reverts to the default value.

The **no** form of this command used at the group level reverts to the value defined at the global level.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Default

keepalive 30

Parameters

seconds

The keepalive timer in seconds, expressed as a decimal integer.

Values 0 to 21845

configure router ldp targeted-session ipv4 keepalive

configure router ldp targeted-session ipv6 keepalive

configure router ldp interface-parameters ipv4 keepalive

configure router ldp targeted-session peer-template keepalive

configure router ldp interface-parameters interface ipv4 keepalive

configure router ldp interface-parameters ipv6 keepalive

configure router ldp interface-parameters interface ipv6 keepalive

Description

This command configures the time interval (in s), that LDP waits before tearing down the session. The **factor** parameter derives the keepalive interval.

The **config**>**router**>**ldp**>**if-params**>**ipv6**>**keepalive** and **config**>**router**>**ldp**>**targ-session**>**ipv6**>**keepalive** commands are not supported on the 7450 ESS.

If no LDP messages are exchanged for the configured time interval, the LDP session is torn down. Keepalive timeout is usually three times the keepalive interval. To maintain the session permanently, regardless of the activity, set the value to zero.

When LDP session is being set up, the keepalive timeout is negotiated to the lower of the two peers. Once an operational value is agreed upon, the keepalive factor is used to derive the value of the keepalive interval.

The **no** form of the command at the interface-parameters and targeted-session levels sets the **keepalive timeout** and the **keepalive factor** to the default value.

The **no** form of this command, at the interface level, sets the **keepalive timeout** and the **keepalive factor** to the value defined under the **interface-parameters** level.

The **no** form of this command, at the peer level, sets the **keepalive timeout** and the **keepalive factor** to the value defined under the **targeted-session** level.

The session must be flapped for the new settings to operate.

Default

Table 49: Timeout Factor Defaults lists the default values.

Table 49: Timeout Factor Defaults

Context	Timeout	Factor
config>router>ldp>if-params	30	3
config>router>ldp>targ-session	40	4
config>router>ldp>if-params>if	Inherits values from interface-parameters context.	
config>router>ldp>targ-session>peer	Inherits values from targeted-session context.	

Parameters

timeout

Configures the time interval, in seconds, that LDP waits before tearing down the session.

Values 1 to 65535

factor

Specifies the number of keepalive messages, expressed as a decimal integer, that should be sent on an idle LDP session in the keepalive timeout interval.

Values 1 to 255

Platforms

All

keepalive

Syntax

[**no**] **keepalive**

keepalive

Syntax

keepalive *deciseconds* **dropcount** *count*

Context

[Tree] (config>isa>nat-group>inter-chassis-redundancy keepalive)

Full Context

configure isa nat-group inter-chassis-redundancy keepalive

Description

This command configures keepalives between the CPMs residing on different chassis. The keepalives are used to detect the presence of the peering node. If the redundant peer connectivity is lost beyond the limit defined by keepalives, then each node in the redundant pair transitions into a standalone mode. Keepalives use UDP transport.

Default

keepalive 30 dropcount 2

Parameters

deciseconds

Specifies the number of keepalives that are transported periodically at intervals defined by this parameter.

Values 2 to 250

count

Specifies the drop count. If the number of consecutive keepalives defined by this parameter is lost, then the peer is considered unreachable and the node transitions into a standalone mode of operation.

Values 2 to 20

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Default

keepalive 30

Parameters

seconds

Specifies the keepalive timer, in seconds, expressed as a decimal integer.

Values 0 to 21845

Platforms

All

keepalive

Syntax

keepalive [**neighbor** *ip-addr* | **group** *name*]

no keepalive

Context

[Tree] (debug>router>bgp keepalive)

Full Context

debug router bgp keepalive

Description

This command decodes and logs all sent and received keepalive messages in the debug log.

The **no** form of this command disables the debugging.

Parameters

neighbor *ip-address*

Debugs only events affecting the specified BGP neighbor.

Values ipv4-address:

- a.b.c.d (host bits must be 0)

ipv6-address:

- x:x:x:x:x:x:x:x [-interface] (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d [-interface]
- x: [0 to FFFF]H
- d: [0 to 255]D
- interface: up to 32 characters for link local addresses

group *name*

Debugs only events affecting the specified peer group name, up to 64 characters, and associated neighbors.

Full Context

configure mcast-management mcast-info-policy bundle keepalive-override

configure mcast-management mcast-info-policy bundle channel source-override keepalive-override

configure mcast-management mcast-info-policy bundle channel keepalive-override

Description

This command configures the keepalive timer override. The PIM (S,G) Keepalive Timer (KAT) is used to maintain the (S,G) state when (S,G) join is not received. Expiry of the KAT causes the (S,G) entry to be removed.

The KAT override configuration is performed with a multicast information policy, which must be applied to the related PIM routing instance. When a KAT override is configured under a channel (a group or a group range), it applies to all (S,G) entries that fall under it, except when the source-override is configured and a KAT override is also configured under the source-override. In this scenario, the specific KAT override must be used for the (S,G) entries that fall under the source-override, while other (S,G) entries under the bundle use the KAT override configured under the channel.

Parameters

keepalive-timer

Specifies the keepalive timer override, in seconds.

Values 10 to 86000

15.11 kernel

kernel

Syntax

kernel password *password*

[Tree] (config>system>security>ssh>server-kex-list kex)

Full Context

configure system security ssh client-kex-list kex

configure system security ssh server-kex-list kex

Description

This command allows the user to configure phase 1 SSH v2 KEX algorithms for SR OS as an SSH server or an SSH client. By default, the client and server lists are empty. If the user configures this list, SSH uses the hard-coded list with the first-listed algorithm having the highest priority and so on. An empty server or client list is the default list and contains the following algorithms:

diffie-hellman-group16-sha512

diffie-hellman-group14-sha256

diffie-hellman-group14-sha1

diffie-hellman-group14-sha1

diffie-hellman-group1-sha1

The **no** form of this command removes the specified KEX index. If all KEX indexes are removed, the default list is used again.

Parameters

index

Specifies the index of the algorithm in the list. The lowest index in the list is negotiated first on the SSH negotiation list, while the highest index is at the bottom of the SSH negotiation list.

Values 1 to 255

kex-name

Specifies the KEX algorithm for computing the shared secret key.

Values diffie-hellman-group16-sha512, diffie-hellman-group14-sha256, diffie-hellman-group14-sha1, diffie-hellman-group-exchange-sha1, diffie-hellman-group1-sha1

Description

This command specifies the RADIUS cache key that is used to match the information in subsequent DHCP requests for authorization.

Parameters

packet-type

Specifies the packet type of the RADIUS messages to use to generate the key for the cache of this RADIUS proxy server.

Values accept, request

attribute-type

Specifies the RADIUS attribute type to cache for this RADIUS proxy. server.

Values 1 to 255

vendor-id

Specifies the RADIUS vendor ID.

Values 1 to 16777215, nokia

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

key

Syntax

key *key-filename*

no key

Context

[Tree] (config>ipsec>cert-profile>entry key)

Full Context

configure ipsec cert-profile entry key

Description

This command specifies the filename of an imported key for the **cert-profile entry**.

The **no** form of this command removes the key filename from the entry configuration.

Default

no key

Parameters

key-filename

Specifies the filename of an imported key.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

key

Syntax

key *password* [**hash** | **hash2** | **custom**] **reference** *reference-number*

no key reference *reference-number*

Context

[Tree] (config>system>security>pki>ca-profile>cmpv2>key-list key)

Full Context

configure system security pki ca-profile cmpv2 key-list key

Description

This command specifies a pre-shared key used for CMPv2 initial registration. Multiples of key commands are allowed to be configured under this context.

The password and reference-number is distributed by the CA via out-of-band means.

The configured password is stored in configuration file in an encrypted form by using SR OS hash2 algorithm.

The **no** form of this command removes the parameters from the configuration.

Parameters

password

Specifies a printable ASCII string, up to 64 characters.

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

custom

Specifies the custom encryption to management interface.

reference *reference-number*

Specifies a printable ASCII string, up to 64 characters in length.

Platforms

All

key

Syntax

key *key-filename*

no key

Context

[Tree] (config>system>security>tls>cert-profile>entry key)

Full Context

configure system security tls cert-profile entry key

Description

This command specifies the file name of an imported key for the **cert-profile** entry.

The **no** form of the command removes the key.

Default

no key

Parameters

key-filename

Specifies the file name of the key.

Platforms

All

15.14 key-generation

key-generation

Syntax

key-generation dsa size *bits*

key-generation ecdsa curve *curve*

key-generation rsa size *bits*

key-generation same-as-existing-key

Context

[Tree] (config>system>security>pki>cert-upd-prof key-generation)

Full Context

configure system security pki certificate-update-profile key-generation

Description

This command configures the key generation algorithm and behavior.

Default

key-generation same-as-existing-key

Parameters

bits

Specifies the size in bits..

Values 512 to 8192

Default 2048

curve

Specifies the elliptic curve for key generation.

Values secp256r1, secp384r1, secp521r1

Default secp256r1

same-as-existing-key
Specifies to use the same algorithm and key or size curve as the existing key.

Platforms
All

15.15 key-list

key-list

Syntax
key-list

Context
[Tree] (config>system>security>pki>ca-profile>cmpv2 key-list)

Full Context
configure system security pki ca-profile cmpv2 key-list

Description
This command enables the context to configure pre-shared key list parameters.

Platforms
All

15.16 key-re-exchange

key-re-exchange

Syntax
key-re-exchange

Context
[Tree] (config>system>security>ssh key-re-exchange)

Full Context

configure system security ssh key-re-exchange

Description

This command enables the key re-exchange context.

Platforms

All

15.17 key-rollover-interval

key-rollover-interval

Syntax

key-rollover-interval *key-rollover-interval*

Context

[Tree] (config>service>vprn>ospf3>area key-rollover-interval)

Full Context

configure service vprn ospf3 area key-rollover-interval

Description

This command configures the key rollover interval.

The **no** form of this command reverts to the default.

Default

key-rollover-interval 10

Parameters

key-rollover-interval

Specifies the time, in seconds, after which a key rollover will start.

Values 10 to 300

Platforms

All

key-rollover-interval

Syntax

key-rollover-interval *seconds*

Context

[Tree] (config>router>ospf3>area key-rollover-interval)

Full Context

configure router ospf3 area key-rollover-interval

Description

This command configures the key rollover interval.

Default

key-rollover-interval 10

Parameters

seconds

Specifies the time, in seconds, after which a key rollover will start.

Values 10 to 300

Platforms

All

15.18 key-update

key-update

Syntax

key-update ca *ca-profile-name* **newkey** *key-filename* **oldkey** *key-filename* **oldcert** *cert-filename* [**hash-alg** *hash-algorithm*] **save-as** *save-path-of-result-cert*

Context

[Tree] (admin>certificate>cmpv2 key-update)

Full Context

admin certificate cmpv2 key-update

Description

This command requests a new certificate from the CA to update an existing certificate due to reasons such as **key refresh** or **replacing compromised key**.

In some cases, the CA may not return certificate immediately, due to reasons such as request processing need manual intervention. In such cases, the admin certificate cmpv2 poll command can be used to poll the status of the request.

Parameters

ca-profile-name

Specifies a ca-profile name which includes CMP server information, up to 32 characters.

newkey *key-filename*

Specifies the key file of the requesting certificate, up to 95 characters.

oldkey *key-filename*

Specifies the key to be replaced, up to 95 characters.

cert-filename

Specifies the file name of an imported certificate to be replaced, up to 95 characters.

hash-algorithm

Specifies the hash algorithm for RSA key.

Values md5,sha1,sha224,sha256,sha384,sha512

save-path-of-result-cert

Specifies the save full path name of saving the result certificate, up to 200 characters.

Platforms

All

15.19 key-value

key-value

Syntax

key-value *public-key-value*

no key-value

Context

[Tree] (config>system>security>user>public-keys>ecdsa>ecdsa-key key-value)

[Tree] (config>system>security>user>public-keys>rsa>rsa-key key-value)

Full Context

configure system security user public-keys ecdsa ecdsa-key key-value

configure system security user public-keys rsa rsa-key key-value

Description

This command configures a value for the RSA or ECDSA public key. The public key must be enclosed in quotation marks. For RSA, the key is between 768 and 4096 bits. For ECDSA, the key is between 1 and 1024 bits.

Default

no key-value

Parameters

public-key-value

Specifies the public key value, up to 800 characters for RSA and up to 255 characters for ECDSA.

Platforms

All

15.20 keychain

keychain

Syntax

[**no**] **keychain** *keychain-name*

Context

[Tree] (config>system>security keychain)

Full Context

configure system security keychain

Description

This command enables the context to configure keychain parameters. A keychain must be configured on the system before it can be applied to a session.

The **no** form of this command removes the keychain nodal context and everything under it from the configuration. If the keychain to be removed is in use when the no keychain command is entered, the command will not be accepted and an error indicating that the keychain is in use will be printed.

Parameters

keychain-name

Specifies a keychain name which identifies this particular keychain entry.

Values An ASCII string up to 32 characters.

Platforms

All

15.21 keygroup-name

keygroup-name

Syntax

keygroup-name *keygroup-name*

no keygroup-name

Context

[Tree] (config>grp-encryp>encryp-keygrp keygroup-name)

Full Context

configure group-encryption encryption-keygroup keygroup-name

Description

This command is used to name the key group. The key group name can be used to reference a key group when configuring services or displaying information.

The **no** form of the command reverts to the default value.

Parameters

keygroup-name

The name of the key group, up to 64 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

15.22 kill-session

kill-session

Syntax

[**no**] **kill-session**

Context

[Tree] (configure>system>security>profile>netconf>base-op-authorization kill-session)

Full Context

configure system security profile netconf base-op-authorization kill-session

Description

This command authorizes a user associated with the profile to send a NETCONF <kill-session> operation. This kill session operation allows a NETCONF client to kill another NETCONF session, but not the session in which the operation is requested.

The **no** form of the command denies the user from requesting a kill-session.

Default

no kill-session

Platforms

All

16 I Commands

16.1 I2

I2

Syntax

[**no**] **I2**

Context

[Tree] (config>subscr-mgmt>wlan-gw>tunnel-query>type I2)

Full Context

configure subscriber-mgmt wlan-gw tunnel-query type I2

Description

This command enables matching on Layer 2 tunnels.

The **no** form of this command disables matching on Layer 2 access points, unless no other tunnel type specifier is configured.

Default

no I2

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

I2

Syntax

[**no**] **I2**

Context

[Tree] (config>subscr-mgmt>wlan-gw>ue-query>state I2)

Full Context

configure subscriber-mgmt wlan-gw ue-query state I2

Description

This command enables matching on UEs in a Layer 2 wholesale state.

The **no** form of this command disables matching on UEs in a Layer 2 wholesale state, unless all state matching is disabled.

Default

no l2

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

16.2 l2-access-id-alias

l2-access-id-alias

Syntax

l2-access-id-alias *string*

no l2-access-id-alias

Context

[Tree] (config>service>vpls>sap>pfcp l2-access-id-alias)

Full Context

configure service vpls sap pfcp l2-access-id-alias

Description

This command defines a Layer 2 access ID alias for the capture SAP. It replaces the default underlying port-based or LAG-based Layer 2 access ID. Different capture SAPs on the same underlying port or LAG can have different Layer 2 access ID aliases.

The **no** form of the command removes the configuration.

Parameters

string

Specifies the Layer 2 access ID alias, up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

16.3 l2-access-points

l2-access-points

Syntax

l2-access-points

Context

[Tree] (config>service>vprn>sub-if>grp-if>wlan-gw l2-access-points)

[Tree] (config>service>ies>sub-if>grp-if>wlan-gw l2-access-points)

Full Context

configure service vprn subscriber-interface group-interface wlan-gw l2-access-points

configure service ies subscriber-interface group-interface wlan-gw l2-access-points

Description

Commands in this context configure Layer 2 access points in WLAN gateway group interfaces.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

16.4 l2-ap

l2-ap

Syntax

l2-ap *sap-id* [**create**]

no l2-ap *sap-id*

Context

[Tree] (config>service>vprn>sub-if>grp-if>wlan-gw>l2-access-points l2-ap)

[Tree] (config>service>ies>sub-if>grp-if>wlan-gw>l2-access-points l2-ap)

Full Context

configure service vprn subscriber-interface group-interface wlan-gw l2-access-points l2-ap

configure service ies subscriber-interface group-interface wlan-gw l2-access-points l2-ap

Description

This command adds a specific SAP where Layer 2 WLAN gateway aggregation is performed. The following SAPs are supported:

- Ethernet
- LAG
- MPLS pseudowire SDPs

This command can be repeated multiple times to create multiple Layer 2 access points.

The **no** form of this command removes the Layer 2 access point. This is only allowed if the Layer 2 access point SAP is shutdown.

Parameters

sap-id

Specifies SAP to be created.

create

Keyword used to create the Layer 2 WLAN gateway aggregation instance. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

16.5 l2-ap-auto-sub-id-fmt

l2-ap-auto-sub-id-fmt

Syntax

l2-ap-auto-sub-id-fmt {**include-ap-tags** | **sap-only**}

Context

[Tree] (config>service>ies>sub-if>grp-if>wlan-gw l2-ap-auto-sub-id-fmt)

[Tree] (config>service>vprn>sub-if>grp-if>wlan-gw l2-ap-auto-sub-id-fmt)

Full Context

configure service ies subscriber-interface group-interface wlan-gw l2-ap-auto-sub-id-fmt

configure service vprn subscriber-interface group-interface wlan-gw l2-ap-auto-sub-id-fmt

Description

This command configures the contents of the auto-generated subscriber ID when the **ipoe-sub-id-key** command is set to include **sap-id** and the **def-sub-id** command is configured with **use-auto-id**. The VLANs must be configured so that the subscriber ID length is not exceeded.

This command can include either the SAP or the SAP + AP delimiting tags.

The **no** form of this command reverts to the default configuration.

Default

l2-ap-auto-sub-id-fmt include-ap-tags

Parameters

include-ap-tags

Specifies that the SAP + AP delimiting tags is used.

sap-only

Specifies that the SAP only is used.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

16.6 l2-ap-encap-type

l2-ap-encap-type

Syntax

l2-ap-encap-type {**null** | **dot1q** | **qinq**}

Context

[Tree] (config>service>ies>sub-if>grp-if>wlan-gw l2-ap-encap-type)

[Tree] (config>service>vprn>sub-if>grp-if>wlan-gw l2-ap-encap-type)

Full Context

configure service ies subscriber-interface group-interface wlan-gw l2-ap-encap-type

configure service vprn subscriber-interface group-interface wlan-gw l2-ap-encap-type

Description

This parameter specifies the number of AP identifying VLAN tags for an AP. This is the default value that can be overridden per SAP. This value must be at least equal to the number of VLANs configured in the SAP or enabling a SAP will fail.

A SAP VLAN is explicitly configured, for example **l2-ap 1/1/1:25**. Other VLANs on the same port can still be used in other contexts.

The number of VLAN tags Epiped to the WLAN gateway IOM equals the **l2-ap-encap-type** minus the encaps of the SAP. Upon receipt of a packet, these VLANs are stored as a Layer 2 tunnel identifier, and are only used in context of WLAN gateway.

The **no** form of this command sets the default value.

Default

l2-ap-encap-type null

Parameters

null

Both the SAP and the AP are not VLAN-tagged.

dot1q

Either the AP or the SAP uses one VLAN tag.

qinq

Up to two VLAN tags are used by the AP or SAP.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

16.7 l2-aware

l2-aware

Syntax

l2-aware

Context

[Tree] (config>service>vprn>nat>inside l2-aware)

Full Context

configure service vprn nat inside l2-aware

Description

Commands in this context configure parameters specific to Layer2-Aware NAT.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

l2-aware

Syntax

l2-aware

Context

[Tree] (config>router>nat>inside l2-aware)

Full Context

configure router nat inside l2-aware

Description

Commands in this context configure Layer2-Aware NAT.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

l2-aware

Syntax

l2-aware subscriber *sub-ident-string* **ip** *ip-address* **protocol** {**tcp** | **udp**} [**port** *port*] [**outside-ip** *ip-address*] [**outside-port** *port*] [**nat-policy** *policy-name*] [**member** *member-id*] [**port-range-start** *port*]

no l2-aware subscriber *sub-ident-string* **ip** *ip-address* **protocol** {**tcp** | **udp port** *port*

Context

[Tree] (config>service>nat>fwd l2-aware)

Full Context

configure service nat port-forwarding l2-aware

Description

This command creates NAT static port forwards for Layer2-Aware subscribers. The ESM subscriber must be present in the system before this command is executed. The **no** form of the command deletes NAT static port forwards for Layer2-Aware subscribers.

Parameters

subscriber *sub-ident-string*

This mandatory parameter specifies the ESM subscriber for which the SPF is to be created; ESM subscriber must be present in the system before the SPF can be created.

ip *ip-address*

This mandatory parameter specifies the source IPv4/IPv6 address for which SPF will be created.

protocol {tcp | udp}

This mandatory parameter specifies the protocol to use, either TCP or UDP.

port *port*

This optional parameter specifies a source port.

Values 1 to 65535

outside-ip *ipv4-address*

This mandatory parameter specifies the outside IPv4 address. If the outside IPv4 address is specified, then all other optional parameters become mandatory.

outside-port ***port***

This optional parameter specifies the outside port.

nat-policy ***policy-name***

If multiple NAT policies are used inside the routing context, then the NAT policy should be specified in the SPF request so the SPF is created in the correct NAT pool. Otherwise, the default NAT policy from the inside routing context will be used.

member ***member-id***

This optional parameter should not be used by the operator. It is used only if the command is replayed via the **exec** command or at **boot-config**. The member ID indicates the identifier of the NAT ISA group member associated with this NAT subscriber.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

16.8 l2-aware-ip-address

l2-aware-ip-address

Syntax

l2-aware-ip-address *ip-address*

l2-aware-ip-address from-pool

no l2-aware-ip-address

Context

[Tree] (config>service>ies>sub-if>grp-if>wlan-gw>ranges>range>dhcp l2-aware-ip-address)

[Tree] (config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range>dhcp l2-aware-ip-address)

Full Context

configure service ies subscriber-interface group-interface wlan-gw vlan-tag-ranges range dhcp l2-aware-ip-address

configure service vprn subscriber-interface group-interface wlan-gw vlan-tag-ranges range dhcp l2-aware-ip-address

Description

This command configures the Layer2-Aware NAT inside IP address to be assigned via DHCP on the WLAN-GW ISA.

If the **from-pool** parameter is specified instead of an IPv4 address, a unique address is allocated to each UE. The pool used is managed by the dhcpv4-nat pool manager, configured under the same subscriber interface. This option is only available when **auth-on-dhcp** is also configured.

The **no** form of this command reverts to the default.

Parameters

ip-address

Specifies the Layer2-Aware NAT inside IP address.

from-pool

Specifies that the Layer2-Aware IP address is allocated from a pool.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

16.9 l2-aware-nat-bypass

l2-aware-nat-bypass

Syntax

[**no**] **l2-aware-nat-bypass**

Context

[Tree] (config>filter>ip-filter>entry>action l2-aware-nat-bypass)

Full Context

configure filter ip-filter entry action l2-aware-nat-bypass

Description

This command enables bypassing NAT for packets pertaining to L2-Aware hosts and matching this entry. This action is only applicable to L2-Aware NAT subscribers and it must be configured together with **action forward**. Traffic identified in the match condition bypasses L2-Aware NAT. A common use case is to bypass NAT for on-net destinations (within the customer network).

Traffic that is not classified for bypass is automatically diverted to L2-Aware NAT, unless it is explicitly configured in the IP filter to be dropped.

For selective NAT bypass to take effect, in addition to the IP filter configuration, the L2-Aware NAT subscriber must be specifically enabled for selective bypass via the **nat-allow-bypass** configuration option in the NAT CLI node in the SLA profile.

The **no** form of this command automatically diverts traffic to L2-Aware NAT, unless it is explicitly configured in the IP filter to be dropped.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

16.10 l2-aware-sub

l2-aware-sub

Syntax

[**no**] **l2-aware-sub** *sub-ident-string*

Context

[Tree] (config>li>li-source>nat l2-aware-sub)

Full Context

configure li li-source nat l2-aware-sub

Description

This command configures a Layer-2-Aware subscriber source.

The **no** form of this command removes the values from the configuration.

Parameters

sub-ident-string

Specifies a source name.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

16.11 l2-inner-vlan

l2-inner-vlan

Syntax

l2-inner-vlan *q-tag*

no l2-inner-vlan

Context

[Tree] (config>subscr-mgmt>wlan-gw>tunnel-query l2-inner-vlan)

Full Context

configure subscriber-mgmt wlan-gw tunnel-query l2-inner-vlan

Description

This command enables matching on a Layer 2 access point with a specified C-VLAN.

The **no** form of this command disables matching on a C-VLAN.

Default

no l2-inner-vlan

Parameters

q-tag

Specifies the *q-tag* for the C-VLAN.

Values 0 to 4095

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

16.12 l2-ip

l2-ip

Syntax

[**no**] **l2-ip**

Context

[Tree] (config>cflowd>collector>export-filter>family l2-ip)

Full Context

configure cflowd collector export-filter family l2-ip

Description

This command filters Layer 2 IP flow data from being sent to the associated collector.

The **no** form of this command removes the filter, allowing Layer 2 IP flow data to be sent to the associated collector.

Default

no l2-ip

Platforms

All

16.13 l2-outer-vlan

l2-outer-vlan

Syntax

l2-outer-vlan *q-tag*

no l2-outer-vlan

Context

[Tree] (config>subscr-mgmt>wlan-gw>tunnel-query l2-outer-vlan)

Full Context

configure subscriber-mgmt wlan-gw tunnel-query l2-outer-vlan

Description

This command enables matching on a Layer 2 access point with a specified S-VLAN.

The **no** form of this command disables matching on an S-VLAN.

Default

no l2-outer-vlan

Parameters

q-tag

Specifies the *q-tag* for the S-VLAN.

Values 0 to 4095

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

16.14 l2-outside

l2-outside

Syntax

l2-outside

no l2-outside

Context

[Tree] (config>service>nat>nat-policy l2-outside)

[Tree] (config>service>nat>firewall-policy l2-outside)

Full Context

configure service nat nat-policy l2-outside

configure service nat firewall-policy l2-outside

Description

This command configures a NAT policy to be used with a Layer 2 outside service instead of a Layer 3 outside service. This command and the **pool** command are mutually exclusive.

Default

no l2-outside

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

- configure service nat nat-policy l2-outside

7750 SR, 7750 SR-e, 7750 SR-s, VSR

- configure service nat firewall-policy l2-outside

16.15 l2-sap

l2-sap

Syntax

l2-sap *sap-id*

no l2-sap

Context

[Tree] (config>subscr-mgmt>wlan-gw>tunnel-query l2-sap)

Full Context

configure subscriber-mgmt wlan-gw tunnel-query l2-sap

Description

This command enables matching on Layer 2 access points active on the specified SAP.

The **no** form of this command disables matching on the SAP.

Default

no l2-sap

Parameters

sap-id

Specifies the SAP ID. For details on SAP ID parameter values, refer to section *Monitor CLI Commands* in the *7450 ESS, 7750 SR, 7950 XRS, and VSR Basic System Configuration Guide*.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

16.16 l2-service

l2-service

Syntax

l2-service *service-id*

no l2-service

Context

[Tree] (config>service>ies>sub-if>grp-if>wlan-gw>ranges>range l2-service)

[Tree] (config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range l2-service)

Full Context

configure service ies subscriber-interface group-interface wlan-gw vlan-tag-ranges range l2-service

configure service vprn subscriber-interface group-interface wlan-gw vlan-tag-ranges range l2-service

Description

This command specifies the VPLS service used for L2 wholesale. When such a service is configured no other configuration is allowed under the vlan-range.

The **no** form of this command removes the L2 wholesale service, this is only allowed if the l2-service node is shut down.

Parameters

service-id

Specifies the VPLS service ID to use for Layer 2 wholesale.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

16.17 l2pt-termination

l2pt-termination

Syntax

l2pt-termination [**cdp**] [**dtp**] [**pagp**] [**stp**] [**udld**] [**vtp**]

no l2pt-termination

Context

[Tree] (config>service>vpls>sap l2pt-termination)

[Tree] (config>service>vpls>spoke-sdp l2pt-termination)

[Tree] (config>service>template>vpls-sap-template l2pt-termination)

Full Context

configure service vpls sap l2pt-termination

configure service vpls spoke-sdp l2pt-termination

configure service template vpls-sap-template l2pt-termination

Description

This command enables Layer 2 Protocol Tunneling (L2PT) termination on a specified SAP or spoke-SDP. L2PT termination is supported only for STP BPDUs. PDUs of other protocols are discarded.

This feature can be enabled only if STP is disabled in the context of the specified VPLS service.

The **no** form of this command reverts to the default.

Default

no l2pt-termination

Parameters

cdp

Specifies the Cisco discovery protocol

dtp

Specifies the dynamic trunking protocol

pagp

Specifies the port aggregation protocol

stp

Specifies all spanning tree protocols: stp, rstp, mstp, pvst (default)

udld

Specifies unidirectional link detection

vtp

Specifies the virtual trunk protocol

Platforms

l2pt-termination

Syntax

l2pt-termination [**cdp**] [**dtp**] [**pagp**] [**stp**] [**udld**] [**vtp**]

no l2pt-termination

Context

[Tree] (config>service>pw-template l2pt-termination)

Full Context

configure service pw-template l2pt-termination

Description

This command enables Layer 2 Protocol Tunneling (L2PT) termination on a given SAP or spoke SDP. L2PT termination will be supported only for STP BPDUs. PDUs of other protocols will be discarded.

This feature can be enabled only if STP is disabled in the context of the given VPLS service.

Default

no l2pt-termination

Parameters

cdp

Specifies the Cisco discovery protocol.

dtp

Specifies the dynamic trunking protocol.

pagp

Specifies the port aggregation protocol.

stp

Specifies all spanning tree protocols: stp, rstp, mstp, pvst (default).

udld

Specifies unidirectional link detection.

vtp

Specifies the virtual trunk protocol.

Platforms

Full Context

configure subscriber-mgmt sla-profile session-limits l2tp-lns

configure subscriber-mgmt sub-profile session-limits l2tp-lns

Description

This command configures the maximum number of L2TP LNS sessions per SLA profile instance or per subscriber.

The **no** form of this command removes the maximum number of L2TP LNS sessions limit.

Parameters

max-nr-of-sessions

Specifies the maximum number of L2TP LNS sessions.

Values 0 to 131071

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

16.21 l2tp-load-balancing

l2tp-load-balancing

Syntax

[**no**] **l2tp-load-balancing**

Context

[Tree] (config>system>load-balancing l2tp-load-balancing)

Full Context

configure system load-balancing l2tp-load-balancing

Description

This command enables the inclusion of the L2TPv2 session ID into the load-balancing hash algorithm to induce more variation and better load distribution over available links and next-hops.

The **no** form of this command disables the inclusion of the session-id.

Platforms

All

no l2tp-tunnel-id-range

Context

[Tree] (config>redundancy>multi-chassis>peer>sync>track-srrp-instances>track-srrp l2tp-tunnel-id-range)

Full Context

configure redundancy multi-chassis peer sync track-srrp-instances track-srrp l2tp-tunnel-id-range

Description

This command sets the tunnel-id range that is used to allocate a new tunnel-id for a tunnel for which multi-chassis redundancy is configured to this MCS peer.

The **no** form of this command reverts to the default.

Parameters

start *l2tp-tunnel-id*

Specifies the start of the range of L2TP tunnel identifiers that can be allocated by L2TP on this system, to be synchronized with Multi Chassis Redundancy Synchronization (MCS).

Values 1 to 16383

end *l2tp-tunnel-id*

Specifies the end of the range of L2TP tunnel identifiers that can be allocated by L2TP on this system, to be synchronized with Multi Chassis Redundancy Synchronization (MCS).

Values 1 to 16383

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

The **no** form of this command reverts to the default.

Platforms

All

16.29 l4-load-balancing

l4-load-balancing

Syntax

[**no**] **l4-load-balancing**

Context

[Tree] (config>system>load-balancing l4-load-balancing)

Full Context

configure system load-balancing l4-load-balancing

Description

This command configures system-wide Layer 4 load balancing. The configuration at the system level can enable or disable load balancing based on Layer 4 fields. If enabled, the Layer 4 source and destination port fields will be included in hashing calculation for TCP/UDP packets.

The hashing algorithm addresses finer spraying granularity where many hosts are connected to the network.

To address more efficient traffic distribution between network links (forming a LAG group), a hashing algorithm extension takes into account L4 information (that is, src/dst L4-protocol port).

The hashing index can be calculated according to the following algorithm:

Example:

```
– If [(TCP or UDP traffic) & enabled]
    – hash (TCP/UDP ports, IP addresses)
– else if (IP traffic)
    – hash (IP addresses)
– else
    – hash (MAC addresses)
– endif
```

This algorithm will be used in all cases where IP information in per-packet hashing is included (refer to "Traffic Load Balancing Options" in the *7450 ESS, 7750 SR, 7950 XRS, and VSR Interface Configuration Guide*). However, the Layer 4 information (TCP/UDP ports) will not be used for fragmented packets.

Default

no l4-load-balancing

Platforms

All

16.30 l4-src-port

l4-src-port

Syntax

l4-src-port *port* [*mask*]

no l4-src-port

Context

[Tree] (config>system>security>mgmt-access-filter>ipv6-filter>entry l4-src-port)

[Tree] (config>system>security>mgmt-access-filter>ip-filter>entry l4-src-port)

Full Context

configure system security management-access-filter ipv6-filter entry l4-src-port

configure system security management-access-filter ip-filter entry l4-src-port

Description

This command configures a destination TCP or UDP port number or port range for a management access filter match criterion.

The **no** form of this command reverts to the default values.

Default

no l4-src-port

Parameters

port

Specifies the destination TCP or UDP port number as a match criterion.

Values 1 to 65535

Default 6 (exact match)

mask

Specifies the mask used to select a range of source port numbers. Table 50: Format Styles to Configure Mask lists the format styles to configure the 16-bit mask.

Table 50: Format Styles to Configure Mask

Format Style	Format Syntax	Example
Decimal	DDDDD	63488
Hexadecimal	0xHHHH	0xF800
Binary	0bBBBBBBBBBBBBBBB	0b1111100000000000

To select a range from 1024 up to 2047, specify 1024 and 0xFC00 for port and maskrespectively.

Values 1 to 65535 (decimal)

Default 65535 (exact match)

Parameters

label

Specifies the label of the specified RIB-API entry.

Values 32 to 1048575

Platforms

All

16.32 label-allocation

label-allocation

Syntax

label-allocation

Context

[Tree] (config>router>bgp label-allocation)

Full Context

configure router bgp label-allocation

Description

This commands enables the context to configure the allocation of MPLS labels to specific BGP routes.

Platforms

All

16.33 label-block

label-block

Syntax

label-block *name*

no label-block

Context

[Tree] (conf>router>segment-routing>srv6>loc>static-function label-block)

Full Context

configure router segment-routing segment-routing-v6 locator static-function label-block

Description

This command configures a reserved label block name to be used in the termination of services on the SRv6 FPE.

Static values of the service SID function are mapped to label values drawn from this reserved label block. A static function value of 1 maps to the first label in this label block and so on.

Dynamic values of service SID function are mapped to label values drawn from the dynamic label range.

An End or End.X function does not map to a label value.

The **no** form of this command removes the label block name from the configuration.

Default

no label-block

Parameters

name

Specifies a reserved label block name, up to 64 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-s, 7950 XRS, VSR

label-block

Syntax

label-block *name*

no label-block

Context

[Tree] (config>router>segment-routing>srv6>locator label-block)

Full Context

configure router segment-routing segment-routing-v6 locator label-block

Description

This command configures a reserved label block name for the termination of services on the SRv6 FPE.

When an operator configures this block, the router maps both static and dynamic values of the service SID functions to label values drawn from the reserved label block. This reserved block and the block defined under **static-function** are mutually exclusive. The configuration of this block does not constrain the configuration of a particular function length.

An End or End.X function does not map to a label value.

The **no** form of this command removes the label block name from the configuration.

Default

no label-block

Parameters

name

Specifies a reserved label block name, up to 64 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-s, 7950 XRS, VSR

label-block

Syntax

label-block *name*

no label-block

Context

[Tree] (conf>router>sr>srv6>ms>block label-block)

Full Context

configure router segment-routing segment-routing-v6 micro-segment block label-block

Description

This command associates a pre-configured reserved label block with the micro-SID block.

The **no** form of this command disassociates the reserved label block.

Default

no label-block

Parameters

name

Specifies a reserved label block name, up to 64 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-s, 7950 XRS, VSR

16.34 label-ipv4

label-ipv4

Syntax

label-ipv4 *max-paths* [**ebgp** *ebgp-max-paths*] [**ibgp** *ibgp-max-paths*] [**restrict** {**same-neighbor-as** | **exact-as-path**}] [**unequal-cost**]

no label-ipv4

Context

[Tree] (config>service>vprn>bgp>multi-path label-ipv4)

Full Context

configure service vprn bgp multi-path label-ipv4

Description

This command sets ECMP multipath parameters that apply only to the label unicast IPv4 address family.

When multipath is enabled, traffic to the destination is load-shared across a set of paths (BGP routes) that the BGP decision process considers equal to the best path. The distribution of traffic over the multiple paths may or may not be equal. The distribution is based on weights derived from the Link Bandwidth Extended Community.

For more information about the criteria a non-best route must meet to qualify as a multipath, see "BGP route installation in the route table" in the *7450 ESS 7750 SR 7950 XRS VSR Unicast Routing Protocols User Guide*.

The **no** form of this command removes label-IPv4-specific overrides.

Default

no label-ipv4

Parameters

max-paths

Specifies the maximum number of multipaths per prefix or NLRI. Setting this value to 1 disables multipath. This limit only applies if neither the *ebgp-max-paths* limit nor the *ibgp-max-paths* limit apply.

Values 1 to 64

ebgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an EBGP learned route. If the **ebgp** option is configured, this value overrides the *max-*

paths limit. If the best path is an EBGP learned route and this value is set to 1, multipath is disabled.

Values 1 to 64

ibgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an IBGP learned route. If the **ibgp** option is configured, this value overrides the *max-paths* limit. If the best path is an IBGP learned route and this value is set to 1, multipath is disabled.

Values 1 to 64

restrict same-neighbor-as

Specifies that the non-best path must have the same neighbor AS in its AS path as the best path.

restrict exact-as-path-as

Specifies that the non-best path must have the same AS path as the best path.

unequal-cost

Instructs BGP to ignore differences in the next-hop cost only when determining eligible multipaths.

Platforms

All

label-ipv4

Syntax

label-ipv4 send *send-limit*

label-ipv4 send *send-limit* **receive** [**none**]

[Tree] (config>router>bgp>group>add-paths label-ipv4)

[Tree] (config>router>bgp>group>neighbor>add-paths label-ipv4)

Full Context

configure router bgp add-paths label-ipv4

configure router bgp group add-paths label-ipv4

configure router bgp group neighbor add-paths label-ipv4

Description

This command configures the add-paths capability for labeled-unicast IPv4 routes. By default, add-paths is not enabled for labeled-unicast IPv4 routes.

The maximum number of labeled-unicast paths per IPv4 prefix to send is the configured *send-limit*, which is a mandatory parameter. The capability to receive multiple labeled-unicast paths per prefix from a peer is configurable using the **receive** keyword, which is optional. If the **receive** keyword is not included in the command, receive capability is enabled by default.

The **no** form of this command disables add-paths support for labeled-unicast IPv4 routes, causing sessions established using add-paths for labeled-unicast IPv4 to go down and come back up without the add-paths capability.

Default

no label-ipv4

Parameters

send-limit

Specifies the maximum number of paths per labeled-unicast IPv4 prefix that are allowed to be advertised to add-paths peers. (The actual number of advertised routes may be less.) If the value is none, the router does not negotiate the send capability with respect to label-IPv4 AFI/SAFI. If the value is **multipaths**, then BGP advertises all the used BGP multipaths for each IPv4 NLRI if the peer has signaled support to receive multiple add paths.

Values 1 to 16, none, multipaths

receive

Specifies the router negotiates to receive multiple labeled-unicast routes per IPv4 prefix.

none

Specifies that the router does not negotiate to receive multiple labeled-unicast routes per IPv4 prefix.

Platforms

All

label-ipv4

Syntax

label-ipv4 *max-paths* [**ebgp** *ebgp-max-paths*] [**ibgp** *ibgp-max-paths*] [**restrict** {**same-neighbor-as** | **exact-as-path**}] [**unequal-cost**]

no label-ipv4

Context

[Tree] (config>router>bgp>multi-path label-ipv4)

Full Context

configure router bgp multi-path label-ipv4

Description

This command sets ECMP multipath parameters that apply only to the label IPv4 unicast address family. These settings override the values set by the **maximum-paths** command.

When multipath is enabled, traffic to the destination is load-shared across a set of paths (BGP routes) that the BGP decision process considers equal to the best path. The actual distribution of traffic over the multiple paths may be equal or unequal (that is, based on weights derived from the Link Bandwidth Extended Community).

The **no** form of this command removes label-IPv4-specific overrides.

Default

no label-ipv4

Parameters

max-paths

Specifies the maximum number of multipaths per prefix/NLRI if *ebgp-max-paths* or *ibgp-max-paths* does not apply.

Values 1 to 64

ebgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an EBGP learned route.

Values 1 to 64

ibgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an IBGP learned route.

Values 1 to 64

restrict same-neighbor-as

Specifies that the non-best path must have the same neighbor AS in its AS path as the best path.

restrict exact-as-path

Specifies that the non-best path must have the same AS path as the best path.

unequal-cost

Instructs BGP to ignore differences in the next-hop cost only when determining eligible multipaths.

Platforms

16.35 label-ipv6

label-ipv6

Syntax

label-ipv6 *max-paths* [**ebgp** *ebgp-max-paths*] [**ibgp** *ibgp-max-paths*] [**restrict** {**same-neighbor-as** | **exact-as-path**}] [**unequal-cost**]

no label-ipv6

Context

[Tree] (config>service>vprn>bgp>multi-path label-ipv6)

Full Context

configure service vprn bgp multi-path label-ipv6

Description

This command sets ECMP multipath parameters that apply only to the label unicast IPv6 address family.

When multipath is enabled, traffic to the destination is load-shared across a set of paths (BGP routes) that the BGP decision process considers equal to the best path. The distribution of traffic over the multiple paths may or may not be equal. The distribution is based on weights derived from the Link Bandwidth Extended Community.

For more information about the criteria a non-best route must meet to qualify as a multipath, see "BGP route installation in the route table" in the *7450 ESS 7750 SR 7950 XRS VSR Unicast Routing Protocols User Guide*.

The **no** form of this command removes label-IPv6-specific overrides.

Default

no label-ipv6

Parameters

max-paths

Specifies the maximum number of multipaths per prefix or NLRI. Setting this value to 1 disables multipath. This limit only applies if neither the *ebgp-max-paths* limit nor the *ibgp-max-paths* limit apply.

Values 1 to 64

ebgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an EBGP learned route. If the **ebgp** option is configured, this value overrides the *max-paths* limit. If the best path is an EBGP learned route and this value is set to 1, multipath is disabled.

Values 1 to 64

ibgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an IBGP learned route. If the **ibgp** option is configured, this value overrides the *max-paths* limit. If the best path is an IBGP learned route and this value is set to 1, multipath is disabled.

Values 1 to 64

restrict same-neighbor-as

Specifies that the non-best path must have the same neighbor AS in its AS path as the best path.

restrict exact-as-path-as

Specifies that the non-best path must have the same AS path as the best path.

unequal-cost

Instructs BGP to ignore differences in the next-hop cost only when determining eligible multipaths.

Full Context

configure router bgp group neighbor add-paths label-ipv6

configure router bgp add-paths label-ipv6

configure router bgp group add-paths label-ipv6

Description

This command configures the add-paths capability for labeled-unicast IPv6 routes. By default, add-paths is not enabled for labeled-unicast IPv6 routes.

The maximum number of labeled-unicast paths per IPv6 prefix to send is the configured *send-limit*, which is a mandatory parameter. The capability to receive multiple labeled-unicast paths per prefix from a peer

is configurable using the **receive** keyword, which is optional. If the **receive** keyword is not included in the command, receive capability is enabled by default.

