configure lag link-map-profile failure-mode

Description

This command defines the failure mode for egress traffic of SAPs/network interfaces that use this link-map-profile when neither primary nor secondary links of this profile are available.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Default

failure-mode per-link-hash

Parameters

discard

Specifies egress traffic for SAPs/network interfaces using this link-map-profile is discarded to protect SAP/network interface traffic on other LAG links from impact of re-hashing the affected SAPs/network interfaces.

per-link-hash

Specifies egress traffic for SAPs/network interfaces using this link-map-profile is rehashed on remaining, available LAG links using per-link-hash algorithm. SAP/network interface QoS configurations dictate what traffic is discarded on any link that may become oversubscribed as result of the re-hash.

Platforms

All

17.12 failure-recovery

failure-recovery

Syntax

[**no**] **failure-recovery**

Context

[Tree] (config>sys>switch-fabric failure-recovery)

Full Context

configure system switch-fabric failure-recovery

Description

Commands in this context configure attributes related to the automatic switch fabric recovery process.

The automatic switch fabric recovery process is triggered when there are two resets of an IOM/XCM due to ICC failures within a small time frame. The recovery process involves the sequential resetting of SFM in case the issues are due to one of the SFM in the ICC communication path. As the final step in the recovery process, a CPM switchover is triggered to reset the active CPM.

17.13 failure-threshold

failure-threshold

Syntax

failure-threshold *number*

no failure-threshold

Context

[Tree] (config>test-oam>icmp>ping-template failure-threshold)

Full Context

configure test-oam icmp ping-template failure-threshold

Description

This command configures the count, when reached, that causes the transition of the IPv4 interface from operationally up to operationally down because of a ping template failure.

The **no** form of this command reverts to the default value.

Default

failure-threshold 3

Parameters

number

Specifies a count that causes the transition of the IP interface from operationally up to operationally down because of ping template failure.

Values 2 to 10

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

17.14 fallback-action

fallback-action

Syntax

fallback-action accept [**force-probing**]

fallback-action user-db *local-user-db-name* [**force-probing**]

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

no fallback-action

Context

[Tree] (config>subscr-mgmt>auth-plcy fallback-action)

Full Context

configure subscriber-mgmt authentication-policy fallback-action

Description

This command configures the action when no RADIUS server is available; servers are either out of service or are in a probing state.

The **no** form of this command removes the action from the configuration.

Parameters

accept

Specifies that all authentication requests are automatically accepted.

local-user-db-name

Specifies that the LUDB is used to authenticate to the server.

force-probing

Specifies that a subscriber or a test user Access-Request**,** depending which arrives first, is used to probe a RADIUS server before continuing with the configured **fallback-action**. This forces an out-of-service server to transition to a probing state.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

Full Context

configure router mpls lsp fallback-path-computation-method

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

configure router mpls lsp-template fallback-path-computation-method

Description

This command configures the fallback path computation method used if all configured PCEs are down or the signaling overload and the redelegation timer has expired. This method is used regardless of whether the LSP is PCE-controlled and PCE-computed, or just PCE-computed.

The **no** form of this command removes the fallback path computation method used.

Default

fallback-path-computation-method none

Parameters

none

Keyword that specifies MPLS should use the default method based on the configured path, which is hop-to-labeled path computation for SR-TE LSPs and IGP-based path computation for RSVP-TE LSPs.

local-cspf

Specifies to fall back to using local CSPF computation.

Platforms

All

17.16 falling-percent-reset

falling-percent-reset

Syntax

falling-percent-reset *percent-of-highest*

no falling-percent-reset

Context

[Tree] (config>mcast-mgmt>bw-plcy falling-percent-reset)

Full Context

configure mcast-management bandwidth-policy falling-percent-reset

Description

This command configures the percentage of bandwidth decrease that must occur to reset the dynamic bandwidth monitoring function for a multicast channel. When a channel is configured to use the ingress dynamic bandwidth as the in-use bandwidth for ingress multicast path management, the system maintains a sliding window in time that defines how long the last highest bandwidth value associated with the channel should be used. The sliding window duration is derived from the channels bw-activity dynamic falling-delay

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

parameter within the multicast information policy. Each time the system detects a current bandwidth for a channel that is equal to or greater than the current highest bandwidth for the channel, the sliding window is reset and the highest value is used when managing the ingress multicast paths. If the system does not detect a higher or equal bandwidth value for the channel within the window period, the system resets the sliding window and uses the next highest rate seen during the duration of the window period. In this way, the system delays relinquishing bandwidth for a dynamic bandwidth channel for a configurable period. If a momentary fluctuation (decrease) in ingress bandwidth occurs, the system ignores the bandwidth change.

While this is useful for momentary fluctuations in bandwidth, it may be desirable to react faster when the current bandwidth monitored for a channel drops significantly relative to the currently in-use bandwidth. When the bandwidth decrease is equal to or greater than the falling-percent-reset value, the system immediately stops using the highest bandwidth and starts using the current bandwidth while resetting the sliding window.

If falling-percent-reset is set to 50%, when the current ingress dynamic bandwidth is 50% of the current in-use highest bandwidth, the system immediately uses the current dynamic ingress bandwidth as the highest bandwidth for the channel.

By default, the falling-percent-reset is 50% when a new bandwidth policy is created. The default bandwidth policy also has a hard configured value of 50%. Setting falling-percent-reset to 100 is equivalent to specifying no falling-percent-reset.

The **no** form of this command restores the default value of 50%.

Default

falling-percent-reset 50

Parameters

percent-of-highest

The percent-of-highest parameter is required and defines the percentage of decline between the current ingress dynamic bandwidth and the current in-use highest bandwidth at which the system resets the dynamic ingress bandwidth monitoring for the channel. When reset in this case, the system uses the current ingress dynamic bandwidth as the highest rate and continues monitoring. The parameter must be defined as an integer value representing a percentage.

Values 1 to 100 percent

Platforms

7450 ESS, 7750 SR-1x-48D, 7750 SR-1x-92S, 7750 SR-7/12/12e, 7750 SR-s, 7950 XRS, VSR

configure service vprn bgp family

configure service vprn bgp group family

configure service vprn bgp group neighbor family

Description

This command configures the set of BGP address families (AFI plus SAFI) to be supported by the applicable VPRN BGP sessions.

The **no** form of this command restores the default, which is equivalent to configuring unlabeled IPv4 unicast routes (AFI 1, SAFI 1) only.

Default

no family

Parameters

ipv4

Keyword to advertise support for the IPv4 unicast (unlabeled) address family.

label-ipv4

Keyword to advertise support for the IPv4 unicast (labeled) address family.

ipv6

Keyword to advertise support for the IPv6 unicast (unlabeled) address family.

mcast-ipv4

Keyword to advertise support for the IPv4 multicast SAFI address family.

flow-ipv4

Keyword to advertise support for the IPv4 FlowSpec address family.

mcast-ipv6

Keyword to advertise support for the IPv6 multicast SAFI address family.

flow-ipv6

Keyword to advertise support for the IPv6 FlowSpec address family.

Platforms

All

family

Syntax

family [**ipv4** | **ipv6**]

Context

[Tree] (config>router>mpls>lsp-template family)

Full Context

configure router mpls lsp-template family

Description

This command specifies if the lsp-template is for use in IPv4 or IPv6 SR-TE LSP.

This command is optional in a IPv4 SR-TE auto-LSP but must be set to **ipv6** value in a IPv6 SR-TE auto-LSP. By default, this command is set to **ipv4** value for backward compatibility.

When establishing both IPv4 and IPv6 SR-TE mesh auto-LSPs with the same parameters and constraints, a separate LSP template of type **mesh-p2p-srte** must be configured for each address family with the **family** CLI leaf set to the IPv4 or IPv6 value. SR-TE one-hop auto-LSPs can only be established for either IPv4 or IPv6 family, but not both. The **family** leaf in the LSP template of type **one-hop-p2p-srte** should be set to the desired IP family value.