The **no** form of this command disables add-paths support for labeled-unicast IPv6 routes, causing sessions established using add-paths for labeled-unicast IPv6 to go down and come back up without the add-paths capability.

Default

no label-ipv6

Parameters

send-limit

Specifies the maximum number of paths per labeled-unicast IPv6 prefix that are allowed to be advertised to add-paths peers. (The actual number of advertised routes may be less.) If the value is none, the router does not negotiate the send capability with respect to label-IPv6 AFI/SAFI. If the value is **multipaths**, then BGP advertises all the used BGP multipaths for each IPv6 NLRI if the peer has signaled support to receive multiple add paths.

Values 1 to 16, none, multipaths

receive

Specifies that the router negotiates to receive multiple labeled-unicast routes per IPv6 prefix.

none

Specifies that the router does not negotiate to receive multiple labeled-unicast routes per IPv6 prefix.

Platforms

All

label-ipv6

Syntax

label-ipv6 *max-paths* [**ebgp** *ebgp-max-paths*] [**ibgp** *ibgp-max-paths*] [**restrict** {**same-neighbor-as** | **exact-as-path**}] [**unequal-cost**]

no label-ipv6

Context

[Tree] (config>router>bgp>multi-path label-ipv6)

Full Context

configure router bgp multi-path label-ipv6

Description

This command sets ECMP multipath parameters that apply only to the label unicast IPv6 address family. These settings override the values set by the **maximum-paths** command.

When multipath is enabled, traffic to the destination is load-shared across a set of paths (BGP routes) that the BGP decision process considers equal to the best path. The actual distribution of traffic over the multiple paths may be equal or unequal (that is, based on weights derived from the Link Bandwidth Extended Community).

The **no** form of this command removes label-IPv6-specific overrides.

Default

no label-ipv6

Parameters

max-paths

Specifies the maximum number of multipaths per prefix/NLRI if *ebgp-max-paths* or *ibgp-max-paths* does not apply.

Values 1 to 64

ebgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an EBGP learned route.

Values 1 to 64

ibgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an IBGP learned route.

Values 1 to 64

restrict same-neighbor-as

Specifies that the non-best path must have the same neighbor AS in its AS path as the best path.

restrict exact-as-path

Specifies that the non-best path must have the same AS path as the best path.

unequal-cost

Instructs BGP to ignore differences in the next-hop cost only when determining eligible multipaths.

Full Context

configure router bgp next-hop-resolution labeled-routes use-bgp-routes label-ipv6-explicit-null

Description

This command allows a labelled IPv6 route with the explicit-null label to be resolved by other labelled IPv6 routes with the explicit-null label, and also by unlabeled IPv4 routes and unlabeled IPv6 routes that are resolved by static routes, interface routes, or tunnels. Up to four levels of recursive resolution are supported when the top route is a labelled IPv6 route with an explicit-null label.

Regardless of setting, a labelled IPv6 route with a regular label (other than explicit-null) is never resolved by other labelled IPv6 routes.

The **no** form of this command disables the label-ipv6-explicit-null functionality. When disabled, a labeled IPv6 route cannot be resolved by other labeled IPv6 routes.

Default

no label-ipv6-explicit-null

Platforms

All

16.37 label-map

label-map

Syntax

[**no**] **label-map** *in-label*

Context

[Tree] (config>router>mpls>interface label-map)

Full Context

configure router mpls interface label-map

Description

This command is used on transit routers when a static LSP is defined. The static LSP on the ingress router is initiated using the **config router mpls static-lsp** *lsp-name* command. An *in-label* can be associated with either a **pop** or a **swap** action, but not both. If both actions are specified, the last action specified takes effect.

The **no** form of this command deletes the static LSP configuration associated with the *in-label*.

Parameters

in-label

Specifies the incoming MPLS label on which to match.

Values 32 to 1023

Platforms

All

16.38 label-mode

label-mode

Syntax

label-mode {**vrf** | **next-hop**}

no label-mode

Context

[Tree] (config>service>vprn label-mode)

Full Context

configure service vprn label-mode

Description

This command controls the method by which service labels are allocated to routes exported by the VPRN as BGP-VPN routes. The **vrf** option selects service label per VRF mode while the **next-hop** option selects service label per next-hop mode.

The **no** form of this command sets the mode to the default mode of service label per VRF.

Default

no label-mode

Parameters

vrf

Selects service label per VRF mode.

next-hop

Selects service label per next-hop mode.

Full Context

configure service vprn bgp label-preference

configure service vprn bgp group neighbor label-preference

configure service vprn bgp group label-preference

Description

This command configures the route preference for routes learned from labeled-unicast peers.

This command can be configured at three levels:

- Global level — applies to all peers
- Group level — applies to all peers in the peer-group
- Neighbor level — applies only to the specified peer

The most specific value is used.

The lower the preference, the higher the chance of the route being the active route.

The **no** form of this command used at the global level reverts to the default *value* of 170.

The **no** form of this command used at the group level reverts to the *value* defined at the global level.

The **no** form of this command used at the neighbor level reverts to the *value* defined at the group level.

Default

no label-preference

Parameters

configure router bgp group label-preference

configure router bgp group neighbor label-preference

Description

This command configures the route preference for routes learned from labeled-unicast peers.

This command can be configured at three levels:

- Global level — applies to all peers
- Group level — applies to all peers in the peer-group
- Neighbor level — applies only to the specified peer

The most specific value is used.

The lower the preference, the higher the chance of the route being the active route.

The **no** form of this command used at the global level reverts to the default *value* of 170.

The **no** form of this command used at the group level reverts to the value defined at the global level.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Default

no label-preference

Parameters

value

Specifies the route preference value.

Values 1 to 255

Platforms

All

16.40 label-route-local

label-route-local

Syntax

label-route-local [{**none** | **all**}]

Context

[Tree] (config>router>ttl-propagate label-route-local)

Full Context

configure router ttl-propagate label-route-local

Description

This command configures the TTL propagation for locally generated packets which are forwarded over a BGP label route in the Global Routing Table (GRT) context.

For IPv4 and IPv6 packets forwarded using an RFC 8277 label route in the global routing instance, including 6PE, the all value of the command enables TTL propagation from the IP header into all labels in the transport label stack. The none value reverts to the default mode which disables TTL propagation from the IP header to the labels in the transport label stack. This command does not have a no version.

The TTL of the IP packet is always propagated into the RFC 8277 label itself, and this command only controls the propagation into the transport labels, for example, labels of the RSVP or LDP LSP to which the BGP label route resolves and which are pushed on top of the BGP label.

If the BGP peer advertised the implicit-null label value for the BGP label route, the TTL propagation will not follow the configuration described, but will follow the configuration to which the BGP label route resolves:

RSVP LSP shortcut:

- configure router mpls shortcut-local-ttl-propagate

LDP LSP shortcut:

- configure router ldp shortcut-local-ttl-propagate

This feature does not impact packets forwarded over BGP shortcuts. The ingress LER operates in uniform mode by default and can be changed into pipe mode using the configuration of TTL propagation for RSVP or LDP LSP shortcut listed.

Default

label-route-local none

Parameters

none

Specifies that the TTL of the IP packet is not propagated into the transport label stack.

all

Specifies that the TTL of the IP packet is propagated into all labels of the transport label stack.

Platforms

All

16.41 label-route-transit

label-route-transit

Syntax

label-route-transit [{**none** | **all**}]

Context

[Tree] (config>router>ttl-propagate label-route-transit)

Full Context

configure router ttl-propagate label-route-transit

Description

This command configures the TTL propagation for transit packets which are forwarded over a BGP label route in the Global Routing Table (GRT) context.

For IPv4 and IPv6 packets forwarded using a RFC 8277 label route in the global routing instance, including 6PE, the all value of the command enables TTL propagation from the IP header into all labels in the transport label stack. The none value reverts to the default mode which disables TTL propagation from the IP header to the labels in the transport label stack. This command does not have a no version.

The TTL of the IP packet is always propagated into the RFC 8277 label itself, and this command only controls the propagation into the transport labels, for example, labels of the RSVP or LDP LSP to which the BGP label route resolves and which are pushed on top of the BGP label.

If the BGP peer advertised the implicit-null label value for the BGP label route, the TTL propagation will not follow the configuration described, but will follow the configuration to which the BGP label route resolves.

RSVP LSP shortcut:

- configure router mpls shortcut-transit-ttl-propagate

LDP LSP shortcut:

- configure router ldp shortcut-transit-ttl-propagate

This feature does not impact packets forwarded over BGP shortcuts. The ingress LER operates in uniform mode by default and can be changed into pipe mode using the configuration of TTL propagation for the listed RSVP or LDP LSP shortcut.

Default

label-route-transit none

Parameters

none

Specifies that the TTL of the IP packet is not propagated into the transport label stack.

all

Specifies that the TTL of the IP packet is propagated into all labels of the transport label stack.

Platforms

configure system ip mpls label-stack-statistics-count

Description

This command enables the system to collect traffic statistics on the specified number of labels of the MPLS label stack.

The **no** form of this command disables the collecting of traffic statistics.

Default

label-stack-statistics-count 1

Parameters

label-stack-statistics-count

Specifies the number of labels on which the system can collect statistics.

Values 1, 2

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

16.44 label-withdrawal-delay

label-withdrawal-delay

Syntax

label-withdrawal-delay *seconds*

no label-withdrawal-delay

Context

[Tree] (config>router>ldp label-withdrawal-delay)

Full Context

configure router ldp label-withdrawal-delay

Description

This command specifies configures the time interval (in s), LDP will delay for the withdrawal of FEC-label binding it distributed to its neighbors when FEC is de-activated. When the timer expires, LDP then sends a label withdrawal for the FEC to all its neighbors. This is applicable only to LDP IPv4 prefix FECs and is not applicable to pseudowires (service FECs).

When there is an upper layer (user of LDP) which depends of LDP control plane for failover detection then label withdrawal delay and tunnel-down-damp-time options must be set to 0.

An example is PW redundancy where the primary PW doesn't have its own fast failover detection mechanism and the node depends on LDP tunnel down event to activate the standby PW.

Default

no label-withdrawal-delay

Parameters

seconds

Specifies the time that LDP delays the withdrawal of FEC-label binding it distributed to its neighbors when FEC is de-activated.

Values 3 to 120

Platforms

All

no lacp

Context

[Tree] (config>lag lacp)

Full Context

configure lag lacp

Description

This command enables the LACP protocol. Per the IEEE 802.1ax standard, the Link Aggregation Control Protocol (LACP) provides a standardized means for exchanging information between Partner Systems on a link to allow their Link Aggregation Control instances to reach agreement on the identity of the Link Aggregation Group to which the link belongs, move the link to that Link Aggregation Group, and enable its transmission and reception functions in an orderly manner.

If any of the parameters are omitted, the existing configuration is preserved. The default parameter values are used if a parameter is never explicitly configured.

Default

no lacp

Parameters

mode

Specifies the mode in which LACP will operate.

Values **passive** — Starts transmitting LACP packets only after receiving packets.

active — Initiates the transmission of LACP packets.

admin-key

Specifies an administrative key value to identify the channel group on each port configured to use LACP. A random key is assigned by default if a value is not specified when using classic CLI only.

Values 1 to 65535

system-id

Specifies the 48-bit system ID in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff, where aa, bb, cc, dd, ee and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.

Values 1 to 65535

Default 32768

priority

Specifies the system priority.

Values 0 to 65535

Default 32768

no lag *lag-id*

Context

[Tree] (config>redundancy>multi-chassis>peer>mc-lag lag)

Full Context

configure redundancy multi-chassis peer mc-lag lag

Description

This command defines a LAG which is forming a redundant-pair for MC-LAG with a LAG configured on the given peer. The same LAG group can be defined only in the scope of 1 peer. In order MC-LAG to become operational, all parameters (**lacp-key**, **system-id**, **system-priority**) must be configured the same on both nodes of the same redundant pair.

The partner system (the system connected to all links forming MC-LAG) will consider all ports using the same **lacp-key**, **system-id**, **system-priority** as the part of the same LAG. In order to achieve this in MC operation, both redundant-pair nodes have to be configured with the same values. In case of the mismatch, MC-LAG is kept in oper-down status.

Note that the correct CLI command to enable MC LAG for a LAG in **standby-signaling power-off mode** is **lag** *lag-id* [**remote-lag** *remote-lag-id*]. In the CLI help output, the first three forms are used to enable MC LAG for a LAG in LACP mode. MC LAG is disabled (regardless of the mode) for a given LAG with **no lag** *lag-id.*

Parameters

lag-id

The LAG identifier, expressed as an integer. Specifying the *lag-id* allows the mismatch between lag-id on redundant-pair. If no **lag-id** is specified it is assumed that neighbor system uses the same *lag-id* as a part of the specific MC-LAG. If no matching MC-LAG group can be found between neighbor systems, the individual LAGs operates as usual (no MC-LAG operation is established).

Values 1 to 800

admin-key

Specifies a 16 bit key that needs to be configured in the same manner on both sides of the MC-LAG in order for the MC-LAG to come up.

Values 1 to 65535

system-id

Specifies a 6 byte value expressed in the same notation as MAC address.

Values xx:xx:xx:xx:xx:xx - xx [00 to FF]

remote-lag-id

Specifies the LAG ID on the remote system.

Values 1 to 800

system-priority

Specifies the system priority to be used in the context of the MC-LAG. The partner system will consider all ports using the same **lacp-key**, **system-id**, and **system-priority** as part of the same LAG.

Values 1 to 65535

MAC-Lsb

Configures the last 16 bit of the MAC address to be used for all traffic ingressing the MC-LAG link(s) or if use-lacp-key option is used, it will only copy the value of lacp-key (redundancy multi-chassis mc-lag lag lacp-key admin-key). The command will fail if the *value* is the same with any of the following configured attributes:

- Source-bmac-lsb assigned to other MC-LAG ports.
- lsb 16 bits value for the source-bmac configured at chassis or BVPLS level

  The first 32 bits will be copied from the source B-MAC of the BVPLS associated with the IVPLS for a specific IVPLS SAP mapped to the MC-LAG. The BVPLS source B-MAC can be provisioned for each BVPLS or can be inherited from the chassis PBB configuration.

  Values 1 to 65535 or xx-xx or xx:xx

Platforms

All

lag

Syntax

lag *lag-id* [**name** *lag-name*]

no lag *lag-id*

Context

[Tree] (config lag)

Full Context

configure lag

Description

Commands in this context configure Link Aggregation Group (LAG) attributes.

A LAG is used to group multiple ports into one logical link. The aggregation of multiple physical links allows for load sharing and offers seamless redundancy. If one link fails, traffic is redistributed over the remaining links.

Note:
For all ports in a LAG group, autonegotiation must be set to "limited" or "off".

There are three possible settings for autonegotiation, as follows:

- "on" or enabled with full port capabilities advertised
- "off" or disabled where there is no autonegotiation advertisements
- "limited" where a single speed/duplex is advertised.

When autonegotiation is enabled on a port, the link attempts to automatically negotiate the link speed and duplex parameters; the configured duplex and speed parameters are ignored.

When autonegotiation is disabled on a port, the port does not attempt to autonegotiate and will only operate at the **speed** and **duplex** settings configured for the port.

Note:
Disabling autonegotiation on gigabit ports is not allowed. This is in accordance with the IEEE 802.3 specification for gigabit Ethernet, which requires gigabyte to be enabled for far end fault indication.

If the **config>port>ethernet autonegotiate limited** keyword option is specified, the port will autonegotiate but only advertise the **speed** and **duplex** settings configured for the port. Use the **limited** mode on multi-speed gigabit ports to force gigabit operation while keeping autonegotiation is enabled for compliance with IEEE 801.3.

The system requires autonegotiation to be disabled or limited for ports in a LAG to guarantee a specific port speed.

The **no** form of this command deletes the LAG from the configuration. A LAG can only be deleted while the LAG is administratively shut down. Any dependencies, such as IP-Interface configurations, must be removed from the configuration before the **no lag** command is issued.

Parameters

lag-id

Specifies the LAG identifier, expressed as an integer.

The LAG ID ranging from 1 to 64 supports up to 64 LAG members and LAG ID above 64 supports 32 LAG members.

Values 1 to 800

lag-name

Specifies an optional LAG name, up to 27 characters.

In model-driven interfaces, the LAG name is used for configuration references and **show** commands. A service provider or administrator can use the defined LAG name to identify and manage LAGs within the SR OS platforms.

In the classic CLI interface, the user must assign a LAG ID to create the LAG. The LAG name is optional and, if specified, must always start with "lag-". If a name is not specified, SR OS automatically assigns a string version of the LAG ID as "lag-<lag-id>".

Values lag-<23 chars max>

debug lag

Description

This command enables debugging for LAG.

Parameters

lag-id

Specifies the link aggregation group ID.

Values 1 to 800

port-id

Specifies the physical port ID.

Values *slot*/*mda*/*port*

all

Specifies to display all LAG information.

sm

Specifies to display trace LACP state machine.

pkt

Specifies to display trace LACP packets.

cfg

Specifies to display trace LAG configuration.

red

Specifies to display trace LAG high availability.

iom-upd

Specifies to display trace LAG IOM updates.

port-state

Specifies to display trace LAG port state transitions.

timers

Specifies to display trace LAG timers.

sel-logic

Specifies to display trace LACP selection logic.

mc

Specifies to display multi-chassis parameters.

mc-packet

Specifies to display the MC-LAG control packets with valid authentication were received on this system.

Context

[Tree] (config>service>system>bgp-evpn>eth-seg lag)

Full Context

configure service system bgp-evpn ethernet-segment lag

Description

This command configures a LAG ID associated with the Ethernet-Segment. When the Ethernet-Segment is configured as **all-active,** then only a lag or PW port can be associated with the Ethernet-Segment. When the Ethernet-Segment is configured as **single-active**, then a lag, port or sdp can be associated to the Ethernet-Segment. In either case, only one of the four objects can be configured in the Ethernet-Segment. A specified lag can be part of only one Ethernet-Segment.

Default

no lag

Parameters

lag-id

Specifies the lag-id associated with the Ethernet-Segment.

Values 1 to 800

Platforms

Full Context

configure router mcac policy bundle mc-constraints lag-port-down

Description

This command configures the bandwidth available both at the interface and bundle level when a specific number of ports in a LAG group fail.

The **no** form of this command removes the values from the configuration.

Parameters

lag-id

Specifies the LAG ID. When the number of ports available in the LAG link is reduced by the number of ports configured in this context then the *level-id* specified here must be applied.

number-lag-port-down

If the number of ports available in the LAG is reduced by the number of ports configured in this command here then bandwidth allowed for bundle and/or interface will be as per the levels configured in this context.

Values 1 to 64 (for 64-link LAG) 1 to 32 (for other LAGs)

level-id

Specifies the amount of bandwidth available within a given bundle for MC traffic for a specified level.

Values 1 to 8

Syntax

[**no**] **lag-port-down** *lag-id*

Context

[Tree] (config>vrrp>policy>priority-event lag-port-down)

Full Context

configure vrrp policy priority-event lag-port-down

Description

This command creates the context to configure Link Aggregation Group (LAG) priority control events that monitor the operational state of the links in the LAG.

The **lag-port-down** command configures a priority control event. The event monitors the operational state of each port in the specified LAG. When one or more of the ports enter the operational down state, the event is considered to be set. When all the ports enter the operational up state, the event is considered to be clear. As ports enter the operational up state, any previous set threshold that represents more down ports is considered cleared, while the event is considered to be set.

Multiple unique **lag-port-down** event nodes can be configured within the **priority-event** node up to the maximum of 32 events.

The **lag-port-down** command can reference an arbitrary LAG. The *lag-id* does have to already exist within the system. The operational state of the **lag-port-down** event will indicate:

- Set – non-existent
- Set – one port down
- Set – two ports down
- Set – three ports down
- Set – four ports down
- Set – five ports down
- Set – six ports down
- Set – seven ports down
- Set – eight ports down
- Cleared – all ports up

When the *lag-id* is created, or a port in *lag-id* becomes operationally up or down, the event operational state must be updated appropriately.

When one or more of the LAG composite ports enters the operationally down state or the *lag-id* is deleted or does not exist, the event is considered to be set. When an event transitions from clear to set, the set is processed immediately and must be reflected in the associated virtual router instances in-use priority value. As the event transitions from clear to set, a hold-set timer is loaded with the value configured by the events **hold-set** command. This timer prevents the event from clearing until it expires, damping the effect of event flapping. If the event clears and becomes set again before the hold-set timer expires, the timer is reset to the **hold-set** value, extending the time before another clear can take effect.

The **lag-port-down** event is considered to have a tiered event set state. While the priority impact per number of ports down is totally configurable, as more ports go down, the effect on the associated virtual router instances in-use priority is expected to increase (lowering the priority). When each configured threshold is crossed, any higher thresholds are considered further event sets and are processed immediately with the hold-set timer reset to the configured value of the **hold-set** command. As the thresholds are crossed in the opposite direction (fewer ports down then previously), the priority effect of the event is not processed until the hold-set timer expires. If the number of ports down threshold again increases before the hold-set timer expires, the timer is only reset to the **hold-set**value if the number of ports down is equal to or greater than the threshold that set the timer.

The event contains **number-down** nodes that define the priority delta or explicit value to be used based on the number of LAG composite ports that are in the operationally down state. These nodes represent the event set thresholds. Not all port down thresholds must be configured. As the number of down ports increase, the **number-down** *ports-down* node that expresses a value equal to or less than the number of down ports describes the delta or explicit priority value to be applied.

The **no** form of the command deletes the specific LAG monitoring event. The event can be removed at anytime. When the event is removed, the in-use priority of all associated virtual router instances must be reevaluated. The events **hold-set** timer has no effect on the removal procedure.

Default

no lag-port-down — No LAG priority control events are created.

Parameters

lag-id

The LAG ID that the specific event is to monitor expressed as a decimal integer. The *lag-id* can only be monitored by a single event in this policy. The LAG may be monitored by multiple VRRP priority control policies. A port within the LAG and the LAG ID itself are considered to be separate entities. A composite port may be monitored with the **port-down** event while the *lag-id* the port is in is monitored by a **lag-port-down** event in the same policy.

Values 1 to 800 (apply to the 7750 SR and 7950 XRS)
1 to 200 (apply to the 7450 ESS)

Platforms

All

16.58 lag-usage-optimization

lag-usage-optimization

Syntax

[**no**] **lag-usage-optimization**

Context

[Tree] (config>router>pim lag-usage-optimization)

Full Context

configure router pim lag-usage-optimization

Description

This command enables the router's usage of the LAG so traffic for a given multicast stream destined to an IP interface using the LAG is sent only to the forwarding complex that owns the LAG link on which it will actually be forwarded.

Changing the value causes the PIM protocol to be restarted.

If this optimization is disabled, the traffic is sent to all forwarding complexes that own at least one link in the LAG.

The **no** form of this command causes the traffic to be sent to all the forwarding complexes that own at least one link in the LAG.

Note:
Changes made for multicast hashing cause Layer 4 multicast traffic to not be hashed. This is independent of if **lag-usage-optimization** is enabled or disabled.

Using this command and the **mc-ecmp-hashing-enabled** command on mixed port speed LAGs is not recommended, because some groups may be forwarded incorrectly.

Default

no lag-usage-optimization

configure service vpls mesh-sdp mld-snooping last-member-query-interval

configure service vpls sap mld-snooping last-member-query-interval

configure service vpls spoke-sdp igmp-snooping last-member-query-interval

Description

This command configures the maximum response time used in group-specific queries sent in response to 'leave' messages, and is also the amount of time between two consecutive group-specific queries. This value may be tuned to modify the leave latency of the network. A reduced value results in reduced time to detect the loss of the last member of a group.

The configured **last-member-query-interval** is ignored when fast leave is enabled on the SAP or SDP.

The **no** form of this command reverts to the default value.

Default

last-member-query-interval 10

Parameters

tenths-of-seconds

Specifies the frequency, in tenths of a second, at which query messages are sent.

Values 1 to 50

configure subscriber-mgmt msap-policy vpls-only-sap-parameters igmp-snooping last-member-query-interval

Description

This command configures the maximum response time used in group-specific queries sent in response to leave messages, and is also the amount of time between two consecutive group-specific queries. This value may be tuned to modify the leave latency of the network. A reduced value results in reduced time to detect the loss of the last member of a group.

The configured interval is ignored when fast-leave is enabled on the SAP or SDP.

The **no** form of this command reverts to the default.

Default

last-member-query-interval 10

Parameters

seconds

Specifies the frequency, in tenths of seconds, at which query messages are sent.

Values 1 to 50

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

last-member-query-interval

Syntax

last-member-query-interval *interval*

no last-member-query-interval

Context

[Tree] (config>service>pw-template>igmp-snooping last-member-query-interval)

Full Context

configure service pw-template igmp-snooping last-member-query-interval

Description

This command configures the maximum response time used in group-specific queries sent in response to 'leave' messages, and is also the amount of time between 2 consecutive group-specific queries. This value may be tuned to modify the leave latency of the network. A reduced value results in reduced time to detect the loss of the last member of a group.

The configured last-member-query-interval is ignored when fast-leave is enabled on the SAP or SDP.

Default

last-member-query-interval 10

Parameters

interval

Specifies the frequency, in tenths of seconds, at which query messages are sent.

Values 1 to 50

Platforms

All

16.66 last-reported-delay-hold

last-reported-delay-hold

Syntax

last-reported-delay-hold *seconds*

no last-reported-delay-hold

Context

[Tree] (config>test-oam>link-meas>template last-reported-delay-hold)

Full Context

configure test-oam link-measurement measurement-template last-reported-delay-hold

Description

This command configures the timer that specifies the wait time before the last reported delay measurement is flushed after a link measurement test enters the operationally down state. The aging timer delays the flushing of the last reported delay metric to the routing engine.

This timer starts a countdown to zero when an administrative function causes the operational state of the test on that specific interface to transition from up to down. If the timer expires before the operational state

transitions to up, the previously reported value is flushed. The Delay Measurement Last Reported indicates "Cleared". The timestamp indicates the time of the clear event. The Triggered By indicates "Expired". If the administrative state recovers to operationally up before the expiration of the timer, the previous reported value is not flushed.

The aging timer does not apply to failure conditions that do not affect the administrative state of the interface, for example interface failure or routing changes.

The **no** form of this command reverts to the default value.

Default

last-reported-delay-hold 86400

Parameters

seconds

Specifies the delay measurement retention time, in seconds, after the interface on which it was collected is administratively disabled. If the configured value is reached, the last reported measurement is cleared.

A configured value of 0 indicates that the previous reported value is cleared without additional wait time.

Values 0 to 86400

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

16.67 latency-event

latency-event

Syntax

latency-event rising-threshold *threshold* [**falling-threshold** *threshold*] [*direction*]

no latency-event

Context

[Tree] (config>saa>test latency-event)

Full Context

configure saa test latency-event

Description

Specifies that at the termination of an SAA test probe, the calculated latency event value is evaluated against the configured rising and falling latency event thresholds. SAA threshold events are generated as required.

Once the threshold (rising/falling) is crossed, it is disabled from generating additional events until the opposite threshold is crossed. If a **falling-threshold** is not supplied, the **rising- threshold** is re-enabled when it falls below the threshold after the initial crossing that generated the event.

The configuration of latency event thresholds is optional.

The **no** form of this command disables the latency event.

Parameters

rising-threshold *threshold*

Specifies a rising threshold latency value, in milliseconds. When the test run is completed, the calculated latency value is compared to the configured latency rising threshold. If the test run latency value is greater than the configured rising threshold value then an SAA threshold event is generated. The SAA threshold event is tmnxOamSaaThreshold, logger application OAM, event #2101.

Values 0 to 2147483

Default 0

falling-threshold *threshold*

Specifies a falling threshold latency value, in milliseconds. When the test run is completed, the calculated latency value is compared to the configured latency falling threshold. If the test run latency value is greater than the configured falling threshold value then an SAA threshold event is generated. The SAA threshold event is tmnxOamSaaThreshold, logger application OAM, event #2101.

Values 0 to 2147483

Default 0

direction

Specifies the direction for OAM ping responses received for an OAM ping test run.

Values **inbound** — Monitor the value of jitter calculated for the inbound, one-way, OAM ping responses received for an OAM ping test run.

outbound — Monitor the value of jitter calculated for the outbound, one-way, OAM ping requests sent for an OAM ping test run.

roundtrip — Monitor the value of jitter calculated for the round trip, two-way, OAM ping requests and replies for an OAM ping test run.

Default roundtrip

Full Context

configure mirror mirror-dest encap layer-3-encap

Description

This command specifies the format of the routable encapsulation to add to each copied packet. Layer 3 encapsulation takes precedence over Ethernet encapsulation configuration in an LI source. No changes are allowed to the Layer 3 encapsulation once a gateway is configured.

The **no** form of this command removes the routable encapsulation.

Default

no layer-3-encap

Parameters

ip-udp-shim

Specifies that the type of Layer 3 encapsulation is an IPv4 header, UDP header, and LI shim header added to the mirrored packets.

ip-gre

Specifies that the type of Layer 3 encapsulation is an IPv4 header and GRE header added to the mirrored packets. This encapsulation type is only supported with *mirror-type ip-only*.

ip-udp-shim-sampled

Specifies that the type of Layer 3 encapsulation is an IPv4 header, UDP header, and a mirror shim header added to the mirrored packets providing direction, mirror type, filter action, interface type, and interface value.

create

Creates a Layer 3 encapsulation.

configure service epipe sap eth-cfm mep lbm-svc-act-responder

configure service epipe spoke-sdp eth-cfm mep lbm-svc-act-responder

Description

This command enables the MEP to process service activation streams encapsulated in ETH-CFM LBM frames that are directed to the MEP. The MEP will be allocated additional resources to rapidly respond to a high-speed stream of LBM messages.

A MEP created with this option will not validate any TLVs, will not validate the ETH-LBM MAC Address, and will not increment or compute any loopback statistics. Statistical computation and reporting is the responsibility of the test head-end. The ETH-CFM level of the high speed ETH-LBM stream must match the level of a MEP configured with this command. The high-speed stream must not target an ETH-CFM level that is not explicitly configured with this option. MEPs act as boundaries for lower levels, below the configured MEP level values. Those boundary levels do not inherit this function.

When the service activation test is complete, the MEP may be returned to standard processing by removing this command. If there is available bandwidth, the MEP will respond to other ETH-CFM PDUs, such as ETH-DMM marker packets, using standard processing.

The interaction between this command and the **tools perform service id** *service-id* **loopback eth** command must be carefully considered. It is recommended that either the **lbm-svc-act-responder** or the **tools perform service id** *service-id* **loopback eth** command be used at any given time within a service. If both commands must be configured, and the target reflection point is the MAC Swap Loopback function, the inbound stream of data must not include ETH-CFM traffic that is equal to or lower than the domain level of any configured MEP which would otherwise extract and process the ETH-CFM message. If the reflection target is a MEP configured with the **lbm-svc-act-responder** option, the mode (ingress or egress) of the SAP or SDP specified with this tools command and the MEP **direction** (up or down) must match when the functions are enabled on the same reflection point, and the domain level of the inbound ETH-LBM must be the same as that of the MEP configured with the **lbm-svc-act-responder** option. At no time should the two functions be conflicting with each other along the path of the stream. This conflict would lead to unpredictable and possibly destabilizing situations.

The **no** form of this command reverts to MEP LBM standard processing.

Default

no lbm-svc-act-responder

Context

[Tree] (config>port>tdm lbo)

Full Context

configure port tdm lbo

Description

This command applies only to a DS-1 port configured with a 'long' buildout (see the **buildout** command). Specify the number of decibels the transmission signal decreases over the line.

For 'short' buildout the following values are valid:

lboNotApplicable — Not applicable

For 'long' buildout the following values are valid:

lbo0dB	For 0 dB
lboNeg7p5dB	For -7.5 dB
lboNeg15p0dB	For -15.0 dB
lboNeg22p5dB	For -22.5 dB

The default for 'short' build out is 'NotApplicable' while the default for 'long' buildout is 'lbo0dB'.

configure router l2tp group ppp lcp-force-ack-accm

configure router l2tp group tunnel ppp lcp-force-ack-accm

configure service vprn l2tp group ppp lcp-force-ack-accm

Description

This command enables the LCP Asynchronous Control Character Map (ACCM) configuration option. When enabled, the LCP ACCM configuration option is acknowledged during LCP negotiation between the LNS and the PPP client. The option is then ignored and no ACCM mapping is done.

By default, an L2TP tunnel inherits the configuration from the L2TP group CLI context.

The **no** form of this command disables the LCP ACCM configuration option.

Parameters

always

Specifies to acknowledge the LCP ACCM configuration option, but not to perform ACCM mapping. This option overrides the group level configuration.

never

Specifies to reject the LCP ACCM configuration option. This option overrides the group level configuration.

Context

[Tree] (config>service>sdp ldp)

Full Context

configure service sdp ldp

Description

This command enables LDP-signaled LSPs on MPLS-encapsulated SDPs.

In MPLS SDP configurations *either* one or more LSP names can be specified *or* LDP can be enabled. The SDP **ldp** and **lsp** commands are mutually exclusive except if the mixed-lsp-mode option is also enabled. If an LSP is specified on an MPLS SDP, then LDP cannot be enabled on the SDP. To enable LDP on the SDP when an LSP is already specified, the LSP must be removed from the configuration using the **no lsp** *lsp-name* command or the mixed-lsp-mode option is also enabled.

Alternatively, if LDP is already enabled on an MPLS SDP, then an LSP cannot be specified on the SDP. To specify an LSP on the SDP, the LDP must be disabled. The LSP must have already been created in the **config>router>mpls** context with a valid far-end IP address. The above rules are relaxed when the **mixed-lsp** option is enabled on the SDP.

Default

Full Context

configure router mpls lsp ldp-over-rsvp

configure router mpls lsp-template ldp-over-rsvp

Description

This command configures an LSP so that it can be used by the IGP to calculate its SPF tree.

When the **ldp-over-rsvp** option is also enabled in ISIS or OSPF, the IGP provides LDP with all ECMP IP next-hops and tunnel endpoints that it considers to be the lowest cost path to its destination.

IGP provides only the endpoints which are the closest to the destination in terms of IGP cost for each IP next-hop of a prefix. If this results in more endpoints than the ECMP value configured on the router, it will further prune the endpoints based on the lowest router-id and for the same router-id, it will select lowest interface-index first.

LDP then looks up the tunnel table to select the actual tunnels to the endpoint provided by IGP and further limits the endpoint selection to the ones which are the closest to destination across all the IP next-hops provided by IGP for a prefix. For each remaining endpoint, LDP selects a tunnel in a round-robin fashion until the router ECMP value is reached. For each endpoint, only tunnels with the same lowest metric are candidates. If more than one tunnel qualifies, the selection begins with the lowest tunnel-id.

[Tree] (config>router ldp-shortcut)

Full Context

configure router ldp-shortcut

Description

This command enables the resolution of IGP routes using LDP LSP across all network interfaces participating in the IS-IS and OSPF routing protocol in the system.

When LDP shortcut is enabled, LDP populates the routing table with next-hop entries corresponding to all prefixes for which it activated an LDP FEC. For a given prefix, two route entries are populated in the system routing table. One corresponds to the LDP shortcut next-hop and has an owner of LDP. The other one is the regular IP next-hop. The LDP shortcut next-hop always has preference over the regular IP next-hop for forwarding user packets and specified control packets over a given outgoing interface to the route next-hop.

All user and specified control packets for which the longest prefix match in RTM yields the FEC prefix will be forwarded over the LDP LSP.

When an IPv4 packet is received on an ingress network interface, a subscriber IES interface, or a regular IES interface, the lookup of the packet by the ingress forwarding engine will result in the packet being sent labeled with the label stack corresponding to the NHLFE of the LDP LSP when the preferred RTM entry corresponds to an LDP shortcut.

If the preferred RTM entry corresponds to an IP next-hop, the IPv4 packet is forwarded without a label.

When ECMP is enabled and multiple equal-cost next-hops exit for the IGP route, the ingress forwarding engine will spray the packets for this route based on hashing routine currently supported for IPv4 packets. When the preferred RTM entry corresponds to an LDP shortcut route, spraying will be performed across the multiple next-hops for the LDP FEC. The FEC next-hops can either be direct link LDP neighbors or T-LDP neighbors reachable over RSVP LSPs in the case of LDP-over-RSVP but not both.

When the preferred RTM entry corresponds to a regular IP route, spraying will be performed across regular IP next-hops for the prefix.

The **no** form of this command disables the resolution of IGP routes using LDP shortcuts.

16.81 ldp-sync

ldp-sync

Syntax

[**no**] **ldp-sync**

Context

[Tree] (config>service>vprn>static-route-entry>indirect ldp-sync)

Full Context

configure service vprn static-route-entry indirect ldp-sync

Description

This command extends the LDP synchronization feature to a static route. When an interface comes back up, it is possible that a preferred static route using the interface as next-hop for a given prefix is enabled before the LDP adjacency to the peer LSR comes up on this interface. In this case, traffic on an SDP that uses the static route for the far-end address would be black-holed until the LDP session comes up and the FECs exchanged.

This option when enabled delays the activation of the static route until the LDP session comes up over the interface and the ldp-sync-timer configured on that interface has expired

Default

no ldp-sync

ldp-sync-timer *seconds* [**end-of-lib**]

no ldp-sync-timer

Context

[Tree] (config>router>if ldp-sync-timer)

Full Context

configure router interface ldp-sync-timer

Description

This command enables synchronization of an IGP and LDP. When a link is restored after a failure, the IGP sets the link cost to infinity and advertises it. The actual value advertised in OSPF is 0xFFFF (65535). The actual value advertised in IS-IS regular metric is 0x3F (63) and in IS-IS wide-metric is 0xFFFFFE (16777214). This feature is not supported on RIP interfaces.

If an interface belongs to both IS-IS and OSPF, a physical failure will cause both IGPs to advertise an infinite metric and to follow the IGP-LDP synchronization procedures. If only one IGP bounces on this interface or on the system, then only the affected IGP advertises the infinite metric and follows the IGP-LDP synchronization procedures.

Next, an LDP Hello adjacency is brought up with the neighbor. The LDP synchronization timer is started by the IGP when the LDP session to the neighbor is up over the interface. This is to allow time for the label-FEC bindings to be exchanged.

When the LDP synchronization timer expires, the link cost is restored and is readvertised. The IGP will announce a new best next hop and LDP will use it if the label binding for the neighbor's FEC is available.

If the user changes the cost of an interface, the new value is advertised at the next flooding of link attributes by the IGP. However, if the LDP synchronization timer is still running, the new cost value will only be advertised after the timer expires. The new cost value will also be advertised after the user executes any of the following commands:

- **tools>perform>router>isis>ldp-sync-exit**
- **tools>perform>router>ospf>ldp-sync-exit**
- **config>router>if>no ldp-sync-timer**
- **config>router>ospf>disable-ldp-sync**
- **router>isis>disable-ldp-sync**

If the user changes the value of the LDP synchronization timer parameter, the new value will take effect at the next synchronization event. If the timer is still running, it will continue to use the previous value.

If parallel links exist to the same neighbor, then the bindings and services should remain up as long as there is one interface that is up. However, the user-configured LDP synchronization timer still applies on the interface that failed and was restored. In this case, the router will only consider this interface for forwarding after the IGP re-advertises its actual cost value.

The LDP Sync Timer State is not always synchronized across to the standby CPM. Therefore, after an activity switch, the timer state might not be same as it was on the previously active CPM.

If the **end-of-lib** option is configured, then the system will start the LDP synchronization timer as usual. If the LDP End of LIB Typed Wildcard FEC messages are received for every FEC type negotiated for a given session to an LDP peer for that IGP interface, the **ldp-sync-timer** is terminated early and the IGP link cost is restored. If the **ldp-sync-timer** expires before the LDP End of LIB messages are received for

every negotiated FEC type, then the system will restore the IGP link cost. The **end-of-lib** option is disabled by default.

The **no** form of this command disables IGP-LDP synchronization and deletes the configuration.

Default

no ldp-sync-timer

Parameters

seconds

Specifies the time interval for the IGP-LDP synchronization timer.

Values 1 to 1800

end-of-lib

Specifies that the system should terminate the **ldp-sync-timer** early if the LDP End of LIB Typed Wildcard FEC messages are received for every FEC type negotiated for a given session to an LDP peer for that IGP interface.

16.83 ldp-treetrace

ldp-treetrace

Syntax

ldp-treetrace {**prefix** *ip-prefixlmask*} [**downstream-map-tlv** {**dsmap** | **ddmap**}] [**fc** *fc-name* [**profile** {**in** | **out**}]] [**max-path** *max-paths*] [**max-ttl** *ttl-value*] [**retry-count** *retry-count*] [**timeout** *timeout*]

Context

[Tree] (oam ldp-treetrace)

Full Context

oam ldp-treetrace

Description

This command allows the user to perform a single run of the LDP ECMP OAM tree trace to discover all ECMP paths of an LDP FEC.

Parameters

ip-prefix/mask

Specifies the address prefix and subnet mask of the target BGP IPv4 label route.

Values ip-prefix: a.b.c.dmask, the value must be 32

downstream-map-tlv {dsmap | ddmap}

Specifies which format of the downstream mapping TLV to use in the LSP trace packet. The DSMAP TLV is the original format in RFC 4379 (obsoleted by RFC 8029). The DDMAP is the new enhanced format specified in RFC 6424 and RFC 8029.

Default Inherited from global configuration of downstream mapping TLV in option **mpls-echo-request-downstream-map** {**dsmap** | **ddmap**}.

fc-name

Specifies the FC and profile parameters are used to indicate the forwarding class and profile of the MPLS echo request packet.

When an MPLS echo request packet is generated in CPM and is forwarded to the outgoing interface, the packet is queued in the egress network queue corresponding to the specified FC and profile parameter values. The marking of the packet's EXP is dictated by the LSP-EXP mappings on the outgoing interface.

When the MPLS echo request packet is received on the responding node, The FC and profile parameter values are dictated by the LSP-EXP mappings of the incoming interface.

When an MPLS echo reply packet is generated in CPM and is forwarded to the outgoing interface, the packet is queued in the egress network queue corresponding to the FC and profile parameter values determined by the classification of the echo request packet, which is being replied to, at the incoming interface. The marking of the packet's EXP is dictated by the LSP-EXP mappings on the outgoing interface. The ToS byte is not modified. Table 51: ldp-treetrace Request Packet and Behavior summarizes this behavior.

Table 51: ldp-treetrace Request Packet and Behavior

CPM (sender node)	Echo request packet: • packet {tos=1, fc1, profile1} • fc1 and profile1 are as entered by user in OAM command or default values • tos1 as per mapping of {fc1, profile1} to IP precedence in network egress QoS policy of outgoing interface
Outgoing interface (sender node)	Echo request packet: • pkt queued as {fc1, profile1} • ToS field=tos1 not remarked • EXP=exp1, as per mapping of {fc1, profile1} to EXP in network egress QoS policy of outgoing interface
Incoming interface (responder node)	Echo request packet: • packet {tos1, exp1} • exp1 mapped to {fc2, profile2} as per classification in network QoS policy of incoming interface

CPM (responder node)	Echo reply packet: • packet {tos=1, fc2, profile2}
Outgoing interface (responder node)	Echo reply packet: • pkt queued as {fc2, profile2} • ToS filed= tos1 not remarked (reply inband or out-of-band) • EXP=exp2, if reply is inband, remarked as per mapping of {fc2, profile2} to EXP in network egress QoS policy of outgoing interface
Incoming interface (sender node)	Echo reply packet: • packet {tos1, exp2} • exp2 mapped to {fc1, profile1} as per classification in network QoS policy of incoming interface

Values be, l2, af, l1, h2, ef, h1, nc

Default be

profile {in | out}

Specifies the profile state of the MPLS echo request packet.

Values in, out

Default out

max-paths

Specifies the maximum number of paths for a ldp-treetrace test, expressed as a decimal integer.

Values 1 to 255

Default 128

ttl-value

Specifies the maximum TTL value in the MPLS label for the LSP trace test, expressed as a decimal integer.

Values 1 to 255

Default 30

retry-count

Specifies the maximum number of consecutive MPLS echo requests, expressed as a decimal integer that do not receive a reply before the trace operation fails for a given TTL.

Values 1 to 255

Default 5

timeout

Specifies the time, in seconds, used to override the default time out value and is the amount of time that the router waits for a message reply after sending the message request. Upon the expiration of the message time out, the requesting router assumes that the message response is not received. Any response received after the request times out is silently discarded.

Values 1 to 60

Default 3

Context

[Tree] (config>router leak-export)

Full Context

configure router leak-export

Description

This command associates up to four policies to control the leaking of GRT routes into the associated VPRN.

If a route is evaluated and the action is accepted, that route is subject leaking into an associated VPRN instance, assuming the route is fully resolved and active.

This process creates the pool of routes that can be leaked. Within each VPRN, a corresponding **import-grt** policy must be configured to import select routes into that specific VPRN instance.

The **no** form of this command removes all route leaking policy associations and effectively disables the leaking of GRT routes into associated VPRNs.

Parameters

plcy-or-long-expr

Specifies the route policy name, up to 64 characters or a policy logical expression, up to 255 characters.

Values *plcy-or-long-expr*: *policy-name* | *long-expr*

policy-name: up to 64 characters

long-expr: up to 255 characters

plcy-or-expr

Specifies the route policy name, up to 64 characters or a policy logical expression, up to 64 characters long. A maximum of four policy names or policy logical expressions can be specified in a single statement.

Values *plcy-or-expr*: *policy-name* | expr

policy-name: up to 64 characters

expr: up to 64 characters

configure service vprn bgp rib-management label-ipv6 leak-import

configure service vprn bgp rib-management ipv6 leak-import

configure service vprn bgp rib-management ipv4 leak-import

Description

This command configures route policies that control the importation of leak-eligible routes from the BGP RIB of another routing instance into the unlabeled-IPv4, unlabeled-IPv6, labeled-IPv4, or labeled-IPv6 RIB of the VPRN instance. To leak a route from one routing instance to another, the origin and destination RIB types must be the same; for example, it is not possible to leak a route from an unlabeled-IPv4 RIB of a VPRN into the labeled-IPv4 RIB of the base router.

The **leak-import** command can reference up to 15 objects, where each object is either a policy logical expression or the name of a single policy. The objects are evaluated in the specified order to determine the final action to accept or reject the route.

Only one of the 15 objects referenced by the **leak-import** command can be a policy logical expression consisting of policy names (enclosed in square brackets) and logical operators (AND, OR, NOT). The first of the 15 objects has a maximum length of 255 characters while the remaining 14 objects have a maximum length of 64 characters each.

When a **leak-import** policy is not specified, no BGP routes from other routing instances are leaked into the VPRN BGP RIB.

The **no** form of this command removes the policy association.

Default

no leak-import

Parameters

plcy-or-long-expr

Specifies the route policy name (up to 64 characters) or a policy logical expression (up to 255 characters). Allowed values are any string of characters composed of printable, 7-bit

ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

plcy-or-expr

Specifies the route policy name (up to 64 characters) or a policy logical expression (up to 255 characters). Allowed values are any string of characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

configure service vprn subscriber-interface group-interface wlan-gw learn-ap-mac

Description

This command enables the sending of ARP or ND packets on the WLAN-GW GRE tunnel for certain events. The target IP address in the ARP/ND packet is the endpoint IP address of the AP. The ARP/ND response from the AP should contain the AP MAC, which subsequently can be reported in a called-station-id message. When enabled, a message will be sent for following events:

- CPM: Mobility to an AP for which the AP-MAC is not yet known
- CPM: RS-triggered authentication on an AP for which the AP-MAC is not yet known

- ISA: Any mobility event
- ISA: Any authentication where the AP-MAC is not yet known (for example, from a RADIUS proxy cache or a DHCP circuit-id). If the optional keyword **delay-auth** is configured, then the authentication will be delayed until the ARP/ND is answered or timed out, after which the AP-MAC can be included in the authentication.

This configuration is ignored for L2-AP and L2TPv3 access.

Parameters

delay-auth

Specifies that authentication will be delayed until the ARP/ND is answered or timed out, after which the AP-MAC can be included in the authentication.

configure service vprn subscriber-interface group-interface wlan-gw learn-l2tp-cookie

configure service ies subscriber-interface group-interface wlan-gw learn-l2tp-cookie

Description

This command specifies when this system will learn the cookie from L2TP tunnels terminating on this interface. Learning the cookie means that the value of the octets 3-8 of the cookie is interpreted as an access point's MAC address, and used as such, for example in the Called-Station-Id attribute of RADIUS Interim-Update messages.

Parameters

if-match

Specifies that the cookie is interpreted only if the value of the first two octets of the cookie is equal to the value of the object tmnxWlanGwSoftGreIfL2tpCookie.

cookie *hex string*

Specifies the value used to compare the first two bytes of the cookie. This parameter is only valid if **if-match** is configured.

Values 0x0000 to 0xFFFF...(4 hex nibbles)

never

Specifies that the cookie value will always be ignored.

always

Always learn the AP-MAC from the cookie, regardless of the value of the first two bytes.

configure service vprn dhcp local-dhcp-server lease-hold-time

configure service vprn dhcp6 local-dhcp-server lease-hold-time

configure router dhcp local-dhcp-server lease-hold-time

Description

This command configures the time to remember this lease and is applicable for unsolicited release conditions such as lease timeout if the **lease-hold-time-for** command is set to the default value **no solicited-release** and is additionally applicable for normal solicited releases from DHCP clients if the **lease-hold-time-for** command is set to **solicited-release**.

The **no** form of this command reverts to the default.

Default

lease-hold-time sec 0

Parameters

lease-hold-time

Specifies the amount of time to remember the lease.

Values

days	0 to 7305
hours	0 to 23

minutes	0 to 59
seconds	0 to 59

Platforms

configure service vpls sap dhcp lease-populate

configure service vprn subscriber-interface group-interface dhcp lease-populate

configure service ies subscriber-interface group-interface dhcp lease-populate

configure service ies interface dhcp lease-populate

Description

Commands in this context configure IPoE host parameters.

For VPLS, DHCP snooping must be explicitly enabled (using the **snoop** command) at all points where DHCP messages requiring snooping enter the VPLS instance (both from the DHCP server and from the subscribers). Lease state information is extracted from snooped DHCP ACK messages to populate lease state table entries for the SAP.

The optional *nbr-of-leases* parameter defines the number lease state table entries allowed.

- for this SAP in case of a VPLS service
- for this interface in case of an IES or VPRN interface
- for each SAP in case of an IES or VPRN group-interface
- for this interface in case of an IES or VPRN retail subscriber-interface

If the *nbr-of-leases* parameter is omitted, only a single entry is allowed. Once the maximum number of entries has been reached, subsequent lease state entries are not allowed and subsequent DHCP ACK messages are discarded.

The retained lease state information representing dynamic hosts may be used to:

- Populate a SAP based anti-spoof filter table to provide dynamic anti-spoof filtering. If the system is unable to populate the dynamic host information in the anti-spoof filter table on the SAP, the DHCP ACK message must be discarded without adding new lease state entry or updating an existing lease state entry.
- Populate the system's ARP cache based on the arp-populate configuration. Applicable to IES and VPRN interfaces or group-interfaces.
- Populate managed entries into a VPLS forwarding database. VPLS forwarding database population is an implicit feature that automatically places the dynamic host's MAC address into the VPLS FDB. When a dynamic host's MAC address is placed in the lease state table, it will automatically be populated into the VPLS forwarding database associated with the SAP on which the host is learned. The dynamic host MAC address will override any static MAC entries using the same MAC and prevent dynamic learning of the MAC on another interface. Existing static MAC entries with the same MAC address as the dynamic host are marked as inactive but not deleted. If all entries in the lease state table associated with the MAC address are removed, the static MAC may be populated. New static MAC definitions for the VPLS instance may be created while a dynamic host exists associated with the static MAC address.
- Generate dynamic ARP replies if **arp-reply-agent** is enabled. Applicable to VPLS service SAPs

The **no** form of this command reverts to the default.

Parameters

nbr-of-leases

Specifies the number of DHCPv4 leases allowed.

l2-header

Indicates a mode of operation where anti-spoof entry associated with the given DHCP state is created based on the *src-mac* address from the Layer 2 header of the DHCP request message. The Layer 2 header flag is not set by default. This parameter is only applicable for group interfaces.

mac

Specifies that the provisioned *ieee-address* is used in the anti-spoofing entries for this SAP. The parameter may be changed mid-session. Existing sessions will not be re-programmed unless a **tools>perform>subscriber-mgmt>remap-lease-state** command is issued for the lease. This parameter is only applicable for group interfaces.

Platforms

no lease-populate

Context

[Tree] (config>service>ies>if>ipv6>dhcp6-relay lease-populate)

Full Context

configure service ies interface ipv6 dhcp6-relay lease-populate

Description

This command specifies the maximum number of DHCPv6 lease states allocated by the DHCPv6 relay function, allowed on this interface.

Optionally, by specifying **route-populate** parameter, system could:

- Create routes based on the IA_PD/IA_NA/IA_TA prefix option in relay-reply message.
- Create black hole routes based on OPTION_PD_EXCLUDE in IA_PD in relay-reply message.

These routes could be redistributed into IGP/BGP by using route-policy, following protocol types that could be used in "from protocol”:

- dhcpv6-pd
- dhcpv6-na
- dhcpv6-ta
- dhcpv6-pd-excl

Parameters

nbr-of-leases

Defines the number lease state table entries allowed for this interface. If this parameter is omitted, only a single entry is allowed. Once the maximum number of entries has been reached, subsequent lease state entries are not allowed and subsequent DHCPv6 REPLY messages are discarded.

Values 1 to 8000

route-populate

Specifies the route populate parameter.

Values pd/na/ta — Create route based on specified option.

exclude — Create blackhole route based on OPTION_PD_EXCLUDE.

16.98 least-fill

least-fill

Syntax

[**no**] **least-fill**

Context

[Tree] (config>router>mpls>lsp-template least-fill)

[Tree] (config>router>mpls>lsp least-fill)

Full Context

configure router mpls lsp-template least-fill

configure router mpls lsp least-fill

Description

This command enables the use of the least-fill path selection method for the computation of the path of this LSP.

When MPLS requests the computation of a path for this LSP, CSPF will find all equal cost shortest paths which satisfy the constraints of this path. Then, CSPF identifies the single link in each of these paths which has the least available bandwidth as a percentage of its maximum reservable bandwidth. It then selects the path which has the largest value of this percentage least available bandwidth figure. CSPF identifies the least available bandwidth link in each equal cost path after it has accounted for the bandwidth of the new requested path of this LSP.

CSPF applies the least-fill path selection method to all requests for a path, primary and secondary, of an LSP for which this option is enabled. The bandwidth of the path can be any value, including zero.

CSPF applies the least-fill criterion separately to each preemption priority in the base TE. A higher setup priority path can preemptively lower holding priority paths.

CSPF also applies the least-fill criterion separately to each Diff-Serv TE class if Diff-Serv TE is enabled on this node. A higher setup priority path can preemptively lower holding priority paths within a Class Type.

MPLS will re-signal and move the LSP to the new path in the following cases:

- Initial LSP path signaling.
- Re-try of an LSP path after failure.
- Make-before-break (MBB) due to pending soft preemption of the LSP path.
- MBB due to LSP path configuration change, that is, a user change to bandwidth parameter of primary or secondary path, or a user enabling of fast-reroute option for the LSP.
- MBB of secondary path due to an update to primary path SRLG.
- MBB due to FRR Global Revertive procedures on the primary path.
- Manual re-signaling of an LSP path or of all LSP paths by the user.

During a manual re-signaling of an LSP path, MPLS will always re-signal the path regardless of whether the new path is exactly the same or different than the current path and regardless of whether the metric of the new path is different or not from that of the current path.

During a timer-based re-signaling of an LSP path which has the least-fill option enabled, MPLS will only re-signal the path if the metric of the new path is different than the one of the current path.

The **no** form of this command deletes a specific node entry in this database.

Default

no least-fill. The path of an LSP is randomly chosen among a set of equal cost paths.

Platforms

All

16.99 least-fill-min-thd

least-fill-min-thd

Syntax

least-fill-min-thd *percent*

no least-fill-min-thd

Context

[Tree] (config>router>mpls least-fill-min-thd)

Full Context

configure router mpls least-fill-min-thd

Description

This parameter is used in the least-fill path selection process. When comparing the percentage of least available link bandwidth across the sorted paths, whenever two percentages differ by less than the value configured as the least-fill-min-thresh, CSPF will consider them equal and will apply a random number generator to select the path among these paths

The **no** form of this command resets this parameter to its default value.

Default

least-fill-min-thd 5

Parameters

percentage

Specifies the least fill minimum threshold value as a percentage.

Values 1 to 100%

Platforms

All

16.100 least-fill-reoptim-thd

least-fill-reoptim-thd

Syntax

least-fill-reoptim-thd *percent*

no least-fill-reoptim-thd

Context

[Tree] (config>router>mpls least-fill-reoptim-thd)

Full Context

configure router mpls least-fill-reoptim-thd

Description

This parameter is used in the least-fill path selection method. During a timer-based re-signaling of an LSP path which has the least-fill option enabled, CSPF will first update the least-available bandwidth figure for the current path of this LSP. It then applies the least-fill path selection method to select a new path for this LSP. If the new computed path has the same cost as the current path, it will compare the least-available bandwidth figures of the two paths and if the difference exceeds the user configured optimization threshold, MPLS will generate a trap to indicate that a better least-fill path is available for this LSP. This trap can be used by an external SNMP based device to trigger a manual re-signaling of the LSP path since the timer-based re-signaling will not re-signal the path in this case. MPLS will generate a path update trap at the first MBB event which results in the re-signaling of the LSP path. This should clear the eligibility status of the path at the SNMP device.

The **no** form of this command resets this parameter to its default value.

Default

least-fill-reoptim-thd 10

Parameters

percentage

Specifies the least fill reoptimization threshold value as a percentage.

Values 1 to 100%

Full Context

configure service vpls spoke-sdp mrp leave-time

configure service vpls sap mrp leave-time

configure service vpls mesh-sdp mrp leave-time

Description

This command controls the period of time that the Registrar state machine will wait in the leave state before transitioning to the MT (Empty) state when it is removed. An instance of the timer is required for each state machine that is in the leave state. The leave period timer is set to the value specified for **leave-time** when it is started.

A registration is normally in an "in" state where there is an MFIB entry and traffic is being forwarded. When a "leave all" is performed (periodically around every 10-15 seconds per SAP/SDP binding - see leave-all-time-below), a node sends a message to its peer indicating a leave all is occurring and puts all of its registrations in leave state.

The peer refreshes its registrations based on the leave all PDU it receives and sends a PDU back to the originating node with the state of all its declarations.

Refer to IEEE 802.1ak-2007 section 10.7.4.2.

Default

leave-time 30

Parameters

value

The period of time that the Registrar state machine waits in the leave state before transitioning to the MT state, in tenths of a second.

Values 30 to 60

configure router isis traffic-engineering-options application-link-attributes legacy

Description

This command enables legacy mode of advertising TE attributes.

The **no** form of this command disables legacy mode, but enables the per-application TE attribute advertisement for RSVP-TE.

Default

legacy

Platforms

All

16.105 legacy-dns-nbns

legacy-dns-nbns

Syntax

[**no**] **legacy-dns-nbns**

Context

[Tree] (config>subscr-mgmt>sys-bhv legacy-dns-nbns)

Full Context

configure subscriber-mgmt system-behavior legacy-dns-nbns

Description

This command enables legacy DNS NBNS behavior, which restricts the supported default extended authentication origins for DNS and NBNS name servers. The main differences include:

- only support DHCP server as origin for DHCP relay: IPoE DHCPv4/DHCPv6 and PPPoE DHCPv6
- Local Address Assignment (LAA) is highest priority origin: IPoE and PPPoE SLAAC DNSv6 and PPPoE DNSv4
- no default DNS for IPoE DHCPv4 proxy

The **no** form of this command reverts to the recommended default extended DNS and NBNS name server origin priorities.

Default

no legacy-dns-nbns

legacy-ipv4-lsr-interop

Syntax

[**no**] **legacy-ipv4-lsr-interop**

Context

[Tree] (config>router>ldp legacy-ipv4-lsr-interop)

Full Context

configure router ldp legacy-ipv4-lsr-interop

Description

This command provides for a global LDP knob to allow interoperability with legacy IPv4 LSR implementations which do not comply with the processing of Hello TLVs with the U-bit set. Specifically, this feature disables the following Hello TLVs:

- The Nokia proprietary Interface Info TLV (0x3E05) in the Hello message sent to the peer. This also results in the non-generation of the Nokia proprietary Hello Adjacency Status TLV (0x3E06) since the Interface Info TLV is not sent.

  This is performed in SR OS releases 12 and higher.

- The RFC 7552 standard dual-stack capability TLV (0x701) and the Nokia proprietary Adjacency capability TLV (0x3E07) in SR OS releases 13 and higher.

length

Syntax

length {**133** | **266** | **399** | **533** | **655**}

Context

[Tree] (config>port>tdm length)

Full Context

configure port tdm length

Description

This command applies only to a DS-1 port configured with a 'short' buildout. The **length** command configures the length of the line (in feet). For line lengths longer than 655 feet, configure the DS-1 port buildout as 'long'.

For 'long' buildout the following values are valid:

NotApplicable — Not applicable

For 'short' buildout the following values are valid:

- 0 to 133 For line length from 0 to 133 feet
- 134 to 266 For line length from 134 to 266 feet
- 267 to 399 For line length from 267 to 399 feet
- 400 to 533 For line length from 400 to 533 feet
- 534 to 655 For line length from 534 to 655 feet

The default for 'long' buildout is 'NotApplicable' while the default for 'short' buildout is '0 to 133'.

Syntax

[**no**] **ler-use-dscp**

Context

[Tree] (config>qos>network>ingress ler-use-dscp)

Full Context

configure qos network ingress ler-use-dscp

Description

This command is used to enable tunnel QoS mapping on all ingress network IP interfaces that the network-qos-policy-id is associated with. The command may be defined at any time after the network QoS policy has been created. Any network IP interfaces currently associated with the policy will immediately start to use the internal IP ToS field of any tunnel terminated IP routed packet received on the interface, ignoring any QoS markings in the tunnel portion of the packet.

This attribute provides the ability to ignore the network ingress QoS mapping of a terminated tunnel containing an IP packet that is to be routed to a base router or VPRN destination. This is advantageous when the mapping for the tunnel QoS marking does not accurately or completely reflect the required QoS handling for the IP routed packet. When the mechanism is enabled on an ingress network IP interface, the IP interface will ignore the tunnel's QoS mapping and derive the internal forwarding class and profile based

on the precedence or DiffServ Code Point (DSCP) values within the routed IP header ToS field compared to the Network QoS policy defined on the IP interface.

The default state is not to enforce tunnel termination IP routed QoS override within the network QoS policy.

The **no** form of this command removes tunnel termination IP routed QoS override from the network QoS policy and all ingress network IP interfaces associated with the policy.

Default

no ler-use-dscp

Platforms

All

16.110 less-specific

less-specific

Syntax

less-specific [**allow-default**]

no less-specific

Context

[Tree] (config>vrrp>policy>priority-event>route-unknown less-specific)

Full Context

configure vrrp policy priority-event route-unknown less-specific

Description

This command allows a CIDR shortest match hit on a route prefix that contains the IP route prefix associated with the route unknown priority event.

The **less-specific** command modifies the search parameters for the IP route prefix specified in the **route-unknown** priority event. Specifying **less-specific** allows a CIDR shortest match hit on a route prefix that contains the IP route prefix.

The **less-specific** command eases the RTM lookup criteria when searching for the *prefix/mask-length*. When the **route-unknown** priority event sends the prefix to the RTM (as if it was a destination lookup), the result route table prefix (if a result is found) is checked to see if it is an exact match or a less specific match. The **less-specific** command enables a less specific route table prefix to match the configured prefix. When **less-specific** is not specified, a less specific route table prefix fails to match the configured prefix. The **allow-default** optional parameter extends the **less-specific** match to include the default route (0.0.0.0).

The **no** form of the command prevents RTM lookup results that are less specific than the route prefix from matching.

Default

no less-specific — The route unknown priority events requires an exact prefix/mask match.

Parameters

allow-default

When the **allow-default** parameter is specified with the **less-specific** command, an RTM return of 0.0.0.0 matches the IP prefix. If **less-specific** is entered without the **allow-default** parameter, a return of 0.0.0.0 will not match the IP prefix. To disable **allow-default**, but continue to allow **less-specific** match operation, only enter the **less-specific** command (without the **allow-default** parameter).

configure port sonet-sdh path egress-scheduler-override level

configure port tdm e3 egress-scheduler-override level

configure port ethernet egress-scheduler-override level

configure port tdm e1 egress-scheduler-override level

configure port tdm ds1 channel-group egress-scheduler-override level

configure port tdm ds3 egress-scheduler-override level

Description

This command overrides the maximum and CIR rate parameters for a specific priority level on the port or channel's port scheduler instance. When the **level** command is executed for a priority level, the corresponding priority level command in the port-scheduler-policy associated with the port is ignored.

The override level command supports the keyword **max** for the **rate** and **cir** parameter. When executing the level override command, at least the **rate** or **cir** keywords and associated parameters must be specified for the command to succeed.

The **no** form of this command removes the local port priority level rate overrides. Once removed, the port priority level will use the port scheduler policies level command for that priority level.

Parameters

priority-level

Identifies which of the eight port priority levels are being overridden.

Values 1 to 8

pir-rate

Overrides the port scheduler policy's maximum level rate and requires either the **max** keyword or a rate defined in kilobits per second to follow.

Values For Ethernet: 1 to 6400000000, **max**

For SONET-SDH and TDM: 1 to 3200000000, **max**

cir-rate

Overrides the port scheduler policy's within-cir level rate and requires either the max keyword or a rate defined in kilobits per second to follow.

Values For Ethernet: 1 to 6400000000, **max**

For SONET-SDH and TDM: 1 to 3200000000, **max**

pir-percent

Specifies the PIR as a percentage.

Values 0.01 to 100.00

cir-percent

Specifies the CIR as a percentage.

Values 0.00 to 100.00

max

removes any existing rate limit imposed by the port scheduler policy for the priority level allowing it to use as much total bandwidth as possible.

Platforms

Full Context

configure service vprn isis level

configure service vprn isis interface level

configure service vprn isis link-group level

Description

This command creates the context to configure IS-IS Level 1 or Level 2 area attributes.

A router can be configured as a Level 1, Level 2, or Level 1/2 system. A Level 1 adjacency can be established if there is at least one area address shared by this router and a neighbor. A Level 2 adjacency cannot be established over this interface.

Level 1/2 adjacency is created if the neighbor is also configured as Level 1/2 router and has at least one area address in common. A Level 2 adjacency is established if there are no common area IDs.

A Level 2 adjacency is established if another router is configured as Level 2 or a Level 1/2 router with interfaces configured as Level 1/2 or Level 2. Level 1 adjacencies are not established over this interface.

To reset global and/or interface level parameters to the default, the following commands must be entered independently:

- **level>no hello-authentication-key**
- **level>no hello-authentication-type**
- **level>no hello-interval**
- **level>no hello-multiplier**
- **level>no metric**
- **level>no passive**
- **level>no priority**

Default

level 1 or level 2

Parameters

level-number

The IS-IS level number.

Values 1, 2

no level *priority-level*

Context

[Tree] (config>qos>port-scheduler-policy level)

Full Context

configure qos port-scheduler-policy level

Description

This command configures an explicit within-CIR bandwidth limit and a total bandwidth limit for each port scheduler's priority level. To understand how to set the level rate and CIR parameters, a basic understanding of the port-level scheduler bandwidth allocation mechanism is required. The port scheduler takes all available bandwidth for the port or channel (after the max-rate and any port egress-rate limits have been accounted for) and offers it to each of the eight priority levels twice.

The first pass is called the within-CIR pass and consists of providing the available port bandwidth to each of the 8 priority levels, starting with level 8 and moving down to level 1. Each level takes the offered load and distributes it to all child members that have a port-parent cir-level equal to the current priority level. (Any child with a cir-weight equal to 0 is skipped in this pass.) Each child may consume bandwidth up to the child's frame-based within-CIR offered load. The remaining available port bandwidth is then offered to the next lower priority level until level 1 is reached.

The second pass is called the above-CIR pass and consists of providing the remaining available port bandwidth to each of the eight priority levels a second time. Again, each level takes the offered load and distributes it to all child members that have a port-parent level equal to the current priority level. Each child may consume bandwidth up to the remainder of the child's frame-based offered load (some of the offered load may have been serviced during the within-CIR pass). The remaining available port bandwidth is then offered to the next priority level until level 1 is again reached.

If the port scheduling policy is using the default orphan behavior (orphan-override has not been configured on the policy), the system then takes any remaining port bandwidth and allocates it to the orphan queues and scheduler on priority level 1. In a non-override orphan state, all orphans are attached to priority level 1 using a weight of 0. The zero weight value causes the system to allocate bandwidth equally to all orphans based on each orphan queue or scheduler's ability to use the bandwidth. If the policy has an orphan-override configured, the orphans are handled based on the override commands parameters in a similar fashion to properly parented queues and schedulers.

The port scheduler priority level command rate keyword is used to optionally limit the total amount of bandwidth that is allocated to a priority level (total for the within-CIR and above-CIR passes). The cir keyword optionally limits the first pass bandwidth allocated to the priority level during the within-CIR pass.

When executing the level command, at least one of the optional keywords, **rate** or **cir,** must be specified. If neither keyword is included, the command will fail.

If a previous explicit value for rate or cir exists when the level command is executed, and either rate or cir is omitted, the previous value for the parameter is overwritten by the default value and the previous value is lost.

The configured priority level rate limits may be overridden at the egress port or channel using the egress-scheduler-override level priority-level command. When a scheduler instance has an override defined for a priority level, both the rate and cir values are overridden even when one of them is not explicitly expressed in the override command. For instance, if the cir kilobits per second portion of the override is not

expressed, the scheduler instance defaults to not having a CIR rate limit for the priority level even when the port scheduler policy has an explicit CIR limit defined.

The **no** form of this command returns the level to its default value.

Default

no level priority-level

Parameters

priority-level

Specifies to which priority level the level command pertains. Each of the eight levels is represented by an integer value of 1 to 8, with 8 being the highest priority level.

Values 1 to 8 (8 is the highest priority)

pir-rate

Specifies the total bandwidth limits allocated to priority-level, in kilobits per second.

Values 1 to 6400000000, **max**

pir-percent

Specifies the percent bandwidth limits allocated to priority-level.

Values 0.01 to 100.00

cir-rate

The cir specified limits the total bandwidth allocated in the within-CIR distribution pass to priority-level. When cir is not specified, all the available port or channel bandwidth may be allocated to the specified priority level during the within-CIR pass.

Values 0 to 6400000000, **max**

The value given for kilobits per second is expressed in kilobits per second on a base 10 scale as is usual for line rate calculations. If a value of 1 is given, the result is 1000 bits per second (as opposed to a base 2 interpretation that would be 1024 bits per second).

cir-percent

Specifies the percent bandwidth limits allocated to priority-level.

Values 0.00 to 100.00

group *name*

specifies the existing group that the weighted scheduler group this level maps to, up to 32 characters.

weight

Specifies the weight of the level within this weighted scheduler group.

Values 1 to 100

Default 1

monitor-threshold *percent*

Specifies the percent of the configured rate. If the offered rate exceeds the configured threshold, a counter monitoring the threshold will be increased.

Values 0 to 100

configure service vprn isis interface level-capability

configure service vprn isis level-capability

Description

This command configures the routing level for an instance of the IS-IS routing process.

An IS-IS router and an IS-IS interface can operate at Level 1, Level 2 or both Level 1 *and* 2.

Table 53: Potential Adjacency Capabilities displays configuration combinations and the potential adjacencies that can be formed.

Table 53: Potential Adjacency Capabilities

Global Level	Interface Level	Potential Adjacency
L 1/2	L 1/2	Level 1 and/or Level 2
L 1/2	L 1	Level 1 only
L 1/2	L 2	Level 2 only

Global Level	Interface Level	Potential Adjacency
L 2	L 1/2	Level 2 only
L 2	L 2	Level 2 only
L 2	L 1	none
L 1	L 1/2	Level 1 only
L 1	L 2	none
L 1	L 1	Level 1 only

The **no** form of this command removes the level capability from the configuration.

Default

level-capability level-1/2

Parameters

level-1

Specifies the router/interface can operate at Level 1 only.

level-2

Specifies the router/interface can operate at Level 2 only.

level-1/2

Specifies the router/interface can operate at both Level 1 and Level 2.

16.113 lfa-policy-map

lfa-policy-map

Syntax

lfa-policy-map route-nh-template *template-name*

no lfa-policy-map

Context

[Tree] (config>service>vprn>isis>if lfa-policy-map)

Full Context

configure service vprn isis interface lfa-policy-map

Description

This command applies a route next-hop policy template to the IS-IS interface for the VPRN instance.

When a route next-hop policy template is applied to an interface in IS-IS, it is applied in both level 1 and level 2. When a route next-hop policy template is applied to an interface in OSPF, it is applied in all areas.

However, the command in an OSPF interface context can only be executed under the area in which the specified interface is primary and then applied in that area and in all other areas where the interface is secondary. If the user attempts to apply it to an area where the interface is secondary, the command fails.

If the user excluded the interface from LFA using the command **loopfree-alternate-exclude**, the LFA policy, if applied to the interface, has no effect.

Finally, if the user applied a route next-hop policy template to a loopback interface or to the system interface, the command will not be rejected, but it will result in no action being taken.

The **no** form deletes the mapping of a route next-hop policy template to an OSPF or IS-IS interface.

Parameters

template-name

Specifies the name of the template, up to 32 characters.

Platforms

All

lfa-policy-map

li-filter-lock-state {**locked** | **unlocked-for-li-users** | **unlocked-for-all-users**}

no li-filter-lock-state

Context

[Tree] (config>li li-filter-lock-state)

Full Context

configure li li-filter-lock-state

Description

This command configures the lock state of the filters used by LI. With the configurable filter lock for LI feature an LI user can control the behavior of filters when they are used for LI.

Prior to Release 12.0.R1, when a filter entry was used as a Lawful Intercept (LI) mirror source criteria, all subsequent attempts to modify the filter were then blocked to avoid having the LI session impacted by a non-LI user.

The **no** form of this command reverts to the default.

Default

li-filter-lock-state locked

Parameters

locked

When an li-source criteria is configured that references any entry of filter Y, then filter Y can no longer be changed (until there are no longer any li-source references to entries of filter Y).

unlocked-for-li-users

Filters can continue to be edited by LI users only even when an li-source references an entry in that filter.

unlocked-for-all-users

Filters can continue to be edited by all users even when an li-source references an entry in that filter.

Specifies an existing li-ip-filter, up to 32 characters.

Platforms

All

li-ip-filter

Syntax

li-ip-filter *li-filter-name* **entry** *li-entry-id* [*li-entry-id*] [**intercept-id** *intercept-id* [*intercept-id*]] [**session-id** *session-id* [*session-id*]]

no li-ip-filter *li-filter-name* [**entry** *li-entry-id* [*li-entry-id*]]

Context

[Tree] (config>li>li-source li-ip-filter)

Full Context

configure li li-source li-ip-filter

Description

This command enables lawful interception (LI) of packets that match specific entries in an existing LI IP filter that has been associated with a normal IP filter. The specification of an li-ip-filter entry as an li-source means that packets matching the li-ip-filter entry will be intercepted on all interfaces/saps/and so on where the associated normal ip-filter(s) are applied.

Parameters

li-filter-name

Specifies the name of the **li-ip-filter**, up to 32 characters.

li-entry-id

Specifies the entry ID in the **li-ip-filter** that is to be used as an li-source criteria.

Values 1 to 65535

intercept-id

Specifies the intercept-id that is inserted into the packet header for all mirrored packets of the associated li-source entry. This intercept ID can be used (for example by a downstream LI gateway) to identify the particular LI session to which the packet belongs. For all types of **li-source** entries (filter, nat, sap, subscriber), when the mirror service is configured with **ip-udp-shim** routable encap, an *intercept-id* field (as part of the routable encap) is always present in the mirrored packets. If there is no *intercept-id* configured for an **li-source** entry, then the default value will be inserted. When the mirror service is configured with **ip-gre** or **ip-udp-shim-sampled** routable encap, no intercept ID is inserted and none can be specified against the **li-source** entries.

session-id

Specifies the session-id that is inserted into the packet header for all mirrored packets of the associated li-source entry. This *session-id* can be used (for example by a downstream LI Gateway) to identify the particular LI session to which the packet belongs. The session-id is only valid and used for mirror services that are configured with ip-udp-shim routable encap (**config>mirror>mirror-dest>encap>ip-udp-shim**). For all types of li-source entries (filter, nat, sap, or subscriber), when the mirror service is configured with **ip-udp-shim** routable encap, a session-id field (as part of the routable encap) is always present in the mirrored packets. If there is no *session-id* configured for an li-source entry, then the default value will be inserted. When a mirror service is configured with **ip-gre** or **ip-**

udp-shim-sampled routable encap, no session-id is inserted and none can be specified against the li-source entries.

Context

[Tree] (config>li>li-source li-ipv6-filter)

Full Context

configure li li-source li-ipv6-filter

Description

This command enables lawful interception (LI) of packets that match specific entries in an existing LI IPv6 filter that has been associated with a normal IPv6 filter. The specification of an li-ipv6-filter entry as an li-source means that packets matching the **li-ipv6-filter** entry will be intercepted on all interfaces/saps/and so on, where the associated normal ip-filter(s) are applied.

Parameters

li-filter-name

Specifies the name of the **li-ipv6-filter** up to 32 characters.

li-entry-id

Specifies the entry ID in the **li-ipv6-filter** that is to be used as an LI source criteria.

Values 1 to 65535

intercept-id

Specifies the intercept ID that is inserted into the packet header for all mirrored packets of the associated li-source entry. This *intercept-id* can be used (for example by a downstream LI gateway) to identify the particular LI session to which the packet belongs. For all types of li-source entries (filter, nat, sap, or subscriber), when the mirror service is configured with **ip-udp-shim** routable encap, an intercept-id field (as part of the routable encapsulation) is always present in the mirrored packets. If there is no *intercept-id* configured for an **li-source** entry, then the default value will be inserted. When the mirror service is configured with **ip-gre** or **ip-udp-shim-sampled** routable encap, no intercept ID is inserted and none can be specified against the LI source entries.

session-id

Specifies the session ID that is inserted into the packet header for all mirrored packets of the associated **li-source** entry. This *session-id* can be used (for example, by a downstream LI gateway) to identify the particular LI session to which the packet belongs. The *session-id* is only valid and used for mirror services that are configured with **ip-udp-shim** routable encap (**config>mirror>mirror-dest>encap>ip-udp-shim**). For all types of li-source entries (filter, nat, sap, subscriber), when the mirror service is configured with ip-udp-shim routable encap, a session-id field (as part of the routable encap) is always present in the mirrored packets. If there is no session ID configured for an **li-source** entry, then the default value is inserted. When a mirror service is configured with **ip-gre** or **ip-udp-shim-sampled** routable encap, no session ID is inserted and none can be specified against the li-source entries.

li-reserved-block

Syntax

li-reserved-block *block-name* [**create**]

no li-reserved-block *block-name*

Context

[Tree] (config>li>li-filter-block-reservation li-reserved-block)

Full Context

configure li li-filter-block-reservation li-reserved-block

Description

This command creates or edits an LI reserved block. An LI reserved block allows an operator to define where entries from an LI filter should be inserted into a normal filter. The block reserves a configurable number of entries in the normal filter that can only be used for entries inserted from associated LI filters. The LI filter entries that get inserted into the reserved block in each normal filter are not visible to non-LI operators. The block also defines to which normal filters the reservation is applied.

The **no** form of this command removes the block name from the configuration.

Parameters

block-name

Specifies the name of the MAC filter. Block names cannot start with an underscore character (for example, "_my-filter”) and cannot use the name "default”.

Platforms

All

16.125 li-separate

li-separate

Syntax

[**no**] **li-separate**

Context

[Tree] (bof li-separate)

Full Context

bof li-separate

Description

This command specifies whether or not a non-LI user has access to lawful intercept (LI) information. When this command is enabled, a user who does not have LI access will not be allowed to access CLI or SNMP objects in the li context. Modifying this command will not take effect until the system is rebooted.

When the **no li-separate** command is set (the default mode), those who are allowed access to the **config>system>security>profile** context and user command nodes are allowed to modify the configuration of the LI parameters. In this mode, a user that has a profile allowing access to the **config>li** and/or **show>li** command contexts can enter and use the commands under those nodes.

When the **li-separate** command is configured, only users that have the LI access capabilities set in the **config>system>security>user>access li** context are allowed to access the **config>li** and/or **show>li**

command contexts. A user who does not have LI access is not allowed to enter the **config>li** and **show>li** contexts even though they have a profile that allows access to these nodes. When in the **li-separate** mode, only users with **config>system>security>user>access li** set in their user account have the ability modify the setting LI parameters in either their own or other profiles and user configurations.

lics

Syntax

lics

Context

[Tree] (config>li>x-interfaces lics)

Full Context

configure li x-interfaces lics

Description

Commands in this context configure the Network Element to communicate with LI Centers (LICs).

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

16.132 lifetime

lifetime

Syntax

lifetime minimum *minimum* **maximum** *maximum*

no lifetime

Context

[Tree] (config>service>nat>pcp-server-policy lifetime)

Full Context

configure service nat pcp-server-policy lifetime

Description

This command configures the lifetime of explicit mappings made by the PCP servers.

Default

lifetime minimum 120 maximum 86400

Parameters

minimum

Specifies the minimum lifetime of explicit mappings made by the PCP servers using this PCP policy, in seconds.

Values 60 to 86399

maximum

Specifies the maximum lifetime of explicit mappings made by the PCP servers using this PCP policy, in seconds.

Values 61 to 86400

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

lifetime

Syntax

lifetime {*seconds* | **forever**}

Context

[Tree] (config>system>script-control>script-policy lifetime)

Full Context

configure system script-control script-policy lifetime

Description

This command is used to configure the maximum amount of time that a script may run.

Default

lifetime 3600

Parameters

seconds

Specifies the maximum amount of time that a script may run, in seconds.

Values 0 to 21474836

Default 3600 (1 hour)

forever

Specifies to allow a script to run indefinitely.

Platforms

All

16.133 limit

limit

Syntax

limit {**all-packet-matches** | **first-session-match**}

Context

[Tree] (debug>app-assure>group>traffic-capture>record limit)

Full Context

debug application-assurance group traffic-capture record limit

Description

This command records limit conditions.

Parameters

all-packet-matches

Records all the packets matching the condition.

first-session-match

Records only the first session matching the condition.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

16.134 limit-init-exchange

limit-init-exchange

Syntax

limit-init-exchange [**reduced-max-exchange-timeout** *seconds*]

no limit-init-exchange

Context

[Tree] (config>ipsec>ike-policy limit-init-exchange)

Full Context

configure ipsec ike-policy limit-init-exchange

Description

This command limits the number of ongoing IKEv2 initial exchanges per tunnel to 1. When the system receives a new IKEv2 IKE_SA_INIT request when there is an ongoing IKEv2 initial exchange from same peer, then system reduces the timeout value of the existing exchange to the specified **reduced-max-exchange-timeout**. If the **reduced-max-exchange-timeout** is **disabled**, then the system does not reduce the timeout value.

The **no** form of this command reverts to the default value.

Default

limit-init-exchange reduced-max-exchange-timeout 2

Parameters

seconds

Specifies the maximum timeout for the in-progress initial IKE exchange.

Values 2 to 60, disabled

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

16.135 limit-mac-move

limit-mac-move

Syntax

limit-mac-move [**blockable** | **non-blockable**]

no limit-mac-move

Context

[Tree] (config>service>vpls>sap limit-mac-move)

[Tree] (config>service>vpls>spoke-sdp limit-mac-move)

Full Context

configure service vpls sap limit-mac-move

configure service vpls spoke-sdp limit-mac-move

Description

This command indicates whether or not the mac-move agent, when enabled using **config>service>vpls>mac-move** or **config>service>epipe>mac-move**, limits the MAC re-learn (move) rate on this SAP.

Default

limit-mac-move blockable

Parameters

blockable

Specifies that the agent monitors the MAC re-learn rate on the SAP, and it blocks it when the re-learn rate is exceeded.

non-blockable

Specifies that this SAP is not blocked, and another blockable SAP is blocked instead.

Platforms

All

limit-mac-move

Syntax

limit-mac-move [**blockable** | **non-blockable**]

no limit-mac-move

Context

[Tree] (config>service>pw-template limit-mac-move)

Full Context

configure service pw-template limit-mac-move

Description

This command indicates whether or not the mac-move agent will limit the MAC re-learn (move) rate.

Default

limit-mac-move blockable

Parameters

blockable

The agent will monitor the MAC re-learn rate, and it will block it when the re-learn rate is exceeded.

non-blockable

When specified, a SAP will not be blocked, and another blockable SAP will be blocked instead.

Platforms

All

16.136 limit-pir-zero-drain

limit-pir-zero-drain

Syntax

[**no**] **limit-pir-zero-drain**

Context

[Tree] (config>qos>adv-config-policy>child-control>bandwidth-distribution limit-pir-zero-drain)

Full Context

configure qos adv-config-policy child-control bandwidth-distribution limit-pir-zero-drain

Description

This command is used to configure the system to use the minimum configurable PIR instead of an H-QoS derived zero operational PIR. The default behavior is to allow the operational PIR of the queue to remain the last configured value while setting the queue MBS to zero (preventing queuing of newly arriving packets). Retaining the previous PIR value may cause a momentary burst above an aggregate rate associated with the queue as it drains. Using the **limit-pir-zero-drain** command causes the queue to drain at the lowest rate possible (typically 1 kb/s) that limits overrun situations.

The **no** form of this command reverts to default behavior.

Platforms

All

16.137 limit-unused-bandwidth

limit-unused-bandwidth

Syntax

[**no**] **limit-unused-bandwidth**

Context

[Tree] (config>service>vprn>sub-if>grp-if>sap>egress limit-unused-bandwidth)

[Tree] (config>port>ethernet>access>egr>qgrp>agg-rate limit-unused-bandwidth)

Full Context

configure port ethernet network egress queue-group agg-rate limit-unused-bandwidth

configure port ethernet access egress vport limit-unused-bandwidth

configure service vprn subscriber-interface group-interface sap egress limit-unused-bandwidth

configure port ethernet access egress queue-group agg-rate limit-unused-bandwidth

Description

This command specifies to limit the unused bandwidth and allow a tighter control in allocation of bandwidth by HQoS. When enabled, HQoS algorithm distributes any unused aggregate bandwidth between queues

operating below their fair share rates. This allows a simplified aggregate rate protection while allocating bandwidth by HQoS.

The **no** form of this command reverts to the default.

Platforms

All

The **no** form of the command disables aggregate rate overrun protection.

Default

no limit-unused-bandwidth

Platforms

All

16.138 line-length

line-length

Syntax

line-length {**110** | **220** | **330** | **440** | **550** | **660**}

Context

[Tree] (config>system>sync-if-timing>bits>output line-length)

Full Context

configure system sync-if-timing bits output line-length

Description

This command configures the **line-length** parameter of the BITS output, This is the distance in feet between the network element and the office clock (BITS/SSU). There are two possible BITS-out interfaces, one for each CPM. They are configured together, but they are displayed separately in the show command. This command is only applicable when the interface-type is DS1.

Default

line-length 110

Parameters

110

Specifies that the distance is from 0 to 110 feet.

220

Specifies that the distance is from 110 to 220 feet.

330

Specifies that the distance is from 220 to 330 feet.

440

Specifies that the distance is from 330 to 440 feet.

550

Specifies that the distance is from 440 to 550 feet.

660

Specifies that the distance is from 550 to 660 feet.

16.139 link

link

Syntax

link *port-id* {**primary** | **secondary**}

no link *port-id*

Context

[Tree] (config>lag>link-map-profile link)

Full Context

configure lag link-map-profile link

Description

This command designates one of the configured ports of the LAG to be used on egress as either a primary or secondary link (based on the option selected) by all SAPs and network interfaces that use this LAG link map profile.

Links are part of a profile When a link is added or deleted, all SAPs and network interfaces that use this link-map-profile may be re-hashed if required.