The **no** form of this command reverts to the default value.

Default

family ipv4

Parameters

ipv4

Specifies the lsp-template is for use in IPv4 SR-TE LSP.

ipv6

Specifies the lsp-template is for use in IPv6 SR-TE LSP.

Default

family ipv4

Parameters

ipv4

Keyword to advertise MP-BGP support for the IPv4 unicast (unlabeled) address family.

label-ipv4

Keyword to advertise MP-BGP support for the IPv4 unicast (labeled) address family.

vpn-ipv4

Keyword to advertise MP-BGP support for the IPv4 VPN (SAFI 128) address family.

ipv6

Keyword to advertise MP-BGP support for the IPv6 unicast (unlabeled) address family.

label-ipv6

Keyword to advertise MP-BGP support for the IPv6 unicast (labeled) address family.

vpn-ipv6

Keyword to advertise MP-BGP support for the IPv6 VPN (SAFI 128) address family.

mcast-ipv4

Keyword to advertise MP-BGP support for the IPv4 multicast SAFI address family.

l2-vpn

Keyword to advertise MP-BGP support for the L2 VPN address family.

mvpn-ipv4

Keyword to advertise MP-BGP support for the IPv4 multicast VPN address family.

mvpn-ipv6

Keyword to advertise MP-BGP support for the IPv6 multicast VPN address family.

mdt-safi

Keyword to advertise MP-BGP support for the MDT SAFI address family.

ms-pw

Keyword to advertise MP-BGP support for the multi-segment pseudowire address family.

flow-ipv4

Keyword to advertise MP-BGP support for the IPv4 FlowSpec address family.

flow-ipv6

Keyword to advertise MP-BGP support for the IPv6 FlowSpec address family.

route-target

Keyword to advertise MP-BGP support for RT constraint routes.

mcast-vpn-ipv4

Keyword to advertise MP-BGP support for the IPv4 VPN multicast (SAFI 129) address family.

evpn

Keyword to advertise MP-BGP support for the EVPN address family.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

bgp-ls

Keyword to advertise MP-BGP support for the BGP-LS address family.

mcast-ipv6

Keyword to advertise MP-BGP support for the IPv6 multicast SAFI address family.

mcast-vpn-ipv6

Keyword to advertise MP-BGP support for the IPv6 multicast routes from a VPRN over the provider network. This family is only applicable in the base BGP routing context.

sr-policy-ipv4

Keyword to advertise MP-BGP support for AFI1/SAFI73 IP address families for BGP routes that encode a segment-routing policy to an IPv4 destination.

sr-policy-ipv6

Keyword to advertise MP-BGP support for AF12/SAF173 IP address families for BGP routes that encode a segment-routing policy to an IPv6 destination.

flow-vpn-ipv4

Keyword to advertise support for the FlowSpec-VPN IPv4 address family (AFI 1, SAFI 134).

flow-vpn-ipv6

Keyword to advertise support for the FlowSpec-VPN IPv6 address family (AFI 2, SAFI 134).

Context

[Tree] (config>mirror>mirror-dest>remote-source far-end)

Full Context

configure mirror mirror-dest remote-source far-end

Description

This command is used on a destination router in a remote mirroring solution. See the description for the **remote-source** command for additional information.

When using L2TPv3, MPLS-TP or LDP IPv6 LSP SDPs in the remote mirroring solution, the destination node should be configured with **remote-src>spoke-sdp** entries. For all other types of SDPs, r**emote-source>far-end** entries are used.

Up to 50 far-end entries can be specified.

The **no** form of this command removes the IP address from the remote source configuration.

Parameters

ip-address

Specifies the service IP address (system IP address) of the remote device sending mirrored traffic to this mirror destination service. If 0.0.0.0 is specified, any remote is allowed to send to this service.

Values 1.0.0.1 to 223.255.255.254

vc-id

Specifies the virtual circuit identifier of the remote source. For mirror services, the *vc-id* defaults to the *service-id*. However, if the *vc-id* is being used by another service a unique vc-id is required to create an SDP binding. For this purpose the mirror service SDP bindings accepts *vc-ids*. This VC ID must match the VC ID used on the spoke SDP that is configured on the source router.

ingress-vc-label

Specifies the ingress service label for mirrored service traffic on the **far end** device for manually configured mirror service labels.

The defined *ing-svc-label* is entered into the ingress service label table which causes ingress packet with that service label to be handled by this mirror destination service.

The specified *ing-svc-label* must not have been used for any other service ID and must match the egress service label being used on the spoke SDP that is configured on the source router. It must be within the range specified for manually configured service labels defined on this router. It may be reused for other far end addresses on this *mirror-dest-service-id*.

Values 2048 to 18431

tldp

Specifies that the label is obtained through signaling via the LDP.

icb

Specifies that the remote source is an inter-chassis backup SDP binding.

Context

[Tree] (config>service>sdp far-end)

Full Context

configure service sdp far-end

Description

This command configures the IPv4 or IPv6 IP address of the far-end destination router for the service destination point (SDP) that is the termination point for a service.

The far-end IP address must be explicitly configured.

If the SDP uses GRE for the destination encapsulation, the IP address is checked against other GRE SDPs to verify uniqueness. If the IP address is not unique within the configured GRE SDPs, an error is generated and the IP address is not associated with the SDP.

If the SDP uses MPLS encapsulation, the **far-end** address is used to check LSP names when added to the SDP. If the " **to** IP address" defined within the LSP configuration does not exactly match the SDP **far-end** address, the LSP will not be added to the SDP and an error is generated. Alternatively, an SDP that uses MPLS can have an MPLS-TP node with an MPLS-TP node-id and (optionally) a global ID. In this case, the SDP must use an MPLS-TP LSP and the SDP **signaling** parameter must be set to **off**.

An SDP cannot be administratively enabled until a **far-end** *ip-address* or MPLS-TP node-id is defined. The SDP is operational when it is administratively enabled (**no shutdown**) and the **far-end** *ip-address* is contained in the IGP routing table as a host route. OSPF ABRs should not summarize host routes between areas. This can cause the SDPs to become operationally down. Static host routes (direct and indirect) can be defined in the local device to alleviate this issue.

On a tunnel configured as SDP with delivery type **eth-gre-bridged**, this command designates L2oGRE tunnel end points. This is the only configuration option allowed for this type of SDP.

The **no** form of this command removes the currently configured destination IP address for the SDP. The *ip-address* parameter is not specified and will generate an error if used in the **no far-end** command. The SDP must be administratively disabled using the **configure service sdp shutdown** command before the **no far-end** command can be executed. Removing the far-end IP address removes all *lsp-name* associations with the SDP.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

far-end

Specifies the far-end termination point for the GRE tunnel.

ip-address* | *ipv6-address

Specifies a IPv4 or IPv6 address of the far-end SR OS for the SDP in dotted decimal notation.

node-id

Specifies the MPLS-TP Node ID of the far-end system for the SDP, either in dotted decimal notation (a.b.c.d) or an unsigned 32-bit integer (1 to 4294967295). This parameter is mandatory for an SDP using an MPLS-TP LSP.

global-id

Specifies a MPLS-TP Global ID of the far-end system for the SDP, in an unsigned 32-bit integer (0 to 4294967295). This parameter is optional for an SDP using an MPLS-TP LSP. If not entered, a default value for the Global ID of '0' is used. A global ID of '0' indicates that the far-end node is in the same domain as the local node. The user must explicitly configure a Global ID if its value is non-zero.

configure service vpls mesh-sdp igmp-snooping fast-leave

configure service vpls sap mld-snooping fast-leave

Description

This command enables fast leave.

When IGMP fast leave processing is enabled, the 7450 ESS or 7750 SR immediately removes a SAP or SDP from the IP multicast group when it detects an IGMP leave message on that SAP or SDP. Fast leave processing allows the switch to remove a SAP or SDP that sends a leave message from the forwarding table without first sending out group-specific queries to the SAP or SDP, which speeds up the process of changing channels.