The **no** form of this command deletes the link from this LAG link mapping profile. A port must be deleted from all LAG link profiles if it is to be deleted from the LAG.

Parameters

port-id

Specifies a physical port ID that is an existing member of this LAG.

port-id	*slot*/*mda*/*port*[.*channel*]		
	eth-sat-id	esat-*id*/*slot*/*port*	
		esat	keyword
		id	1 to 20
	pxc-id	pxc-*id*.*sub-port*	
		pxc	keyword
		id	1 to 64
		sub-port	a, b

primary

Designates one of the configured ports of the LAG to be used on egress as a primary link by SAPs/network interfaces that use this LAG link map profile.

secondary

Designates one of the configured ports of the LAG to be used on egress as a secondary link by SAPs/network interfaces that use this LAG link map profile.

Platforms

All

link

Syntax

[**no**] **link**

Context

[Tree] (config>test-oam>link-meas>template>ret-path link)

Full Context

configure test-oam link-measurement measurement-template twamp-light return-path link

Description

This command includes a return path sub-TLV link. The link sub-tlv instructs a Session-Reflector configured for type **stamp** to use the receiving logical IP interface for the transmission of the response

packet from the reflector to the **session-sender**. The destination of the reflected packet must be installed in the forwarding table and reachable out the IP interface or the packet is dropped by the Session-Reflector. When there are parallel non-equal cost return paths between the Session-Reflector and the Session-Sender the response packet can only be returned on the lowest cost path.

Default

no link

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

configure service vprn subscriber-interface wlan-gw pool-manager dhcpv6-client dhcpv4-nat link-addr

configure service ies subscriber-interface wlan-gw pool-manager dhcpv6-client ia-na link-addr

Description

This command specifies the ipv6-address that should be included in the link-address field of the relay header. This can be used for pool selection by the DHCPv6 server.

The **no** form of this command falls back to the default.

Parameters

ipv6-address

Specifies the IPv6 address up to 32 characters.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

16.141 link-address

configure service vprn interface ipv6 dhcp6-relay link-address

configure service ies subscriber-interface group-interface ipv6 dhcp6 relay link-address

configure service ies interface ipv6 dhcp6-relay link-address

Description

This command configures the link address used for prefix selection at the DHCP server.

The link-address is a field in DHCP6 Relay-Forward message that is used in DHCP6 server to select the IPv6 address (IA-NA) or IPv6 prefix (IA-PD) from a pool with configured prefix range covering the link-address. The selection scope is the pool or a prefix range within the pool.

The **no** form of this command reverts to the default.

Default

no link-address

Parameters

ipv6-address

Specifies the link-address.

Values

ipv6-address	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x - [0 to FFFF]H
	d - [0 to 255]D

16.143 link-fault

link-fault

Syntax

link-fault local-port-action {**log-only** | **out-of-service**}

Context

[Tree] (config>port>ethernet>efm-oam>peer-rdi-rx link-fault)

Full Context

configure port ethernet efm-oam peer-rdi-rx link-fault

Description

This command defines how to react to the reception of a link fault flag set in the informational PDU from a peer.

Default

link-fault local-port-action out-of-service

Parameters

local-port-action

Defines whether or not the local port will be affected when a link fault is received from a peer.

log-only

Keyword that prevents the port from being affected when the local peer receives a link fault. The dying gasp will be logged but the port will remain operational.

out-of-service

Keyword that causes the port to enter a non-operation down state with a port state of link up. The error will be logged upon reception of link fault event. The port will not be available to service data but will continue to carry Link OAM traffic to ensure the link is monitored.

Full Context

configure service ies subscriber-interface ipv6 link-local-address

configure router interface ipv6 link-local-address

configure service vprn interface ipv6 link-local-address

configure service ies interface ipv6 link-local-address

configure service vprn subscriber-interface ipv6 link-local-address

Description

This command configures the IPv6 Link Local address that is used as a virtual SRRP IPv6 address by the Master SRRP node. This address is sent in the Router Advertisements initiated by the Master SRRP node. Clients use this address as IPv6 default-gateway. Both SRRP nodes, Master and Backup, must be configured with the same Link Local address.

Only one link-local-address is allowed per interface.

Caution:
Removing a manually configured link local address may impact routing protocols or static routes that have a dependency on that address. It is not recommended to remove a link local address when there are active IPv6 subscriber hosts on an IES or VPRN interface.

The **no** form of this command reverts to the default.

Parameters

ipv6-address

Specifies the IPv6 address in the form:

Values

ipv6-address:	x:x:x:x:x:x:x:x
	x:x:x:x:x:x:d.d.d.d
	x - [0..FFFF]H
	d - [0..255]D

dad-disable

Disables Duplicate Address Detection (DAD) and sets the address to preferred, even if there is a duplicated address.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

- configure service vprn subscriber-interface ipv6 link-local-address

configure service vprn interface secure-nd link-local-modifier

Description

This command configures the Cryptographically Generated Address (CGA) modifier for link-local addresses.

Parameters

modifier

Specifies the modifier in 32 hexadecimal nibbles.

Values 0x0–0xFFFFFFFF

link-local-modifier

Syntax

link-local-modifier *modifier*

no link-local-modifier

Context

[Tree] (config>router>if>ipv6>secure-nd link-local-modifier)

Full Context

configure router interface ipv6 secure-nd link-local-modifier

Description

This command configures the Cryptographically Generated Address (CGA) modifier for link-local addresses.

Parameters

modifier

Specifies the modifier in 32 hexadecimal nibbles.

Values 0x0 to 0xFFFFFFFF

Platforms

All

16.147 link-map-profile

link-map-profile

Syntax

link-map-profile *link-map-profile-id* [**create**]

no link-map-profile *link-map-profile-id*

Context

[Tree] (config lag link-map-profile)

Full Context

configure lag link-map-profile

Description

This command creates the link map profile that can to control which LAG ports are to be used on egress or enables the configuration context for previously created link map profile. link map profiles are not created by default.

The **no** form of this command, deletes the specified link map profile.

Parameters

link-map-profile-id

An integer from 1 to 64 that defines a unique LAG link map profile on this LAG.

Platforms

All

16.148 link-measurement

link-measurement

Syntax

link-measurement

Context

[Tree] (config>test-oam link-measurement)

Full Context

configure test-oam link-measurement

Description

Commands in this context configure various link measurement template attributes that are inherited on associated IP interfaces for delay reporting to the routing engine.

Platforms

16.149 link-monitoring

link-monitoring

Syntax

[**no**] **link-monitoring**

Context

[Tree] (config>port>ethernet>efm-oam>discovery>advertise-capabilities link-monitoring)

Full Context

configure port ethernet efm-oam discovery advertise-capabilities link-monitoring

Description

When the link monitoring function is in a no shutdown state, the Link Monitoring capability (EV) is advertised to the peer through the EFM OAM protocol. This may not be desired if the remote peer does not support the Link Monitoring functionality.

The **no** version of this command suppresses the advertisement of capabilities.

Default

link-monitoring

Platforms

All

link-monitoring

Syntax

link-monitoring

Context

[Tree] (config>port>ethernet>efm-oam link-monitoring)

Full Context

configure port ethernet efm-oam link-monitoring

Description

This context contains link monitoring specific options defining the various local thresholds, port interaction and peer notification methods. In order to activate Link monitoring function, this context must be configured with the no shutdown option. Shutting down link monitoring will clear all historical link monitoring counters. If the port was removed from service and placed in a non-operational down state and a port state of link up

because a signal failure threshold was crossed and link monitoring is shutdown, the port will be returned to service assuming no underlying conditions prevent this return to service.

When the link monitoring function is in a **no shutdown** state, the Link Monitoring capability (EV) is advertised to the peer through the EFM OAM protocol. This may not be desired if the remote peer does not support the Link Monitoring functionality.

Platforms

16.150 link-specific-rate

link-specific-rate

Syntax

link-specific-rate *packet-rate-limit*

no link-specific-rate

Context

[Tree] (config>sys>security>cpu-protection link-specific-rate)

Full Context

configure system security cpu-protection link-specific-rate

Description

This command configures a link-specific rate for CPU protection. This limit is applied to all ports within the system. The CPU will receive no more than the configured packet rate for all link level protocols such as LACP from any one port. The measurement is cleared each second and is based on the ingress port.

Default

link-specific-rate 15000

Parameters

packet-rate-limit

Specifies a packet arrival rate limit, in packets per second, for link level protocols.

Values 1 to 65535, **max** (no limit)

Platforms

7450 ESS, 7750 SR-7/12/12e, 7750 SR-7s, 7750 SR-14s, 7950 XRS

16.151 link-state-export-enable

link-state-export-enable

Syntax

[**no**] **link-state-export-enable**

Context

[Tree] (config>router>bgp link-state-export-enable)

Full Context

configure router bgp link-state-export-enable

Description

This command enables the export of link-state information from the BGP-LS address family into the local Traffic Engineering Database (TED).

The **no** form of this command disables the export of link state information into the TED.

Default

no link-state-export-enable

Context

[Tree] (oam>eth-cfm linktrace)

Full Context

oam eth-cfm linktrace

Description

The command initiates a linktrace test.

Parameters

mac-address

Specifies a unicast MAC address destination.

Values xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx

remote-mepid *mep-id*

Specifies the remote MEP ID of the peer within the association. The domain and association information are derived from the **source mep** for the session. The Layer 2 IEEE MAC address is resolved from previously-learned remote MAC addressing, derived from the reception and processing of the ETH-CC PDU. The local MEP must be administratively enabled.

Values 1 to 8191

mep *mep-id*

Specifies the local MEP ID.

Values 1 to 8191

md-index

Specifies the MD index.

Values 1 to 4294967295

ma-index

Specifies the MA index.

Values 1 to 4294967295

ttl-value

Specifies the TTL for a returned linktrace.

Values 0 to 255

Default 64

Syntax

listening-port *port*

no listening-port

Context

[Tree] (config>system>grpc listening-port)

Full Context

configure system grpc listening-port

Description

This command configures the listening port for the gRPC server.

The **no** form of this command reverts to the default.

Default

listening-port 57400

Parameters

port

Specifies the port number.

Values 1024 to 49151, 57400

Default 57400

Platforms

All

16.156 live-output

live-output

Syntax

live-output {*ip-address* | *fqdn*} [**port** *port*] [**router** {*router-instance* | **service-name** *service-name*}]

no live-output

Context

[Tree] (config>call-trace>trace-profile live-output)

Full Context

configure call-trace trace-profile live-output

Description

This command specifies a live output destination for this trace. When configured, captures will not be stored locally but sent (over UDP) to the server in the specified routing context. The destination can be

specified as either an IP address or a DNS FQDN. The **live-output** and **debug-output** commands are mutually exclusive.

The **no** form of this command disables live output streaming.

Parameters

ip-address

Specifies the IPv4 or IPv6 address of the server to stream to.

fqdn

Specifies the FQDN that represents the server in DNS, up to 255 characters.

port

Specifies the UDP port on which the server is listening.

Values 1 to 65535

Default 29770

router-instance

Specifies the router instance in which the live output is forwarded.

service-name

Specifies the name of the Layer 3 service in which the live output is forwarded.

Platforms

16.158 llf

llf

Syntax

[**no**] **llf**

Context

[Tree] (config>service>epipe>sap>ethernet llf)

Full Context

configure service epipe sap ethernet llf

Description

This command enables Link Loss Forwarding (LLF) on an Ethernet port. This feature provides an end-to-end OAM fault notification for Ethernet VLL service. It brings down the Ethernet port (Ethernet LLF) or sends a SONET/SDH Path AIS (ATM LLF) toward the attached CE when there is a local fault on the Pseudowire or service, or a remote fault on the SAP or pseudowire, signaled with label withdrawal or T-LDP status bits. It ceases when the fault disappears.

The Ethernet port must be configured for null encapsulation.

This feature is also supported in Epipes with BGP-EVPN enabled. In this case, upon removal of the EVPN destination, the port is brought oper-down with flag LinkLossFwd, however the AD per-EVI route for the SAP is still advertised (the SAP is kept oper-up).

The **no** form of this command disables LLF on an Ethernet port.

Default

no llf

configure isa lns-group

Description

This command configures an LNS group.

The **no** form of the command removes the LNS group ID from the configuration.

Parameters

lns-group-id

Specifies the LNS group identifier.

Values 1 to 4

create

Mandatory keyword used when creating tunnel group in the ISA context. The create keyword requirement can be enabled/disabled in the **environment>create** context.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

16.161 load

load

Syntax

load *file-url* [**overwrite** | **insert** | **append**]

Context

[Tree] (candidate load)

Full Context

candidate load

Description

This command loads a previously saved candidate configuration into the current candidate. The edit point will be set to the end of the loaded configuration lines. The candidate configuration cannot be modified while a load is in progress.

Default

If the candidate is empty then a load without any of the optional parameters (such as overwrite, and so on) will load the file-url into the candidate. If the candidate is not empty then one of the options, such as overwrite, insert, and so on, must be specified.

Parameters

file-url

Specifies the directory and filename to load.

overwrite

Discards the contents of the current candidate and replace it with the contents of the file.

insert

Inserts the contents of the file at the current edit point.

append

Inserts the contents of the file at the end of the current candidate.

[Tree] (config>service>vprn>radius-proxy>server load-balance-key)

Full Context

configure router radius-proxy server load-balance-key

configure service vprn radius-proxy server load-balance-key

Description

This command specifies the key used in calculating a hash to select an external RADIUS server from the pool of configured servers.

The key can be the source IP and source UDP port tuple, or the specified RADIUS attribute in RADIUS packets.

The **no** form of this command removes the parameters from the configuration.

Parameters

vendor-id

Specifies the vendor-id of vendor-specific attribute.

Values 0 to 16777215

attribute-type

Specifies that the key is constructed with the attributes in the RADIUS message.

Values 1 to 255

source-ip-udp

Specifies that the key consists of the source IP address and source UDP port of the RADIUS message.

Platforms

Full Context

configure service vprn l2tp group load-balance-method

configure router l2tp group load-balance-method

configure router l2tp group tunnel load-balance-method

configure service vprn l2tp group tunnel load-balance-method

Description

This command is applicable only to LNS. By default traffic load balancing between the BB-ISAs is based on sessions. Each session is individually assigned to an BB-ISA during session establishment phase.

By introducing MLPPPoX, all sessions of a bundle must be terminated on the same LNS BB-ISA. This is necessary for two reasons:

- QoS in the carrier IOM has a uniform view of the subscriber
- a single BB-ISA is responsible for MLPPPoX encapsulation/fragmentation for a given bundle.

Therefore, if fragmentation is enabled, load-balancing per tunnel must be configured. In the per tunnel load-balancing mode, all sessions within the same tunnel are terminated on the same LNS BB-ISA.

In the case that we have MLPPPoX sessions with a single member link, both load-balancing methods are valid.

The **no** form of this command reverts to the default.

Default

load-balance-method per-session

Parameters

per-session

Specifies that the traffic load balancing between the LNS BB-ISAs is based on individual PPPoE sessions.

per-tunnel

Specifies that the traffic load balancing between the LNS BB-ISAs is based on tunnels.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

configure port tdm e3 load-balancing-algorithm

configure port sonet-sdh path load-balancing-algorithm

configure port tdm ds3 load-balancing-algorithm

configure port tdm ds1 channel-group load-balancing-algorithm

Description

This command specifies the load balancing algorithm to be used on this port.

In the default mode, **no load-balancing-algorithm**, the port inherits the global settings. The value is not applicable for ports that do not pass any traffic.

The configuration of load-balancing-algorithm at logical port level has three possible values:

- **include-l4** — Enables inherits system-wide settings including Layer 4 source and destination port value in hashing algorithm.
- **exclude-l4** — Layer 4 source and destination port value will not be included in hashing.
- **no load-balancing-algorithm** — Inherits system-wide settings.

The hashing algorithm addresses finer spraying granularity where many hosts are connected to the network. To address more efficient traffic distribution between network links (forming a LAG group), a hashing algorithm extension takes into account Layer 4 information (src/dst L4-protocol port). The hashing index can be calculated according to the following algorithm:

If [(TCP or UDP traffic) & enabled]

hash (<TCP/UDP ports>, <IP addresses>)

else if (IP traffic)

hash (<IP addresses>)

else

hash (<MAC addresses>)

endif

This algorithm will be used in all cases where IP information in per-packet hashing is included (refer to "Traffic Load Balancing Options” in the *7450 ESS, 7750 SR, 7950 XRS, and VSR Interface Configuration Guide*). However the Layer 4 information (TCP/UDP ports) will not be used in the following cases:

- fragmented packets

Default

no load-balancing-algorithm

Parameters

option

Specifies the load balancing algorithm to be used on this port.

Values **include-l4** — Specifies that the source and destination ports are used in the hashing algorithm.**exclude-l4** — Specifies that the source and destination ports are not used in the hashing algorithm.

16.166 load-balancing-weight

load-balancing-weight

Syntax

load-balancing-weight *value*

no load-balancing-weight [*value*]

Context

[Tree] (config>service>vprn>static-route-entry>next-hop load-balancing-weight)

Full Context

configure service vprn static-route-entry next-hop load-balancing-weight

Description

This command configures a weighted ECMP load-balancing weight for a static route next-hop.

If all of the ECMP next-hops of a static route have a configured load-balancing-weight then packets matching the route are sprayed according to the relative weights. In other words, the next-hop interface with the largest load-balancing weight should receive the most forwarded traffic if weighted ECMP is applicable.

The **no** form of this command disables weighted ECMP for the interface and effectively disables weighted ECMP for the entire static route.

Parameters

value

Specifies the cost metric value.

Values 0 to 4294967295

Platforms

All

load-balancing-weight

Syntax

load-balancing-weight [*weight*]

no load-balancing-weight

Context

[Tree] (config>service>vprn>ospf3>area>if load-balancing-weight)

[Tree] (config>service>vprn>ospf>area>if load-balancing-weight)

Full Context

configure service vprn ospf3 area interface load-balancing-weight

configure service vprn ospf area interface load-balancing-weight

Description

This command configures the weighted ECMP load-balancing weight for an IS-IS, OSPF, and OSPF3 interface. If the interface becomes an ECMP next hop for an IPv4 or IPv6 route, and all the other ECMP next hops are interfaces with configured (non-zero) load-balancing weights, then the traffic distribution over the ECMP interfaces is proportional to the weights. This means that the interface with the largest load-balancing weight receives the most forwarded traffic if weighted ECMP is applicable.

The **no** form of this command disables weighted ECMP for the interface which effectively disables weighted ECMP for any IP prefix that has this interface as a next hop.

Default

no load-balancing-weight

Parameters

weight

Specifies the load balancing weight.

Values 1 to 4294967295

Platforms

All

load-balancing-weight

Syntax

load-balancing-weight *weight*

no load-balancing-weight

Context

[Tree] (config>service>vprn>isis>if load-balancing-weight)

Full Context

configure service vprn isis interface load-balancing-weight

Description

This command configures the weighted ECMP load-balancing weight for an IS-IS interface of the VPRN. If the interface becomes an ECMP next-hop for IPv4 or IPv6 route and all the other ECMP next-hops are interfaces with configured (non-zero) load-balancing weights, then the traffic distribution over the ECMP

interfaces is proportional to the weights. In other words, the interface with the largest **load-balancing-weight** should receive the most forwarded traffic if weighted ECMP is applicable.

The **no** form of this command disables weighted ECMP for the interface and, therefore, effectively disables weighted ECMP for any IP prefix that has this interface as a next-hop.

Default

no load-balancing-weight

Parameters

weight

Specifies the load balancing weight.

Values 0 to 4294967295

Platforms

All

load-balancing-weight

Syntax

load-balancing-weight *weight*

no load-balancing-weight

Context

[Tree] (config>router>ldp>if-params>if load-balancing-weight)

Full Context

configure router ldp interface-parameters interface load-balancing-weight

Description

This command configures the load balancing weight for the LDP interface. The load balancing weight, normalized to 64, is used for weighted ECMP of LDP labeled packets over direct network IP interfaces.

If the interface becomes an ECMP next hop for an LDP FEC, and all the other ECMP next hops are interfaces with configured (non-zero) load-balancing weights, then the traffic distribution over the ECMP interfaces is proportional to the normalized weight with a granularity of 64.

If one or more of the LDP interfaces in the ECMP set does not have a configured load-balancing weight, then the system falls back to ECMP.

The **no** form of this command removes the load balancing weight for the LDP interface.

Parameters

weight

Specifies the load balancing weight value.

Values 0 to 4294967295

Platforms

All

load-balancing-weight

Syntax

load-balancing-weight *weight*

no load-balancing-weight

Context

[Tree] (config>router>mpls>lsp load-balancing-weight)

Full Context

configure router mpls lsp load-balancing-weight

Description

This command assigns a weight to an MPLS LSP for use in the weighted load-balancing, or weighted ECMP, over MPLS feature.

Parameters

weight

Specifies a 32-bit integer representing the weight of the LSP.

Values 0 to 4294967295

Platforms

All

load-balancing-weight

Syntax

load-balancing-weight *weight*

no load-balancing-weight

Context

[Tree] (config>router>mpls>fwd-policies>fwd-policy>nh-grp load-balancing-weight)

Full Context

configure router mpls forwarding-policies forwarding-policy next-hop-group load-balancing-weight

Description

This command configures the load balancing weight of an NHG entry in a forwarding policy.

A weight for each NHG of a policy must be assigned to the weighted ECMP forwarding to operate over the set of NHGs of the policy.

The **no** form of this command removes the load balancing weight from an NHG entry in a forwarding policy.

Parameters

weight

Specifies the load balancing weight value.

Values 1 to 4294967295

Platforms

All

load-balancing-weight

Syntax

load-balancing-weight *value*

no load-balancing-weight [*value*]

Context

[Tree] (config>router>static-route-entry>next-hop load-balancing-weight)

Full Context

configure router static-route-entry next-hop load-balancing-weight

Description

This command configures a weighted ECMP load-balancing weight for a static route next-hop.

If all of the ECMP next-hops of a static route have a configured load-balancing-weight then packets matching the route are sprayed according to the relative weights. In other words, the next-hop interface with the largest load-balancing weight should receive the most forwarded traffic if weighted ECMP is applicable.

The **no** form of this command disables weighted ECMP for the interface and effectively disables weighted ECMP for the entire static route.

Parameters

value

Specifies the load balancing weight value.

Values 0 to 4294967295

Platforms

All

load-balancing-weight

Syntax

load-balancing-weight [*value*]

no load-balancing-weight

Context

[Tree] (config>router>isis>interface load-balancing-weight)

Full Context

configure router isis interface load-balancing-weight

Description

This command configures the weighted ECMP load-balancing weight for an IS-IS interface. If the interface becomes an ECMP next hop for an IPv4 or IPv6 route, and all the other ECMP next hops are interfaces with configured (non-zero) load-balancing weights, then the traffic distribution over the ECMP interfaces is proportional to the weights. In other words, the interface with the largest load-balancing weight should receive the most forwarded traffic if weighted ECMP is applicable.

The **no** form of this command disables weighted ECMP for the interface and therefore effectively disables weighted ECMP for any IP prefix that has this interface as a next hop.

Default

no load-balancing-weight

Parameters

value

0 to 4294967295

Platforms

All

load-balancing-weight

Syntax

load-balancing-weight [*weight*]

no load-balancing-weight

Context

[Tree] (config>router>ospf3>area>if load-balancing-weight)

[Tree] (config>router>ospf>area>if load-balancing-weight)

Full Context

configure router ospf3 area interface load-balancing-weight

configure router ospf area interface load-balancing-weight

Description

This command configures the weighted ECMP load-balancing weight for an OSPF or OSPF3 interface. If the interface becomes an ECMP next hop for an IPv4 or IPv6 route, and all the other ECMP next hops are interfaces with configured (non-zero) load-balancing weights, then the traffic distribution over the ECMP interfaces is proportional to the weights. This means that the interface with the largest load-balancing weight receives the most forwarded traffic if weighted ECMP is applicable.

The **no** form of this command disables weighted ECMP for the interface which effectively disables weighted ECMP for any IP prefix that has this interface as a next hop.

Default

no load-balancing-weight

Parameters

weight

Specifies the load balancing weight.

Values 1 to 4294967295

Platforms

Syntax

local [**inherit** | **all** | **vc-only** | **none**]

Context

[Tree] (config>service>vprn>ttl-propagate local)

Full Context

configure service vprn ttl-propagate local

Description

This command overrides the global configuration of the TTL propagation for locally generated packets which are forwarded over a MPLS LSPs in a given VPRN service context.

The global configuration is performed under config>router>ttl-propagate>vprn-local.

The default behavior for a given VPRN instance is to inherit the global configuration for the same command. The user can explicitly set the default behavior by configuring the inherit value

Default

local inherit

Parameters

inherit

Specifies the TTL propagation behavior is inherited from the global configuration under **config**>**router**>**ttl-propagate**>**vprn-local**.

none

Specifies the TTL of the IP packet is not propagated into the VC label or labels in the transport label stack.

vc-only

Specifies the TTL of the IP packet is propagated into the VC label and not into the labels in the transport label stack.

all

Specifies the TTL of the IP packet is propagated into the VC label and all labels in the transport label stack.

Context

[Tree] (config>subscr-mgmt>bgp-prng-plcy local-address)

Full Context

configure subscriber-mgmt bgp-peering-policy local-address

Description

This command configures the local IP address used by the group or neighbor when communicating with BGP peers.

Outgoing connections use the **local-address** as the source of the TCP connection when initiating connections with a peer.

When a local address is not specified, the 7750 SR OS uses the system IP address when communicating with IBGP peers and uses the interface address for directly connected EBGP peers. This command is used at the neighbor level to revert to the value defined under the group level.

The **no** form of this command removes the configured local-address for BGP.

The **no** form of this command used at the group level reverts to the value defined at the global level.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Parameters

ip-address

Specifies the IPv4 or IPv6 address of the local address.

For IPv4, the local address is expressed in dotted decimal notation. Allowed values are a valid routable IP address on the router, either an interface or system IP address.

For IPv6, the local address is expressed in semi-colon hexadecimal notation. Allowed values is an interface or a system IP address.

Values

ipv4-address:	a.b.c.d
ipv6-address:	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x - [0 to FFFF]H

d - [0 to 255]D

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

configure service vprn msdp local-address

configure service vprn msdp group peer local-address

Description

This command configures the local end of a Multicast Source Discovery Protocol (MSDP) session. For MSDP to function, at least one peer must be configured. When configuring a peer, you must include this **local-address** command to configure the local end of the MSDP session. This address must be present on the node and is used to validate incoming connections to the peer and to establish connections to the remote peer.

If the user enters this command, then the address provided is validated and will be used as the local address for MSDP peers from that point. If a subsequent **local-address** command is entered, it will replace the existing configuration and existing sessions will be terminated.

Similarly, when the **no** form of this command is entered, the existing local address will be removed from the configuration and the existing sessions will be terminated.

Whenever a session is terminated, all information pertaining to and learned from that peer will be removed.

Whenever a new peering session is created or a peering session is lost, an event message should be generated.

The **no** form of this command removes the local address from the configuration.

Default

no local-address

Parameters

ip-address

Specifies an existing address on the node.

[Tree] (config>router>pcep>pce local-address)

Full Context

configure router pcep pcc local-address

configure router pcep pce local-address

Description

This command configures the local IPv4 address of the PCEP speaker.

The PCEP protocol operates over TCP using destination TCP port 4189. The PCE client (PCC) always initiates the connection. After the user configures the PCEP local IPv4 address and the peer IPv4 address on the PCC, the latter initiates a TCP connection to the PCE. If both a local IPv4 and a local IPv6 address are configured, the connection uses the local address that is the same family as the peer address. When the connection is established, the PCC and PCE exchange OPEN messages, which initializes the PCEP session and exchanges the session parameters to be negotiated.

By default, the PCC attempts to reach the remote PCE address out of band using the management port. If it cannot, it attempts to reach the remote PCE address in band. The user can change the configuration of the peer to attempt connecting in band only or out of band only. When the session comes up out of band, the management IP address is used as the local address. The local IPv4 address configured by the user is only used for in-band sessions and is otherwise ignored.

The **no** form of the command removes the configured local address of the PCEP speaker.

Parameters

ip-address

Specifies the IP address of the PCEP speaker to be used for in-band sessions.

Context

[Tree] (config>router>bgp>group>neighbor local-address)

[Tree] (config>router>bgp>group local-address)

Full Context

configure router bgp group neighbor local-address

configure router bgp group local-address

Description

This command configures the local IP address used by the group or neighbor when communicating with BGP peers.

Outgoing connections use the **local-address** as the source of the TCP connection when initiating connections with a peer.

When a local address is not specified, the router uses the system IP address when communicating with IBGP peers and uses the interface address for directly connected EBGP peers. This command is used at the neighbor level to revert to the value defined under the group level.

When set to a router interface, the **local-address** inherits the primary IPv4 or IPv6 address of the router interface depending on whether BGP is configured for IPv4 or IPv6. If the corresponding IPv4 or IPv6 address is not configured on the router interface, the BGP sessions that have this interface set as the **local-address** are kept down until an interface address is configured on the router interface.

The **no** form of this command removes the configured local-address for BGP.

The **no** form of this command used at the group level returns the configuration to the value defined at the global level.

The **no** form of this command used at the neighbor level returns the configuration to the value defined at the group level.

Default

no local-address

Parameters

ip-address

Specifies the local address expressed in dotted decimal notation. Allowed value is a valid routable IP address on the router, either an interface or system IP address.

Values ipv4-address:

- a.b.c.d (host bits must be 0)

ipv6-address

Specifies the local address expressed in dotted decimal notation. Allowed value is a valid routable IPv6 address on the router, either an interface or system IPv6 address.

Values ipv6-address:

- x:x:x:x:x:x:x:x (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d
- x: [0 to FFFF]H
- d: [0 to 255]D

ip-int-name

Specifies the IP interface name whose address the local address will inherit. The interface can be any network interface configured on the system.

Platforms

All

local-address

Syntax

local-address *ip-address* | *ipv6-address*

no local-address

Context

[Tree] (config>bmp>station>connection local-address)

Full Context

configure bmp station connection local-address

Description

This command configures the local IP address used by the local router when communicating with the BMP monitoring station. This configuration is optional.

Outgoing connections use the local-address as the source of the TCP connection when initiating connections with a monitoring station.

The BMP session may flap when this parameter is changed. Shut down the BMP session before changing the values.

The **no** form of this command removes the configured local-address for the BMP session. The default is to use the system IP address.

Default

local-address ip-address (system IP address)

Parameters

ip-address

Specifies the local address expressed in dotted decimal notation. Allowed value is a valid routable IP address on the router, either an interface or system IP address.

Values ipv4-address:

- a.b.c.d (host bits must be 0)

ipv6-address

Specifies the local address expressed in dotted decimal notation. Allowed value is a valid routable IPv6 address on the router, either an interface or system IPv6 address.

Values ipv6-address:

- x:x:x:x:x:x:x:x (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d
- x: [0 to FFFF]H

16.171 local-age

local-age

Syntax

local-age *aging-timer*

no local-age [*aging-timer*]

Context

[Tree] (config>service>vpls local-age)

[Tree] (config>service>template>vpls-template local-age)

Full Context

configure service vpls local-age

configure service template vpls-template local-age

Description

Specifies the aging time for locally learned MAC addresses in the forwarding database (FDB) for the Virtual Private LAN Service (VPLS) instance. In a VPLS service, MAC addresses are associated with a Service Access Point (SAP) or with a Service Distribution Point (SDP). MACs associated with a SAP are classified as local MACs, and MACs associated with an SDP are remote MACs.

Like in a Layer 2 switch, learned MACs can be aged out if no packets are sourced from the MAC address for a period of time (the aging time). In each VPLS service instance, there are independent aging timers for local learned MAC and remote learned MAC entries in the FDB. The **local-age** timer specifies the aging time for local learned MAC addresses.

The **no** form of this command returns the local aging timer to the default value.

Default

local age 300 — Local MACs aged after 300 seconds.

Parameters

aging-timer

Specifies the aging time for local MACs expressed in seconds

Values 60 to 86400

Platforms

All

16.172 local-as

local-as

Syntax

local-as *as-number* [**private**]

no local-as

Context

[Tree] (config>subscr-mgmt>bgp-prng-plcy local-as)

Full Context

configure subscriber-mgmt bgp-peering-policy local-as

Description

This command configures a BGP virtual autonomous system (AS) number.

In addition to the AS number configured for BGP in the config>router>autonomous-system context, a virtual (local) AS number is configured. The virtual AS number is added to the as-path message before the router's AS number makes the virtual AS the second AS in the as-path.

This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). Thus, by specifying this at each neighbor level, it is possible to have a separate as-number per EBGP session.

When a command is entered multiple times for the same AS, the last command entered is used in the configuration. The **private** attribute can be added or removed dynamically by reissuing the command.

Changing the local AS at the global level in an active BGP instance causes the BGP instance to restart with the new local AS number. Changing the local AS at the global level in an active BGP instance causes BGP to re-establish the peer relationships with all peers in the group with the new local AS number. Changing the local AS at the neighbor level in an active BGP instance causes BGP to re-establish the peer relationship with the new local AS number.

This is an optional command and can be used in the following circumstance:

Provider router P is moved from AS1 to AS2. The customer router that is connected to P, however, is configured to belong to AS1. To avoid reconfiguring the customer router, the **local-as** value on router P can

be set to AS1. Thus, router P adds AS1 to the as-path message for routes it advertises to the customer router.

The **no** form of this command used at the global level will remove any virtual AS number configured.

The **no** form of this command used at the group level reverts to the value defined at the global level.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Parameters

as-number

Specifies the virtual autonomous system number, expressed as a decimal integer.

Values 1 to 4294967295

private

Specifies that the local-as number is hidden in paths learned from the peering.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

[Tree] (config>service>vprn>bgp>group local-as)

Full Context

configure service vprn bgp group neighbor local-as

configure service vprn bgp local-as

configure service vprn bgp group local-as

Description

This command configures a BGP virtual autonomous system (AS) number.

In addition to the global AS number configured for BGP in the config>router>autonomous-system context, a virtual (local) AS number can be configured to support various AS number migration scenarios. The local AS number is added to the to the beginning the as-path attribute ahead of the router's AS number.

This configuration parameter can be set at three levels: global level (applies to all EBGP peers), group level (applies to all EBGP peers in peer-group) or neighbor level (only applies to EBGP specified peer). Thus, by specifying this at each neighbor level, it is possible to have a separate local-as per EBGP session. The local-as command is not supported for IBGP sessions. When the optional **private** keyword is

specified in the command the local-as number is not added to inbound routes from the EBGP peer that has **local-as** in effect.

When a command is entered multiple times for the same AS, the last command entered is used in the configuration. The **private** attribute can be added or removed dynamically by reissuing the command.

Changing the local AS at the global level in an active BGP instance causes the BGP instance to restart with the new local AS number. Changing the local AS at the global level in an active BGP instance causes BGP to re-establish the peer relationships with all peers in the group with the new local AS number. Changing the local AS at the neighbor level in an active BGP instance causes BGP to re-establish the peer relationship with the new local AS number.

This is an optional command and can be used in the following circumstance:

Provider router P is moved from AS1 to AS2. The customer router that is connected to P, however, is configured to belong to AS1. To avoid reconfiguring the customer router, the **local-as** value on router P can be set to AS1. Thus, router P adds AS1 to the as-path message for routes it advertises to the customer router.

The **no** form of this command used at the global level removes any virtual AS number configured.

The **no** form of this command used at the group level reverts to the value defined at the global level.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Default

no local-as

Parameters

as-number

The virtual autonomous system number, expressed as a decimal integer.

Values 1 to 65535

private

Specifies the local-as is hidden in paths learned from the peering.

no-prepend-global-as

Specifies that the global-as is hidden in paths announced to the EBGP peer.

Platforms

All

[Tree] (config>router>bgp>group>neighbor local-as)

Full Context

configure router bgp group local-as

configure router bgp local-as

configure router bgp group neighbor local-as

Description

This command configures a BGP local autonomous system (AS) number. In addition to the global AS number configured for BGP using the autonomous-system command, a local AS number can be configured to support various AS number migration scenarios.

When the **local-as** command is applied to a BGP neighbor and the local-as is different from the peer-as, the session comes up as EBGP and by default the global-AS number and then (in that order) the local-as number are prepended to the AS_PATH attribute in outbound routes sent to the peer. In received routes from the EBGP peer, the local AS is prepended to the AS path by default, but this can be disabled with the **private** option.

When the **local-as** command is applied to a BGP neighbor and the local-as is the same as the peer-as, the session comes up as IBGP, and by default, the global-AS number is prepended to the AS_PATH attribute in outbound routes sent to the peer.

This configuration parameter can be set at three levels: global level (applies to all BGP peers), group level (applies to all BGP peers in group) or neighbor level (only applies to one specific BGP neighbor). By specifying this at the neighbor level, it is possible to have a separate **local-as** for each BGP session.

When the optional **no-prepend-global-as** command is configured, the global-as number is not added in outbound routes sent to an IBGP or EBGP peer.

When a command is entered multiple times for the same AS, the last command entered is used in the configuration. The private option can be added or removed dynamically by reissuing the command. Changing the local AS at the global level in an active BGP instance causes the BGP instance to restart with the new local AS number. Changing the local AS at the global level in an active BGP instance causes BGP to re-establish the peer relationships with all peers in the group with the new local AS number. Changing the local AS at the neighbor level in an active BGP instance causes BGP to re-establish the peer relationship with the new local AS number.

The **no** form of this command used at the group level reverts to the value defined at the global level.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Default

no local-as

Parameters

as-number

Specifies the virtual autonomous system number expressed as a decimal integer.

Values 1 to 4294967295

private

Specifies the local-as is hidden in paths learned from the peering.

no-prepend-global-as

Specifies that the global-as is hidden in paths announced to the BGP peer.

Full Context

configure service vprn dhcp local-dhcp-server

configure router dhcp local-dhcp-server

Description

This command instantiates a local DHCP server. A local DHCP server can serve multiple interfaces but is limited to the routing context it was which it was created.

The **no** form of this command reverts to the default.

Parameters

server-name

Specifies the name of local DHCP server, up to 32 characters.

create

Keyword used to create the local DHCP server. The **create** keyword requirement can be enabled or disabled in the **environment>create** context.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

local-dhcp-server

Syntax

local-dhcp-server *server-name* [**create**] [**auto-provisioned**]

no local-dhcp-server *server-name*

Context

[Tree] (config>router>dhcp6 local-dhcp-server)

Full Context

configure router dhcp6 local-dhcp-server

Description

This command instantiates a DHCP6 server. A local DHCP6 server can serve multiple interfaces but is limited to the routing context it was which it was created.

The **no** form of this command reverts to the default.

Parameters

server-name

Specifies the name of local DHCP6 server, up to 32 characters.

create

Keyword used to create the local DHCP or DHCP6 server. The **create** keyword requirement can be enabled or disabled in the **environment>create** context.

auto-provisioned

Specifies the auto provisioning mode. This parameter only applies to DHCP6 creation to configure DHCP6 default values.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

local-dhcp-server

Syntax

[**no**] **local-dhcp-server** *server-name* [**lease-address** *ip-prefix*[*prefix-length*]]

[**no**] **local-dhcp-server** *server-name* [**mac** *ieee-address*]

[**no**] **local-dhcp-server** *server-name* [**link-local-address** *ipv6z-address*]

Context

[Tree] (debug>router local-dhcp-server)

Full Context

debug router local-dhcp-server

Description

This command enables, disables or configures debugging for a local DHCP server.

Parameters

server-name

Specifies an existing local DHCP server name.

ip-prefix[/prefix-length]

Specifies the IP prefix and prefix length of the subnet.

Values ip-prefix — a.b.c.d (host bits must be 0)
length — 0 to 32

ieee-address

Specifies that the provisioned MAC address for the local DHCP server.

ipv6z-address

Specifies the IPv6z address.

ipv6-address:	x:x:x:x:x:x:x:x [-interface]
	x:x:x:x:x:x:d.d.d.d [-interface]
	x: [0 to FFFF]H
	d: [0 to 255]D
interface	up to 32 characters, mandatory for link local addresses

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

local-ecid

Syntax

local-ecid *emulated circuit identifier*

no local-ecid

Context

[Tree] (config>service>epipe>sap>cem local-ecid)

Full Context

configure service epipe sap cem local-ecid

Description

This command defines the Emulated Circuit Identifiers (ECID) to be used for the local (source) end of the circuit emulation service.

The **no** form of this command removes the ECID from the configuration.

Default

local-ecid 65535

Parameters

emulated circuit identifier

Specifies the value to be used as the local (source) ECID for the circuit emulation service. On CES packet reception, the ECID in the packet will be compared to the configured local-ecid value. These must match for the packet payload to be used for the TDM circuit. The remote-ecid value is inserted into the MEF-8 CES packet to be transmitted.

Values 0 to 1048575

Platforms

7450 ESS, 7750 SR-7/12/12e, 7750 SR-a, 7750 SR-e

16.177 local-end

local-end

Syntax

local-end {*ip-address* | *ipv6-address*}

no local-end

Context

[Tree] (config>service>sdp local-end)

Full Context

configure service sdp local-end

Description

This command configures the local-end address of the following SDP encapsulation types:

- IPv6 address of the termination point of a SDP of encapsulation **l2tpv3** (L2TP v3 tunnel).
- IPv4/IPv6 source address of a SDP of encapsulation **eth-gre-bridged** (L2oGRE SDP).
- IPv4 source address of a SDP of encapsulation **gre** (GRE SDP).

A change to the value of the local-end parameter requires that the SDP be shut down.

When used as the source address of a SDP of encapsulation **gre** (GRE SDP), the primary IPv4 address of any local network IP interface, loopback or otherwise, may be used.

The address of the following interfaces are not supported:

- unnumbered network IP interface
- IES interface
- VPRN interface
- CSC VPRN interface

The **local-end** parameter value adheres to the following rules:

- A maximum of 15 distinct address values can be configured for all GRE SDPs under the **config**>**service**>**sdp**>**local-end** context, and all L2oGRE SDPs under the **config**>**service**>**system**>**gre-eth-bridged**>**tunnel-termination** context.
- The same source address cannot be used in both contexts since an address configured for a L2oGRE SDP matches an internally created interface that is not available to other applications.
- The **local-end** address of a GRE SDP, when different from system, need not match the primary address of an interface that has the MPLS-over-GRE termination subnet configured, unless a GRE SDP or tunnel from the far-end router terminates on this address.

The **no** form of the command removes the address from the local-end configuration.

Parameters

ip-address* | *ipv6-address

Specifies a IPv4 or IPv6 address for local-end of an SDP in dotted decimal notation.

Values

ip-address	a.b.c.d
ipv6-address	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x - [0..FFFF]H
	d - [0..255]D

configure mcast-management multicast-info-policy bundle video local-fcc-port

configure mcast-management multicast-info-policy bundle channel video local-fcc-port

configure mcast-management multicast-info-policy bundle channel source-override video local-fcc-port

Description

This command configures the local port on which Fast Channel Change (FCC) requests are received. The value of this object can only be set for the default bundle and will be used by all bundles and channels.

The **local-fcc-port** *port* value is the only configuration parameter in the bundle "default" context.

The **no** form of the command removes the port from the video configuration.

Parameters

port

Specifies a local port for FCC requests.

Values 1024 to 5999, 6251 to 65535

Platforms

7450 ESS, 7750 SR-1, 7750 SR-7/12/12e, 7750 SR-1s, 7750 SR-2s, 7750 SR-7s, 7750 SR-14s

local-forward

Syntax

local-forward *local-forward-id* [**create**]

no local-forward *local-forward-id*

Context

[Tree] (config>system>satellite local-forward)

Full Context

configure system satellite local-forward

Description

This command creates a local-forward instance.

A local-forward instance creates a traffic bypass within the Ethernet satellite, which allows traffic to be forwarded between satellite client ports.

The **no** form of this command deletes the specified local-forward instance.

Parameters

local-forward-id

Specifies the ID number for the local-forward instance.

Values 1 to 10240

create

Creates a new local-forward instance.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

configure service ies interface sap ipsec-gw local-gateway-address

Description

This command configures local gateway address of the IPsec gateway.

Parameters

ip-address

Specifies a unicast IPv4 address or a global unicast IPv6 address. This address must be within the subnet of the public interface.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

local-gateway-address

Syntax

local-gateway-address *ip-address* **peer** *ip-address* **delivery-service** *service-id*

no local-gateway-address

Context

[Tree] (config>service>vprn>if>sap>ipsec-tunnel local-gateway-address)

Full Context

configure service vprn interface sap ipsec-tunnel local-gateway-address

Description

This command specifies the local gateway address used for the tunnel and the address of the remote security gateway at the other end of the tunnel remote peer IP address to use.

Default

no local-gateway-address

Parameters

ip-address

IP address of the local end of the tunnel.

delivery-service *service-id*

The ID of the IES or VPRN (front-door) delivery service of this tunnel. Use this service-id to find the VPRN used for delivery.

Values *service-id*: 1 to 2147483648

svc-name: Specifies an existing service name up to 64 characters in length.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

16.182 local-id

local-id

configure router interface ipsec ipsec-tunnel dynamic-keying local-id

configure service vprn interface sap ipsec-gw local-id

configure service vprn interface ipsec ipsec-tunnel dynamic-keying local-id

configure ipsec ipsec-transport-mode-profile dynamic-keying local-id

configure service ies interface ipsec ipsec-tunnel dynamic-keying local-id

configure service vprn interface sap ipsec-tunnel dynamic-keying local-id

configure service ies interface sap ipsec-gw local-id

Description

This command specifies the local ID used for IDi or IDr for IKEv2 negotiation.

The default behavior depends on the local-auth-method as follows:

- Psk: local tunnel IP address
- Cert-auth: subject of the local certificate

The **no** form of this command removes the parameters from the configuration.

Default

no local-id

Parameters

type

Specifies the type of local ID payload, which could be IPv4 or IPv6 address or FQDN domain name or distinguish the name of the subject in the X.509 certificate.

Values ipv4 — Specifies to use IPv4 as the local ID type; the default value is the local tunnel end-point address.

ipv6 — Specifies to use IPv6 as the local ID type; the default value is the local tunnel end-point address.

fq1dn — Specifies to use FQDN as the local ID type. The value must be configured.

value

Specifies the data type as an enumerated integer that describes the local identifier type used for IDi or IDr for IKEv2, up to 255 characters.

Platforms

VSR

- configure service ies interface ipsec ipsec-tunnel dynamic-keying local-id
- configure router interface ipsec ipsec-tunnel dynamic-keying local-id
- configure service vprn interface ipsec ipsec-tunnel dynamic-keying local-id

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

- configure service vprn interface sap ipsec-gw local-id
- configure ipsec ipsec-transport-mode-profile dynamic-keying local-id

local-ip

Syntax

local-ip {*ip-prefix/prefix-length* | *ip-prefix netmask* | **any**}

Context

[Tree] (config>service>vprn>ipsec>sec-plcy>entry local-ip)

[Tree] (config>router>ipsec>sec-plcy>entry local-ip)

Full Context

configure service vprn ipsec security-policy entry local-ip

configure router ipsec security-policy entry local-ip

Description

This command configures the local (from the VPN) IP prefix/mask for the policy parameter entry.

Only one entry is necessary to describe a potential flow. The **local-ip** and **remote-ip** commands can be defined only once. The system evaluates:

- the local IP as the source IP when traffic is examined in the direction of the flows from private to public and as the destination IP when traffic flows from public to private
- the remote IP as the source IP when traffic flows public to private and as the destination IP when traffic flows from private to public

Parameters

ip-prefix

The destination address of the aggregate route in dotted decimal notation

Values a.b.c.d (host bits must be 0)
prefix-length 1 to 32

netmask

The subnet mask in dotted decimal notation

any

keyword to specify that it can be any address

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

- configure service vprn ipsec security-policy entry local-ip

VSR

- configure router ipsec security-policy entry local-ip

16.184 local-ip-address

local-ip-address

Syntax

local-ip-address *ip-address*

no local-ip-address

Context

[Tree] (config>lag>bfd>family local-ip-address)

Full Context

configure lag bfd family local-ip-address

Description

This command is used to specify the IPv4 or IPv6 address of the BFD source.

The **no** form of this command removes this address from the configuration.

Default

no local-ip-address

Parameters

ip-address

Specifies the IP address.

Values

ipv4-address:	a.b.c.d
ipv6-address:	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d

no local-ip-range-start

Context

[Tree] (config>isa>nat-group>inter-chassis-redundancy local-ip-range-start)

Full Context

configure isa nat-group inter-chassis-redundancy local-ip-range-start

Description

This command configures the first IP address that is assigned to a first member ISA in the nat-group. The remaining member ISAs in the **nat-group** are automatically assigned the consecutive IP addresses, starting from the first IP address. These IP addresses are used to communicate between the ISAs on redundant nodes for the purpose of flow synchronization. Traffic from the first local IP address (member ISA), is sent to the first IP address from the remote IP range.

The **no** form of this command reverts to the default.

Default

no local-ip-range-start

Parameters

ip-address

Specifies the first IP address from the range assigned to the first member ISA in the form of a.b.c.d

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

configure router ldp interface-parameters interface ipv6 local-lsr-id

Description

This command enables the use of the address of the local LDP interface, or any other network interface configured on the system, as the LSR-ID to establish link LDP Hello adjacency and LDP session with directly connected LDP peers. The network interface can be a loopback or not.

Link LDP sessions to all peers discovered over a given LDP interface share the same local LSR-ID. However, LDP sessions on different LDP interfaces can use different network interface addresses as their local LSR-ID.

By default, the LDP session to a peer uses the system interface address as the LSR-ID unless explicitly configured using this command. The system interface must always be configured on the router, or the LDP protocol will not come up on the node. There is no requirement to include the system interface in any routing protocol.

At initial configuration, the LDP session to a peer will remain down while the network interface used as LSR-ID is down. LDP will not try to bring it up using the system interface.

If the network IP interface used as LSR-ID goes down, the LDP sessions to all discovered peers using this LSR-ID go down.

When an interface other than the system is used as the LSR-ID, the transport connection (TCP) for the link LDP session will also use the address of that interface as the transport address. If the system or interface value is configured in the **config**>**router**>**ldp**>**if-params**>**if**>**ipv4** or **config**>**router**>**ldp**>**if-params**>**if**>**ipv6**> **transport-address** context, it will be overridden with the address of the LSR-ID interface.

When the **local-lsr-id** command is enabled with the **32bit-format** option, an SR OS LSR will be able to establish an LDP IPv6 Hello adjacency and an LDP IPv6 session with an RFC 7552 compliant peer LSR. The LSR uses a 32-bit LSR-ID set to the value of the IPv4 address of the specified local LSR-ID interface and a 128-bit transport address set to the value of the IPv6 address of the specified local LSR-ID interface.

Note:
The system interface cannot be used as a local LSR-ID with the **32bit-format** option enabled because the system interface is the default LSR-ID and transport address for all LDP sessions to peers on this LSR. This configuration is blocked in the CLI.

If the user enables the **32bit-format** option in the IPv6 context of a running LDP interface, the already established LDP IPv6 Hello adjacency and LDP IPv6 session will be brought down and re-established with the new 32-bit LSR-ID value.

If the user changes the LSR-ID value between **system**, **interface**, and *interface-name*, or enables the **32bit-format** option while the LDP session is up, LDP will immediately tear down all sessions using this LSR-ID and will attempt to re-establish them using the new LSR-ID.

The **no** form of this command returns to the default behavior, in which case the system interface address is used as the LSR-ID.

Default

no local-lsr-id

Parameters

system

Specifies the use of the address of the system interface as the value of the LSR-ID of this LDP LSR.

interface

Specifies the use of the address of the local LDP interface as the value of the LSR-ID of this LDP LSR.

interface-name interface-name

Specifies the name, up to 32 character, of the network IP interface (which address is used as the LSR-ID of this LDP LSP). An interface name cannot be in the form of an IP address. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

32bit-format

Specifies the use of the IPv4 address of the local LSR-ID interface as the LSR-ID of this LDP LSR.

[Tree] (config>router>ldp>targ-session>peer-template local-lsr-id)

Full Context

configure router ldp targeted-session peer local-lsr-id

configure router ldp targeted-session peer-template local-lsr-id

Description

This command enables the use of the address of any network interface configured on the system, as the LSR-ID to establish a targeted LDP Hello adjacency and a targeted LDP session with an LDP peer. The network interface can be a loopback or not.

By default, the targeted LDP session to a peer uses the system interface address as the LSR-ID and as the transport address, unless explicitly configured using this command. The system interface must always be configured on the router, or the LDP protocol will not come up on the node. There is no requirement to include the system interface in any routing protocol.

When the **local-lsr-id** command is enabled with the **32bit-format** option, an SR OS LSR will be able to establish a targeted LDP IPv6 Hello adjacency and a targeted LDP IPv6 session with an RFC 7552 compliant peer LSR. The LSR uses a 32-bit LSR-ID set to the value of the IPv4 address of the specified local LSR-ID interface and a 128-bit transport address set to the value of the IPv6 address of the specified local LSR-ID interface.

Note:
The system interface cannot be used as a local LSR-ID with the 3**2bit-format** option enabled because the system interface is the default LSR-ID and transport address for all targeted LDP sessions to peers on this LSR. This configuration is blocked in the CLI.

If the user enables the **32bit-format** option in the IPv6 context of a running targeted LDP peer, the already established targeted LDP IPv6 Hello adjacency and targeted LDP IPv6 session will be brought down and re-established with the new 32-bit LSR-ID value.

If the user changes the local LSR-ID value or enables/disables the **32bit-format** option, while the targeted LDP session is up, LDP will immediately tear down the targeted session using this LSR-ID and will attempt to re-establish it using the new LSR-ID.

The **no** form of this command returns to the default behavior, in which case the system interface address is used as the LSR-ID.

Default

no local-lsr-id

Parameters

interface-name

Specifies the name, up to 32 characters, of the network IP interface (which address is used as the LSR-ID of this LDP LSP). An interface name cannot be in the form of an IP address. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

32bit-format

Specifies the use of the IPv4 address of the local LSR-ID interface as the LSR-ID of this LDP LSR.

local-monitoring-policer

Syntax

[**no**] **local-monitoring-policer** *policer-name* [**create**]

Context

[Tree] (config>sys>security>dist-cpu-protection>policy local-monitoring-policer)

Full Context

configure system security dist-cpu-protection policy local-monitoring-policer

Description

This command configures a monitoring policer that is used to monitor the aggregate rate of several protocols arriving on an object (for example, SAP). When the **local-monitoring-policer** is determined to be in a nonconforming state (at the end of a minimum monitoring time of 60 seconds) then the system will attempt to allocate dynamic policers for the particular object for any protocols associated with the local monitor (for example, using the **protocol** *name* **enforcement dynamic** *policer-name* CLI command).

If the system cannot allocate all the dynamic policers within 150 seconds, it will stop attempting to allocate dynamic policers, raise a LocMonExcdAllDynAlloc log event, and go back to using the local monitor. The local monitor may then detect exceeded packets again and make another attempt at allocating dynamic policers.

Once this *policer-name* is referenced by a protocol then this policer will be instantiated for each "object" that is created and references this DDoS policy. If there is no policer free then the object will be blocked from being created.

Parameters

policy-name

Specifies name of the policy, up to 32 characters.

Full Context

configure port ethernet efm-oam link-monitoring local-sf-action local-port-action

Description

This command configures the parameters that define if and how the local port will be affected when the local signal failure threshold (**sf-threshold**) has been reached within the configured window.

Interactions: The signal failure threshold will trigger these actions.

Default

local-port-action out-of-service

Parameters

log-only

Keyword that prevents the port from being affected when the configured signal failure threshold is reach within the window. The event will be logged but the port will remain operational.

out-of-service

Keyword that causes the port to enter a non-operation down state with a port state of link up. The error will be logged when the configured signal failure threshold (**sf-threshold**) is reached within the window. The port will not be available to service data but will continue to carry Link OAM traffic to ensure the link is monitored.

configure service vprn bgp group local-preference

configure service vprn bgp local-preference

Description

This command enables setting the BGP local-preference attribute in incoming routes if not specified and configures the default value for the attribute. This value is used if the BGP route arrives from a BGP peer without the **local-preference** integer set.

The specified value can be overridden by any value set via a route policy. This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). The most specific value is used.

The **no** form of this command at the global level specifies that incoming routes with local-preference set are not overridden and routes arriving without local-preference set are interpreted as if the route had local-preference value of 100.

The **no** form of this command used at the group level reverts to the value defined at the global level.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Default

no local-preference - Does not override the local-preference value set in arriving routes and analyze routes without local preference with value of 100.

Parameters

local-preference

The local preference value to be used as the override value, expressed as a decimal integer.

Values 0 to 4294967295

Description

This command enables setting the BGP local-preference attribute in incoming routes if not specified and configures the default value for the attribute.

This value is used if the BGP route arrives from a BGP peer without the **local-preference** integer set.

The specified value can be overridden by any value set via a route policy. This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to the specified peer). The most specific value is used.

The **no** form of this command at the global level specifies that incoming routes with local-preference set are not overridden and routes arriving without local-preference set are interpreted as if the route had local-preference value of 100.

The **no** form of this command used at the group level reverts to the value defined at the global level.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Default

no local-preference

Parameters

local-preference

Specifies the local preference value to be used as the override value expressed as a decimal integer.

Values 0 to 4294967295

Platforms

All

local-preference

Syntax

local-preference *preference* [**equal** | **or-higher** | **or-lower**]

no local-preference

Context

[Tree] (config>router>policy-options>policy-statement>entry>from local-preference)

Full Context

configure router policy-options policy-statement entry from local-preference

Description

This command matches BGP routes based on local preference (the value in the LOCAL_PREF attribute).

If no comparison qualifiers are present (**equal**, **or-higher**, **or-lower**), then **equal** is the implied default.

A non-BGP route does not match a policy entry if it contains the **local-preference** command.

Default

no local-preference

Parameters

preference

Specifies the local preference value.

Values 0 to 4294967295, or a parameter name delimited by starting and ending at-sign (@) characters

equal

Specifies that matched routes should have the same local preference as the value specified.

or-higher

Specifies that matched routes should have the same or a greater local preference as the value specified.

or-lower

Specifies that matched routes should have the same or a lower local preference as the value specified.

configure router policy-options policy-statement default-action local-preference

configure router policy-options policy-statement entry local-preference

Description

This command assigns a BGP local preference to routes matching a route policy statement entry.

If no local preference is specified, the BGP configured local preference is used.

The **no** form of this command disables assigning a local preference in the route policy entry.

Default

no local-preference

Parameters

preference

Specifies the local preference expressed as a decimal integer.

Values 0 to 4294967295 name — Specifies the local preference parameter variable name. Allowed values are any string up to 32 characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes. Policy parameters must start and end with at-signs (@); for example, "@variable@”.

Syntax

local-prefix *local-prefix* [**create**]

no local-prefix *local-prefix*

Context

[Tree] (config>service>pw-routing local-prefix)

Full Context

configure service pw-routing local-prefix

Description

This command configures one or more node prefix values to be used for MS-PW routing. At least one prefix must be configured on each node that is an S-PE or a T-PE.

The **no** form of this command removes a previously configured prefix, and will cause the corresponding route to be withdrawn if it has been advertised in BGP.

Default

no local-prefix

Parameters

local-prefix

Specifies a 32 bit prefix for the AII. One or more prefix values, up to a maximum of 16, may be assigned to the 7450 ESS, 7750 SR, or 7950 XRS node. The global ID can contain the 2-octet or 4-octet value of the provider's Autonomous System Number (ASN). The presence of a global ID based on the provider's ASN ensures that the AII for spoke-SDPs configured on the node will be globally unique.

Values <global-id>:<ip-addr>| <raw-prefix>

ip-addr	a.b.c.d
raw-prefix	1 to 4294967295
global-id	1 to 4294967295

no local-routes-domain-id

Context

[Tree] (config>service>vprn local-routes-domain-id)

Full Context

configure service vprn local-routes-domain-id

Description

This command specifies the domain ID that is used in the D-PATH attribute for local routes before those routes are exported to a BGP neighbor using BGP-IPVPN, EVPN-IFF, EVPN-IFL or PE-CE BGP. A local route is a non-BGP route installed in the VPRN route table and learned using static route or an IGP.

The domain IDs are used in the D-PATH attribute, in accordance with *draft-ietf-bess-evpn-ipvpn-interworking*. The D-PATH attribute is modified by gateway routers, where a gateway is defined as a PE where a VPRN is instantiated, and that VPRN advertises or receives routes from multiple BGP owners (for example, EVPN-IFL and BGP-IPVPN).

The D-PATH attribute is used on gateways to detect loops (for received routes where the D-PATH contains a local domain ID) and to make BGP best path selection decisions based on the D-PATH length (shorter D-PATH is preferred).

The **no** form of this command removes the domain ID for local routes.

Default

no local-routes-domain-id

Parameters

global-field:local-field

Specifies the domain ID for local routes.

Values *4byte-GlobalAdminValue:2byte-LocalAdminValue*

4byte-GlobalAdminValue:	0 to 4294967295
2byte-LocalAdminValue	0 to 65535

[Tree] (config>mcast-mgmt>mcast-info-plcy>bundle>channel>video local-rt-server)

Full Context

configure mcast-management multicast-info-policy bundle channel source-override video local-rt-server

configure mcast-management multicast-info-policy bundle video local-rt-server

configure mcast-management multicast-info-policy bundle channel video local-rt-server

Description

This command enables the local retransmission server capability on the ISA video group.

RET server parameters can be configured in a multicast information policy or a service, but the parameters will have no effect if the RET server is disabled or if the video group is administratively disabled (shutdown).

The **no** form of the command returns the parameter to the default value where the RET server is disabled on the video group.

Default

no local-rt-server

Parameters

disable

Specifies to disable the RET server.

Platforms

7450 ESS, 7750 SR-1, 7750 SR-7/12/12e, 7750 SR-1s, 7750 SR-2s, 7750 SR-7s, 7750 SR-14s

Context

[Tree] (config>system>telemetry>persistent-subscriptions>subscription>local-ip-address local-source-address)

Full Context

configure system telemetry persistent-subscriptions subscription local-ip-address local-source-address

Description

This command is used to assign a source IP address in the respective persistent subscription context for use when packets are sent out.

The **no** form of this command removes this address from the configuration.

Parameters

ip-int-name

Specifies the source IP address name, up to 64 characters.

ip-address

Specifies the source IP address.

Values ipv4-address: a.b.c.d

ipv6-address:	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x:-[0 to FFFF]H
	d: [0 to 255]D

Full Context

configure system grpc-tunnel destination-group destination local-source-address

Description

This command configures a local source IP address in the destination group context for use when packets are sent out.

The **no** form of this command removes this address from the configuration.

Default

no local-source-address

Parameters

ip-int-name

Specifies the source IP address name, up to 64 characters.

ip-address

Specifies the source IPv4 address (in dotted decimal notation) or IPv6 address.

Values

ipv4-address:	a.b.c.d
ipv6-address:	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d

16.201 local-sr-protection

local-sr-protection

Syntax

local-sr-protection *local-sr-protection*

no local-sr-protection

Context

[Tree] (config>router>mpls>lsp local-sr-protection)

[Tree] (config>router>mpls>lsp-template local-sr-protection)

Full Context

configure router mpls lsp local-sr-protection

configure router mpls lsp-template local-sr-protection

Description

This command configures the SR LFA protection needed for the adjacencies used in the path computation of an SR-TE LSP by the local CSPF.

The default value of the command is **preferred**. The local CSPF will prefer a protected adjacency over an unprotected adjacency whenever both exist for a TE link. However, the entire computed path can combine both types of adjacencies.

When the user enables the **mandatory** value, CSPF uses it as an additional path constraint and selects protected adjacencies exclusively in computing the path of the SR-TE LSP. CSPF will return no path if all candidate paths that otherwise satisfy all other LSP path constraints do not have an unprotected SID for each of their TE links.

Similarly, if the user enables the value **none**, CSPF uses it as an additional path constraint and selects unprotected adjacencies exclusively in computing the path of the SR-TE LSP. CSPF will return no path if all candidate paths that otherwise satisfy all other LSP path constraints do not have a protected SID for each of their TE links.

The **no** form of this command returns the command to its default value.

Default

no local-sr-protection

Parameters

local-sr-protection

Specifies the local-sr-protection for LSPs.

Values none — Selects unprotected adjacencies only in the SR-TE LSP path computation.

preferred — Prefers protected adjacencies in the SR-TE LSP path computation.

mandatory — Selects protected adjacencies only in the SR-TE LSP path computation.

Context

[Tree] (config>service>epipe>pbb local-switching-service-state)

Full Context

configure service epipe pbb local-switching-service-state

Description

In a PBB Epipe with two SAPs and a PBB tunnel, this command controls whether the operational status of the PBB-Epipe service depends on the status of the PBB tunnel only.

Default

local-switching-service-state sap

Parameters

pbb-tunnel

Specifies that the operational state of the PBB-Epipe service is up if the PBB tunnel is operationally up, irrespective of the operational state of the two SAPs.

sap

Specifies that the operational state of the PBB-Epipe service is up, if two of the three endpoints (PBB tunnel and two SAPs) are up. This option implies that at least one of the SAPs must be up for the PBB-Epipe service to be operationally up.

16.206 location

location

Syntax

location *cflash-id*

no location

Context

[Tree] (config>system>persistence>dhcp-server location)

[Tree] (config>system>persistence>ancp location)

[Tree] (config>system>persistence>subscriber-mgmt location)

[Tree] (config>system>persistence>python location)

[Tree] (config>system>persistence>nat-fwd location)

Full Context

configure system persistence dhcp-server location

configure system persistence ancp location

configure system persistence subscriber-mgmt location

configure system persistence python-policy-cache location

configure system persistence nat-port-forwarding location

Description

This command instructs the system where to write the persistency files for the corresponding application. Each application creates two files on the flash card, one with suffix .i<version>, referencing an index file, and the other with suffix .0<version>, where <version> is a 2-digit number reflecting the file version. These versions are not related to the SR OS release running on the node. The <version> can remain the same over two major releases, for example, when no format change is made to the persistency file. On boot, the system scans the file systems looking for the corresponding persistency files, and the load begins.

For example, in the subscriber management context, the location specifies the flash device on a CPM card where the data for handling subscriber management persistency is stored.

The **no** form of this command returns the system to the default. If there is a change in file location while persistence is running, a new file will be written on the new flash, and then the old file will be removed.

Default

no location

Parameters

cflash-id

Specifies the compact flash device name.

Values cf1:, cf2:, cf3:

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

- configure system persistence subscriber-mgmt location

location

Syntax

location *cflash-id*

no location

Context

[Tree] (config>system>persistence>application-assurance location)

Full Context

configure system persistence application-assurance location

Description

This command instructs the system where to write the file. The name of the file is: appassure.db. On boot the system scans the file systems looking for appassure.db, if it finds it, it starts to load it.

The **no** form of this command returns the system to the default. If there is a change in file location while persistence is running, a new file will be written on the new flash, and then the old file will be removed.

Default

no location

Parameters

cflash-id

Specifies the compact flash type.

Values cf1:, cf2:, cf3:

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

location

Syntax

location *remote-url*

no location

Context

[Tree] (config>service>nat>deterministic-script location)

Full Context

configure service nat deterministic-script location

Description

This command configures the remote location where the Python script will be exported. The Python script is then used off-line to perform reverse query. If this command is configured, the Python script generation is triggered by any modification of the deterministic NAT configuration. The new script reflects the change in mappings caused by configuration change. However, the script must be manually exported to the outside location with the **admin nat save-deterministic-nat** command. The script cannot be stored locally on the system.

The script allows two forms of queries:

- Forward – input is NAT inside parameters, output is NAT outside parameters.
- Backward – input is NAT outside parameters, output is NAT inside parameters.

Forward Query:

```
user@external-server:/home/ftp/pub/det-nat-script$ ./det-nat.py -f -s 10 -a 10.0.5.10
```

output:

```
subscriber has public ip address 198.51.100.1 from service 0 and is using ports [1324 - 1353]
```

Reverse Query:

```
user@external-server:/home/ftp/pub/det-nat-script$./det-nat.py -b -s 0 -a 198.51.100.1 -p 3020
```

output:

```
subscriber has private ip address 10.0.5.66 from service 10
```

Default

no location

Parameters

remote-url

A remote location where the script is stored:

[{ftp:// | tftp://}<login>:<pswd>@ <remote-locn>/][<file-path>]

Maximum length is 180 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

location

Syntax

location *location*

no location

Context

[Tree] (config>system location)

Full Context

configure system location

Description

This command creates a text string that identifies the system location for the device.

Only one location can be configured. If multiple locations are configured, the last one entered overwrites the previous entry.

The **no** form of the command reverts to the default value.

Parameters

location

Specifies the location as a character string. The string may be up to 80 characters. Any printable, seven-bit ASCII characters can be used within the string. If the string contains special characters (#, $, spaces, and so on), the entire string must be enclosed within double quotes.

Platforms

Platforms

All

location

Syntax

location *cflash-id* [*backup-cflash-id*]

no location

Context

[Tree] (config>log>file>file-id location)

Full Context

configure log file file-id location

Description

This command specifies the primary and optional backup location where the log or billing file will be created.

The **location** command is optional. If the location command not explicitly configured, log files will be created on cf1: and accounting files will be created on cf2: without overflow onto other devices. Generally, cf3: is reserved for system files (configurations, images, and so on).

When multiple location commands are entered in a single file ID context, the last command overwrites the previous command.

When the location of a file ID that is associated with an active log ID is changed, the log events are not immediately written to the new location. The new location does not take effect until the log is rolled over either because the rollover period has expired or a **clear log log-id** command is entered to manually rollover the log file.

When creating files, the primary location is used as long as there is available space. If no space is available, an attempt is made to delete unnecessary files that are past their retention date.

If sufficient space is not available an attempt is made to remove the oldest to newest closed log or accounting files. After each file is deleted, the system attempts to create the new file.

A medium severity trap is issued to indicate that a compact flash is either not available or that no space is available on the specified flash and that the backup location is being used.

A high priority alarm condition is raised if none of the configured compact flash devices for this file ID are present or if there is insufficient space available. If space does becomes available, then the alarm condition will be cleared.

Log files are created on cf1: and accounting files are created on cf2.

Use the **no** form of this command to revert to default settings.

Default

no location

Parameters

cflash-id

Specify the primary location.

Values cflash-id: cf1:, cf2:, cf3:

backup-cflash-id

Specify the secondary location.

Values cflash-id: cf1:, cf2:, cf3:

location

Syntax

location *location-id* [**primary-ip-address** *ipv4-address*] [**secondary-ip-address** *ipv4-address*] [**tertiary-ip-address** *ipv4-address*]

locator

Syntax

locator *name* **function end-b6-encaps-red** [**function-value** *function-value*]

no locator

Context

[Tree] (conf>router>segment-routing>sr-policies>policy>srv6>binding-sid locator)

Full Context

configure router segment-routing sr-policies static-policy segment-routing-v6 binding-sid locator

Description

This command configures binding SID locator parameters for a local SRv6 policy. This command and the **ip-address** command in the **conf>router>segment-routing>sr-policies>policy>srv6>binding-sid** context for a remote SRv6 policy are mutually exclusive.

The **no** form of the command removes the configuration.

Parameters

name

Specifies the name of the locator, up to 64 characters. A corresponding locator name must exist in the **config>router>segment-routing>srv6** context.

end-b6-encaps-red

Keyword to configure End.B6.Encaps.Red as the End.B6 function that must be implemented by the datapath.

function-value

Specifies the optional function value. If a function value is configured, the router checks whether this function value is available for the named locator. If no function value is configured, the router dynamically allocates a value.

Values 1 to 1048575

Default no function value

Platforms

lock

Syntax

[**no**] **lock**

Context

[Tree] (configure>system>security>profile>netconf>base-op-authorization lock)

Full Context

configure system security profile netconf base-op-authorization lock

Description

This command authorizes a user associated with the profile to send a NETCONF <lock> operation. This lock operation allows a NETCONF client to lock a configuration datastore.

The **no** form of the command denies the user from requesting a lock.

Default

no lock

Platforms

All

16.209 lock-override

lock-override

Syntax

[**no**] **lock-override**

Context

[Tree] (config>system>script-control>script-policy lock-override)

Full Context

configure system script-control script-policy lock-override

Description

This command allows a triggered EHS/CRON script to execute while there is a datastore lock, started by an MD interface, in place.

A triggered EHS/CRON script queues until an **ongoing commit** (or **confirmed-commit**) is done. When an EHS/CRON script is triggered while the **lock-override** CLI knob is on, SR OS behaves as follows.

When an exclusive session is in place:

- Keep if it is an MD-CLI session. Disconnect if it is a NETCONF session
- Lose the exclusive lock
- Lose any uncommitted configuration changes

When a global session is in place:

- Keep the MD-CLI or NETCONF session
- Keep the uncommitted configuration changes
- An update may be required after committing the EHS/CRON script configuration changes

The **no** form of this command does not allow the script to execute while there is a datastore lock in place.

Default

lock-override

16.210 lockout

lockout

Syntax

lockout failed-attempts *count* **duration** *duration-minutes* **block** *block-minutes* [**max-port-per-ip** *number-of-ports*]

no lockout

Context

[Tree] (config>ipsec>ike-policy lockout)

Full Context

configure ipsec ike-policy lockout

Description

This command enables the lockout mechanism for the IPsec tunnel. The system will lock out an IPsec client for the configured time interval if the number of failed authentications exceeds the configured value within the specified duration. This command only applies when the system acts as a tunnel responder.

A client is defined as the tunnel IP address plus the port.

Optionally, the **max-port-per-ip** parameter can be configured as the maximum number of ports allowed behind the same IP address. If this threshold is exceeded, then all ports behind the IP address are blocked.

The **no** form of this command disables the lockout mechanism.

Default

no lockout

Parameters

count

Specifies the maximum number of failed authentications allowed during the *duration-minutes* interval.

Values 1 to 64

Default 3

duration-minutes

Specifies the interval of time, in minutes, during which the configured failed authentication count must be exceeded in order to trigger a lockout.

Values 1 to 60

Default 5

block-minutes

Specifies the number of minutes that the client is blocked if the configured failed authentication count is exceeded.

Values 1 to 1440, infinite

Default 10

number-of-ports

Specifies the maximum number of ports allowed behind the same IP address.

Values 1 to 32000

Default 16

Platforms

configure subscriber-mgmt host-lockout-policy lockout-time

Description

This command configures the time for which a client stays in the lockout state during which authentication and ESM host creation is suppressed.

The **no** form of this command reverts to the default value.

Default

lockout-time min 10 max 3600

Parameters

min *seconds*

Specifies the minimum lockout-time for this host lockout policy.

Values 1 to 86400

Default 10 seconds

max *seconds*

Specifies the maximum lockout-time for this host lockout policy.

Values 1 to 86400

Default 3600 seconds

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

16.213 log

log

Syntax

log

Context

[Tree] (config log)

Full Context

configure log

Description

Commands in this context are used to configure both event logs and accounting logs. Event logs control the generation, dissemination and recording of system events for monitoring status and troubleshooting faults within the system. Event logging configuration includes syslog, snmp notifications (traps), NETCONF notifications and other types of event log outputs. Accounting logs collect comprehensive accounting statistics and write them to XML files on the compact flash in order to support a variety of billing models.

Full Context

configure filter mac-filter entry log

configure filter ipv6-filter entry log

configure filter ip-filter entry log

Description

This command associates a filter log to the current filter policy entry and therefore enables logging for that filter entry.

The filter log must exist before a filter entry can be enabled to use the filter log.

The **no** form of the command disables logging for the filter entry.

Default

no log

Parameters

log-id

Specifies the filter log ID expressed as a decimal integer.

Values 101 to 199

Platforms

All

log

Syntax

log *log-id* [**create**]

no log *log-id*

Context

[Tree] (config>filter log)

Full Context

configure filter log

Description

This command, creates a configuration context for the specified filter log if it does not exist, and enables the context to configure the specified filter log.

The **no** form of the command deletes the filter log. The log cannot be deleted if there are filter entries configured to write to the log. All filter entry logging associations need to be removed before the log can be deleted.

Default

log 101

Parameters

log-id

Specifies the filter log ID expressed as a decimal integer.

Values 101 to 199

create

This keyword is required to create the configuration context. After it is created, the context can be enabled with or without the **create** keyword.

Platforms

configure system security cpm-filter mac-filter entry log

configure system security cpm-filter ip-filter entry log

Description

This command specifies the log in which packets matching this entry should be entered. The value zero indicates that logging is disabled.

The **no** form of this command deletes the log ID.

Parameters

log-id

Specifies the log ID where packets matching this entry should be entered.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

16.214 log-anno-interval

log-anno-interval

Syntax

log-anno-interval *log-interval*

no log-anno-interval

Context

[Tree] (config>system>ptp log-anno-interval)

Full Context

configure system ptp log-anno-interval

Description

This command configures the announce message interval used for both unicast and multicast messages.

For unicast messages, it defines the announce message interval that is requested during unicast negotiation to any peer. This controls the announce message rate sent from remote peers to the local

node. It does not affect the announce message rate that may be sent from the local node to remote peers. Remote peers may request an announce message rate anywhere within the acceptable grant range.

For multicast messages, used on PTP Ethernet ports, this configures the message interval used for Announce messages transmitted by the local node.

This value also defines the interval between executions of the BTCA within the node.

The announce-interval cannot be changed unless the PTP is shut down.

Note:
In order to minimize BTCA driven reconfigurations, the IEEE recommends that the announce-interval should be consistent across the entire 1588 network.

The **no** form of this command reverts the configuration to the default value. The default value varies depending on the configuration of the **profile** command.

Default

log-anno-interval 1 (1 packet every 2 seconds) for **ieee1588-2008**

log-anno-interval 1 (1 packet every 2 seconds) for **g8265dot1-2010**

log-anno-interval -3 (8 packets per second) for **g8275dot1-2014**

log-anno-interval 1 (1 packet every 2 seconds) for **g8275dot2-2016**

Parameters

log-interval

Specifies the announce packet interval, in log form.

Values -3 to 4

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

log-anno-interval

Syntax

log-anno-interval *log-interval*

no log-anno-interval

Context

[Tree] (config>system>ptp>alternate-profile log-anno-interval)

Full Context

configure system ptp alternate-profile log-anno-interval

Description

This command configures the announce message interval used for multicast messages within the alternate profile.

For multicast messages used on PTP Ethernet ports, this command configures the message interval used for announce messages transmitted by the local node

This value has no impact on the interval used for the BTCA, which is controlled by the value defined for the primary profile.

This value can only be changed when the alternate profile is shut down.

The **no** form of this command reverts to the default value.

Default

log-anno-interval -3 (eight packets per second)

Parameters

log-interval

Specifies the announce packet interval, in log form.

Values -3 to 4

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

16.215 log-delay-interval

log-delay-interval

Syntax

log-delay-interval *log-interval*

no log-delay-interval

Context

[Tree] (config>system>ptp>port log-delay-interval)

Full Context

configure system ptp port log-delay-interval

Description

This command configures the minimum interval used for multicast Delay_Req messages. This parameter is applied on a per-port basis. For ports in a timeReceiver state, it shall be the interval used, unless the parent port indicates a longer interval. For a port in timeTransmitter state, it shall be the interval advertised

to external timeReceiver ports as the minimum acceptable interval for Delay_Req messages from those timeReceiver ports.

It is a requirement of the 1588 standard that a port in timeReceiver state shall check the logMessageInterval field of received multicast Delay_Resp messages. If the value of the logMessageInterval field of those messages is greater than the value programmed locally for the generation of Delay_Req messages, then the timeReceiver must change to use the greater value (i.e. longer interval) for the generation of Delay_Req messages. This requirement is supported in the router.

The parameter is only applicable to ports and not to peers.

The **no** form of this command reverts the configuration to the default value. The default value varies depending on the configuration of the **profile** command.

Default

log-delay-interval -6 (64 packets per second) for **ieee1588-2008**

log-delay-interval -6 (64 packets per second) for **g8265dot1-2010**

log-delay-interval -4 (16 packets per second) for **g8275dot1-2014**

log-delay-interval -6 (64 packets per second) for **g8275dot2-2016**

Parameters

log-interval

Specifies the Delay_Req message interval, in log form.

Values -6 to 0

Default -6

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

configure system security dist-cpu-protection policy local-monitoring-policer log-events

Description

This command controls the creation of log events related to **local-monitoring-policer** status and activity.

Default

log-events

Parameters

verbose

Sends the same events as just "log-events" plus DcpLocMonExcd, DcpLocMonExcdAllDynAlloc, and DcpLocMonExcdAllDynFreed. The optional "verbose" includes some events that are more likely used during debug/tuning/investigations

Platforms

All

log-events

Syntax

[**no**] **log-events** [**verbose**]

no log-events

Context

[Tree] (config>sys>security>dist-cpu-protection>policy>protocol>dyn-para log-events)

Full Context

configure system security dist-cpu-protection policy protocol dynamic-parameters log-events

Description

This command controls the creation of log events related to dynamic enforcement policer status and activity.

Default

log-events

Parameters

verbose

This parameter sends the same events as just "log-events" plus Hold Down Start, Hold Down End, DcpDynamicEnforceAlloc and DcpDynamicEnforceFreed events. This includes the allocation/de-allocation events (typically used for debug/tuning only – could be very noisy even when there is nothing much of concern).

Platforms

All

log-events

Syntax

log-events [**verbose**]

no log-events

Context

[Tree] (config>sys>security>dist-cpu-protection>policy>static-policer log-events)

configure system security dist-cpu-protection policy static-policer log-events

Description

This command controls the creation of log events related to static-policer status and activity.

Default

log-events

Parameters

verbose

Sends the same events as just "log-events" plus Hold Down Start and Down End events. The optional "verbose" includes some events that are more likely used during debug/tuning/investigations.

Platforms

All

16.217 log-files-total-size

log-files-total-size

Syntax

log-files-total-size *megabytes*

no log-files-total-size

Context

[Tree] (config>log>storage log-files-total-size)

Full Context

configure log file-storage-control log-files-total-size

Description

This command configures the limit for the total space that all log files can occupy on each storage device on the active CPM.

When this threshold is reached, log events are no longer written to the files in the `\log` directory until SR OS removes older log files and the occupancy is below the limit.

When unconfigured, there is no specific limit for the total size of all log files.

Only log files in the `\log` directory with system generated names (including no file extension) are applicable toward the total size limit.

If a user manually adds or deletes log files from the `\log` directory, the size of the files is not taken into account for up to 1 hour.

The configured total size limit is not validated against the actual size of the installed storage devices. If the configured limit is larger than the installed CF device, the limit is never reached.

Default

no log-files-total-size

Parameters

megabytes

Specifies the total size limit for log files, in MB.

Values 50 to 4,194,304 MB (4 TBytes, 2^{22} MB)

Default 0

Platforms

All

16.218 log-filter

log-filter

Syntax

log-filter *filter-id*

no log-filter

Context

[Tree] (config>log>event-trigger>event>trigger-entry log-filter)

Full Context

configure log event-trigger event trigger-entry log-filter

Description

This command configures the log filter to be used for this trigger entry. The log filter defines the matching criteria that must be met in order for the log event to trigger the handler execution. The log filter is applied to the log event and, if the filtering decision results in a forward action, then the handler is triggered.

It is typically unnecessary to configure match criteria for the application or number in the log filter used for EHS since the particular filter is only applied for a specific log event application and number, as configured under the **config**>**log**>**event-trigger** context.

The **no** form of this command removes the log filter configuration.

Parameters

filter-id

Specifies the identifier of the filter.

Values 1 to 1500

Platforms

All

16.219 log-id

log-id

Syntax

log-id *log-id* [**name** *log-name*]

no log-id *log-id*

Context

[Tree] (config>service>vprn>log log-id)

Full Context

configure service vprn log log-id

Description

This command creates a context to configure destinations for event streams.

The **log-id** context is used to direct events, alarms or traps, and debug information to respective destinations.

A maximum of 30 logs can be configured.

Before an event can be associated with this log-id, the **from** command identifying the source of the event must be configured.

Only one destination can be specified for a *log-id*. The destination of an event stream can be an in-memory buffer, console, session, snmp-trap-group, Syslog, or file.

Use the **event-control** command to suppress the generation of events, alarms, and traps for all log destinations.

An event filter policy can be applied in the log-id context to limit which events, alarms, and traps are sent to the specified log-id.

By default, the log events in a VPRN log are a subset of the complete set of possible log events in SR OS. See the **config**>**log**>**services-all-events** command for more details.

The **no** form of this command deletes the log destination ID from the configuration.

Default

No log destinations are defined.

Parameters

log-id

Specifies the log ID number, expressed as a decimal integer.

Values 1 to 100

name log-name

Configures an optional log name, up to 64 characters, that can be used to refer to the log destination after it is created.

Platforms

All

log-id

Syntax

log-id *log-id* [**name** *li-log-name*]

no log-id *log-id*

Context

[Tree] (config>li>log log-id)

configure li log log-id

Description

This command configures an LI event log destination. The *log-id* is used to direct events, alarms or traps, and debug information for specific destinations.

Parameters

log-id

Specifies the log ID, expressed as a decimal number.

Values 1 to 100

name li-log-name

Configures an optional log name, up to 64 characters, that can be used to refer to the log destination after it is created.

Platforms

All

log-id

Syntax

log-id *log-id* [**name** *log-name*]

no log-id *log-id*

Context

[Tree] (config>log log-id)

Full Context

configure log log-id

Description

This command creates a context to configure destinations for event streams.

The **log-id** context is used to direct events, alarms or traps, and debug information for specific destinations.

A maximum of 30 logs can be configured.

Before an event can be associated with this log ID, the **from** command identifying the source of the event must be configured.

Only one destination can be specified for a *log-id*. The destination of an event stream can be an in-memory buffer, console, session, snmp-trap-group, syslog, or file.

Use the **event-control** command to suppress the generation of events, alarms, and traps for all log destinations.

An event filter policy can be applied in the log-id context to limit which events, alarms, and traps are sent to the specified log-id.

Log-IDs 99 and 100 are created by the agent. Log-ID 99 captures all log messages. Log-ID 100 captures log messages with a severity level of major and above.

Note:
Log-ID 99 provides valuable information for the admin-tech file. Removing or changing the log configuration may hinder debugging capabilities. It is strongly recommended not to alter the configuration for Log-ID 99.

The **no** form of this command deletes the log destination ID from the configuration.

Parameters

log-id

Specifies the log ID, expressed as a decimal integer.

Values 1 to 101

name log-name

Configures an optional log name, up to 64 characters, that can be used to refer to the log destination after it is created.

Platforms

All

16.220 log-prefix

log-prefix

Syntax

log-prefix *log-prefix-string*

no log-prefix

Context

[Tree] (config>service>vprn>log>syslog log-prefix)

Full Context

configure service vprn log syslog log-prefix

Description

This command adds the string prepended to every syslog message sent to the syslog host.

RFC3164, *The BSD syslog Protocol,* allows an alphanumeric string (tag) to be prepended to the content of every log message sent to the syslog host. This alphanumeric string can, for example, be used to identify the node that generates the log entry. The software appends a colon (:) and a space to the string and it is inserted in the syslog message after the date stamp and before the syslog message content.

Only one string can be entered. If multiple strings are entered, the last string overwrites the previous string. The alphanumeric string can contain lowercase (a-z), uppercase (A-Z) and numeric (0-9) characters.

The **no** form of this command removes the log prefix string.

Default

log-prefix "TMNX".

Parameters

log-prefix-string

Specifies the alphanumeric string of up to 32 characters. Spaces and colons (:) cannot be used in the string.

Platforms

All

log-prefix

Syntax

log-prefix *prefix-text*

Context

16.221 log-sync-interval

log-sync-interval

Syntax

log-sync-interval *log-interval*

no log-sync-interval

Context

[Tree] (config>service>vprn>ptp>peer log-sync-interval)

Full Context

configure service vprn ptp peer log-sync-interval

Description

This command configures the message interval used for unicast event messages. It defines the message interval for both Sync and Delay_Resp messages that are requested during unicast negotiation to the

specific peer. This controls the Sync and Delay_Resp message rate sent from remote peers to the local node. It does not affect the Sync or Delay_Resp packet rate that may be sent from the local node to remote peers. Remote peers may request a Sync or Delay_Resp packet rate anywhere within the acceptable grant range.

The **log-sync-interval** cannot be changed unless the peer is shutdown.

This command only applies to the 7450 ESS and 7750 SR.