Fast leave should only be enabled when there is a single receiver present on the SAP or SDP.

When fast leave is enabled, the configured **last-member-query-interval** value is ignored.

17.21 fast-reroute

fast-reroute

Syntax

fast-reroute [**backup-sr-tunnel**]

no fast-reroute

Context

[Tree] (config>router>ldp fast-reroute)

Full Context

configure router ldp fast-reroute

Description

This command enables LDP Fast-Reroute (FRR) procedures. When enabled, LDP uses both the primary next-hop and LFA next-hop, when available, for resolving the next-hop of an LDP FEC against the corresponding prefix in the routing table. This will result in LDP programming a primary NHLFE and a backup NHLFE into the forwarding engine for each next-hop of a FEC prefix for the purpose of forwarding packets over the LDP FEC.

When any of the following events occurs, LDP instructs in the fast path the forwarding engines to enable the backup NHLFE for each FEC next-hop impacted by this event:

- An LDP interface goes operationally down, or is admin shutdown.
- An LDP session to a peer went down as the result of the Hello or Keep-Alive timer expiring.
- The TCP connection used by a link LDP session to a peer went down, due say to next-hop tracking of the LDP transport address in RTM, which brings down the LDP session.
- A BFD session, enabled on a T-LDP session to a peer, times-out and as a result the link LDP session to the same peer and which uses the same TCP connection as the T-LDP session goes also down.
- A BFD session enabled on the LDP interface to a directly connected peer, times out and brings down the link LDP session to this peer.

The **tunnel-down-dump-time** option or the **label-withdrawal-delay** option, when enabled, does not cause the corresponding timer to be activated for a FEC as long as a backup NHLFE is still available.

Because LDP can detect the loss of a neighbor/next-hop independently, it is possible that it switches to the LFA next-hop while IGP is still using the primary next-hop. Also, when the interface for the previous primary next-hop is restored, IGP may re-converge before LDP completed the FEC exchange with it neighbor over that interface. This may cause LDP to de-program the LFA next-hop from the FEC and blackhole traffic. In order to avoid this situation, it is recommended to enable IGP-LDP synchronization on the LDP interface.

When the SPF computation determines there is more than one primary next-hop for a prefix, it will not program any LFA next-hop in RTM. Thus, the LDP FEC will resolve to the multiple primary next-hops that provide the required protection.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **backup-sr-tunnel** option enables the use of SR tunnel, as a remote LFA or TI-LFA backup tunnel next-hop by an LDP FEC.

As a pre-requisite, the user must enable the stitching of LDP and SR in the LDP-to-SR direction. That is because the LSR must perform the stitching of the LDP ILM to SR tunnel when the primary LDP next-hop of the FEC fails. Thus LDP must listen to SR tunnels programmed by the IGP in TTM but the mapping server feature is not required.

Assuming the following:

- the **backup-sr-tunnel** option is enabled in LDP
- the {**loopfree-alternates remote-lfa**} and/or the {**loopfree-alternates ti-lfa**} option is enabled in the IGP instance
- LDP was able to resolve the primary next-hop of the LDP FEC in RTM

IGP SPF will run both the base LFA and the TI-LFA algorithms and if it does not find a backup next-hop for a prefix of an LDP FEC, it will also run the remote LFA algorithm. If IGP finds a TI-LFA or a remote LFA tunnel next-hop, LDP programs the primary next-hop of the FEC using a LDP NHLFE and programs the LFA backup next-hop using a LDP NHLFE pointing to the SR tunnel endpoint. Note that the LDP packet is not "tunneled" over the SR tunnel. The LDP label is actually stitched to the segment routing label stack. LDP points both the LDP ILM and the LTN to the backup LDP NHLFE which itself uses the SR tunnel endpoint.

The behavior of the feature is thus similar to the LDP-to-SR stitching feature, except the behavior is augmented to allow the stitching of an LDP ILM/LTN to a SR tunnel also when the primary LDP next-hop of the FEC fails.

If the LDP FEC primary next-hop failed and LDP has pre-programmed a remote LFA or TI-LFA next-hop with a LDP backup NHLFE pointing to SR tunnel, the LDP ILM/LTN switches to it. Note that if for some reason the failure impacted only the LDP tunnel primary next-hop but not the SR tunnel primary next-hop, the LDP backup NHLFE will effectively point to the primary next-hop of the SR tunnel and traffic of the LDP ILM/LTN will follow this path instead of the TI-LFA or remote LFA next-hop of the SR tunnel until the latter is activated.

This feature is limited to IPv4 /32 prefixes in both LDP and SR.

The **no** form of this command disables the use of SR tunnels as backups for LDP FECs and disables LDP FRR.

[Tree] (config>router>mpls>lsp fast-reroute)

[Tree] (config>router>mpls>lsp-template fast-reroute)

Full Context

configure router mpls lsp fast-reroute

configure router mpls lsp-template fast-reroute

Description

This command creates a pre-computed detour LSP from each node in the path of the LSP. In case of failure of a link or LSP between two nodes, traffic is immediately rerouted on the pre-computed detour LSP, thus avoiding packet-loss.

When **fast-reroute** is enabled, each node along the path of the LSP tries to establish a detour LSP as follows:

- Each upstream node sets up a detour LSP that avoids only the immediate downstream node, and merges back on to the actual path of the LSP as soon as possible.

  If it is not possible to set up a detour LSP that avoids the immediate downstream node, a detour can be set up to the downstream node on a different interface.
- The detour LSP may take one or more hops (see **config>router>mpls>lsp hop-limit**, **config>router>mpls>lsp>primary-p2mp-instance hop-limit**) before merging back on to the main LSP path.
- When the upstream node detects a downstream link or node failure, the ingress router switches traffic to a standby path if one was set up for the LSP.

Fast reroute is available only for the primary path. No configuration is required on the transit hops of the LSP. The ingress router will signal all intermediate routers using RSVP to set up their detours. TE must be enabled for fast-reroute to work.

If an LSP is configured with **fast-reroute** *frr-method* specified but does not enable CSPF, then global revertive will not be available for the LSP to recover.

The **no** form of the **fast-reroute** command removes the detour LSP from each node on the primary path. This command will also remove configuration information about the hop-limit and the bandwidth for the detour routes.

The **no** form of **fast-reroute hop-limit** command reverts to the default value.

Note:
A one-to-one detour backup LSP cannot be used at the PLR for ABR node protection. As a result, a PLR node does not signal a one-to-one detour LSP for ABR protection. In addition, the ABR node rejects a Path message that it has received from a third-party implementation configured with a detour object and a loose ERO next-hop. The Path message is rejected regardless of whether the **cspf-on-loose-hop** command is enabled on the node. When the router transits ABR for the detour path, the router rejects the signaling of an inter-area detour backup LSP.

Default

no fast-reroute — When fast-reroute is specified, the default fast-reroute method is one-to-one.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

frr-method

Configures the fast-reroute method.

Values **one-to-one** — In the one-to-one technique, a label switched path is established which intersects the original LSP somewhere downstream of the point of link or node failure. For each LSP which is backed up, a separate backup LSP is established.

Values **facility** — This option, sometimes called many-to-one, takes advantage of the MPLS label stack. Instead of creating a separate LSP for every backed-up LSP, a single LSP is created which serves to backup up a set of LSPs. This LSP tunnel is called a bypass tunnel.

The bypass tunnel must intersect the path of the original LSP(s) somewhere downstream of the point of local repair (PLR). Naturally, this constrains the set of LSPs being backed-up through that bypass tunnel to those that pass through a common downstream node. All LSPs which pass through the PLR and through this common node which do not also use the facilities involved in the bypass tunnel are candidates for this set of LSPs.

17.22 fast-start

fast-start

Syntax

[**no**] **fast-start**

Context

[Tree] (config>qos>adv-config-policy>child-control>offered-measurement fast-start)

Full Context

configure qos adv-config-policy child-control offered-measurement fast-start

Description

This command is used to enable fast detection of initial bandwidth on a child policer or queue associated with the policy. Multiple offered rate counter reads may be performed per the sampling interval. The system accumulates these counter values and evaluates the delta at the conclusion of the sampling interval. When fast-start is enabled, the system identifies all children associated with the policy that enter the inactive state (current offered rate is zero). Any inactive 'fast start' child that has a positive offered counter during a sampling period bypasses the normal sampling interval and does an immediate offered rate evaluation.

This option is intended for use with children that would benefit from faster than normal startup detection, typically those of a real-time nature.

When this parameter is not enabled, the system uses the normal sampling interval behavior of both newly active and currently active children.

The **no** form of this command is used to restore the sampling-interval-based offered rate evaluation for newly active children.

Description

This command creates individual counters for the specified FCs without regard for profile. All countable packets that match a configured FC, regardless of profile, will be included in this counter.

A differential is performed when this command is re-entered. Omitted FCs will stop counting, newly added FCs will start counting, and unchanged FCs will continue to count.

Up to eight FCs may be specified. An FC that is specified as part of this command for this specific context cannot be specified as a profile-aware FC using the **fc-in-profile** command under the same context.

The **no** form of this command removes all previously defined FCs and stops counting for those FCs.

Default

no fc

Parameters

fc-name

Specifies the name of the FC for which to create an individual profile-unaware counter. In order for the counter to be used, the **config**>**oam-pm**>**session**> **ethernet**>**priority** command must be configured with a numerical value representing the FC name (7

Context

[Tree] (config>router>mpls>class-forwarding-policy fc)

Full Context

configure router mpls class-forwarding-policy fc

Description

This command configures the mapping of FCs to up to six forwarding sets for the class-based forwarding (CBF) of an LDP FEC or a BGP prefix over IGP shortcuts.

All FCs are mapped to set 1 as soon as the policy is created. The user can then make changes to the mapping of FCs as required. An FC that is not added to the class forwarding policy is thus always mapped to set 1. An FC can only be mapped to one forwarding set. One or more FCs can map to the same set. The user can indicate the initial default set by including the **default-set** option.

The default forwarding set forwards packets of an FC when all LSPs of the forwarding set that the FC maps to become operationally down. The router uses the user-configured default set as the initial default set if no default is configured; otherwise, it elects the lowest numbered set as the default forwarding set in a class forwarding policy. When the last LSP in a default forwarding set goes into an operationally down state, the router designates the next lowest numbered set as the new default forwarding set.

Context

[Tree] (config>mirror>mirror-dest fc)

Full Context

configure mirror mirror-dest fc

Description

This command specifies a forwarding class for all mirrored packets transmitted to the destination SAP or SDP overriding the default (be) forwarding class. All packets are sent with the same class of service to minimize out-of-sequence issues. The mirrored packet does not inherit the forwarding class of the original packet.

When the destination is on a SAP, a single egress queue is created that pulls buffers from the buffer pool associated with the *fc-name*.

When the destination is on an SDP, the *fc-name* defines the DiffServ-based egress queue that is used to reach the destination. The *fc-name* also defines the encoded forwarding class of the encapsulation.

The FC configuration also affects how mirrored packets are treated at the ingress queuing point on the line cards. One ingress queue is used per mirror destination (service) and that is an expedited queue if the configured FC is expedited (one of nc, h1, ef or h2). The ingress mirror queues have no CIR, but a line-rate PIR.

The **no** form of this command reverts the mirror-dest service ID forwarding class to the default forwarding class.

Default

The best effort (be) forwarding class is associated with the mirror-dest service ID.

Parameters

fc-name

The name of the forwarding class with which to associate mirrored service traffic. The forwarding class name must already be defined within the system. If the *fc-name* does not

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

exist, an error is returned and the **fc** command has no effect. If the *fc-name* does exist, the forwarding class associated with *fc-name* overrides the default forwarding class.

Values be, l2, af, l1, h2, ef, h1, nc

Platforms

All

fc

Syntax

fc *fc-name* [**profile** { **in** | **out**}]

no fc

Context

[Tree] (config>test-oam>ldp-treetrace fc)

Full Context

configure test-oam ldp-treetrace fc

Description

This command indicates the forwarding class and profile of the MPLS echo request packet.

When an MPLS echo request packet is generated in CPM and is forwarded to the outgoing interface, the packet is queued in the egress network queue corresponding to the specified FC and profile parameter values. The marking of the packet's EXP is dictated by the LSP-EXP mappings on the outgoing interface.

When the MPLS echo request packet is received on the responding node, The FC and profile parameter values are dictated by the LSP-EXP mappings of the incoming interface.

When an MPLS echo reply packet is generated in CPM and is forwarded to the outgoing interface, the packet is queued in the egress network queue corresponding to the FC and profile parameter values determined by the classification of the echo request packet, which is being replied to, at the incoming interface. The marking of the packet's EXP is dictated by the LSP-EXP mappings on the outgoing interface. The ToS byte is not modified. Table 47: fc Request Packet and Behavior summarizes this behavior.

Table 47: fc Request Packet and Behavior

CPM (sender node)	Echo request packet: • packet {tos=1, fc1, profile1} • fc1 and profile1 are as entered by user in OAM command or default values • tos1 as per mapping of {fc1, profile1} to IP precedence in network egress QoS policy of outgoing interface
Outgoing interface (sender node)	Echo request packet: • pkt queued as {fc1, profile1}

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

	• ToS field=tos1 not remarked • EXP=exp1, as per mapping of {fc1, profile1} to EXP in network egress QoS policy of outgoing interface
Incoming interface (responder node)	Echo request packet: • packet {tos1, exp1} • exp1 mapped to {fc2, profile2} as per classification in network QoS policy of incoming interface
CPM (responder node)	Echo reply packet: • packet {tos=1, fc2, profile2}
Outgoing interface (responder node)	Echo reply packet: • pkt queued as {fc2, profile2} • ToS filed= tos1 not remarked (reply inband or out-of-band) • EXP=exp2, if reply is inband, remarked as per mapping of {fc2, profile2} to EXP in network egress QoS policy of outgoing interface
Incoming interface (sender node)	Echo reply packet: • packet {tos1, exp2} • exp2 mapped to {fc1, profile1} as per classification in network QoS policy of incoming interface

Default

no fc

Parameters

fc-name

Specifies the forwarding class of the MPLS echo request packets.

Values be, l2, af, l1, h2, ef, h1, nc

profile {in | out}

Specifies the profile value to be used with the forwarding class specified in the **fc-name** parameter.

Context

[Tree] (config>qos>post-policer-mapping fc)

Full Context

configure qos post-policer-mapping fc

Description

This command specifies the forwarding class and profile state of an egress policed packet that is to be mapped to another forwarding class and profile, where the profile state is that of the resulting profile after the packet has been processed by the egress policer.

The new forwarding class and profile state is configured using the **maps-to** command.

The traffic remarking is based on the marking configured for the forwarding class and profile of the traffic after being policed but before it is remapped.

The **no** form of this command deletes the forwarding class and profile remapping statement, including the **maps-to** command.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

fc-name

Specifies one of the eight forwarding classes supported by the system.

Values be, l2, af, l1, h2, ef, h1, nc

profile

Specifies one of the egress packet profile states.

Values exceed, in, inplus, out

Platforms

fc

Syntax

fc *fc-name* [**create**]

no fc *fc-name*

Context

[Tree] (config>qos>sap-ingress fc)

Full Context

configure qos sap-ingress fc

Description

The **fc** command creates a class or subclass instance of the forwarding class fc-name. When the *fc-name* is created, classification actions can be applied and the subclass can be used in match classification criteria. Attempting to use an undefined subclass in a classification command will result in an execution error and the command will fail.