The **no** form of this command reverts the value to the profile default.

Default

log-sync-interval -6 (64 packets per second) for **ieee1588-2008**

log-sync-interval -6 (64 packets per second) for **g8265dot1-2010**

log-sync-interval -4 (16 packets per second) for **g8275dot1-2014**

log-sync-interval -6 (64 packets per second) for **g8275dot2-2016**

Parameters

log-interval

Specifies the sync message interval, in log form.

Values -6 to 0

16.222 logger-event-bundling

logger-event-bundling

Syntax

[**no**] **logger-event-bundling**

Context

[Tree] (config>router>mpls logger-event-bundling)

Full Context

configure router mpls logger-event-bundling

Description

This feature merges two of the most commonly generated MPLS traps, vRtrMplsXCCreate and vRtrMplsXCDelete, which can be generated at both LER and LSR into a new specific trap vRtrMplsSessionsModified. In addition, this feature perform bundling of traps of multiple RSVP sessions, that is LSPs, into this new specific trap.

The intent is to provide a tool for the user to minimize trap generation in an MPLS network. Note that the MPLS trap throttling will not be applied to this new trap.

The **no** version of this command disables the merging and bundling of the above MPLS traps.

[Tree] (config>open-flow>of-switch logical-port-status)

Full Context

configure open-flow of-switch logical-port-status

Description

This command enables status change reporting to the OpenFlow controller for the specified logical port type. To report on multiple logical port types, the command needs to be executed multiple times with different logical port specified as required.

The **no** form of this command disables status reporting for specified or all (no argument) logical ports.

Default

no logical-port-status

Parameters

rsvp-te

Enables reporting on RSVP-TE LSP logical ports.

mpls-te

Enables reporting on MPLS-TE logical ports.

sr-te

Enables reporting on SR-TE logical ports.

Platforms

All

16.225 login-banner

login-banner

Syntax

[**no**] **login-banner**

Context

[Tree] (config>system>login-control login-banner)

Full Context

configure system login-control login-banner

Description

This command enables or disables the display of a login banner. The login banner contains the SR OS copyright and build date information for a console login attempt.

The **no** form of this command causes only the configured pre-login-message and a generic login prompt to display.

Platforms

All

16.226 login-control

login-control

Syntax

login-control

Context

[Tree] (config>system login-control)

Full Context

configure system login-control

Description

This command creates the context to configure the session control for console, Telnet, SSH, and FTP sessions.

Platforms

All

16.227 login-exec

login-exec

Syntax

login-exec *url-prefix*: *source-url*

no login-exec

Context

[Tree] (config>system>security>user>console login-exec)

[Tree] (config>system>security>user-template>console login-exec)

Full Context

configure system security user console login-exec

configure system security user-template console login-exec

Description

This command configures a user's login exec file which executes whenever the user successfully logs in to a console session.

Only one exec file can be configured. If multiple **login-exec** commands are entered for the same user, each subsequent entry overwrites the previous entry.

The **no** form of this command disables the login exec file for the user.

Default

no login-exec

Parameters

url-prefix: source-url

Specifies either a local or remote URL, up to 200 characters, that identifies the exec file that is executed after the user successfully logs in.

Platforms

All

16.228 login-scripts

login-scripts

Syntax

login-scripts

Context

[Tree] (config>system>login-control login-scripts)

Full Context

configure system login-control login-scripts

Description

Commands in this context configure CLI scripts that execute when a user (authenticated via any method including local user database, TACACS+, or RADIUS) first logs into a CLI session.

Platforms

All

16.229 logout

logout

Syntax

logout

Context

[Tree] (logout)

Full Context

logout

Description

This command logs out of the router session.

When the **logout** command is issued from the console, the login prompt is displayed, and any log IDs directed to the console are discarded. When the console session resumes (regardless of the user), the log output to the console resumes.

When a Telnet session is terminated from a **logout** command, all log IDs directed to the session are removed. When a user logs back in, the log IDs must be re-created.

Platforms

All

16.230 long-duration-flow-count

long-duration-flow-count

Syntax

[**no**] **long-duration-flow-count**

Context

[Tree] (config>log>acct-policy>cr>aa>aa-sub-cntr long-duration-flow-count)

Full Context

configure log accounting-policy custom-record aa-specific aa-sub-counters long-duration-flow-count

Description

This command includes the long duration flow count. This command only applies to the 7750 SR.

The **no** form of this command excludes the long duration flow count in the AA subscriber's custom record.

Default

no long-duration-flow-count

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

16.231 long-lived

long-lived

Syntax

[**no**] **long-lived**

[Tree] (config>service>vprn>bgp>group>neighbor>graceful-restart long-lived)

[Tree] (config>service>vprn>bgp>group>graceful-restart long-lived)

Full Context

configure service vprn bgp graceful-restart long-lived

configure service vprn bgp group neighbor graceful-restart long-lived

configure service vprn bgp group graceful-restart long-lived

Description

Commands in this context configure BGP Long-Lived Graceful-Restart (LLGR) procedures.

LLGR, known informally as BGP persistence, is an extension of BGP graceful restart that allows a session to stay down for a longer period of time. During this time, learned routes are marked and re-advertised as stale but they can continue to be used as routes of last resort.

The LLGR handling of a session failure can be invoked immediately or it can be delayed until the end of the traditional GR restart window.

Default

no long-lived

Platforms

All

long-lived

Syntax

[**no**] **long-lived**

Context

[Tree] (config>router>bgp>graceful-restart long-lived)

[Tree] (config>router>bgp>group>graceful-restart long-lived)

16.232 loop-detect

loop-detect

Syntax

loop-detect {**drop-peer** | **discard-route** | **ignore-loop** | **off**}

no loop-detect

Context

[Tree] (config>subscr-mgmt>bgp-prng-plcy loop-detect)

Full Context

configure subscriber-mgmt bgp-peering-policy loop-detect

Description

This command configures how the BGP peer session handles loop detection in the AS path.

Note:
Dynamic configuration changes of **loop-detect** are not recognized.

The **no** form of this command used at the global level reverts to default, which is **loop-detect ignore-loop**.

Parameters

drop-peer

Sends a notification to the remote peer and drops the session.

discard-route

Discards routes received with loops in the AS path.

ignore-loop

Ignores routes with loops in the AS path but maintains peering.

off

Disables loop detection.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

loop-detect

Syntax

loop-detect {**drop-peer** | **discard-route** | **ignore-loop** | **off**}

no loop-detect

Context

[Tree] (config>service>vprn>bgp>group loop-detect)

[Tree] (config>service>vprn>bgp>group>neighbor loop-detect)

[Tree] (config>service>vprn>bgp loop-detect)

Full Context

configure service vprn bgp group loop-detect

configure service vprn bgp group neighbor loop-detect

configure service vprn bgp loop-detect

Description

This command configures how the BGP peer session handles loop detection in the AS path.

This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). The most specific value is used.

Dynamic configuration changes of **loop-detect** are not recognized.

The **no** form of this command used at the global level reverts to default, which is **loop-detect ignore-loop**.

The **no** form of this command used at the group level reverts to the value defined at the global level.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Default

loop-detect ignore-loop

Parameters

drop-peer

Sends a notification to the remote peer and drops the session.

discard-route

Discards routes received with loops in the AS path.

ignore-loop

ignores routes with loops in the AS path but maintains peering.

off

Disables loop detection.

Platforms

loop-detect

Syntax

loop-detect {**drop-peer** | **discard-route** | **ignore-loop** | **off**}

no loop-detect

Context

[Tree] (config>router>bgp>group loop-detect)

[Tree] (config>router>bgp loop-detect)

[Tree] (config>router>bgp>group>neighbor loop-detect)

Full Context

configure router bgp group loop-detect

configure router bgp loop-detect

configure router bgp group neighbor loop-detect

Description

This command configures how the BGP peer session handles loop detection in the AS path.

This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). The most specific value is used.

Note:
Dynamic configuration changes of **loop-detect** are not recognized.

The **no** form of this command used at the global level reverts to default, which is **loop-detect ignore-loop**.

The **no** form of this command used at the group level reverts to the value defined at the global level.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Default

loop-detect ignore-loop

Parameters

drop-peer

Sends a notification to the remote peer and drops the session.

discard-route

Discards routes received from a peer with the same AS number as the router itself. This option prevents routes looped back to the router from being added to the routing information base and consuming memory. When this option is changed, the change will not be active for an established peer until the connection is re-established for the peer.

ignore-loop

Ignores routes with loops in the AS path but maintains peering.

off

Disables loop detection.

Platforms

All

16.233 loop-detect-threshold

loop-detect-threshold

Syntax

loop-detect-threshold *loop-detect-threshold*

no loop-detect-threshold

Context

[Tree] (config>service>vprn>bgp>group>neighbor loop-detect-threshold)

[Tree] (config>service>vprn>bgp loop-detect-threshold)

[Tree] (config>service>vprn>bgp>group loop-detect-threshold)

Full Context

configure service vprn bgp group neighbor loop-detect-threshold

configure service vprn bgp loop-detect-threshold

configure service vprn bgp group loop-detect-threshold

Description

This command provides additional control over the behavior enabled by the **loop-detect** command. If this command specifies a threshold value of *n,* then a route received by the local BGP speaker with an AS path that contains up to *n* occurrences of the local speaker's AS number is considered valid and not treated as an AS path loop. An AS loop is considered to occur only when the received AS path has more than *n* occurrences of the local speaker's AS number.

The **no** form of this command removes the configuration and sets the value to 0. One or more occurrence of the local speaker's AS number in the received AS path triggers the **loop-detect** behavior.

Default

no loop-detect-threshold

Parameters

loop-detect-threshold

The maximum number of occurrences of the local speaker's AS number in the received AS path before the AS path is considered to be a loop.

Values 0 to 15

Default 0

Platforms

All

loop-detect-threshold

Syntax

loop-detect-threshold *loop-detect-threshold*

no loop-detect-threshold

Context

[Tree] (config>router>bgp>group loop-detect-threshold)

[Tree] (config>router>bgp>group>neighbor loop-detect-threshold)

Full Context

configure router bgp group loop-detect-threshold

configure router bgp loop-detect-threshold

configure router bgp group neighbor loop-detect-threshold

Description

This command provides additional control over the behavior enabled by the **loop-detect** command. If this command specifies a threshold value of *n*, then a route received by the local BGP speaker with an AS path

that contains up to *n* occurrences of the local speaker's AS number is considered valid and not treated as an AS path loop. An AS loop is considered to occur only when the received AS path has more than *n* occurrences of the local speaker's AS number.

The **no** form of this command removes the configuration and sets the value to 0. One or more occurrence of the local speaker's AS number in the received AS path triggers the **loop-detect** behavior.

Default

no loop-detect-threshold

Parameters

loop-detect-threshold

The maximum number of occurrences of the local speaker's AS number in the received AS path before the AS path is considered to be a loop.

Values 0 to 15

Default 0

Platforms

All

16.234 loopback

loopback

Syntax

[**no**] **loopback**

Context

[Tree] (config>service>vprn>if loopback)

[Tree] (config>service>ies>if loopback)

Full Context

configure service vprn interface loopback

configure service ies interface loopback

Description

This command specifies that the associated interface is a loopback interface that has no associated physical interface. As a result, the associated IES/VPRN interface cannot be bound to a SAP.

Note:
Configure an IES interface as a loopback interface by issuing the **loopback** command instead of the **sap** *sap-id* command. The loopback flag cannot be set on an interface where a SAP is already defined and a SAP cannot be defined on a loopback interface.

The **no** form of this command reverts to the default.

Platforms

All

loopback

Syntax

[**no**] **loopback**

Context

[Tree] (config>service>vprn>nw-if loopback)

Full Context

configure service vprn network-interface loopback

Description

This command specifies that the associated interface is a loopback interface that has no associated physical interface. As a result, the associated interface cannot be bound to a SAP.

When using mtrace/mstat in a Layer 3 VPN context then the configuration for the VPRN should have a loopback address configured which has the same address as the core instance's system address (BGP next-hop).

Default

no loopback

Platforms

All

loopback

Syntax

loopback {**line** | **internal**}

no loopback

Context

[Tree] (config>port>sonet-sdh loopback)

Full Context

configure port sonet-sdh loopback

Description

This command activates a loopback on the SONET/SDH port.

The SONET port must be in a shut down state to activate any type of loopback. The loopback setting is never saved to the generated/saved configuration file.

Note that loopback mode changes on a SONET/SDH port can affect traffic on the remaining ports.

This command is supported by TDM satellite.

Default

no loopback

Parameters

line

Set the port into line loopback state.

internal

Set the port into internal loopback state.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

loopback

Syntax

loopback {**line** | **internal** | **fdl-ansi** | **fdl-bellcore** | **payload-ansi** | **inband-ansi** | **inband-bellcore**}

no loopback

Context

[Tree] (config>port>tdm>ds1 loopback)

Full Context

configure port tdm ds1 loopback

Description

This command puts the specified port or channel into a loopback mode.

The corresponding port or channel must be in a shutdown state in order for the loopback mode to be enabled. The upper level port or channel or parallel channels should not be affected by the loopback mode.

Note that this command is not saved in the router configuration between boots.

The **no** form of this command disables the specified type of loopback.

Default

no loopback

Parameters

line

Places the associated port or channel into a line loopback mode. A line loopback loops frames received on the corresponding port or channels back to the remote router.

internal

Places the associated port or channel into an internal loopback mode. An internal loopback loops the frames from the local router back at the framer.

fdl-ansi

Requests FDL line loopback according to ANSI T1.403.

fdl-bellcore

Requests FDL line loopback according to Bellcore TR-TSY-000312.

payload-ansi

Requests payload loopback using ANSI signaling.

inband-ansi

Requests inband line loopback according to ANSI T1.403.

inband-bellcore

Requests inband line loopback according to Bellcore signaling.

Platforms

7450 ESS, 7750 SR-7/12/12e, 7750 SR-a, 7750 SR-e

loopback

Syntax

loopback {*mac-address* | **multicast** | **remote-mepid** *mep-id*} **mep** *mep-id* **domain** *md-index* **association** *ma-index* [**send-count** *send-count*] [**size** *data-size*] [**priority** *priority*] [**lbm-padding** *padding-size*] [**timeout** *timeout-time*] [**interval** *interval-time*]

Context

[Tree] (oam>eth-cfm loopback)

Full Context

oam eth-cfm loopback

Description

The command initiates a loopback test.

Parameters

mac-address

Specifies a unicast MAC address or multicast MAC address. The last nibble of the multicast address must match the level of the local MEP, or the command fails and the test is not instantiated.

Values xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx or multicast

multicast

Builds the class one destination multicast address based on the level of the local MEP. The last nibble of the multicast address must match the level of the local MEP or the command fails and the test is not instantiated.

remote-mepid *mep-id*

Specifies the remote MEP ID of the peer within the association. The domain and association information are derived from the **source mep** for the session. The Layer 2 IEEE MAC address is resolved from previously-learned remote MAC addressing, derived from the reception and processing of the ETH-CC PDU. The local MEP must be administratively enabled.

Values 1 to 8191

mep *mep-id*

Specifies the local MEP ID.

Values 1 to 8191

md-index

Specifies the MD index.

Values 1 to 4294967295

ma-index

Specifies the MA index.

Values 1 to 4294967295

send-count

Specifies the number of messages to send, expressed as a decimal integer. Loopback messages are sent back-to-back, with no delay between the transmissions.

Values 1 to 1024

Default 1

data-size

Specifies the size of the variable data pattern only of the data TLV. This value does not include the 1 Byte Type, 2 Byte Length. This means that the total size of the data TLV is the configured value plus the 3 addition bytes to accommodate the type and length fields. If 0 is specified, no data TLV is added to the packet. This parameter and **lbm-padding** are mutually exclusive.

Values 0 to 1500

Default 0

priority

Specifies a 3-bit value to be used in the VLAN tag, if present, in the transmitted frame.

Values 0 to 7

Default The CCM and LTM priority of the MEP

padding-size

Specifies the complete size of the data TLV, which includes the 1 Byte Type, 2 Byte Length, and the variable data pad. If 0 is specified, no data TLV is added to the packet. MSDU is not processed when **lbm-padding** is in use. This parameter and **size** are mutually exclusive.

Values 0, 3 to 9000

Default 0

timeout-time

Specifies the time, in seconds, used to override the default *timeout-time* value and is the amount of time that the router waits for a message reply after sending the message request. Upon the expiration of message time out, the requesting router assumes that the message response is not received. Any response received after the request times out is silently discarded.

Values 1 to 10

Default 5

interval-time

Specifies the time, in deciseconds (100 ms), to configure the spacing between probes within the test run. A value of 0 means probes are sent with no enforced delay. This value is only applicable to tests where the **send-count** is 5 or less.

Values 0 to 600

Default 0 or 10 depending on the **send-count**

[Tree] (config>card>xiom>mda>xcon>mac loopback)

Full Context

configure card mda xconnect mac loopback

configure card xiom mda xconnect mac loopback

Description

This command configures a MAC loopback on a MAC chip. The system and services can start using the loopback only when a port is associated with it (for example, port 1/1/m1/1, where m1 represents the MAC ID).

The **no** form of this command removes the loopback ID from the configuration.

Parameters

loopback-id

Specifies the loopback ID for the MDA cross-connect.

Values 1, 2

create

Keyword used to create a new loopback. The **create** keyword requirement can be enabled or disabled in the **environment>create** context.

configure router isis level loopfree-alternate-exclude

configure router isis interface loopfree-alternate-exclude

configure service vprn isis level loopfree-alternate-exclude

Description

This command instructs IGP to not include a specific interface or all interfaces participating in a specific IS-IS level or OSPF area in the SPF LFA computation. This provides a way of reducing the LFA SPF calculation where it is not needed.

When an interface is excluded from the LFA SPF in IS-IS, it is excluded in both level 1 and level 2. When it is excluded from the LFA SPF in OSPF, it is excluded in all areas. However, the above OSPF command can only be executed under the area in which the specified interface is primary and once enabled, the interface is excluded in that area and in all other areas where the interface is secondary. If the user attempts to apply it to an area where the interface is secondary, the command will fail.

The **no** form of this command re-instates the default value for this command.

[Tree] (config>router>ospf3 loopfree-alternate-exclude)

Full Context

configure router ospf loopfree-alternate-exclude

configure router ospf3 loopfree-alternate-exclude

Description

This command excludes from the LFA SPF calculation those prefixes that match a prefix entry or a tag entry in a prefix policy. If a prefix is excluded from LFA, it is not included in LFA calculations regardless of its priority. The prefix tag will, however, be used in the main SPF.

The implementation also allows the user to exclude a specific interface in IS-IS or OSPF, a or all interfaces in an OSPF area or IS-IS level from the LFA SPF.

Note:
Prefix tags are defined for the IS-IS protocol but not for the OSPF protocol.

The default action of the **loopfree-alternate-exclude** command, when not explicitly specified by the user in the prefix policy, is "reject". Therefore, regardless of whether the user explicitly added the statement "default-action reject" to the prefix policy, a prefix that does not match any entry in the policy will be accepted into LFA SPF.

The **no** form of this command deletes the exclude prefix policy.

Default

no loopfree-alternate-exclude

Parameters

prefix-policy

Specifies up to five policy prefix names. The specified policy name must already be defined. Prefix policies are created with the command **config>router>policy-options>prefix-list**; for information on prefix lists, refer to "Route Policies" in the *7450 ESS, 7750 SR, 7950 XRS, and VSR Unicast Routing Protocols Guide*.

configure router ospf3 area interface loopfree-alternate-exclude

Description

This command instructs IGP to not include a specific interface or all interfaces participating in a specific IS-IS level or OSPF area in the SPF LFA computation. This provides a way of reducing the LFA SPF calculation where it is not needed.

When an interface is excluded from the LFA SPF in IS-IS, it is excluded in both level 1 and level 2. When it is excluded from the LFA SPF in OSPF, it is excluded in all areas. However, the above OSPF command can only be executed under the area in which the specified interface is primary and once enabled, the interface is excluded in that area and in all other areas where the interface is secondary. If the user attempts to apply it to an area where the interface is secondary, the command will fail.

The **no** form of this command re-instates the default value for this command.

configure service vprn ospf3 loopfree-alternates

Description

This command enables Loop-Free Alternate (LFA) computation by SPF under the IS-IS routing protocol level, or under the OSPF routing protocol instance level.

When this command is enabled, it instructs the IGP SPF to attempt to pre-compute both a primary next-hop and an LFA next-hop for every learned prefix. IS-IS computes the primary SPF first and then computes the LFA SPF. The LFA backup next-hop is only available after the LFA SPF is completed. When found, the LFA next-hop is populated into the routing table along with the primary next-hop for the prefix.

The **no** form of this command disables the LFA computation by IGP SPF.

configure router ospf flexible-algorithms flex-algo loopfree-alternates

configure router isis flexible-algorithms flex-algo loopfree-alternates

Description

This command enables the advertisement of flexible-algorithm aware loop free alternates (LFAs).

The flexible algorithm LFA configuration (for example, LFA, remote-LFA or TI-LFA) inherits the LFA configuration for base SPF algorithm 0.

LFAs are administratively disabled for flexible algorithms in which IS-IS is participating. LFAs must be explicitly enabled using the **loopfree-alternates** command.

The **no** form of this command disables LFAs for the specific flexible algorithm in which the router is participating.

configure router isis loopfree-alternates

Description

This command enables Loop-Free Alternate (LFA) computation by SPF for the IS-IS routing protocol.

When this command is enabled, it instructs the IGP SPF to attempt to pre-compute both a primary nexthop and an LFA next-hop for every learned prefix. When found, the LFA next-hop is populated into the routing table along with the primary next-hop for the prefix.

The user enables the remote LFA next-hop calculation by the IGP LFA SPF by appending the remote-lfa option. When this option is enabled in an IGP instance, SPF performs the remote LFA additional computation following the regular LFA next-hop calculation when the latter resulted in no protection for one or more prefixes which are resolved to a given interface.

Remote LFA extends the protection coverage of LFA-FRR to any topology by automatically computing and establishing/tearing-down shortcut tunnels, also referred to as repair tunnels, to a remote LFA node which puts the packets back into the shortest without looping them back to the node which forwarded them over the repair tunnel. The remote LFA node is referred to as PQ node. A repair tunnel can in theory be an

RSVP LSP, a LDP-in-LDP tunnel, or a SR tunnel. In this feature, it is restricted to use SR repair tunnel to the remote LFA node.

The remote LFA algorithm is a per-link LFA SPF calculation and not a per-prefix like the regular LFA one. So, it provides protection for all destination prefixes which share the protected link by using the neighbor on the other side of the protected link as a proxy for all these destinations.

The Topology-Independent LFA (TI-LFA) further improves the protection coverage of a network topology by computing and automatically instantiating a repair tunnel to a Q node which is not in shortest path from the computing node. The repair tunnel uses shortest path to the P node and a source routed path from the P node to the Q node.

In addition, the TI-LFA algorithm selects the backup path which matches the post-convergence path. This helps the capacity planning in the network since traffic will always flow on the same path when transitioning to the FRR next-hop and then onto the new primary next-hop.

At a high level, the TI-LFA protection algorithm is searching for a candidate P-Q set separated with a number of hops such that the label stack size does not exceed the value of **ti-lfa max-sr-frr-labels**, on each of the post-convergence paths to each destination node or prefix D.

When the **ti-lfa** option is enabled in IS-IS, it provides TI-LFA node-protect or link-protect backup path in IS-IS MT=0 for an SR-ISIS IPV4/IPv6 tunnel (node SID and adjacency SID), for an IPv4 SR-TE LSP, and for LDP IPv4 FEC when the LDP **fast-reroute backup-sr-tunnel** option is enabled.

The **max-sr-frr-labels** parameter is used to limit the search for the TI-LFA backup next-hop:

1. 0 — The IGP LFA SPF restricts the search to TI-LFA backup next-hop which does not require a repair tunnel, meaning that P node and Q node are the same and match a neighbor. This is also the case when both P and Q node match the advertising router for a prefix.
2. 1 to 3 — The IGP LFA SPF will widen the search to include a repair tunnel to a P node which itself is connected to the Q nodes with a 0-to-2 hops for a total of maximum of three labels: one node SID to P node and two adjacency SIDs from P node to the Q node. If the P node is a neighbor of the computing node, its node SID is compressed and meaning that up to three adjacency SIDs can separate the P and Q nodes.
3. 2 (default) — Corresponds to a repair tunnel to a non-adjacent P which is adjacent to the Q node. If the P node is a neighbor of the computing node, then the node SID of the P node is compressed and the default value of two labels corresponds to two adjacency SIDs between the P and Q nodes.

When the **node-protect** command is enabled, the router will prefer a node-protect over a link-protect repair tunnel for a given prefix if both are found in the Remote LFA or TI-LFA SPF computations. The SPF computations may only find a link-protect repair tunnel for prefixes owned by the protected node. This node-protect backup protects against the failure of a downstream node in the path of the prefix of a node SID except for the node owner of the node SID.

The parameter **max-pq-nodes** in Remote LFA controls the maximum number of PQ nodes found in the LFA SPFs for which the node protection check is performed. The node-protect condition means the router must run the original Remote LFA algorithm plus one extra forward SPF on behalf of each PQ node found, potentially after applying the **max-pq-cost** parameter, to check if the path from the PQ node to the destination does not traverse the protected node. Setting this parameter to a lower value means the LFA SPFs will use less computation time and resources but may result in not finding a node-protect repair tunnel.

The **no** form of this command disables the LFA computation by IGP SPF.

configure router ospf3 loopfree-alternates

configure router ospf loopfree-alternates

Description

This command enables Loop-Free Alternate (LFA) computation by SPF under the OSPF or OSPFv3 routing protocol instance.

When this command is enabled, it instructs the IGP SPF to attempt to precalculate both a primary next hop and an LFA next hop for every learned prefix. When found, the LFA next hop is populated into the routing table along with the primary next hop for the prefix.

The user enables the remote LFA next hop calculation by the IGP LFA SPF by appending the **remote-lfa** option. When this option is enabled in an IGP instance, SPF performs the remote LFA additional computation following the regular LFA next hop calculation when the latter resulted in no protection for one or more prefixes which are resolved to a particular interface.

Remote LFA extends the protection coverage of LFA-FRR to any topology by automatically computing and establishing or tearing down shortcut tunnels, also referred to as repair tunnels, to a remote LFA node that puts the packets back into the shortest path without looping them back to the node that forwarded them over the repair tunnel. The remote LFA node is referred to as a PQ node. A repair tunnel can, in theory, be an RSVP-TE LSP, an LDP-in-LDP tunnel, or a segment routing (SR) tunnel. In this command, **remote-lfa** is restricted to using an SR repair tunnel to the remote LFA node.

The remote LFA algorithm is a per-link LFA SPF calculation and not a per-prefix calculation like the regular LFA algorithm. The remote LFA algorithm provides protection for all destination prefixes that share the protected link by using the neighbor on the other side of the protected link as a proxy for all the destinations.

The Topology-Independent LFA (TI-LFA) further improves the protection coverage of a network topology by computing and automatically instantiating a repair tunnel to a Q node which is not in shortest path from the computing node. The repair tunnel uses shortest path to the P node and a source routed path from the P node to the Q node.

In addition, the TI-LFA algorithm selects the backup path which matches the post-convergence path. This helps the capacity planning in the network since traffic will always flow on the same path when transitioning to the FRR next hop and then onto the new primary next hop.

At a high level, the TI-LFA protection algorithm is searching for a candidate P-Q set separated with a number of hops such that the label stack size does not exceed the value of **ti-lfa max-sr-frr-labels**, on each of the post-convergence paths to each destination node or prefix D.

When the **ti-lfa** option is enabled in OSPF, it provides TI-LFA node-protect or link-protect backup path for a SR-OSPF IPV4 tunnel (node SID and adjacency SID), and for a IPv4 SR-TE LSP.

The **max-sr-frr-labels** parameter is used to limit the search for the TI-LFA backup next hop:

1. 0 — The IGP LFA SPF restricts the search to TI-LFA backup next hop which does not require a repair tunnel, meaning that P node and Q node are the same and match a neighbor. This is also the case when both P and Q node match the advertising router for a prefix.
2. 1 to 3 — The IGP LFA SPF will widen the search to include a repair tunnel to a P node which itself is connected to the Q nodes with a 0-to-2 hops for a total of maximum of three labels: one node SID to P node and two adjacency SIDs from P node to the Q node. If the P node is a neighbor of the computing node, its node SID is compressed and meaning that up to three adjacency SIDs can separate the P and Q nodes.
3. 2 (default) — Corresponds to a repair tunnel to a non-adjacent P which is adjacent to the Q node. If the P node is a neighbor of the computing node, then the node SID of the P node is compressed and the default value of two labels corresponds to two adjacency SIDs between the P and Q nodes.

The TI-LFA repair tunnel can have a maximum of three labels pushed in addition to the label of the destination node or prefix. The user can set a lower maximum value for the additional FRR labels by configuring the CLI option **max-sr-frr-labels** *labels*. The default value is 2.

When the **node-protect** command is enabled, the router will prefer a node-protect over a link-protect repair tunnel for a given prefix if both are found in the Remote LFA or TI-LFA SPF computations. The SPF computations may only find a link-protect repair tunnel for prefixes owned by the protected node. This node-protect backup protects against the failure of a downstream node in the path of the prefix of a node SID except for the node owner of the node SID.

The parameter **max-pq-nodes** in Remote LFA controls the maximum number of PQ nodes found in the LFA SPFs for which the node protection check is performed. The node-protect condition means the router must run the original Remote LFA algorithm plus one extra forward SPF on behalf of each PQ node found, potentially after applying the **max-pq-cost** parameter, to check if the path from the PQ node to the destination does not traverse the protected node. Setting this parameter to a lower value means the LFA SPFs will use less computation time and resources but may result in not finding a node-protect repair tunnel.

The **no** form of this command disables the LFA computation by the IGP SPF.

configure saa test loss-event

Description

Specifies that at the termination of an SAA test run, the calculated loss event value is evaluated against the configured rising and falling loss event thresholds. SAA threshold events are generated as required.

The configuration of loss event thresholds is optional.

The **no** form of this command disables the loss-event test run.

Parameters

rising-threshold *threshold*

Specifies a rising threshold loss event value, in packets. When the test run is completed, the calculated loss event value is compared to the configured loss event rising threshold.

If the test run loss event value is greater than the configured rising threshold value then an SAA threshold event is generated. The SAA threshold event is tmnxOamSaaThreshold, logger application OAM, event #2101.

Values 0 to 2147483647

Default 0

falling-threshold ***threshold***

Specifies a falling threshold loss event value, in packets. When the test run is completed, the calculated loss event value is compared to the configured loss event falling threshold. If the test run loss event value is greater than the configured falling threshold value then an SAA threshold event is generated. The SAA threshold event is tmnxOamSaaThreshold, logger application OAM, event #2101.

Values 0 to 2147483647

Default 0

direction

Specifies the direction for OAM ping responses received for an OAM ping test run.

Values **inbound** — Monitor the value of jitter calculated for the inbound, one-way, OAM ping responses received for an OAM ping test run.

outbound — Monitor the value of jitter calculated for the outbound, one-way, OAM ping requests sent for an OAM ping test run.

roundtrip — Monitor the value of jitter calculated for the round trip, two-way, OAM ping requests and replies for an OAM ping test run.

Context

[Tree] (config>port>ethernet>egress>hs-sec-shaper>agg low-burst-max-class)

Full Context

configure port ethernet egress hs-secondary-shaper aggregate low-burst-max-class

Description

This command specifies which scheduling classes map to the low burst-limit threshold of an egress HS secondary shaper. Egress SAPs can be configured to use an HS secondary shaper that manages their maximum burst limit over a specified aggregate shaping rate. Each HS secondary shaper supports two thresholds, a low burst limit threshold and a high burst limit threshold.

By default, all scheduling classes are mapped to the low burst limit threshold. It is important to note that when mapping scheduling classes to the high burst limit threshold an adequate value for the **card>fp>egress>hs-fixed-high-thresh-delta** must be specified. This is due to the fact that the queues associated with the lower classes may burst over the lower threshold in normal operation due to the scheduler forwarding whole packets. The **hs-fixed-high-thresh-delta** value should be set to at least two times the maximum frame size to prevent lower threshold class forwarding from also affecting the higher threshold classes when forwarding larger packet sizes. An insufficient high threshold delta defeats the intended purpose of mapping classes to the higher threshold.

The system utilizes the lowest value attainable for each low threshold aggregate burst limit without causing shaper underrun conditions. The high burst limit threshold is determined by adding the **hs-fixed-high-thresh-delta** value configured in the **config>card>fp>egress** context to the aggregate's low burst limit threshold value.

The low-burst-max-class value can be changed at any time for an HS secondary shaper.

The **no** form of this command restores the HS secondary shaper's aggregate low burst limit threshold maximum scheduling class mapping to the default value. This causes all sets of queues associated with the hs-secondary-shaper secondary-shaper-name to have all scheduling classes mapped to the low burst limit threshold.

Default

low-burst-max-class 6

Parameters

class

Specifies the low burst maximum class. This parameter is required when executing the **low-burst-max-class** command. The parameter reflects the highest scheduling class that will be associated with the low burst limit threshold associated with the HS secondary aggregate shaper. Scheduling classes higher than scheduling class ID will be associated with the high burst limit threshold.

no low-burst-max-class

Context

[Tree] (config>qos>hs-attachment-policy low-burst-max-class)

Full Context

configure qos hs-attachment-policy low-burst-max-class

Description

This command specifies which scheduling classes map to the low burst-limit threshold of the queue-level aggregate shaper. Each egress SAP or subscriber SLA profile instance (SPI), per port set of network interface queues and egress queue group template instance has an aggregate shaper that manages the maximum burst limit over a specified shaping rate. Each aggregate shaper supports two thresholds. As the scheduling rate for the set of queues increases, eventually the aggregate rate exceeds the rate limit and the aggregate burst limit starts to be consumed. If this continues, the low burst limit threshold is exceeded and the queues mapped to the scheduling classes associated with low threshold are removed from the scheduler. If the remaining aggregate rate (from the higher scheduling classes) continues to exceed the shaping rate, then the burst limit continues to be consumed and eventually the high burst limit threshold is exceeded. This causes the queues for all scheduling classes to be removed from the scheduler.

The second (high) threshold exists to allow the higher priority classes to continue to forward, thereby mitigating the effects of low priority bursts beyond the aggregate shaping rate. Typically, the higher scheduling class queues are either individually rate-limited so their aggregate allowed throughput is less than the aggregate rate or the expected aggregate unshaped traffic from the individual higher scheduling classes does not exceed the aggregate shaping rate. Determining the value of **low-burst-max-class** class involves anticipating the proper dividing line between the low and high scheduling classes by evaluating the forwarding behavior and SLA enforcement of each class.

By default, all scheduling classes are mapped to the low burst limit threshold. When mapping scheduling classes to the high burst limit threshold, an adequate value for the **card>fp>egress>hs-fixed-high-thresh-delta** must be specified. This is due to the fact that the queues associated with the lower classes may burst over the lower threshold in normal operation due to the scheduler forwarding whole packets. Set the **hs-fixed-highthresh- delta** value to at least two times the maximum frame size to prevent lower threshold class forwarding from also affecting the higher threshold classes when forwarding larger packet sizes. An insufficient high threshold delta defeats the intended purpose of mapping classes to the higher threshold.

The system utilizes the lowest value attainable for each low threshold aggregate burst limit without causing shaper underrun conditions. The high burst limit threshold is determined by adding the **hs-fixed-high-**

thresh-delta value configured in the **config>card>fp>egress** CLI context to the aggregate's low burst limit threshold value.

The **low-burst-max-class** value can be changed at any time in the HS attachment policy. Modifying the setting causes all queue aggregate shapers to reconfigure the scheduling class mappings to the low and high burst limit thresholds to reflect the new value for scheduling class ID.

Scheduling Classes — As described in the **queue** and **wrr-group** attachment commands, each queue is either directly or indirectly (through a WRR group) mapped to a scheduling class. Each scheduling class has an inherent priority at the port scheduler. The inherent descending priority is as follows:

- Scheduling Class 6 (Highest)
- Scheduling Class 5
- Scheduling Class 4
- Scheduling Class 3
- Scheduling Class 2
- Scheduling Class 1 (lowest)

Placing scheduling classes into the port level WRR group causes those classes to compete for scheduling opportunities based on their associated weights instead of inherent priority. If higher weights are given to higher scheduling class IDs, then the relative proportional scheduling priority may continue to exhibit the priority level indicated by the class ID.

Setting Low and High Burst Limit Threshold Association — Table 55: Low and High Burst Limit Threshold Association demonstrates the effect of the **low-burst-max-class** command parameters on scheduling class mappings to the low and high burst limit thresholds.

Table 55: Low and High Burst Limit Threshold Association

low-burst-max-class ***sched-class***	**Scheduling Classes on Low Threshold**	**Scheduling Classes on High Threshold**
1	1	2, 3, 4, 5, and 6
2	1 and 2	3, 4, 5, and 6
3	1, 2, and 3	4, 5, and 6
4	1, 2, 3, and 4	5 and 6
5	1, 2, 3, 4, and 5	6
6	1, 2, 3, 4, 5, and 6	—

The **no** form of the command restores the queue aggregate low burst limit threshold maximum scheduling class mapping to the default value. This causes all sets of queues associated with the specified **hs-attachment-policy** *policy-name* to have all scheduling classes mapped to the low burst limit threshold.

Default

low-burst-max-class 6

Parameters

class

Specifies the low burst maximum class. This parameter is required when executing the **low-burst max-class** command. The parameter reflects the highest scheduling class that is associated with the low burst limit threshold associated with the queue aggregate shaper. Scheduling classes higher than the scheduling class ID are associated with the high burst limit threshold.

Values 1 to 6

16.247 low-slope

low-slope

Syntax

[**no**] **low-slope**

Context

[Tree] (config>qos>slope-policy low-slope)

Full Context

configure qos slope-policy low-slope

Description

The **low-slope** context contains the commands and parameters for defining the low Random Early Detection (RED) slope graph. Each buffer pool supports a low RED slope for managing access to the shared portion of the buffer pool for low out-of-profile packets.

The **low-slope** parameters can be changed at any time and the affected buffer pool low RED slopes must be adjusted appropriately.

The **no** form of this command restores the low slope configuration commands to the default values. If the leaf commands within **low-slope** are set to the default parameters, the **low-slope** node will not appear in save config and show config output unless the detail parameter is present.

16.249 lower-bound

lower-bound

Syntax

lower-bound *microseconds*

no lower-bound

Context

[Tree] (config>oam-pm>bin-group>bin-type>bin lower-bound)

Full Context

configure oam-pm bin-group bin-type bin lower-bound

Description

This command allows the operator specify the individual floors thresholds for the bins. The operator does not have to specific a lower threshold for every bin that was previously defined by the bin-count for the specific type. By default, each bin is the bin-number times 5000 microseconds. Lower thresholds in the previous adjacent bin must be lower than the threshold of the next higher bin threshold. A separate line per bin is required to configure an operator-specific threshold. An error prevents the bin from entering the active state if this is not maintained, at the time the **no shutdown** is issued. Bin 0 is the result of the difference between 0 and the configured lower-threshold of bin 1. The highest bin in the bin-count captures every result above the threshold. Any negative delay metric result is treated as zero and placed in bin 0.

The **no** form of this command removes the user configured threshold value and applies the default for the bin.

Parameters

microseconds

Specifies the threshold that defines the floor of the bin. The bin range is the difference between its configured threshold and the threshold of the next higher bin in microsecond threshold value.

Values 1 to 4294967295

Default bin-number * 5000

16.250 lsa-accumulate

lsa-accumulate

Syntax

lsa-accumulate *lsa-accumulate*

no lsa-accumulate

Context

[Tree] (config>router>ospf3>timers lsa-accumulate)

[Tree] (config>router>ospf>timers lsa-accumulate)

Full Context

configure router ospf3 timers lsa-accumulate

configure router ospf timers lsa-accumulate

Description

This command sets the internal OSPF delay to allow for the accumulation of multiple LSA so OSPF messages can be sent as efficiently as possible. The **lsa-accumulate** timer applies to all LSAs except Type 1 and Type 2 LSAs, which are sent immediately. LSAs are accumulated and then sent when:

- its size reaches the MTU size of the interface
- a new LSA is received on the interface
- the **lsa-accumulate** timer expires

Shorting this delay can speed up the advertisement of LSAs to OSPF neighbors but may increase the number of OSPF messages sent.

The **no** form of this command reverts to the default value.

Note:
The timer granularity is 10 ms if the value is less than 500 ms, and 100 ms if the value is greater than or equal to 500 ms. Timer values are rounded down to the nearest granularity, for example a configured value of 550 ms is internally rounded down to 500 ms.

Default

lsa-accumulate 1000

Parameters

lsa-accumulate

Specifies the LSA accumulation delay in milliseconds.

Values 0 to 1000

Platforms

All

[Tree] (config>service>vprn>ospf3>timers lsa-arrival)

Full Context

configure service vprn ospf timers lsa-arrival

configure service vprn ospf3 timers lsa-arrival

Description

This parameter defines the minimum delay that must pass between receipt of the same Link State Advertisements (LSAs) arriving from neighbors.

It is recommended that the neighbor's configured **lsa-generate** *lsa-second-wait* interval is equal to or greater than the **lsa-arrival** timer configured here.

Use the **no** form of this command to return to the default.

Note:
The timer granularity is 10 ms if the value is less than 500 ms, and 100 ms if the value is ≥ 500 ms. Timer values are rounded down to the nearest granularity, for example a configured value of 550 ms is internally rounded down to 500 ms.

Default

lsa-arrival 1000

Parameters

lsa-arrival-time

Specifies the timer in milliseconds.

Values 0 to 600000

configure service vprn ospf area interface lsa-filter-out

configure router ospf area interface lsa-filter-out

configure router ospf3 area interface lsa-filter-out

configure service vprn ospf3 area interface lsa-filter-out

Description

This command enables filtering of outgoing OSPF LSAs on the selected OSPFv2 or OSPFv3 interface. Three filtering options are provided:

- Do not flood any LSAs out the interface. This option is suitable if the neighbor is simply-connected and has a statically configured default route with the address of this interface as next-hop.
- Flood the router's own router-LSA out the interface and suppress all other flooded LSAs. This option is suitable if the neighbor is simply-connected and has a statically configured default route with a loopback or system interface address (contained in the router-LSA) as next-hop.

- Flood the router's own router-LSA and all self-generated type-3, type-5 and type-7 LSAs advertising a default route (0/0) out the interface; suppress all other flooded LSAs. This option is suitable if the neighbor is simply-connected and does not have a statically configured default route.

The **no** form of this command disables OSPF LSA filtering (normal operation).

Default

no lsa-filter-out

no lsa-generate-interval

Context

[Tree] (config>service>vprn>ospf>timers lsa-generate)

[Tree] (config>service>vprn>ospf3>timers lsa-generate)

Full Context

configure service vprn ospf timers lsa-generate

configure service vprn ospf3 timers lsa-generate

Description

This parameter customizes the throttling of OSPF LSA-generation. Timers that determine when to generate the first, second, and subsequent LSAs can be controlled with this command. Subsequent LSAs are generated at increasing intervals of the *lsa-second-wait* timer until a maximum value is reached.

Configuring the **lsa-arrival** interval to equal or less than the *lsa-second-wait* interval configured in the **lsa-generate** command is recommended.

The **no** form of this command reverts to the default.

Note:
The timer granularity is 10 ms if the value is less than 500 ms, and 100 ms if the value is ≥ 500 ms. Timer values are rounded down to the nearest granularity, for example a configured value of 550 ms is internally rounded down to 500 ms.

Parameters

max-lsa-wait

Specifies the maximum interval, in milliseconds, between two consecutive occurrences of an LSA being generated.

Values 10 to 600000

Default 5000

lsa-initial-wait

Specifies the first waiting period between link-state advertisements (LSA) originate(s), in milliseconds. When the LSA exceeds the **lsa-initial-wait** timer value and the topology changes, there is no wait period and the LSA is immediately generated.

When an LSA is generated, the initial wait period commences. If, within the specified **lsa-initial-wait** period and another topology change occurs, then the **lsa-initial-wait** timer applies.