The **no** form of this command removes all the explicit queue mappings for *fc-name* forwarding types. The queue mappings revert to the default queues for *fc-name*. To successfully remove a subclass, all associations with the subclass in the classification commands within the policy must first be removed or diverted to another forwarding class or subclass.

Parameters

fc-name

The parameter subclass-name is optional and must be defined using a dot separated notation with a preceding valid system-wide forwarding class name. Creating a subclass follows normal naming conventions. Up to sixteen ASCII characters may be used. If the same sub-name is used with two or more forwarding class names, each is considered a different instance of subclass. A subclass must always be specified with its preceding forwarding class name. When a forwarding class is created or specified without the optional subclass, the parent forwarding class is assumed.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Within the SAP ingress QoS policy, up to 56 subclasses may be created. Each of the 56 subclasses may be created within any of the eight parental forwarding classes. When the limit of 56 is reached, any further subclass creations will fail and the subclass will not exist.

Successfully creating a subclass places the CLI within the context of the subclass for further subclass parameter definitions. Within the subclass context, commands may be executed that define subclass priority (within the parent forwarding class queue mapping), subclass color aware profile settings, subclass in-profile and out-of-profile precedence or DSCP markings.

The *subclass-name* parameter is optional and used with the *fc-name* parameter to define a pre-existing subclass. The *fc-name* and *subclass-name* parameters must be separated by a period (.). If *subclass-name* does not exist in the context of *fc-name*, an error will occur. If *subclass-name* is removed using the **no fc** *fc-name.subclass-name* **force** command, the **default-fc** command will automatically drop the *subclass-name* and only use *fc-name* (the parent forwarding class for the subclass) as the forwarding class.

Values

fc: *class*[.*subclass*]

class: be, l2, af, l1, h2, ef, h1, nc

subclass: 29 characters max

configure qos sap-egress fc

Description

The **fc** fc-*name* node within the SAP egress QoS policy is used to contain the explicitly defined queue mapping and dot1p marking commands for *fc-name*. When the mapping for *fc-name* points to the default queue and the dot1p marking is not defined, the node for *fc-name* is not displayed in the **show configuration** or **save configuration** output unless the detail option is specified.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **no** form of this command removes the explicit queue mapping and dot1p marking commands for *fc-name*. The queue mapping reverts to the default queue for *fc-name* and the dot1p marking (if appropriate) uses the default of 0.

Default

no fc

Parameters

fc-name

This parameter specifies that the forwarding class queue mapping or dot1p marking is to be edited. The value given for *fc-name* must be one of the predefined forwarding classes in the system.

Values be, l2, af, l1, h2, ef, h1, nc

configure qos network egress fc

Description

This command is used to enter the CLI node to configure QoS parameters for the specified forwarding class. The FC name represents a CLI parent node that contains parameters describing the egress marking criteria of packets flowing through it. This command overrides the default parameters for that forwarding class from the values defined in the network default policy. It can also be used to redirect packets to a policer or queue in a network egress queue group instance.

The **no** form of this command removes the forwarding class name configuration. The forwarding class reverts to the parameters defined in the default network policy.

Parameters

fc-name

The case-sensitive, system-defined forwarding class name for which policy entries will be created.

Values be, l2, af, l1, h2, ef, h1, nc

Platforms

Full Context

configure qos network-queue fc

Description

The **fc** command is used to enter the forwarding class mapping context for the given *fc-name*. Each forwarding class maps by default to queues 1 (unicast) and 9 (multipoint).

Parameters

fc-name

A valid forwarding class must be specified as *fc-name* when the **fc** command is executed. When the **fc** *fc-name* command is successfully executed, the system will enter the specified forwarding class context where the **queue** *queue-id* command may be executed.

Values be, l2, af, l1, h2, ef, h1, nc

Context

[Tree] (cfg>qos>qgrps>egr>qgrp fc)

Full Context

configure qos queue-group-templates egress queue-group fc

Description

The **fc** command is used to enter the forwarding class mapping context for the given fc-name. Each forwarding class has a default mapping depending on the egress queue group template. The system-created policer-output-queue template contains queues 1 and 2 by default with queue 1 being best-effort and queue 2 expedited. Forwarding classes be, l1, af and l2 all map to queue 1 by default. Forwarding classes h1, ef, h2 and nc all map to queue 2 by default. More queues may be created within the policer-output-queues template and the default forwarding classes may be changed to any defined queue within the template.

When all other user-defined egress queue group templates are created, only queue 1 (best-effort) exists and all forwarding classes are mapped to that queue. Other queues may be created and the forwarding classes may be changed to any defined queue within the template.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Besides the default mappings within the templates, the egress queue group template forwarding class queue mappings operate the same as the forwarding class mappings in a sap-egress QoS policy.

The template forwarding class mappings are the default mechanism for mapping egress policed traffic to a queue within an egress port queue group associated with the template. If a queue-id is explicitly specified in the QoS policy forwarding class policer mapping, and that queue exists within the queue group, the template forwarding class mapping is ignored.

On the 7450 ESS and 7750 SR, egress policed subscriber traffic works in a slightly different way. The subscriber and subscriber host support destination and organization strings are used to identify the egress port queue group. In this instance, the forwarding class mappings are always used and any queue overrides in the QoS policy are ignored. If neither string exists for the subscriber host, the egress queue group queue-id can be derived from either the QoS policy policer mapping or the template forwarding class queue mappings.

The **no** form of this command is used to return the specified forwarding class to its default template queue mapping.

Parameters

fc-name

A valid forwarding class must be specified as *fc-name* when the **fc** command is executed. When the **fc** *fc-name* command is successfully executed, the system will enter the specified forwarding class context where the **queue** *queue-id* command may be executed.

Values **be**, **l1**, **af**, **l2**, **h1**, **ef**, **h2**, **nc**

Full Context

configure router interface eth-cfm mep collect-lmm-fc-stats fc

Description

This command creates individual counters for the specified FCs without regard for profile. All countable packets that match a configured FC, regardless of profile, will be included in this counter.

A differential is performed when this command is re-entered. Omitted FCs will stop counting, newly added FCs will start counting, and unchanged FCs will continue to count.

Up to eight FCs may be specified. An FC that is specified as part of this command for this specific context cannot be specified as a profile-aware FC using the **fc-in-profile** command under the same context.

The **no** form of this command removes all previously defined FCs and stops counting for those FCs.

Default

no fc

Parameters

fc-name

Specifies the name of the FC for which to create an individual profile-unaware counter. A maximum of eight fc-names can be specified in a single statement. In order for the counter to be used, the **config**>**oam-pm**>**session**> **ethernet**>**priority** command must be configured with a numerical value representing the FC name (7 = NC, 6 = H1, 5 = EF, 4 = H2, 3 = L1, 2 = AF, 1 = L2, 0 = BE), and the **config**>**oam-pm**>**session**>**ethernet**>**lmm**>**enable-fc-collection** command must be enabled.

Values nc, h1, ef, h2, l1, af, l2, be

no fc {fc}

Context

[Tree] (config>service>sdp>class-forwarding fc)

Full Context

configure service sdp class-forwarding fc

Description

This command makes an explicit association between a forwarding class and an LSP. The LSP name must exist and must have been associated with this SDP using the command config>service>sdp>lsp. Multiple forwarding classes can be associated with the same LSP. However, a forwarding class can only be associated with a single LSP in a given SDP. All subclasses will be assigned to the same LSP as the parent forwarding class.

Parameters

lsp *lsp-name*

Specifies the RSVP or static LSP to use to forward service packets which are classified into the specified forwarding class.

fc

Specifies a forwarding class to LSP mapping.

Values be, l2, af, 1, h2, ef, h1, nc

Platforms

All

fc

Syntax

fc *fc* [**priority** {**low** | **high**}]

no fc

Context

[Tree] (config>router>policy-options>policy-statement>entry>action fc)

Full Context

configure router policy-options policy-statement entry action fc

Description

This command associates a forwarding-class and optionally priority with the routes matched by a route policy entry. The command takes effect when the action of the route policy entry is accept, next-entry, or next-policy. It has no effect except in route policies applied as VRF import policies, BGP import policies, or RIP import policies.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **no** form of this command removes the QoS association of the routes matched by the route policy entry.

Default

no fc

Parameters

fc

Specify the name of one of the predefined forwarding classes in the system.

Values be, l2, af, l1, h2, ef, h1, nc

Default none (no QoS information is associated with matched routes)

priority {low | high}

This parameter associates an enqueuing priority with routes matched by the policy entry. Specifying a priority is optional.

Values **high** — Setting the enqueuing parameter to **high** for a packet increases the likelihood of enqueuing the packet when the ingress queue is congested. Ingress enqueuing priority only affects ingress SAP queuing. After the packet is placed in a buffer on the ingress queue, the significance of the enqueuing priority is lost.

low — Setting the enqueuing parameter to **low** for a packet decreases the likelihood of enqueuing the packet when the ingress queue is congested. Ingress enqueuing priority only affects ingress SAP queuing. After the packet is placed in a buffer on the ingress queue, the significance of the enqueuing priority is lost.

Default low

[Tree] (config>isa>video-group>watermark>bandwidth fcc)

Full Context

configure isa video-group watermark session fcc

configure isa video-group watermark bandwidth fcc

Description

This command sets the watermark to trigger the SNMP trap if the FCC bandwidth or session exceeds the configured percentage. The bandwidth is the available egress bandwidth of the ISA. The SNMP trap is cleared when the consumption is lowered by 10%. For example, if the system resource of the available bandwidth is 10 Gb/s and the watermark is configured to be 90%, the SNMP trap is raised as the bandwidth exceeds 9 Gb/s (90% of 10 Gb/s). The SNMP trap is cleared when the bandwidth drops below 8.1 Gb/s (10% of 9 Gb/s = 0.9 Gb/s, and 9 Gb/s - 0.9 Gb/s = 8.1 Gb/s). The default value of the watermark is set at 90% of the system resources for both bandwidth and session.

Default

fcc 90

Parameters

percent

Specifies the percentage of the system resources per ISA.

Values 1 to 99

configure mcast-management multicast-info-policy bundle video fcc-channel-type

configure mcast-management multicast-info-policy bundle channel source-override video fcc-channel-type

configure mcast-management multicast-info-policy bundle channel video fcc-channel-type

Description

This command configures the channel type for the bundle/channel. The channel type is used in the video policy to set various Fast Channel Change (FCC) parameters including the type of FCC and various FCC rates.

The **no** form of this command returns the parameter to the default value.

Default

no fcc-channel-type

Parameters

hd

The channel type is High-Definition (HD) (Default).

sd

The channel type is Standard Definition (SD).

pip

The channel type is Picture in Picture (PIP).

Platforms

7450 ESS, 7750 SR, 7750 SR-s

Full Context

configure mcast-management multicast-info-policy bundle channel video fcc-min-duration

configure mcast-management multicast-info-policy bundle video fcc-min-duration

Description

This command configures the minimum time duration, in milliseconds, of the Fast Channel Change (FCC) burst. The value of this object determines the starting point of the FCC burst. If the current Group of Pictures (GOP) has less than the minimum duration worth of data, FCC burst begins from the previous GOP.

The **no** form of the command reverts to the default value.

Default

fcc-min-duration 300

Parameters

time

Specifies the FCC burst minimum duration, in milliseconds.

Values 300 to 8000

Platforms

7450 ESS, 7750 SR, 7750 SR-s

17.33 fcc-server

fcc-server

Syntax

[**no**] **fcc-server**

Context

[Tree] (config>isa>video-group fcc-server)

Full Context

configure isa video-group fcc-server

Description

This command enables the FCC server capability for the ISA video group. FCC server cannot be enabled if ad insertion or the local RET server is enabled.

FCC server parameters can be configured in a multicast information policy or a service, but the parameters will have no effect if the FCC server is disabled or if the video group is administratively disabled (shutdown).

The **no** form of the command disables the FCC server.

Default

no fcc-server

Platforms

7450 ESS, 7750 SR, 7750 SR-s

Use subject to Terms available at: www.nokia.com/terms.

configure mcast-management multicast-info-policy video-policy video-interface hd fcc-server

configure mcast-management multicast-info-policy video-policy video-interface sd fcc-server

Description

This command enables the Fast Channel Change (FCC) server and sets the mode to send the FCC unicast stream.

The mode indicates how the FCC server will send information to the client. When **burst** is specified, the FCC server will send the channel at a nominally faster rate than the channel was received based on the applicable fcc-burst setting. When **dent** is specified, the FCC server will selectively discard frames from the original stream based on the applicable dent-threshold setting. If no mode is specified, burst is the default mode.

The **no** form of the command disables the FCC server at that context and subordinate contexts.

Default

no fcc-server

Parameters

mode burst

Sets the mode of the FCC server to burst when sending the channel to the FCC client.

mode dent

Sets the mode of the FCC server to dent when sending the channel to the FCC client.

mode hybrid

Combines the burst and dent modes.

Platforms

configure mcast-management multicast-info-policy bundle channel video fcc-server

Description

This command enables Fast Channel Change (FCC) for a multicast bundle or channel. Additional parameters such as **fcc-channel-type** should also be configured to match the characteristics of the bundle/channel.

The **no** form of the command disables removes the FCC configuration for the bundle/channel context and implies the setting is inherited from a higher context or the default policy.

Default

no fcc-server

Parameters

disable

Explicitly disables the FCC server within the policy. For the default bundle within the default multicast information policy, the **no** form of the command and the **disable** keyword have the same meaning and imply that the server is disabled.

Platforms

7450 ESS, 7750 SR, 7750 SR-s

fdb-table-size

Syntax

fdb-table-size *table-size*

Context

[Tree] (config>service>system fdb-table-size)

Full Context

configure service system fdb-table-size

Description

This command configures the maximum system FDB table size, which is dependent on the chassis type. CPMs with at least 16 GB of memory are required when exceeding 500k MAC addresses in a system. The table size cannot be reduced below its default value, which is also chassis-dependent.

The maximum system FDB table size also limits the maximum FDB table size of any card within the system.

The command default depends on the chassis type and available memory.

Parameters

table-size

Specifies the maximum system FDB table size.

Note: The *table-size* range values are platform dependent.

Values 4095 to 2047999

17.42 fec

fec

Syntax

fec {**g709** | **enhanced**}

no fec

Context

[Tree] (config>port>otu fec)

Full Context

configure port otu fec

Description

This command enables the Forwarding Error Correction (FEC) encoder/decoder and specifies the FEC encoder/decoder mode to use when enabled.

The following rules must be followed:

- The port's OTU must be enabled to set or change the FEC mode.
- The port must be shut down before changing the FEC mode.
- The sf-sd-method must be changed to BIP8 before setting the FEC mode to disabled.

Note that FEC cannot be disabled on OTU3 encapsulated OC768 or 40-Gigabit Ethernet by the **no fec** command. Therefore, the default depends on the port type. The default for OTU3 encapsulated OC768 or 40-Gigabit Ethernet is **fec enhanced**.

The **no** form of this command disables FEC encoder and decoder.

Default

no fec

Parameters

enhanced

Enables the FEC encoder and decoder with a proprietary enhanced FEC algorithm.

g709

Enables the FEC encoder and decoder with the standard G.709 FEC algorithm.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

17.43 fec-limit

fec-limit

Syntax

fec-limit *limit* [**log-only**] [**threshold** *percentage*]

no fec-limit

Context

[Tree] (config>router>ldp>session-params>peer fec-limit)

Full Context

configure router ldp session-parameters peer fec-limit

Description

This command configures a limit on the number of FECs which an LSR will accept from a given peer and add into the LDP label database. The limit applies to the aggregate count of all FEC types including service FEC. Once the limit is reached, any FEC received will be released back to the peer. This behavior is different from the per-peer import policy which will still accept the FEC into the label database but will not resolve it.