Values 10 to 600000

Default 5000

lsa-second-wait

Specifies the hold time in milliseconds between the first and second LSA generation. The next topology change is subject to this second wait period. With each subsequent topology change, the wait time doubles (this is 2x the previous wait time). This assumes that each failure occurs within the relevant wait period.

Values 10 to 600000

Default 5000

debug router ospf3 lsdb

debug router ospf lsdb

Description

This command enables debugging for an OSPF link-state database (LSDB).

Parameters

type

Specifies the OSPF link-state database (LSDB) type.

Values in the **ospf** context — router, network, summary, asbr, extern, nssa, area-opaque, as-opaque, link-opaque

in the **ospf3** context — router, network, inter-area-pfx, inter-area-rtr, external, nssa, intra-area-pfx, rtr-info-link, rtr-info-area, rtr-info-as

ls-id

Specifies an LSA type specific field containing either a router ID or an IP address. It identifies the piece of the routing domain being described by the advertisement.

adv-rtr-id

Specifies the router identifier of the router advertising the LSA.

area area-id

Specifies a 32-bit integer uniquely identifying an area.

Values ip-address — a.b.c.d

area — 0 to 4294967295

Context

[Tree] (config>service>nat>fwd lsn)

Full Context

configure service nat port-forwarding lsn

Description

This command creates NAT static port forwards for LSN44, Ds-Lite and NAT64. Static port forwards (SPF) are static mappings created so that certain applications on the inside (private side) can be reached from host that are on the outside of the NAT. SPF statically map the subscriber (inside IP address in LSN44, CPE IPv6 address/prefix in DS-Lite and IPv6 prefix in NAT64), inside port and protocol to an outside IPv4 address, port and the same protocol.

If only the inside router, the inside IPv4/v6 address/prefix and the protocol are configured as parameters in the SPF request, the remaining fields in the mapping (outside port and outside IPv4 address) will be selected automatically by the node and reported in CLI once the command execution is completed.

Specifying the outside IPv4 address in the SPF request, mandates that all other, otherwise optional, parameters be also specified in the request (inside port and outside port). This creates a fully specified SPF request. Fully specified SPF request can be used in multi-chassis NAT redundancy deployments where the SPF is manually replicated between the SR OS nodes. In single chassis NAT deployments, fully specified SPF request is guaranteed to work only in the system with a single MS-ISA in it. Otherwise (multiple MS-ISAs in the system) a conflict may arise where two distinct inside IP addresses that may reside on separate MS-ISAs are requested to be mapped to the same outside IPv4 address. This will not be possible since the outside IPv4 address cannot be split across the MS-ISAs (each IP address, inside or outside, is tied to a single MS-ISA).

In non-fully specified SPF requests (missing the inside port and/or outside port and the outside IPv4 address within the SPF request), the outside IPv4 address selection will depend on the configuration of the outside port in the SPF request:

- If the outside port is not specified or is specified from the configured **port-forwarding-range** [1024..port-forwarding-range], then the outside IPv4 address will be the same as the outside IPv4 address in an existing dynamic mapping for the same subscriber. If the subscriber does not exist (no dynamic mappings exist at the time of SPF creation request), then the subscriber will be automatically created and an outside IPv4 address will be assigned. In case that the outside ports are not available from the outside IPv4 address of the corresponding dynamic mapping, then the SPF request will fail. In other words, the dynamic and static mappings (created in this manner) for the same subscriber must use the same outside IPv4 address.
- If the outside port from the well-known port range [0 to 1023] is requested, then the outside IPv4 address does not have to match the outside IPv4 address of an existing dynamic mapping for the same subscriber, but can instead be any outside IPv4 address.

If multiple NAT policies per inside routing context are used, then the NAT policy must be specified in the SPF creation request. This is needed so the SPF be created in the correct pool.

SPFs are disabled by default and they must be explicitly enabled by the **port-limits forwarding** command within the NAT policy.

Configured SPFs, unlike SPFs created with the **tools** commands, are preserved across reboots without having to configure persistency (**config>system>persistence>nat-port-forwarding**) since they are part of the configuration. When the pool is shutdown the SPFs are deactivated. When the pool is enabled (no shutdown), the SPFs (as created by the **tools** command or by configuration) are activated.

To avoid possible persistency related conflicts, SPFs can only be created using one method on a given node: either as configuration (the CLI **configure** branch) or using the **tools** command. For example: if a first SPF entry is created via CLI **tools** commands, the node prevents SPF creation via configuration (the CLI **configure** branch) and vice versa.

The **no** form of the command deletes NAT static port forwards for LSN44, Ds-Lite and NAT64.

Parameters

router *router-instance*

This mandatory parameter specifies the inside routing instance; router name or service-id.

Values router-name, service-id

b4 *ipv6-address*

This optional parameter specifies the IPv6 address of the B4 element in DS-Lite.

Values <ipv6-address> : ipv6-address - x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x - [0..FFFF]H

d - [0..255]D

aftr *ipv6-address*

This optional parameter specifies IPv6 address of the AFTR element in DS-Lite.

Values <ip-address> : ipv4-address - a.b.c.d

ipv6-address - x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x - [0..FFFF]H

d - [0..255]D

protocol {tcp | udp}

This mandatory parameter specifies the protocol to use, either TCP or UDP.

port *port*

This optional parameter specifies a source port.

Values 1 to 65535

outside-ip *ipv4-address*

This mandatory parameter specifies the outside IPv4 address. If the outside IPv4 address is specified, then all other optional parameters become mandatory.

outside-port *port*

This optional parameter specifies the outside port.

nat-policy *policy-name*

If multiple NAT policies are used inside the routing context, then the NAT policy should be specified in the SPF request so the SPF is created in the correct NAT pool. Otherwise, the default NAT policy from the inside routing context will be used.

Syntax

[**no**] **lsp** *lsp-name*

Context

[Tree] (config>router>ldp>targ-session>peer>tunneling lsp)

Full Context

configure router ldp targeted-session peer tunneling lsp

Description

This command configures a specific LSP destined to this peer and to be used for tunneling of LDP FEC over RSVP. A maximum of 4 RSVP LSPs can be explicitly used for tunneling LDP FECs to the T-LDP peer.

It is not necessary to specify any RSVP LSP in this context unless there is a need to restrict the tunneling to selected LSPs. All RSVP LSPs with a to address matching that of the T-LDP peer are eligible by default.

The user can also exclude specific LSP names by using the ldp-over-rsvp exclude command in the **config>router>mpls>lsp** context.

Parameters

lsp-name

Specifies the LSP name, up to 64 characters in length.

Platforms

All

lsp

Syntax

[**no**] **lsp** *lsp-name* **sender** *sender-address*

Context

[Tree] (config>router>mpls>ingress-statistics lsp)

Full Context

configure router mpls ingress-statistics lsp

Description

This command configures statistics in the ingress data path of a terminating RSVP LSP at an egress LER. The LSP name must correspond to the name configured by the operator at the ingress LER. It must not

contain the special character ":" which is used as a field separator by the ingress LER for encoding the LSP and path names into the RSVP session name field in the session_attribute object. The operator must execute the **no shutdown** for this command to effectively enable statistics.

The same set of counters is updated for packets received over any path of this LSP and over the lifetime of the LSP. In steady-state, the counters are updated for packets received over the active path of the LSP. The active path can be the primary path, one of the secondary paths, the FRR detour path, or the FRR bypass path when the tail-end node is also the MP.

When a hierarchy of LSPs is in use, statistics collection on the outermost label corresponding to the tunneling LSP and on the inner labels, corresponding to the tunneled LSPs are mutually exclusive. A consequence of this is that when the operator enables statistics collection on an RSVP LSP which is also used for tunneling LDP FECs with the LDP over RSVP feature, then statistics will be collected on the RSVP LSP only. There will be no statistics collected for an LDP FEC tunneled over this RSVP LSP and also egressing on the same node regardless if the operator enabled statistics collection on this FEC. When, the operator disables statistics collection on the RSVP LSP, then statistics collection, if enabled, will be performed on a tunneled LDP FEC.

The operator can enable statistics collection on a manual bypass terminating on the egress LER. However all LSPs which primary path is protected by the manual bypass will not collect statistics when they activate forwarding over the manual bypass. When, the operator disables statistics collection on the manual bypass LSP, then statistics collection on the protected LSP, if enabled, will continue when the bypass LSP is activated.

The **no** form of this command disables statistics for this RSVP LSP in the ingress data path and removes the accounting policy association from the LSP.

Parameters

sender-address *ip-address*

Specifies a string of 15 characters representing the IP address of the ingress LER for the LSP.

lsp-name

Specifies the LSP name, up to 64 characters in length, as configured at the ingress LER.

Platforms

All

lsp

Syntax

[**no**] **lsp** *lsp-name* [**bypass-only** | **p2mp-lsp** | **mpls-tp** *src-tunnel-num* | **sr-te**]

Context

[Tree] (config>router>mpls lsp)

Full Context

configure router mpls lsp

Description

This command creates an LSP that is either signaled dynamically by the router, or a statically provisioned MPLS-TP LSP.

When the LSP is created, the egress router must be specified using the **to** command and at least one **primary** or **secondary** path must be specified for signaled LSPs, or at least one working path for MPLS-TP LSPs. All other statements under the LSP hierarchy are optional.

LSPs are created in the administratively down (**shutdown**) state.

The **no** form of this command deletes the LSP. All configuration information associated with this LSP is lost. The LSP must be administratively shutdown before it can be deleted. The LSP must also be unbound from all SDPs before it can be deleted.

Parameters

lsp-name

Specifies the name that identifies the LSP. The LSP name can be up to 64 characters long and must be unique.

bypass-only

Defines an LSP as a manual bypass LSP exclusively. When a path message for a new LSP requests bypass protection, the PLR first checks if a manual bypass tunnel satisfying the path constraints exists. If one if found, the router selects it. If no manual bypass tunnel is found, the router dynamically signals a bypass LSP in the default behavior. The CLI for this feature includes a knob that provides the user with the option to disable dynamic bypass creation on a per node basis.

p2mp-lsp

Defines an LSP as a point-to-multipoint LSP. The following parameters can be used with a P2MP LSP: adaptive, adspec, cspf, exclude, fast-reroute, from, hop-limit, include, metric, retry-limit, retry-timer, resignal-timer. The following parameters cannot be used with a P2MP LSP: primary, secondary, to, dest-global-id, dest-tunnel-number, working-tp-path, protect-tp-path.

This option is not supported on the 7450 ESS.

mpls-tp *src-tunnel-num*

Defines an LSP as an MPLS-TP LSP. The *src-tunnel-num* is a mandatory create time parameter for mpls-tp LSPs, and has to be assigned by the user based on the configured range of tunnel IDs. The following parameters can only be used with an MPLS-TP LSP: to, dest-global-id, dest-tunnel-number, working-tp-path, protect-tp-path. Other parameters defined for the above LSP types cannot be used.

sr-te

Defines an LSP of type Segment Routing Traffic Engineering (SR-TE) LSP. The user can associate an empty path or a path with strict or loose explicit hops with the primary path of the SR-TE LSP. A hop which corresponds to an adjacency SID must be identified with its far-end host IP address (next-hop) on the subnet. If the local end host IP address is provided, this hop is ignored since this router can have multiple adjacencies (next-hops) on the same subnet. A hop which corresponds to a node SID is identified by the prefix address. The user is only allowed to configure a primary path for the SR-TE LSP.

configure router static-route-entry indirect tunnel-next-hop resolution-filter rsvp-te lsp

Description

This command restricts the search for a resolving LSP to a specific set of named LSPs. Only those LSPs named in the associated name list will be searched for a match to resolve the associated static route.

Parameters

lsp-name

Specifies the name of the LSP to be searched for a valid resolving tunnel for the static route's next-hop.

Platforms

All

lsp

Syntax

[**no**] **lsp** *lsp-name*

Context

[Tree] (config>service>sdp lsp)

Full Context

configure service sdp lsp

Description

This command creates associations between one or more label switched paths (LSPs) and an Multi-Protocol Label Switching (MPLS) Service Distribution Point (SDP). This command is implemented *only* on MPLS-type encapsulated SDPs.

In MPLS SDP configurations *either* one or more LSP names can be specified *or* LDP can be enabled. The SDP **ldp** and **lsp** commands are mutually exclusive except if the mixed-lsp-mode option is also enabled. If an LSP is specified on an MPLS SDP, then LDP cannot be enabled on the SDP. To enable LDP on the SDP when an LSP is already specified, the LSP must be removed from the configuration using the **no lsp lsp-name** command.

Alternatively, if LDP is already enabled on an MPLS SDP, then an LSP cannot be specified on the SDP. To specify an LSP on the SDP, the LDP must be disabled or the mixed-lsp-mode option is also enabled. The LSP must have already been created in the **config>router>mpls** context. with a valid far-end IP address. RSVP must be enabled.

If no LSP is associated with an MPLS SDP, the SDP cannot enter the operationally up state. The SDP can be administratively enabled (**no shutdown)** with no LSP associations. The *lsp-name* may be shutdown, causing the association with the SDP to be operationally down (the LSP will not be used by the SDP).

Up to 16 LSP names can be entered on a single command line.

The **no** form of this command deletes one or more LSP associations from an SDP. If the *lsp-name* does not exist as an association or as a configured LSP, no error is returned. An *lsp-name* must be removed from all SDP associations before the *lsp-name* can be deleted from the system. The SDP must be administratively disabled (**shutdown)** before the last *lsp-name* association with the SDP is deleted.

Parameters

lsp-name

Specifies the name of the LSP to associate with the SDP. An LSP name is case sensitive and is limited to 32 ASCII 7-bit printable characters with no spaces. If an exact match of *lsp-name* does not already exist as a defined LSP, an error message is generated. If the *lsp-name* does exist and the LSP **to** IP address matches the SDP **far-end** IP address, the association is created.

Full Context

configure router ldp lsp-bfd

Description

Commands in this context configure LSP BFD for a set of LDP LSPs with FECs matching those defined in the specified prefix list.

Up to 16 LSP BFD instances can be configured for LDP.

If a prefix corresponding to an LDP FEC appears in more than one prefix list, then the system will apply the LSP BFD configuration to the LSP only once. A prefix list may contain a longest match corresponding to one or more LDP FECs, in which case the BFD configuration is applied to all of those LDP LSPs.

The **no** form of the command removes LSP BFD. Specifying a prefix list name will remove LSP BFD for all LDP FECs that match the specified prefix list, except those LDP FECs that also match another LSP BFD prefix list.

Default

no lsp-bfd

Parameters

prefix-list-name

Specifies the name of the prefix list configured using the **configure router policy-options prefix-list** *name* command, up to 32 characters maximum. The prefix list name can be specified by the **lsp-bfd** command prior to the prefix list being defined in the **config**>**router**>**policy-options** context.

configure qos sap-ingress lsp-exp

Description

This command explicitly sets the forwarding class or subclass enqueuing priority when a packet is marked with a MPLS EXP bits specified. Adding a lsp-exp rule on the policy forces packets that match the MPLS LSP EXP specified to override the forwarding class and enqueuing priority based on the parameters included in the lsp-exp rule. When the forwarding class is not specified in the rule, a matching packet preserves (or inherits) the existing forwarding class derived from earlier matches in the classification hierarchy. When the enqueuing priority is not specified in the rule, a matching packet preserves (or inherits) the existing enqueuing priority derived from earlier matches in the classification hierarchy.

The *lsp-exp-value* is derived from the MPLS LSP EXP bits of the top label.

Multiple commands can be entered to define the association of some or all eight LSP EX bit values to the forwarding class.

The **no** form of this command removes the explicit lsp-exp classification rule from the SAP ingress policy. Removing the rule on the policy immediately removes the rule on all ingress SAPs using the policy.

This command applies to Ethernet Layer 2 SAPs only.

Parameters

lsp-exp-value

This value is a required parameter that specifies the unique MPLS LSP EXP value that will match the lsp-exp rule. If the command is executed multiple times with the same *lsp-exp-value*, the previous forwarding class and enqueuing priority is completely overridden by the new parameters or defined to be inherited when a forwarding class or enqueuing priority parameter is missing.

A maximum of eight lsp-exp rules are allowed on a single policy.

Values 0 to 7

fc *fc-name*

The value given for the *fc-name* parameter must be one of the predefined forwarding classes in the system. Specifying the *fc-name* is optional. When a packet matches the rule, the forwarding class is only overridden when the *fc-name* parameter is defined on the rule. If the packet matches and the forwarding class is not explicitly defined in the rule, the forwarding class is inherited based on previous rule matches.

The *subclass-name* parameter is optional and used with the *fc-name* parameter to define a pre-existing subclass. The *fc-name* and *subclass-name* parameters must be separated by a period (dot). If *subclass-name* does not exist in the context of *fc -name*, an error will occur.

Values *class*[.*subclass*]

class: be, l2, af, l1, h2, ef, h1, nc

subclass: 29 characters max

priority

The **priority** parameter is used to override the default enqueuing priority for all packets received on an ingress SAP using this policy that match this rule. Specifying the priority is optional. When a packet matches the rule, the enqueuing priority is only overridden when the **priority** parameter is defined on the rule. If the packet matches and priority is not explicitly defined in the rule, the enqueuing priority is inherited based on previous rule matches.

high

The **high** parameter is used in conjunction with the **priority** parameter. Setting the enqueuing parameter to **high** for a packet increases the likelihood of enqueuing the packet when the ingress queue is congested. Ingress enqueuing priority only affects ingress SAP queuing. When the packet is placed in a buffer on the ingress queue, the significance of the enqueuing priority is lost.

low

The **low** parameter is used in conjunction with the **priority** parameter. Setting the enqueuing parameter to **low** for a packet decreases the likelihood of enqueuing the packet when the ingress queue is congested. Ingress enqueuing priority only affects ingress SAP queuing. When the packet is placed in a buffer on the ingress queue, the significance of the enqueuing priority is lost.

Default no override

lsp-exp *lsp-exp-value* **fc** *fc-name* **profile** {**in** | **out**}

no lsp-exp

Context

[Tree] (config>qos>network>ingress lsp-exp)

Full Context

configure qos network ingress lsp-exp

Description

This command creates a mapping between the LSP EXP bits of the network ingress traffic and the forwarding class.

Ingress traffic that matches the specified LSP EXP bits will be assigned to the corresponding forwarding class. Multiple commands can be entered to define the association of some or all eight LSP EXP bit values to the forwarding class. For undefined values, packets are assigned to the forwarding class specified under the **default-action** command.

The **no** form of this command removes the association of the LSP EXP bit value to the forwarding class. The **default-action** then applies to that LSP EXP bit pattern.

Default

no lsp-exp

Parameters

lsp-exp-value

Specify the LSP EXP values to be associated with the forwarding class.

Values 0 to 8 (Decimal representation of three EXP bit field)

fc *fc-name*

Enter this required parameter to specify the fc-name that the EXP bit pattern will be associated with.

Values be, l2, af, l1, h2, ef, h1, nc

profile {in | out}

Enter this required parameter to indicate whether the LSP EXP value is the in-profile or out-of-profile value.

Values in, out

lsp-exp-in-profile

Syntax

lsp-exp-in-profile *lsp-exp-value*

no lsp-exp-in-profile

Context

[Tree] (config qos network egress fc lsp-exp-in-profile)

Full Context

configure qos network egress fc lsp-exp-in-profile

Description

This command specifies the in-profile LSP EXP value for the forwarding class. The EXP value will be used for all LSP labeled packets requiring marking that require marking at egress on this forwarding class queue, and that are in-profile. The inplus-profile traffic is marked with the same value as in-profile traffic.

When multiple EXP values are associated with the forwarding class at network egress, the last name entered will overwrite the previous value.

The **no** form of this command resets the configuration to the factory default in-profile EXP setting.

Default

Policy-id 1:	Factory setting
Policy-id 2 to 65535:	Policy-id setting

Parameters

lsp-exp-value

Specifies the 3-bit LSP EXP bit value, expressed as a decimal integer.

Values 0 to 7

Platforms

All

16.261 lsp-exp-out-profile

lsp-exp-out-profile

Syntax

no lsp-exp-out-profile

Context

[Tree] (config qos network egress fc lsp-exp-out-profile)

Full Context

configure qos network egress fc lsp-exp-out-profile

Description

This command specifies the out-of-profile LSP EXP value for the forwarding class. The EXP value will be used for all LSP labeled packets that require marking at egress on this forwarding class queue, and that are out-of-profile. The exceed-profile traffic is marked with the same value as out-of-profile traffic.

When multiple EXP values are associated with the forwarding class at network egress, the last name entered will overwrite the previous value.

The **no** form of this command resets the configuration to the factory default out-of-profile EXP setting.

Default

Policy-id 1:	Factory setting
Policy-id 2 to 65535:	Policy-id setting

Parameters

mpls-exp-value

Specifies the 3-bit MPLS EXP bit value, expressed as a decimal integer.

Values 0 to 7

no lsp-init-retry-timeout

Context

[Tree] (config>router>mpls lsp-init-retry-timeout)

Full Context

configure router mpls lsp-init-retry-timeout

Description

This command configures the initial LSP path retry-timer.

The new LSP path initial retry-timer is used instead of the retry-timer to abort the retry cycle when no RESV is received. The retry-timer exclusively governs the time between two retry cycles and to handle retrying of an LSP path in a failure case with PATH errors or RESVTear.

The intent is that the user can now control how many refreshes of the pending PATH state can be performed before starting a new retry-cycle with a new LSP ID. This is all done without affecting the ability to react faster to failures of the LSP path, which will continue to be governed by the retry-timer.

The **no** form of this command returns the timer to the default value.

Default

lsp-init-retry-timeout 30

Parameters

seconds

Specifies the value (in s), used as the fast retry timer for a secondary path.

Values 10 to 600

Default 30

no lsp-lifetime

Context

[Tree] (config>service>vpls>spb lsp-lifetime)

Full Context

configure service vpls spb lsp-lifetime

Description

This command sets the time, in seconds, SPB wants the LSPs it originates to be considered valid by other routers in the domain. This is a control B-VPLS command.

Each LSP received is maintained in an LSP database until the lsp-lifetime expires unless the originating router refreshes the LSP. By default, each router refreshes its LSPs every 20 minutes (1200 seconds) so other routers will not age out the LSP.

The LSP refresh timer is derived from this formula: lsp-lifetime/2.

LSPs originated by SPB should be valid for 1200 seconds (20 minutes).

The **no** form of this command reverts to the default value.

Default

lsp-lifetime 1200

Parameters

seconds

The time, in seconds, that SPB wants the LSPs it originates to be considered valid by other routers in the domain.

Values 350 to 65535

configure service vpls sap spb lsp-pacing-interval

configure service vpls spoke-sdp spb lsp-pacing-interval

Description

This command configures the interval during which LSPs are sent from the interface.

To avoid overwhelming neighbors that have less CPU processing power with LSPs, the pacing interval can be configured to limit how many LSPs are sent during an interval. LSPs may be sent in bursts during the interval up to the configured limit. If a value of 0 is configured, no LSPs are sent from the interface.

If configured to the default LSP pacing interval of 100, LSPs are sent in 100 millisecond intervals.

The **no** form of this command reverts to the default value.

Note:
The IS-IS timer granularity is 100 ms. Timer values are rounded down to the nearest granularity, for example a configured value of 550 ms is internally rounded down to 500 ms.

Default

lsp-pacing-interval 100

Parameters

milli-seconds

The interval in milliseconds during which IS-IS LSPs are sent from the interface, expressed as a decimal integer.

0 to 65535

Platforms

All

lsp-pacing-interval

Syntax

lsp-pacing-interval *milliseconds*

Context

[Tree] (config>service>vprn>isis>if lsp-pacing-interval)

Full Context

configure service vprn isis interface lsp-pacing-interval

Description

This command configures the interval at which LSPs are sent from the interface.

To avoid overwhelming neighbors that have less CPU processing power with LSPs, the pacing interval can be configured to limit how many LSPs are sent at the interval. LSPs are sent in bursts at the interval up to the configured limit. If a value of 0 is configured, no LSPs are sent from the interface.

If configured to the default LSP pacing interval of 100, LSPs are sent in 100 millisecond intervals.

The **no** form of this command reverts to the default value.

Note:
The IS-IS LSP pacing interval is 100 milliseconds for values < 100 milliseconds, and 1 second for values ≥ 100 milliseconds. For example, a pacing interval of 2 milliseconds means that a maximum of 50 LSPs are sent in a burst at 100 millisecond intervals. The default pacing interval of 100 milliseconds means that a maximum of 10 LSPs are sent in a burst at 1 second intervals.

Default

lsp-pacing-interval 100

Parameters

milliseconds

Specifies the pacing interval in milliseconds at which IS-IS LSPs are sent from the interface at each interval expressed as a decimal integer.

Values 0 to 65535

Platforms

All

lsp-pacing-interval

Syntax

lsp-pacing-interval *milliseconds*

Context

[Tree] (config>saa>test>type lsp-ping)

[Tree] (oam lsp-ping)

Full Context

configure saa test type lsp-ping

oam lsp-ping

Description

This command performs in-band LSP connectivity tests.

This command performs an LSP ping using the protocol and data structures defined in the RFC 8029, *Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures*.

The LSP ping operation is modeled after the IP ping utility which uses ICMP echo request and reply packets to determine IP connectivity.

In an LSP ping, the originating device creates an MPLS echo request packet for the LSP and path to be tested. The MPLS echo request packet is sent through the data plane and awaits an MPLS echo reply packet from the device terminating the LSP. The status of the LSP is displayed when the MPLS echo reply packet is received.

This command, when used with the **static** option, performs in-band on-demand LSP connectivity verification tests for static MPLS-TP LSPs. For other LSP types, the **static** option should be excluded and these are described elsewhere in this user guide.

The **lsp-ping static** command performs an LSP ping using the protocol and data structures defined in the RFC 8029, *Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures*, as extended by RFC 6426, *MPLS On-Demand Connectivity Verification and Route Tracing*.

In MPLS-TP, the echo request and echo reply messages are always sent in-band over the LSP, either in a G-ACh channel or encapsulated as an IP packet below the LSP label.

The timestamp format to be sent, and to be expected when received in a PDU, is as configured by the **config>test-oam>mpls-time-stamp-format** command. If RFC 4379 (obsoleted by RFC 8029) is selected, then the timestamp is in seconds and microseconds since 1900, otherwise it is in seconds and microseconds since 1970.

Default

The active LSP path

Values: Any path name associated with the LSP

Parameters

lsp-name

Specifies the name of the target RSVP-TE LSP, up to 64 characters.

rsvp-te lsp-name

Specifies the name of the target RSVP-TE LSP, up to 64 characters.

Note:
The **rsvp-te** explicit target FEC type is not supported under the SAA context.

path-name

Specifies the LSP path name, up to 32 characters, to which to send the LSP ping request.

Values Any path name associated with the LSP.

Default The active LSP path.

bgp-label prefix *ip-prefix/prefix-length*

Specifies the address prefix and subnet mask of the target BGP IPv4 /32 label route or the target BGP IPv6 /128 label route.

Values <ipv4-prefix>/32 | <ipv6-prefix>/128

ipv4-prefix a.b.c.d

ipv6-prefix x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x: [0 to FFFF]H

d: [0 to 255]D

path-destination *ip-address*

Specifies the IP address of the path destination from the range 127/8. When the LDP FEC prefix is IPv6, the user must enter a 127/8 IPv4 mapped IPv6 address, that is, in the range ::ffff:127/104.

ipv4-address: a.b.c.d

ipv6-address: x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x: [0 to FFFF]H

d: [0 to 255]D

flex-algo *flex-algo-num*

Specifies the Segment Routing Flexible Algorithm for the test.

Values 128 to 255

interface if-name

Specifies the name of an IP interface, up to 32 characters, to send the MPLS echo request message to. The name must already exist in the **config>router>interface** context.

next-hop ***ip-address***

Specifies the next-hop address to send the MPLS echo request message to.

Values

ipv4-address: a.b.c.d

ipv6-address: x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x: [0 to FFFF]H

d: [0 to 255]D

prefix ***ip-prefix/prefix-length***

Specifies the address prefix and subnet mask of the target LDP FEC.

Values <ipv4-prefix>/32 | <ipv6-prefix>/128

ipv4-prefix a.b.c.d

ipv6-prefix x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x: [0 to FFFF]H

d: [0 to 255]D

ldp prefix ***ip-prefix/prefix-length***

Specifies the address prefix and subnet mask of the target LDP FEC.

Values <ipv4-prefix>/32 | <ipv6-prefix>/128

ipv4-prefix a.b.c.d

ipv6-prefix x:x:x:x:x:x:x:x (eight 16-bit pieces)
x:x:x:x:x:x:d.d.d.d
x: [0 to FFFF]H
d: [0 to 255]D

sr-isis prefix *ip-prefix/prefix-length*

Specifies the address prefix and subnet mask of the target node SID of the SR-IS-IS tunnel.

Values <ipv4-prefix>/32 | <ipv6-prefix>/128

ipv4-prefix a.b.c.d
ipv6-prefix x:x:x:x:x:x:x:x (eight 16-bit pieces)
x:x:x:x:x:x:d.d.d.d
x: [0 to FFFF]H
d: [0 to 255]D

igp-instance

Specifies the IGP instance of the node SID prefix.

Values isis-inst: 0 to 127
ospf3-inst: 0 to 31, 64 to 95
ospf-inst: 0 to 31

sr-ospf prefix *ip-prefix/prefix-length*

Specifies the address prefix and subnet mask of the target node SID of the SR-OSPF tunnel.

Values <ipv4-prefix>/32 | <ipv6-prefix>/128

ipv4-prefix - a.b.c.d
ipv6-prefix - x:x:x:x:x:x:x:x (eight 16-bit pieces)
x:x:x:x:x:x:d.d.d.d
x - [0 to FFFF]H
d - [0 to 255]D

sr-ospf3 prefix *ip-prefix/prefix-length*

Specifies the address prefix and subnet mask of the target node SID of the SR-OSPF3 tunnel. Note that only IPv6 prefixes in OSPFv3 instance ID 0-31 are supported.

Values

ipv6-prefix - x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x - [0 to FFFF]H

d - [0 to 255]D

sr-policy color *color-id* endpoint *ip-address* segment-list *segment-list-id*

Specifies the name of the target IPv4 or IPv6 SR policy.

Note:
The **sr-policy** target FEC type is supported under the OAM context and under **type-multi-line node** in the SAA context.

color *color-id* — Specifies the color ID.

Values 0 to 4294967295

endpoint *ip-address* — Specifies the endpoint address.

Values

ipv4-address: a.b.c.d

ipv6-address: x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x: [0 to FFFF]H

d: [0 to 255]D

segment-list *segment-list-id* — Specifies the segment list ID.

Values 1 to 32

detail

Displays detailed information.

sr-te *lsp-name*

Specifies the name of the target SR-TE LSP, up to 64 characters.

static

Specifies the target FEC stack sub-type "Static LSP”.

assoc-channel {ipv4 | non-ip | none}

Specifies the launched echo request’s usage of the Associated Channel (ACH) mechanism, when testing an MPLS-TP LSP.

Values **ipv4** — Use an Associated Channel with IP encapsulation, as described in RFC 6426, Section 3.2.

non-ip — Do not use an Associated Channel, as described in RFC 6426, Section 3.1.

none — Use the Associated Channel mechanism described in RFC 6426, Section 3.3.

Default non-ip

global-id

Specifies the MPLS-TP global ID for the far end node of the LSP under test. If this is not entered, then the dest-global-id is taken from the LSP context.

Values 0 to 4294967295

Default 0

node-id

Specifies the MPLS-TP global ID for the far end node of the LSP under test. If this is not entered, then the dest-global-id is taken from the LSP context.

Values a.b.c.d, 1 to 4294967295

Default 0

force

Allows LSP ping to test a path that is operationally down, including cases where MPLS-TP BFD CC/V is enabled and has taken a path down. This parameter is only allowed in the OAM context; it is not allowed for a test configured as a part of an SAA.

Default disabled

path-type {active | working | protect}

The LSP path to test.

Values **active** — The currently active path. If MPLS-TP linear protection is configured on the LSP, then this is the path that is selected by the MPLS-TP PSC protocol for sending user plane traffic. If MPLS-TP linear protection is not configured, then this is the working path.

working — The working path of the MPLS-TP LSP.

protect — The protect path of the MPLS-TP LSP.

Default active

fc-name

Specifies the FC and profile parameters that are used to indicate the forwarding class and profile of the MPLS echo request packet.

When an MPLS echo request packet is generated in CPM and is forwarded to the outgoing interface, the packet is queued in the egress network queue corresponding to the specified fc and profile parameter values. The marking of the packet's EXP is dictated by the LSP-EXP mappings on the outgoing interface.

When the MPLS echo request packet is received on the responding node, The FC and profile parameter values are dictated by the LSP-EXP mappings of the incoming interface.

When an MPLS echo reply packet is generated in CPM and is forwarded to the outgoing interface, the packet is queued in the egress network queue corresponding to the FC and profile parameter values determined by the classification of the echo request packet, which is being replied to, at the incoming interface. The marking of the packet's EXP is dictated by the LSP-EXP mappings on the outgoing interface. The ToS byte is not modified. Table 56: lsp-ping Request Packet and Behavior summarizes this behavior.

Table 56: lsp-ping Request Packet and Behavior

CPM (sender node)	Echo request packet: • packet {tos=1, fc1, profile1} • fc1 and profile1 are as entered by user in OAM command or default values • tos1 as per mapping of {fc1, profile1} to IP precedence in network egress QoS policy of outgoing interface
Outgoing interface (sender node)	Echo request packet: • packet queued as {fc1, profile1} • ToS field=tos1 not remarked • EXP=exp1, as per mapping of {fc1, profile1} to EXP in network egress QoS policy of outgoing interface
Incoming interface (responder node)	Echo request packet: • packet {tos1, exp1} • exp1 mapped to {fc2, profile2} as per classification in network QoS policy of incoming interface
CPM (responder node)	Echo reply packet: • packet{tos=1, fc2, profile2}
Outgoing interface (responder node)	Echo reply packet: • packet queued as {fc2, profile2} • ToS filed= tos1 not remarked (reply inband or out-of-band) • EXP=exp2, if reply is inband, remarked as per mapping of {fc2, profile2} to EXP in network egress QoS policy of outgoing interface
Incoming interface (sender node)	Echo reply packet: • packet {tos1, exp2} • exp2 mapped to {fc1, profile1} as per classification in network QoS policy of incoming interface

The LSP-EXP mappings on the receive network interface controls the mapping of the message reply at the originating router**.**

Values be, l2, af, l1, h2, ef, h1, nc

Default be

profile {in | out}

Specifies the profile state of the MPLS echo request packet.

Default out

flex-algo *flex-algo-num*

Specifies the Segment Routing Flexible Algorithm for the test. This option is only supported for **oam lsp-ping sr-isis** and **oam lsp-ping sr-ospf**. This option is not supported for SAA. If this option is not set, then the system looks up the prefix without flex-algo awareness.

Values 128 to 255

Default **none**

interval

Specifies the time, in seconds, used to override the default request message send interval and defines the minimum amount of time that must expire before the next message request is sent.

Values 1 to 10

Default 1

send-count

Specifies the number of messages to send, expressed as a decimal integer. The **send-count** parameter is used to override the default number of message requests sent. Each message request must either time out or receive a reply before the next message request is sent. The message **interval** value must be expired before the next message request is sent.

Values 1 to 100

Default 1

octets

Specifies the MPLS echo request packet size in octets, expressed as a decimal integer. The request payload is padded with zeros to the specified size.

Values 1 to 9786

Default 1

src-ip-address ***ip-address***

Specifies the source IP address. This option is used when an OAM packet must be generated from a different address than the node’s system interface address. An

example is when the OAM packet is sent over an LDP LSP and the LDP LSR-ID of the corresponding LDP session to the next-hop is set to an address other than the system interface address.

Values

ipv4-address:	a.b.c.d
ipv6-address:	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x: [0 to FFFF]H
	d: [0 to 255]D

timeout

Specifies number, in seconds, used to override the default *timeout* value and is the amount of time that the router waits for a message reply after sending the last probe for a specific test. Upon the expiration of the time out, the test is marked complete and no more packets are processed for any of those request probes.

Values 1 to 10

Default 5

label-ttl

Specifies the TTL value for the MPLS label, expressed as a decimal integer.

Values 1 to 255

Default 255

Platforms

Syntax

lsp-ping-interval *seconds*

no lsp-ping-interval

Context

[Tree] (config>router>ldp>lsp-bfd lsp-ping-interval)

Full Context

configure router ldp lsp-bfd lsp-ping-interval

Description

This command configures the interval between periodic LSP ping messages for LSPs on which **bfd-enable** is configured. The LSP ping messages are used to bootstrap and maintain the LSP BFD session.

Configuring an interval of 0 seconds disables periodic LSP ping. An LSP ping message containing a bootstrap TLV will only be sent when the BFD session is first initialized.

In scaled environments, LSP BFD sessions should use longer intervals to reduce congestion and common resource loading. Unless required, the interval should not be set lower than 300 s.

The **no** form of this command restores the default interval.

Default

lsp-ping-interval 60

Parameters

seconds

Specifies the interval between periodic LSP ping messages, in seconds.

Values 0, 60 to 300

Platforms

All

lsp-ping-interval

configure router mpls lsp secondary bfd lsp-ping-interval

configure router mpls lsp primary bfd lsp-ping-interval

configure router mpls lsp-template bfd lsp-ping-interval

Description

This command configures the interval for the periodic LSP ping for RSVP LSPs on which **bfd-enable** has been configured. This interval is used to bootstrap and maintain the LSP BFD session. A value of 0 disables periodic LSP Ping, such that an LSP Ping containing a bootstrap TLV is only sent when the BFD session is first initialized.

In scaled environments, LSP BFD sessions should use longer timers to reduce the chance of congestion and loading of common resources. Unless required, the **lsp-ping-interva**l should not be set lower than 300 seconds.

The **no** form of this command reverts to the default value.

Default

no lsp-ping-interval

Parameters

seconds

Sets the periodic LSP Ping interval in seconds.

Values 0, 60 to 300

Default 60

Platforms

All

[Tree] (config>service>vpls>spb lsp-refresh-interval)

Full Context

configure service vpls spb lsp-refresh-interval

Description

This command configures the LSP refresh timer interval. When configuring the LSP refresh interval, the value that is specified for **lsp-lifetime** must also be considered. The LSP refresh interval cannot be greater than 90% of the LSP lifetime.

The no form of this command reverts to the default (600 seconds), unless this value is greater than 90% of the LSP lifetime. For example, if the LSP lifetime is 400, then the **no lsp-refresh-interval** command will be rejected.

Default

lsp-refresh-interval 600 half-lifetime enable

Parameters

seconds

Specifies the refresh interval.

Values 150 to 65535

half-lifetime

Sets the refresh interval to always be half the **lsp-lifetime** value. When this parameter is set to **enable**, the configured refresh interval is ignored.

Values enable, disable

Platforms

Values enable, disable

Platforms

All

16.273 lsp-self-ping

lsp-self-ping

Syntax

[**no**] **lsp-self-ping**

Context

[Tree] (config>router>mpls lsp-self-ping)

Full Context

configure router mpls lsp-self-ping

Description

Commands in this context configure LSP self-ping parameters.

LSP Self-ping checks that the datapath of an RSVP LSP has been programmed by all LSRs along its path before switching the traffic to it. If enabled, LSP Self-ping packets are sent periodically at a configurable interval following the receipt of the RESV message for an RSVP LSP path following an MBB or other event where the active path changes while the previous active path stayed up. The router will not switch traffic to the new path until an LSP Self-ping reply is received from the far-end LER.

When configured under the MPLS context, LSP Self-ping is enabled for all RSVP LSPs, unless it is explicitly disabled for a given LSP.

The **no** form of this command disables the system check for LSP Self-ping.

Default

no lsp-self-ping

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

Full Context

configure router mpls lsp-template lsp-self-ping

configure router mpls lsp lsp-self-ping

Description

This command enables LSP Self-ping on a given RSVP-TE LSP or LSP template. If set to **disable**, then LSP Self-ping is disabled irrespective of the setting of **lsp-self-ping**>**rsvp-te** under the **mpls** context. By default, each LSP and LSP template inherits this value.

The **no** form of this command reverts to the default.

Default

lsp-self-ping inherit

Parameters

enable

Enables LSP Self-ping on this RSVP LSP or RSVP LSPs (one-hop-p2p or mesh-p2p) using this LSP template.

disable

Disables LSP Self-ping on this RSVP LSP or RSVP LSPs using this LSP template.

inherit

Inherits the value configured under **config**>**router**>**mpls**>**lsp-self-ping**>**rsvp-te**.

Platforms

Syntax

lsp-template *p2mp-lsp-template-name*

no lsp-template

Context

[Tree] (config>service>vpls>provider-tunnel>inclusive>rsvp lsp-template)

Full Context

configure service vpls provider-tunnel inclusive rsvp lsp-template

Description

This command specifies the template name of the RSVP P2MP LSP instance to be used by the leaf node or the root-and-leaf node that participates in BGP-AD VPLS. The P2MP LSP is referred to as the Inclusive Provider Multicast Service Interface (I-PMSI).

After the user performs a **no shutdown** under the context of the inclusive node and the delay timer expires, BUM packets will be forwarded over an automatically signaled instance of the RSVP P2MP LSP specified in the LSP template.

The **no** version of this command removes the P2MP LSP template from the I-PMSI configuration.

Parameters

p2mp-lsp-template-name

Specifies the name of the P2MP LSP template up to 32 characters in length.

Full Context

configure service vprn mvpn provider-tunnel selective rsvp lsp-template

configure service vprn mvpn pt inclusive lsp-template

Description

This command specifies the use of automatically created P2MP LSP as the inclusive or selective provider tunnel. The P2MP LSP will be signaled using the parameters specified in the template, such as bandwidth constraints, and so on.

Default

no lsp-template

Parameters

lsp-template

Specifies the LSP template name, up to 32 characters.

Platforms

All

lsp-template

Syntax

lsp-template *template-name* [**mesh-p2p** | **mesh-p2p-srte** | **one-hop-p2p** | **on-demand-p2p-srte** | **one-hop-p2p-srte** | **p2mp** | **pce-init-p2p-srte template-id** {**default** | *template-id*}]

no lsp-template *template-name*

Context

[Tree] (config>router>mpls lsp-template)

Full Context

configure router mpls lsp-template

Description

This command creates a template that can be referenced by a client application where dynamic LSP creation is required. The LSP template type (**p2mp**, **one-hop-p2p**, **mesh-p2p**, **one-hop-p2p-srte**, **mesh-p2p-srte**, **pce-init-p2p-srte**, or **on-demand-p2p-srte**) is mandatory.

The **no** form of this command deletes the LSP template. An LSP template cannot be deleted if a client application is using it.

Parameters

template-name

Specifies the name of the LSP template, up to 32 characters. An LSP template name and LSP name must not be the same.

mesh-p2p | mesh-p2p-srte | one-hop-p2p | one-hop-p2p-srte | p2mp | pce-init-p2p-srte | on-demand-p2p-srte

Identifies the type of LSP this template will signal.

The **p2mp** option is supported on the 7750 SR, 7950 XRS, and with VPLS only on the 7450 ESS.

default

Sets the template to be the default LSP template for PCE-initiated SR-TE LSPs.

template-id

Specifies the value that is signaled in the PCE to identify the LSP template.

lsp-template

Syntax

lsp-template *template-name*

no lsp-template

Context

[Tree] (config>oam-pm>session>mpls>lsp>rsvp-auto lsp-template)

Full Context

configure oam-pm session mpls lsp rsvp-auto lsp-template

Description

This command specifies the LSP template used to identify the LSP for testing.

One of three mandatory configuration statements that are required to identify automatically created RSVP LSPs, created using **config>router>mpls>lsp-template**. The **config>router>mpls>auto-lsp>lsp-template** links three distinct functions.

The **lsp-template** *template-name* must match the name of **config>router>mpls>lsp-template** used to dynamically create the RSVP LSP. This is a lose reference and does not impede the manipulation of the **config>router>mpls>lsp-template**. The required identifiers are **from**, **lsp-template** and **to**, all under this node.

The **no** form of this command deletes the *template-name* reference from the configuration.