When the FEC limit for a peer is reached, the LSR performs the following actions:

1. Generates a trap and a syslog message.
2. Generates a LDP notification message with the LSR overload status TLV, for each LDP FEC type including service FEC, to this peer only if this peer advertised support for the LSR overload sub-TLV via the LSR Overload Protection Capability TLV at session initialization.
3. Releases, with LDP Status Code of "No_Label_Resources", any new FEC, including service FEC, from this peer which exceeds the limit.

If a legitimate FEC is released back to a peer, while the FEC limit was exceeded, the user must have a means to replay that FEC back to the router LSR once the condition clears. This is done automatically if the peer is an SR OS-based router and supports the LDP overload status TLV (SR OS 11.0R5 and higher). Third-party peer implementations must support the LDP overload status TLV or provide a manual command to replay the FEC.

The **threshold** option allows to set a threshold value when a trap and an syslog message are generated as a warning to the user in addition to when the limit is reached. The default value for the threshold when not configured is 90%.

The **log-only** option causes a trap and syslog message to be generated when reaching the threshold and limit. However, LDP labels are not released back to the peer.

If the user decreases the limit value such that it is lower than the current number of FECs accepted from the peer, the LDP LSR raises the trap for exceeding the limit. In addition, it will set overload for peers which signaled support for LDP overload protection capability TLV. However, no existing resolved FECs from the peer which does not support the overload protection capability TLV should be de-programmed or released.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

A different trap is released when crossing the threshold in the upward direction, when reaching the FEC limit, and when crossing the threshold in the downward direction. However the same trap will not be generated more often than 2 minutes apart if the number of FECs oscillates around the threshold or the FEC limit.

Default

no fec-limit

Parameters

limit

Specifies the aggregate count of FECs of all types which can be accepted from this LDP peer.

log-only

Specifies that only a trap and syslog message are generated when reaching the threshold and limit. However, LDP labels are not released back to the peer.

percentage

Specifies the threshold value (as a percentage) that triggers a warning syslog message and trap to be sent.

Full Context

configure router ldp fec-originate

Description

This command defines a way to originate a FEC (with a swap action) for which the LSR is not egress, or to originate a FEC (with a pop action) for which the LSR is egress.

Parameters

ip-prefix/mask

Specifies information for the specified IP prefix and mask length.

Values

ipv4-prefix - a.b.c.d	
ipv4-prefix-le - [0..32]	
ipv6-prefix	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x - [0..FFFF]H
	d - [0..255]D
	ipv6-prefix-le - [0..128]

next-hop

Specifies the IP address of the next hop of the prefix.

advertised-label

Specifies the label advertised to the upstream peer. If not configured, then the label advertised should be from the label pool. If the configured static label is not available then the IP prefix is not advertised.

out-label

Specifies the LSR to swap the label. If configured, then the LSR should swap the label with the configured swap-label. If not configured, then the default action is pop if the next-hop parameter is not defined.

The next-hop, advertised-label, swap-label parameters are all optional. If next-hop is configured but no swap label specified, it will be a swap with label 3, such as, pop and forward to the next-hop. If the next-hop and swap-label are configured, then it is a regular swap. If no parameters are specified, a pop and route is performed.

Values 16 to 1048575

in-label

Specifies the number of labels to send to the peer associated with this FEC.

Values 32 to 1023

pop

Specifies to pop the label and transmit without the label.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

interface *interface-name*

Specifies the name of the interface the label for the originated FEC is swapped to. For an unnumbered interface, this parameter is mandatory since there is no address for the next-hop. For a numbered interface, it is optional.

Platforms

All

17.45 fec-prefix

Syntax

[**no**] **fec-prefix** *ip-prefix*[*mask*]

Context

[Tree] (config>router>ldp>egr-stats fec-prefix)

Full Context

configure router ldp egress-statistics fec-prefix

Description

This command configures statistics in the egress data path at the ingress LER or LSR for an LDP FEC. The user must execute the **no shutdown** command for this command to effectively enable statistics. The egress data path counters will be updated for both originating and transit packets. Originating packets may be service packets or IP user and control packets forwarded over the LDP LSP when used as an IGP shortcut. Transit packets of the FEC which are label switched on this node.

When ECMP is enabled and multiple paths exist for a FEC, the same set of counters are updated for each packet forwarded over any of the NHLFEs associated with this FEC and for as long as this FEC is active.

The statistics can be enabled on prefix FECs imported from both LDP neighbors and T-LDP neighbors (LDP over RSVP). LDP sets up egress statistics collection for the LDP tunnels whose FECs match the exact prefix specified in this command. Service FECs, that is, FEC 128 and FEC 129, are not valid. LDP FEC egress statistics are collected at the Penultimate-Popping Hop (PHP) node for a LDP FEC using an implicit null egress label.

The **no** form of this command disables the statistics in the egress data path and removes the accounting policy association from the LDP FEC.

Parameters

ip-prefix

Specifies the IP address representing the FEC.

Values	IPv4 prefix:	*a.b.c.d*	*a*, *b*, *c*, *d* - 0 to 255; decimal

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

field

Syntax

[**no**] **field** *field-name*

Context

[Tree] (config>app-assure>group>http-enrich field)

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Full Context

configure application-assurance group http-enrich field

Description

This command specifies the fields to insert into the HTTP header. The command must be repeated for each field to be inserted. The same field cannot be inserted twice into the header under different header names.

Note:
AA can insert two copies of the following fields in the same HTTP header (with a different header name): **imei-hyphenated**, i**mei-hyphenated-2**, **imsi**, **imsi-2**, **static-string**, **static-string-2**, **user-location-raw**, and **user-location-raw2**.

The **no** form of this command removes the specified field so that it is not inserted into the HTTP header.

Parameters

field-name

Specifies the fields to insert into the HTTP header.

Values The following parameters are supported in any deployment:

- **static-string** — header name for the inserted string
- **static-string-2** — header name for the inserted string
- **subscriber-id** — header name for the subscriber ID
- **subscriber-ip** — header name for the subscriber IP address

The following parameters are supported in Fixed Wireless Access (FWA) deployments only:

- **apn** — APN used by the UE
- **apn-ni** — APN Network Identifier (APN-NI) used by the UE
- **billing-type** — UE charging type (charging characteristics)
- **dynamic-acr** — dynamic Anonymous Customer Record (ACR)
- **static-acr** — static ACR
- **imei-sv** — subscriber IMEI with format AABBBBBBCCCCCCEE
- **imei-hyphenated** — subscriber IMEI with format AABBBBBB-CCCCCC-EE
- **imei-hyphenated-2** — subscriber IMEI with format AABBBBBB-CCCCCC-EE
- **imsi** — subscriber IMSI
- **imsi-2** — subscriber IMSI
- **msisdn** — subscriber MSISDN
- **msisdn-ts** — subscriber MSISDN appended with the UNIX timestamp
- **msisdn-without-cc** — subscriber MSISDN without a country code

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- **pgw_ggsn-address** — PGW/GGSN address serving the UE
- **plmn-id** — Public Land Mobile Network (PLMN) ID of the SGSN/MME
- **rat-type** — Radio Access Technology (RAT) type
- **timestamp** — timestamp inserted in UNIX time format Example: 1531204313
- **user-location** — UE LOCATION (ULI)
- **user-location-3gpp** — ULI encoded as defined in 3GPP 29.061
- **user-location-raw** — ULI in raw format <ULI-TYPE1>[+<ULI-TYPE2>]=<ULI HEX>

  Example: x-locinfo: TAI+ECGI=1300622c46130062014adf16
- **user-location-raw-2** — ULI in raw format <ULI-TYPE1>[+<ULI-TYPE2>]=<ULI HEX>

  Example: x-locinfo: TAI+ECGI=1300622c46130062014adf16

All

17.54 file-id

file-id

Syntax

[**no**] **file-id** *file-id* [**name** *file-policy-name*]

Context

[Tree] (config>log file-id)

Full Context

configure log file-id

Description

This command creates the context to configure a file policy that is used as the destination for an event log or billing (accounting) file.