Parameters

template-name

Specifies the name of the LSP template, up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

lsp-template

Syntax

lsp-template *template-name*

no lsp-template

Context

[Tree] (config>oam-pm>session>ip>tunnel>mpls>rsvp-te-auto lsp-template)

Full Context

configure oam-pm session ip tunnel mpls rsvp-te-auto lsp-template

Description

This command configures the name of the LSP template used to identify the unique LSP. Configure the following three commands to identify an RSVP-TE Auto LSP: **from**, **to**, and **lsp-template**. When all three of these values are configured, the specific RSVP LSP can be identified and the test packets can be carried across the tunnel

The **no** form of this command removes the LSP template name from the configuration.

Parameters

template-name

Specifies the LSP template name, up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

Context

[Tree] (oam lsp-trace)

[Tree] (config>saa>test>type lsp-trace)

Full Context

oam lsp-trace

configure saa test type lsp-trace

Description

This command performs an LSP traceroute using the protocol and data structures defined in IETF RFC 8029.

The LSP trace operation is modeled after the IP traceroute utility, which uses ICMP echo request and reply packets with increasing TTL values to determine the hop-by-hop route to a destination IP.

In an LSP trace, the originating device creates an MPLS echo request packet for the LSP to be tested with increasing values of the TTL in the outermost label. The MPLS echo request packet is sent through the data plane and awaits a TTL exceeded response or the MPLS echo reply packet from the device terminating the LSP. The devices that reply to the MPLS echo request packets with the TTL exceeded and the MPLS echo reply are displayed.

The downstream mapping TLV is used in **lsp-trace** to provide a mechanism for the sender and responder nodes to exchange and validate interface and label stack information for each downstream hop in the path of the LDP FEC an RSVP LSP, or a BGP IPv4 label route.

Two downstream mapping TLVs are supported. The original Downstream Mapping (DSMAP) TLV defined in RFC 4379 (obsoleted by RFC 8029) and the new Downstream Detailed Mapping (DDMAP) TLV defined in RFC 6424 AND RFC 8029. More details are provided in the DDMAP TLV sub-section below.

In addition, when the responder node has multiple equal cost next hops for an LDP FEC, a BGP label IPv4 prefix, an SR-ISIS node SID, an SR-OSPF node SID, or an SR-TE LSP, it replies in the Downstream Mapping TLV with the downstream information for each outgoing interface which is part of the ECMP next-hop set for the prefix. The downstream mapping TLV can further be used to exercise a specific path of the ECMP set using the **path-destination** option.

This command, when used with the **static** option, performs in-band on-demand LSP traceroute tests for static MPLS-TP LSPs. For other LSP types, the **static** option should be excluded and these are described elsewhere in this user guide.

The **lsp-trace static** command performs an LSP trace using the protocol and data structures defined in the RFC 8029, Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures, as extended by RFC 6426, MPLS On-Demand Connectivity Verification and Route Tracing.

In MPLS-TP, the echo request and echo reply messages are always sent in-band over the LSP, either in a G-ACh channel or encapsulated as an IP packet below the LSP label.

The timestamp format to be sent, and to be expected when received in a PDU, is as configured by the **configure test-oam mpls-time-stamp-format** command. If RFC 4379 (obsoleted by RFC 8029) is selected, the timestamp is in seconds and microseconds since 1900, otherwise it is in seconds and microseconds since 1970.

Parameters

lsp-name

Specifies the name of the target RSVP-TE LSP, up to 64 characters.

rsvp-te lsp-name

Specifies the name of the target RSVP-TE LSP, up to 64 characters.

Note:
The **rsvp-te** explicit target FEC type is not supported under the SAA context.

path-name

Specifies the LSP path name along which to send the LSP trace request.

Values Any path name associated with the LSP.

Default The active LSP path.

bgp-label prefix *ip-prefix/prefix-length*

Specifies the address prefix and subnet mask of the target BGP IPv4 /32 label route or the target IPv6 /128 label route.

Values <ipv4-prefix>/32 | <ipv6-prefix>/128

ipv4-prefix a.b.c.d

ipv6-prefix x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x: [0 to FFFF]H

d: [0 to 255]D

path-destination *ip-address*

Specifies the IP address of the path destination from the range 127/8. When the LDP FEC prefix is IPv6, the user must enter a 127/8 IPv4 mapped IPv6 address, that is, in the range ::ffff:127/104.

if-name

Specifies the name of an IP interface, up 32 characters, to send the MPLS echo request to. The name must already exist in the **config>router>interface** context.

next-hop *ip-address*

Specifies the next hop to send the MPLS echo request message to.

Values ipv4-address: a.b.c.d

ipv6-address: x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x: [0 to FFFF]H

d: [0 to 255]D

prefix *ip-prefix/prefix-length*

Specifies the address prefix and subnet mask of the target LDP FEC.

Values <ipv4-prefix>/32 | <ipv6-prefix>/128

ipv4-prefix - a.b.c.d

ipv6-prefix - x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x - [0 to FFFF]H

d - [0 to 255]D

ldp prefix *ip-prefix/prefix-length*

Specifies the address prefix and subnet mask of the target LDP FEC.

Values <ipv4-prefix>/32 | <ipv6-prefix>/128

ipv4-prefix a.b.c.d

ipv6-prefix x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x: [0 to FFFF]H

d: [0 to 255]D

sr-isis prefix *ip-prefix/prefix-length*

Specifies the address prefix and subnet mask of the target node SID of the SR-ISIS tunnel.

Values <ipv4-prefix>/32 | <ipv6-prefix>/128

ipv4-prefix a.b.c.d

ipv6-prefix x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x: [0 to FFFF]H

d: [0 to 255]D

igp-instance

Specifies the IGP instance of the node SID prefix.

Values isis-inst: 0 to 127

ospf3-inst: 0 to 31, 64 to 95

ospf-inst: 0 to 31

sr-ospf prefix *ip-prefix/prefix-length*

Specifies the address prefix and subnet mask of the target node SID of the SR-OSPF tunnel.

Values <ipv4-prefix>/32 | <ipv6-prefix>/128

ipv4-prefix - a.b.c.d

ipv6-prefix - x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x - [0 to FFFF]H

d - [0 to 255]D

sr-ospf3 prefix *ip-prefix/prefix-length*

Specifies the address prefix and subnet mask of the target node SID of the SR-OSPF3 tunnel. Only IPv6 prefixes in OSPFv3 instance ID 0-31 are supported.

Values

ipv6-prefix - x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x - [0 to FFFF]H

d - [0 to 255]D

sr-policy color *color-id* endpoint *ip-address* segment-list *segment-list-id*

Specifies the name of the target IPv4 or IPv6 SR policy.

Note:
The **sr-policy** target FEC type is supported under the OAM context and under **type-multi-line node** in the SAA context.

color *color-id* — Specifies the color ID.

Values 0 to 4294967295

endpoint *ip-address* — Specifies the endpoint address.

Values

ipv4-address: a.b.c.d

ipv6-address: x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x: [0 to FFFF]H

d: [0 to 255]D

segment-list *segment-list-id* — Specifies the segment list ID.

Values 1 to 32

detail

Displays detailed information and allows the user to display hop 0 (that is, ingress) information. When this parameter is applied to static LSPs, the next hop 0 information is not displayed. This information is also not displayed if the **min-ttl** *min-label-ttl* value is greater than 1.

sr-te *lsp-name*

Specifies the name of the target SR-TE LSP, up to 64 characters.

static

Specifies the selection of the target FEC Stack sub-type "Static LSP”.

assoc-channel {ipv4 | non-ip | none}

Specifies the launched echo request’s usage of the Associated Channel (ACH) mechanism, when testing an MPLS-TP LSP.

Values **ipv4** — Use the Associated Channel mechanism with IP encapsulation, as described in RFC 6426, Section 3.2.

non-ip — Do not use an Associated Channel, as described in RFC 6426, Section 3.1.

none — Use the Associated Channel mechanism described in RFC 6426, Section 3.3.

path-type {active | working | protect}

Specifies the LSP path to test.

Values **active** — Specifies the currently active path. If MPLS-TP linear protection is configured on the LSP, then this is the path that is selected by the MPLS-TP PSC protocol for sending user plane traffic. If MPLS-TP linear protection is not configured, then this is the working path.

working — Specifies the working path of the MPLS-TP LSP.

protect — Specifies the protect path of the MPLS-TP LSP.

Default active

downstream-map-tlv

Specifies which format of the downstream mapping TLV to use in the LSP trace packet. The DSMAP TLV is the original format in RFC 4379 (obsoleted by RFC 8029). The DDMAP is the new enhanced format specified in RFC 6424 and RFC 8029. The user can also choose not to include the downstream mapping TLV by entering the value none. When lsp-trace is used on a MPLS-TP LSP (static option), it can only be executed if the control-channel is set to none. In addition, the DSMAP/DDMAP TLV is only included in the echo request message if the egress interface is either a numbered IP interface, or an unnumbered IP interface. The TLV is not included if the egress interface is of type **unnumbered-mpls-tp**.

Values ddmap: Sends a detailed downstream mapping TLV.

dsmap: Sends a downstream mapping TLV.

none: No mapping TLV is sent.

Default Inherited from global configuration of downstream mapping TLV in option **mpls-echo-request-downstream-map {dsmap | ddmap}**.

fc-name

Specifies the FC and profile parameters are used to indicate the forwarding class and profile of the MPLS echo request packet.

When an MPLS echo request packet is generated in CPM and is forwarded to the outgoing interface, the packet is queued in the egress network queue corresponding to the specified FC and profile parameter values. The marking of the packet EXP is dictated by the LSP-EXP mappings on the outgoing interface.

When the MPLS echo request packet is received on the responding node, The FC and profile parameter values are dictated by the LSP-EXP mappings of the incoming interface.

When an MPLS echo reply packet is generated in CPM and is forwarded to the outgoing interface, the packet is queued in the egress network queue corresponding to the fc and profile parameter values determined by the classification of the echo request packet, which is being replied to, at the incoming interface. The marking of the packet's EXP is dictated by the LSP-EXP mappings on the outgoing interface. The ToS byte is not modified. Table 57: lsp-trace Request Packet and Behavior summarizes this behavior.

Table 57: lsp-trace Request Packet and Behavior

CPM (sender node)	Echo request packet: • packet {tos=1, fc1, profile1} • fc1 and profile1 are as entered by user in OAM command or default values • tos1 as per mapping of {fc1, profile1} to IP precedence in network egress QoS policy of outgoing interface
Outgoing interface (sender node)	Echo request packet: • pkt queued as {fc1, profile1} • ToS field=tos1 not remarked • EXP=exp1, as per mapping of {fc1, profile1} to EXP in network egress QoS policy of outgoing interface
Incoming interface (responder node)	Echo request packet: • packet {tos1, exp1} • exp1 mapped to {fc2, profile2} as per classification in network QoS policy of incoming interface
CPM (responder node)	Echo reply packet: • packet {tos=1, fc2, profile2}
Outgoing interface (responder node)	Echo reply packet: • pkt queued as {fc2, profile2} • ToS filed= tos1 not remarked (reply inband or out-of-band) • EXP=exp2, if reply is inband, remarked as per mapping of {fc2, profile2} to EXP in network egress QoS policy of outgoing interface

Incoming interface (sender node)	Echo reply packet: • packet {tos1, exp2} • exp2 mapped to {fc1, profile1} as per classification in network QoS policy of incoming interface

Values be, l2, af, l1, h2, ef, h1, nc

Default be

profile {in | out}

Specifies the profile state of the MPLS echo request packet.

Default out

interval

Specifies the number of seconds to override the default request message send interval and defines the minimum amount of time that must expire before the next message request is sent.

If the **interval** is set to 1 second, and the *timeout* value is set to 10 seconds, then the maximum time between message requests is 10 seconds and the minimum is 1 second. This depends upon the receipt of a message reply corresponding to the outstanding message request.

Values 1 to 10

Default **1**

no-response-count

Specifies the maximum number of consecutive MPLS echo requests, expressed as a decimal integer that do not receive a reply before the trace operation fails for a given TTL.

Values 1 to 255

Default 5

max-label-ttl

Specifies the maximum TTL value in the MPLS label for the LDP treetrace test, expressed as a decimal integer.

Values 1 to 255

Default 30

min-label-ttl

Specifies the minimum TTL value in the MPLS label for the LSP trace test, expressed as a decimal integer.

Values 1 to 255

Default 1

probes-per-hop

Specifies the probes per hop.

Values 1 to 10

Default 1

octets

Specifies the size in octets, expressed as a decimal integer, of the MPLS echo request packet, including the IP header but not the label stack. The request payload is padded with zeros to the specified size. Note that an OAM command is not failed if the user entered a size lower than the minimum required to build the packet for the echo request message. The payload is automatically padded to meet the minimum size.

Values 1 to 9786

Default 1

src-ip-address *ip-address*

Specifies the source IP address. This option is used when an OAM packet must be generated from a different address than the node's system interface address. An example is when the OAM packet is sent over an LDP LSP and the LDP LSR-ID of the corresponding LDP session to the next-hop is set to an address other than the system interface address.

Values

ipv4-address: a.b.c.d

ipv6-address: x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x - [0 to FFFF]H

d - [0 to 255]D

timeout

Specifies the time, in seconds, used to override the default *timeout* value and is the amount of time that the router waits for a message reply after sending the message request. Upon the expiration of the message time out, the requesting router assumes that the message response is not received. A **request timeout** message is displayed by the CLI for each message request sent that expires. Any response received after the request times out is silently discarded.

Values 1 to 60

Default 3

lsp-trace

Syntax

lsp-trace

Context

[Tree] (config>saa>test>type-multi-line lsp-trace)

Full Context

configure saa test type-multi-line lsp-trace

Description

This command creates the context to perform an LSP traceroute using the protocol and data structures defined in IETF RFC 4379 (obsoleted by RFC 8029).

Platforms

All

16.277 lsp-wait

lsp-wait

Syntax

lsp-wait *lsp-wait* [**lsp-initial-wait** *lsp-initial-wait*] [**lsp-second-wait** *lsp-second-wait*]

no lsp-wait

Context

[Tree] (config>service>vpls>spb>timers lsp-wait)

Full Context

configure service vpls spb timers lsp-wait

Description

This command is used to customize LSP generation throttling. Timers that determine when to generate the first, second and subsequent LSPs can be controlled with this command. Subsequent LSPs are generated at increasing intervals of the second **lsp-wait** timer until a maximum value is reached.

Note:
The IS-IS timer granularity is 100 ms. Timer values are rounded down to the nearest granularity, for example a configured value of 550 ms is internally rounded down to 500 ms.

Parameters

lsp-wait

Specifies the maximum interval in milliseconds between two consecutive occurrences of an LSP being generated.

Values 10 to 120000

Default 5000

lsp-initial-wait

Specifies the initial LSP generation delay in milliseconds. Values < 100 ms are internally rounded down to 0, so that there is no added initial LSP generation delay.

Values 10 to 100000

Default 10

lsp-second-wait

Specifies the hold time in milliseconds between the first and second LSP generation.

Values 10 to 100000

Default 1000

Platforms

Context

[Tree] (config>service>vprn>isis>timers lsp-wait)

Full Context

configure service vprn isis timers lsp-wait

Description

This command is used to customize LSP generation throttling. Timers that determine when to generate the first, second, and subsequent LSPs can be controlled with this command. Subsequent LSPs are generated at increasing intervals of the second **lsp-wait** timer until a maximum value is reached.

Note:
The timer granularity is 10 ms if the value is < 500 ms, and 100 ms if the value is ≥ 500 ms. Timer values are rounded down to the nearest granularity, for example a configured value of 550 ms is internally rounded down to 500 ms.

Parameters

lsp-wait

Specifies the maximum interval, in milliseconds, between two consecutive occurrences of an LSP being generated.

Values 10 to 120000

Default 5000

initial-wait

Specifies the initial LSP generation delay, in milliseconds. Values less than 100 ms are internally rounded down to 0, so that there is no added initial LSP generation delay.

Values 10 to 100000

Default 10

second-wait

Specifies the hold time, in milliseconds, between the first and second LSP generation.

Values 10 to 100000

Default 1000

Context

[Tree] (config>router>isis>timers lsp-wait)

Full Context

configure router isis timers lsp-wait

Description

This command customizes LSP generation throttling. Timers that determine when to generate the first, second and subsequent LSPs can be controlled with this command. Subsequent LSPs are generated at increasing intervals of the second **lsp-wait** timer until a maximum value is reached.

Note:
The timer granularity is 10 ms if the value is less than 500 ms, and 100 ms if the value is greater than or equal to 500 ms. Timer values are rounded down to the nearest granularity, for example a configured value of 550 ms is internally rounded down to 500 ms.

Default

lsp-wait 5000 lsp-initial-wait 10 lsp-second-wait 1000

Parameters

lsp-max-wait

Specifies the maximum interval in milliseconds between two consecutive occurrences of an LSP being generated.

Values 10 to 120000

initial-wait

Specifies the initial LSP generation delay in milliseconds. Values less than 100 ms are internally rounded down to 0, so that there is no added initial LSP generation delay.

Values 10 to 100000

second-wait

Specifies the hold time in milliseconds between the first and second LSP generation.

Values 10 to 100000

Platforms

16.278 lsr-label-route

lsr-label-route

Syntax

lsr-label-route [{**none** | **all**}]

Context

[Tree] (config>router>ttl-propagate lsr-label-route)

Full Context

configure router ttl-propagate lsr-label-route

Description

This command configures the TTL propagation for transit packets at a router acting as an LSR for a BGP label route.

When an LSR swaps the BGP label for a ipv4 prefix packet, therefore acting as a ABR, ASBR, or data-path Route-Reflector (RR) in the base routing instance, or swaps the BGP label for a vpn-ipv4 or vpn-ipv6 prefix packet, therefore acting as an inter-AS Option B VPRN ASBR or VPRN data path Route-Reflector (RR), the all value of this command enables TTL propagation of the decremented TTL of the swapped BGP label into all outgoing LDP or RSVP transport labels.

When an LSR swaps a label or stitches a label, it always writes the decremented TTL value into the outgoing swapped or stitched label. What this feature controls is whether this decremented TTL value is also propagated to the transport label stack pushed on top of the swapped or stitched label.

The none value reverts to the default mode which disables TTL propagation. This changes the existing default behavior which propagates the TTL to the transport label stack. When a customer upgrades, the new default becomes in effect. This command does not have a no version.

This feature also controls the TTL propagation at an LDP-BGP stitching LSR in the LDP to BGP stitching direction. It also controls the TTL propagation in Carrier Supporting Carrier (CsC) VPRN at both the CsC CE and CsC PE.

SR OS does not support ASBR or data path RR functionality for labeled IPv6 routes in the global routing instance (6PE). As such the CLI command of this feature has no impact on prefix packets forwarded in this context.

Default

lsr-label-route none

Parameters

none

Specifies that the TTL of the swapped label is not propagated into the transport label stack.

all

Specifies that the TTL of the swapped label is propagated into all labels of the transport label stack.

no lsr-load-balancing

Context

[Tree] (config>service>vprn>nw-if>load-balancing lsr-load-balancing)

Full Context

configure service vprn network-interface load-balancing lsr-load-balancing

Description

This command specifies whether the IP header is used in the LAG and ECMP LSR hashing algorithm. This is the per interface setting.

Default

no lsr-load-balancing

Parameters

lbl-only

Only the label is used in the hashing algorithm.

lbl-ip

The IP header is included in the hashing algorithm.

ip-only

The IP header is used exclusively in the hashing algorithm.

eth-encap-ip

The hash algorithm parses down the label stack and once it hits the bottom, the stack assumes Ethernet II non-tagged/dot1q or qinq header follows. At the expected Ethertype offset location, algorithm checks whether the value present is IPv4/v6 (0x0800 or 0x86DD). If the check passes, the hash algorithm checks the first nibble at the expected IP header location for IPv4/IPv6 (0x0100/0x0110). If the secondary check passes, the hash is performed using IP SA/DA fields in the expected IP header; otherwise (if any of the checks failed) label-stack hash is performed.

Platforms

All

lsr-load-balancing

Syntax

lsr-load-balancing {**lbl-only** | **lbl-ip** | **ip-only** | **eth-encap-ip** | **lbl-ip-l4-teid**}

Full Context

configure router interface load-balancing lsr-load-balancing

Description

This command specifies whether the IP header is used in the LAG and ECMP LSR hashing algorithm. This is the per interface setting.

Default

no lsr-load-balancing

Parameters

lbl-only

Specifies that only the label is used in the hashing algorithm

lbl-ip

Specifies that only the IP header is included in the hashing algorithm.

ip-only

Specifies that only the IP header is used exclusively in the hashing algorithm

eth-encap-ip

Specifies that the hash algorithm parses down the label stack and once it hits the bottom, the stack assumes Ethernet II non-tagged/dot1q or qinq header follows. At the expected Ethertype offset location, algorithm checks whether the value present is IPv4/v6 (0x0800 or0x86DD). If the check passes, the hash algorithm checks the first nibble at the expected IP header location for IPv4/IPv6 (0x0100/0x0110). If the secondary check passes, the hash is performed using IP SA/DA fields in the expected IP header; otherwise (any of the check failed) label-stack hash is performed.

lbl-ip-l4-teid

Specifies that this hashing algorithm hashes based on label, IP header, Layer 4 header and GTP header (TEID) in order. The algorithm uses all the supported headers that are found in the header fragment of incoming traffic.

Platforms

All

lsr-load-balancing

Syntax

lsr-load-balancing *hashing-algorithm*

no lsr-load-balancing

Context

[Tree] (config>system>load-balancing lsr-load-balancing)

Full Context

configure system load-balancing lsr-load-balancing

Description

This command configures system-wide LSR load balancing. Hashing can be enabled on the label stack and/or IP header at an LSR for spraying labeled IP packets over multiple equal cost paths and/or over multiple links of a LAG group.

The LSR hash routine operates on the label stack and the IP header if a packet is IPv4. An LSR will consider a packet to be IPv4 if the first nibble following the bottom of the label stack is 4. The hash on label and IPv4 and IPv6 headers can be enabled or disabled at the system level or incoming network IP interface level.

Default

no lsr-load-balancing

Parameters

lbl-only

Specifies that only the label is used in the hashing algorithm

lbl-ip

Specifies that the IP header is included in the hashing algorithm

ip-only

Specifies that the IP header is used exclusively in the hashing algorithm

eth-encap-ip

Specifies that the hash algorithm parses down the label stack and once it hits the bottom, the stack assumes Ethernet II non-tagged/dot1q or qinq header follows. At the expected Ethertype offset location, the algorithm checks whether the value present is IPv4/v6 (0x0800 or 0x86DD). If the check passes, the hash algorithm checks the first nibble at the expected IP header location for IPv4/IPv6 (0x0100/0x0110). If the secondary check passes, the hash is performed using IP SA/DA fields in the expected IP header; if any of the checks fail, the label-stack hash is performed.

lbl-ip-l4-teid

Specifies that this hashing algorithm hashes based on label, IP header, Layer 4 header and GTP header (TEID) in order. The algorithm uses all the supported headers that are found in the header fragment of incoming traffic.

16.280 lub-init-min-pir

lub-init-min-pir

Syntax

[**no**] **lub-init-min-pir**

Context

[Tree] (config>qos>adv-config-policy>child-control>bandwidth-distribution lub-init-min-pir)

Full Context

configure qos adv-config-policy child-control bandwidth-distribution lub-init-min-pir

Description

This command enables new queues associated with a LUB context to use a minimum PIR similar to the effect of the **limit-pir-zero-drain** command. When a queue is initially created in a LUB context, it defaults to a zero value PIR until H-QoS has an opportunity to configure an offered rate based operational PIR. Enabling this command forces a minimum rate operational PIR to be applied to the queue for use by enqueued packets prior to an H-QoS iteration.

The **no** form of this command reverts to default behavior.

Default

no lub-init-min-pir

17 m Commands

17.1 ma-index-range

ma-index-range

Syntax

ma-index-range start *ma-index* **end** *ma-index*

no ma-index-range

Context

[Tree] (config>eth-cfm>md-auto-id ma-index-range)

Full Context

configure eth-cfm md-auto-id ma-index-range

Description

This command specifies the range of indexes used by SR OS to automatically assign an index to ETH-CFM associations that are created in model-driven interfaces without an index explicitly specified by the user or client.

An association created with an explicitly-specified index cannot use an index in this range. In classic CLI and SNMP, the ID range cannot be changed while objects exist inside the previous or new range. In MD interfaces, the range can be changed, which causes any previously existing objects in the previous ID range to be deleted and re-created using a new ID in the new range.

The **no** form of this command removes the range values.

See the **md-auto-id** command for further details.

Parameters

start *ma-index*

Specifies the lower value of the index range. The value must be less than or equal to the **end** value.

Values 1 to 4294967295

end *ma-index*

Specifies the upper value of the index range. The value must be greater than or equal to the **start** value.

Values 1 to 4294967295

Full Context

configure service ies subscriber-interface group-interface mac

configure service ies interface mac

Description

This command assigns a specific MAC address to an IES IP interface.

For Routed Central Office (CO), a group interface has no IP address explicitly configured but inherits an address from the parent subscriber interface when needed. For example, a MAC will respond to an ARP request when an ARP is requested for one of the IPs associated with the subscriber interface through the group interface.

The **no** form of this command returns the MAC address of the IP interface to the default value.

Default

The physical MAC address associated with the Ethernet interface that the SAP is configured on (the default MAC address assigned to the interface, assigned by the system).

Parameters

ieee-address

Specifies the 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff, where aa, bb, cc, dd, ee, and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.

configure lag mac

configure port tdm ds1 channel-group mac

configure eth-tunnel mac

configure port sonet-sdh path mac

configure port tdm ds3 mac

configure port tdm e3 mac

configure port ethernet mac

Description

This command assigns a specific MAC address to an Ethernet port, Link Aggregation Group (LAG), Ethernet tunnel, or BCP-enabled port or sub-port.

Only one MAC address can be assigned to a port. When multiple **mac** commands are entered, the last command overwrites the previous command. When the command is issued while the port is operational, IP will issue an ARP, if appropriate, and BPDUs are sent with the new MAC address.

The **no** form of this command returns the MAC address to the default value.

By default, a MAC address is assigned by the system from the chassis MAC address pool. The use of an all-zeroes MAC address indicates that an operational MAC address should be assigned from the chassis MAC address pool.

Default

mac 00:00:00:00:00:00

Parameters

ieee-address

Specifies the 48-bit MAC address in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.

Platforms

Context

[Tree] (config>service>vpls>static-mac mac)

Full Context

configure service vpls static-mac mac

Description

This command assigns a conditional static MAC address entry to an SPBM B-VPLS SAP/spoke-SDP allowing external MACs for single and multi-homed operation.

For the 7450 ESS or 7750 SR, this command also assigns a conditional static MAC address entry to an EVPN VPLS SAP/spoke-SDP.

Static MACs are used for PBB Epipe and I-VPLS services that may terminate external to SPBM. If this is configured under a Control B-VPLS the interface referenced will not use IS-IS for this neighbor. This may also be configured under a User B-VPLS where the corresponding interface is not supported under the Control B-VPLS.

Parameters

ieee-address

Specifies the static MAC address to an SPBM/sdp-binding interface.

Values 6-byte mac-address (xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx) Cannot be all zeros.

sap-id

Specifies the SAP identifier.

sdp-id

Specifies the SDP identifier.

Values 1 to 17407

vc-id

Specifies the virtual circuit identifier.

Values 1 to 4294967295

create

Mandatory keyword used to create a static MAC.

fwd-status

Specifies that this static mac is based on the forwarding status of the SAP or spoke-SDP for multi-homed operation.

black-hole

Specifies for TLS FDB entries defined on a local SAP the value 'sap', remote entries defined on an SDP have the value 'sdp'.

Description

This command adds a protected MAC address entry.

The **no** form of this command removes the protected MAC address entry.

Parameters

ieee-address

Specifies the address in xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx format (cannot be all zeros), up to 30 characters.

six-byte-mask

Specifies the mask address in xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx format (cannot be all zeros), up to 30 characters.

Platforms

All

mac

Syntax

mac *ieee-address*

no mac

Context

[Tree] (config>service>vpls>interface mac)

Full Context

configure service vpls interface mac

Description

This command assigns a specific MAC address to a VPLS IP interface.

For Routed Central Office (CO), a group interface has no IP address explicitly configured but inherits an address from the parent subscriber interface when needed. For example, a MAC will respond to an ARP request when an ARP is requested for one of the IPs associated with the subscriber interface through the group interface.

The **no** form of this command returns the MAC address of the IP interface to the default value.

Default

mac

Parameters

ieee-address

Specifies the 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee, and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.

Default The system chassis MAC address.

[Tree] (config>router>if>vrrp mac)

[Tree] (config>router>if>ipv6>vrrp mac)

Full Context

configure router interface vrrp mac

configure router interface ipv6 vrrp mac

Description

This command sets an explicit MAC address used by the virtual router instance overriding the VRRP default derived from the VRID.

Changing the default MAC address is useful when an existing HSRP or other non-VRRP default MAC is in use by the IP hosts using the virtual router IP address. Many hosts do not monitor unessential ARPs and continue to use the cached non-VRRP MAC address after the virtual router becomes master of the host's gateway address.

The **mac** command sets the MAC address used in ARP responses when the virtual router instance is master. Routing of IP packets with *mac-address* as the destination MAC is also enabled. The **mac** setting must be the same for all virtual routers participating as a virtual router or indeterminate connectivity by the attached IP hosts will result. All VRRP advertisement messages are transmitted with *mac-address* as the source MAC.

The command can be configured in both non-owner and owner **vrrp** nodal contexts.

The **mac** command can be executed at any time and takes effect immediately. When the virtual router MAC on a master virtual router instance changes, a gratuitous ARP is immediately sent with a VRRP advertisement message. If the virtual router instance is disabled or operating as backup, the gratuitous ARP and VRRP advertisement message is not sent.

The **no** form of the command restores the default VRRP MAC address to the virtual router instance.

Default

no mac

Parameters

mac-address

The 48-bit MAC address for the virtual router instance in the form *aa*:*bb*:*cc*:*dd*:*ee*:*ff* or *aa-bb-cc-dd-ee-ff* where *aa*, *bb*, *cc*, *dd*, *ee* and *ff* are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC, and non-IEEE reserved MAC addresses.

[Tree] (config>card>xiom>mda>xconnect mac)

Full Context

configure card mda xconnect mac

configure card xiom mda xconnect mac

Description

This command creates a loopback in the MAC chip. It does not require the allocation of a faceplate. After the loopback is instantiated, a PXC can be configured on top of it.

For a list of MAC chip IDs per forwarding complex (datapath), use the **show datapath datapath-id** *datapath-id* command.

When considering loopback creation, the operation should consider the MAC chip's bandwidth capacity and the bandwidth utilization of all the faceplate ports connected to it.The selection of MAC chips for loopback creation should be taken into consideration.

The **no** form of this command removes the MAC ID from the configuration.

Parameters

mac-id

Specifies the MAC ID.

Values 1 to 12

create

Keyword used to create the MAC ID instance. The **create** keyword requirement can be enabled or disabled in the **environment>create** context.

17.8 mac-filter

mac-filter

Syntax

mac-filter *mac-filter-id* **entry** *entry-id* [*entry-id*]

no mac-filter *mac-filter-id* [**entry** *entry-id*]

Context

[Tree] (config>mirror>mirror-source mac-filter)

Full Context

configure mirror mirror-source mac-filter

Description

This command enables mirroring of packets that match specific entries in an existing MAC filter.

The **mac-filter** command directs packets which match the defined list of entry IDs to be mirrored to the mirror destination referenced by the *mirror-dest-service-id* of the **mirror-source**.

The MAC filter must already exist in order for the command to execute. Filters are configured in the **config**>**filter** context. If the MAC filter does not exist, an error will occur. If the filter exists but has not been associated with a SAP or IP interface, an error is not be generated but mirroring will not be enabled (there are no packets to mirror). Once the filter is defined to a SAP or MAC interface, mirroring is enabled.

If the MAC filter is defined as ingress, only ingress packets are mirrored. Ingress mirrored packets are mirrored to the mirror destination prior to any ingress packet modifications.

If the MAC filter is defined as egress, only egress packets are mirrored. Egress mirrored packets are mirrored to the mirror destination after all egress packet modifications.

An *entry-id* within a MAC filter can only be mirrored to a single mirror destination. If the same *entry-id* is defined multiple times, an error occurs and only the first **mirror-source** definition is in effect.

By default, no packets matching any MAC filters are mirrored. Mirroring of MAC filter entries must be explicitly defined.

The **no** form of this command, without the **entry** keyword, removes mirroring on all *entry-id*'s within the *mac-filter-id*.

When the **no** command is executed with the **entry** keyword and one or more *entry-id*'s, mirroring of that list of *entry-id*'s is terminated within the *mac-filter-id*. If an *entry-id* is listed that does not exist, an error will

occur and the command will not execute. If an *entry-id* is listed that is not currently being mirrored, no error will occur for that *entry-id* and the command will execute normally.

Parameters

mac-filter-id

Specifies the MAC filter ID whose entries are mirrored. If the *mac-filter-id* does not exist, an error will occur and the command will not execute. Mirroring of packets will commence once the *mac-filter-id* is defined on a SAP.

entry-id

Specifies the MAC filter entries to use as match criteria for packet mirroring. The **entry** keyword begins a list of *entry-id*'s for mirroring. Multiple *entry-id* entries may be specified with a single command. Each *entry-id* must be separated by a space. Up to 8 entry IDs may be specified in a single command.

Each *entry-id* must exist within the *mac-filter-id*. If the *entry-id* is renumbered within the MAC filter definition, the old *entry-id* is removed from the list and the new *entry-id* will need to be manually added to the list if mirroring is still desired.

If no *entry-id* entries are specified in the command, mirroring will not occur for that MAC filter ID. The command will have no effect.

configure li li-source mac-filter

Description

This command enables lawful interception (LI) of packets that match specific entries in an existing MAC filter. Multiple entries can be created using unique *entry-id* numbers within the filter. The router implementation exits the filter on the first match found and executes the actions in accordance with the accompanying action command. For this reason, entries must be sequenced correctly from most to least explicit.

An entry may not have any match criteria defined (in which case, everything matches) but must have at least the keyword **action** for it to be considered complete. Entries without the **action** keyword will be considered incomplete and hence will be rendered inactive.

An *entry-id* within an MAC filter can only be intercepted to a single destination. If the same *entry-id* is defined multiple times, an error occurs and only the first definition is in effect.

The **no** form of this command removes the specified entry from the IP or MAC filter. Entries removed from the IP or MAC filter are immediately removed from all services or network ports where that filter is applied.

Parameters

mac-filter-id

Specifies the MAC filter ID. If the *mac-filter-id* does not exist, an error will occur and the command will not execute.

entry-id

The MAC filter entries to use as match criteria.

intercept-id

Specifies the intercept-id that is inserted into the packet header for all mirrored packets of the associated li-source entry. This *intercept-id* can be used (for example by a downstream LI gateway) to identify the particular LI session to which the packet belongs. For all types of **li-source** entries (filter, nat, sap, subscriber), when the mirror service is configured with **ip-udp-shim** routable encap, an *intercept-id* field (as part of the routable encap) is always present in the mirrored packets. If there is no *intercept-id* configured for an **li-source** entry, then the default value will be inserted. When the mirror service is configured with **ip-gre** routable encap, no *intercept-id* is inserted and none should be specified against the **li-source** entries.

Values 1 to 4294967295 (32b) — For nat li-source entries that are using a mirror service that is not configured with routable encapsulation

Values 1 to 1,073,741,824 (30b) — For all types of li-source entries that are using a mirror service with routable **ip-udp-shim** encapsulation and no direction-bit.

Values 1 to 536,870,912 (29b) — For all types of li-source entries that are using a mirror service with routable **ip-udp-shim** encapsulation and with the direction-bit enabled.

session-id

Specifies the *session-id* that is inserted into the packet header for all mirrored packets of the associated **li-source** entry. This *session-id* can be used (for example by a downstream LI gateway) to identify the particular LI session to which the packet belongs. The *session-id* is only valid and used for mirror services that are configured with **ip-udp-shim** routable encap (**config>mirror>mirror-dest>encap>ip-udp-shim**). For all types of **li-source** entries (filter, nat, sap, or subscriber), when the mirror service is configured with **ip-udp-shim** routable encap, a *session-id* field (as part of the routable encap) is always present in the mirrored packets. If there is no *session-id* configured for an **li-source** entry, then the default value will be inserted. When a mirror service is configured with **ip-gre** routable encap, no *session-id* is inserted and none should be specified against the **li-source** entries.

Context

[Tree] (debug>mirror-source mac-filter)

Full Context

debug mirror-source mac-filter

Description

This command enables mirroring of packets that match specific entries in an existing MAC filter.

The **mac-filter** command directs packets which match the defined list of entry IDs to be mirrored to the mirror destination referenced by the *mirror-dest-service-id* of the **mirror-source**.

The MAC filter must already exist in order for the command to execute. Filters are configured in the config>filter context. If the MAC filter does not exist, an error will occur. If the filter exists but has not been associated with a SAP or IP interface, an error is not be generated but mirroring will not be enabled (there are no packets to mirror). Once the filter is defined to a SAP or MAC interface, mirroring is enabled.

If the MAC filter is defined as ingress, only ingress packets are mirrored. Ingress mirrored packets are mirrored to the mirror destination prior to any ingress packet modifications.

If the MAC filter is defined as egress, only egress packets are mirrored. Egress mirrored packets are mirrored to the mirror destination after all egress packet modifications.

An *entry-id* within a MAC filter can only be mirrored to a single mirror destination. If the same *entry-id* is defined multiple times, an error occurs and only the first **mirror-source** definition is in effect.

By default, no packets matching any MAC filters are mirrored. Mirroring of MAC filter entries must be explicitly defined.

The **no** form of this command command, without the **entry** keyword, removes mirroring on all *entry-id*'s within the *mac-filter-id*.

When the **no** command is executed with the **entry** keyword and one or more *entry-id*'s, mirroring of that list of *entry-id*'s is terminated within the *mac-filter-id*. If an *entry-id* is listed that does not exist, an error will occur and the command will not execute. If an *entry-id* is listed that is not currently being mirrored, no error will occur for that *entry-id* and the command will execute normally.

Parameters

mac-filter-id

Specifies the MAC filter ID whose entries are mirrored. If the *mac-filter-id* does not exist, an error will occur and the command will not execute. Mirroring of packets will commence once the *mac-filter-id* is defined on a SAP.

entry-id

Specifies the MAC filter entries to use as match criteria for packet mirroring. The **entry** keyword begins a list of *entry-id*'s for mirroring. Multiple *entry-id* entries may be specified with a single command. Each *entry-id* must be separated by a space. Up to 8 entry IDs may be specified in a single command.

Each *entry-id* must exist within the *mac-filter-id*. If the *entry-id* is renumbered within the MAC filter definition, the old *entry-id* is removed from the list and the new *entry-id* will need to be manually added to the list if mirroring is still desired.

If no *entry-id* entries are specified in the command, mirroring will not occur for that MAC filter ID. The command will have no effect.

Context

[Tree] (config>filter mac-filter)

Full Context

configure filter mac-filter

Description

This command creates a configuration context for the specified MAC filter policy.

The **no** form of the command deletes the MAC filter policy. A filter policy cannot be deleted until it is removed from all objects where it is applied.

Parameters

filter-id

Specifies the MAC filter policy ID expressed as a decimal integer.

Values 1 to 65535

create

Keyword required to create the configuration context. After it is created, the context can be enabled with or without the **create** keyword.

name

Sets an optional filter name, up to 64 characters in length, to a given filter. This filter name can then be used in configuration references, display, and show commands throughout the system. A defined filter name can help the service provider or administrator to identify and manage filters within the SR OS platforms.

To create a filter, you must assign a filter ID, however, after it is created, either the filter ID or filter name can be used to identify and reference a filter.

If a name is not specified at creation time, then SR OS assigns a string version of the *filter-id* as the name.

Filter names may not begin with an integer (0 to 9).

Values *name*: 64 characters maximum

filter-name

Specifies a string of up to 64 characters uniquely identifying this MAC filter policy.

Context

[Tree] (config>filter>copy mac-filter)

Full Context

configure filter copy mac-filter

Description

This command copies an existing filter entry for a specific filter ID to another filter ID. The **copy** command is a configuration level maintenance tool used to create new entries using an existing filter policy. If **overwrite** is not specified, an error will occur if the destination filter entry exists.

Parameters

src-filter-id

Specifies the source filter policy from which the copy command will attempt to copy. The filter policy must exist within the context of the preceding keyword (**mac-filter**).

dst-filter-id

Specifies the destination filter policy to which the copy command will attempt to copy. If the **overwrite** keyword is not specified, the filter entry ID cannot already exist in the destination filter policy. If the **overwrite** keyword is present, the destination entry ID may or may not exist.

overwrite

Specifies that the destination filter entry may exist. If it does, everything in the existing destination filter entry will be completely overwritten with the contents of the source filter entry. If the destination filter entry exists, either **overwrite** must be specified or an error message will be returned. If **overwrite** is specified, the function of copying from source to destination occurs in a "break before make" manner and therefore should be handled with care.

Syntax

mac-list *name* [**create**]

no mac-list *name*

Context

[Tree] (config>service>proxy-arp-nd mac-list)

Full Context

configure service proxy-arp-nd mac-list

Description

This command creates a list of MAC addresses that can be pointed at from the service for a specified IP. The list may contain up to 10 MAC addresses; an empty list is also allowed.

The MAC list allows on-the-fly changes, but a change in the list deletes the proxy entries for all the IPs using that list.

The **no** form of the command deletes the entire MAC-list. Deleting a MAC list is only possible if it is not referenced in the configuration.

Parameters

name

Specifies the name of the MAC address list, which can be up to 32 characters.

create

Mandatory keyword to create a MAC list.

Platforms

All

mac-list

Syntax

mac-list *name* [**create**]

no mac-list *name*

Context

[Tree] (config>service mac-list)

Full Context

configure service mac-list

Description

This command configures a MAC list name. The MAC list is composed of a list of MAC addresses and masks, which along with Auto-Learn Mac Protect (ALMP) can be used to exclude certain MACs from being protected in a given object. This is typically used on SAPs and spoke SDPs configured with ALMP where certain MACs must be able to move to other objects (for example, VRRP virtual MACs).

The **no** form of this command removes the MAC list name.

Parameters

name

Specifies the MAC list name, up to 32 characters.

create

Keyword used to create the MAC list.

17.14 mac-move

mac-move

Syntax

[**no**] **mac-move**

Context

[Tree] (config>service>template>vpls-template mac-move)

[Tree] (config>service>vpls mac-move)

Full Context

configure service template vpls-template mac-move

configure service vpls mac-move

Description

Commands in this context configure MAC move attributes. A sustained high re-learn rate can be a sign of a loop somewhere in the VPLS topology. Typically, STP detects loops in the topology, but for those networks that do not run STP, the mac-move feature is an alternative way to protect your network against loops.

When enabled in a VPLS, **mac-move** monitors the re-learn rate of each MAC. If the rate exceeds the configured maximum allowed limit, it disables the SAP where the source MAC was last seen. The SAP can be disabled permanently (until a **shutdown**/**no shutdown** command is executed) or for a length of time that grows linearly with the number of times the specified SAP was disabled. You have the option of marking a SAP as non-blockable in the **config>service>vpls>sap>limit-mac-move** or **config>service>vpls>spoke-sdp>limit-mac-move** contexts. This means that when the re-learn rate has exceeded the limit, another (blockable) SAP will be disabled instead.

The **mac-move** command enables the feature at the service level for SAPs and spoke-SDPs, as only those objects can be blocked by this feature. Mesh SDPs are never blocked, but their re-learn rates (sap-to-mesh/spoke-to-mesh or vice versa) are still measured.

The operation of this feature is the same on the SAP and spoke-SDP. For example, if a MAC address moves from SAP to SAP, from SAP to spoke-SDP, or between spoke-SDPs, one will be blocked to prevent thrashing. If the MAC address moves between a SAP and mesh SDP or spoke-SDP and mesh SDP combinations, the respective SAP or spoke-SDP will be blocked.

mac-move will disable a VPLS port when the number of relearns detected has reached the number of relearns needed to reach the move-frequency in the 5-second interval. For example, when the move-frequency is configured to 1 (relearn per second) mac-move will disable one of the VPLS ports when 5 relearns were detected during the 5-second interval because then the average move-frequency of 1 relearn per second has been reached. This can already occur in the first second if the real relearn rate is 5 relearns per second or higher.

The **no** form of this command disables MAC move.