This command defines the file location and characteristics that are to be used as the destination for a log event message stream or accounting/billing information. The file defined in this context is subsequently specified in the **to** command under **log-id** or **accounting-policy** to direct specific logging or billing source streams to the file destination.

A file policy can only be assigned to either *one* **log-id** or *one* **accounting-policy**. It cannot be reused for multiple instances. A file policy and associated file definition must exist for each log and billing file that must be stored in the file system.

A file is created when the file policy defined in this command is selected as the destination type for a specific log or accounting record. Log files are collected in a "log” directory. Accounting files are collected in an "act” directory.

The file names for a log are created by the system as summarized in Table 48: Log File Names.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Table 48: Log File Names

File Type	File Name
Log File	log*llff-timestamp*
Accounting File	act*aaff-timestamp*

Where:

- *ll* is the *log-id*
- *aa* is the accounting *policy-id*
- *ff* is the file-id
- The *timestamp* is the actual timestamp when the file is created. The format for the timestamp is *yyyymmdd-hhmmss* where:
  - *yyyy* is the year (for example, 2006)
  - *mm* is the month number (for example, 12 for December)
  - *dd* is the day of the month (for example, 03 for the 3rd of the month)
  - *hh* is the hour of the day in 24 hour format (for example, 04 for 4 a.m.)
  - *mm* is the minutes (for example, 30 for 30 minutes past the hour)
  - *ss* is the number of seconds (for example, 14 for 14 seconds)
- The accounting file is compressed and has a gz extension.

When initialized, each file contains:

- The *log-id* description.
- The time the file was opened.
- The reason the file was created.
- If the event log file was closed properly, the sequence number of the last event stored on the log is recorded.

If the process of writing to a log file fails (for example, the compact flash card is full) and if a backup location is not specified or fails, the log file will not become operational even if the compact flash card is replaced. Enter either a **clear log** command or a **shutdown/no shutdown** command to reinitialize the file.

If the primary location fails (for example, the compact flash card fills up during the write process), a trap is sent and logging continues to the specified backup location. This can result in truncated files in different locations.

The **no** form of this command removes the file policy from the configuration. A file policy can only be removed from the configuration if the policy is not the designated output for a log destination. The actual log or accounting file remain on the file system when a file policy is deleted.

Parameters

file-id

The file identification number for the file policy, expressed as a decimal integer.

Values 1 to 99

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

name file-policy-name

Configures an optional file policy name, up to 64 characters, that can be used to refer to the file policy after it is created. If the name begins with a numerical digit (from 1 to 9), the name is a number from 1 to 99.

file-url

Syntax

file-url *file-url*

no file-url

Context

[Tree] (config>mirror>mirror-dest>pcap file-url)

Full Context

configure mirror mirror-dest pcap file-url

Description

This command specifies a file URL for the FTP or TFTP server, including the filename for packet capture transfer. After the file URL is entered, the system attempts to establish a connection and creates a file using the filename specified. The command prompt displays an error and rejects the file URL if the session establishment fails, if write privilege to remote server fails, or if the session experiences a sudden termination. If the FTP or TFTP server is unreachable, the command prompt is halted for further input until the retires are timed out after 24 seconds (after four attempts of about six seconds each). This command overwrites any file on the FTP or TFTP server with the same filename.

The **no** form of this command removes the *file-url* instance and stops the packet capture and file transfer session.

Parameters

file-url

Specifies the URL for the file to direct the search.

Values [*local-url* | *remote-url*]

where:

- *local-url* — [*cflash-id/*] [*file-path*]
  180 chars max, including *cflash-id*
  directory length 99 chars max each

configure service vprn interface spoke-sdp egress filter

configure service vprn network-interface egress filter

configure service vprn redundant-interface spoke-sdp ingress filter

configure service vprn redundant-interface spoke-sdp egress filter

configure service vprn interface spoke-sdp ingress filter

Description

This command associates an IP filter policy with an ingress or egress Service Access Point (SAP) or IP interface. An IP filter policy can be associated with spoke SDPs. Filter policies control the forwarding and dropping of packets based on IP or MAC matching criteria.

The filter command is used to associate a filter policy with a specified ip-filter-id with an ingress or egress SAP. The ip-filter-id must already be defined before the filter command is executed. If the filter policy does not exist, the operation fails and an error message returned.

In general, filters applied to SAPs (ingress or egress) apply to all packets on the SAP. One exception is non-IP packets are not applied to IP match criteria, so the default action in the filter policy applies to these packets.

The **no** form of this command removes any configured filter ID association with the SAP or IP interface. The filter ID itself is not removed from the system unless the scope of the created filter is set to local. To avoid deletion of the filter ID and only break the association with the service object, use scope command within the filter definition to change the scope to local or global. The default scope of a filter is local.

Parameters

ip *ip-filter-id*

Specifies IP filter policy. The filter ID must already exist within the created IP filters.

Description

This command associates an IP filter policy or MAC filter policy with an ingress or egress Service Access Point (SAP) or IP interface.

Filter policies control the forwarding and dropping of packets based on IP or MAC matching criteria. There are two types of filter policies: IP and MAC. Only one type may be applied to a SAP at a time.

The **filter** command is used to associate a filter policy with a specified *filter ID* with an ingress or egress SAP. The *filter ID* must already be defined before the **filter** command is executed. If the filter policy does not exist, the operation will fail and an error message returned.

In general, filters applied to SAPs (ingress or egress) apply to all packets on the SAP. One exception is non-IP packets are not applied to IP match criteria, so the default action in the filter policy applies to these packets.

The **no** form of this command removes any configured filter ID association with the SAP or IP interface. The filter ID itself is not removed from the system unless the scope of the created filter is set to local. To avoid deletion of the filter ID and only break the association with the service object, use **scope** command within the filter definition to change the scope to **local** or **global**. The default scope of a filter is **local**.

Parameters

ip *ip-filter-id*

Specifies IP filter policy. The filter ID must already exist within the created IP filters.

Values 1 to 65535

© 2025 Nokia.

Filter policies control the forwarding and dropping of packets based on IP matching criteria. Only one filter can be applied to a SAP at a time.

The **filter** command is used to associate a filter policy with a specified *ip-filter-id* with an ingress or egress SAP. The *ip-filter-id* must already be defined before the **filter** command is executed. If the filter policy does not exist, the operation will fail and an error message returned.

IP filters apply only to RFC 2427-routed IP packets. Frames that do not contain IP packets will not be subject to the filter and will always be passed, even if the filter's default action is to drop.

The **no** form of this command removes any configured filter ID association with the SAP or IP interface. The filter ID itself is not removed from the system unless the scope of the created filter is set to local. To avoid deletion of the filter ID and only break the association with the service object, use **scope** command within the filter definition to change the scope to **local** or **global**. The default scope of a filter is **local**.

Parameters

ip-filter-id

Specifies IP filter policy. The filter ID must already exist within the created IP filters.

Values 1 to 65535

ipv6-filter-id

Specifies the IPv6 filter policy. The filter ID must already exist within the created IPv6 filters.

Values 1 to 65535

Description

This command associates an IP filter policy with an ingress or egress Service Access Point (SAP) or IP interface.

Filter policies control the forwarding and dropping of packets based on IP matching criteria. Only one filter can be applied to a SAP at a time.

The **filter** command is used to associate a filter policy with a specified *filter-id* with an ingress or egress SAP. The *filter-id* must already be defined before the **filter** command is executed. If the filter policy does not exist, the operation will fail and an error message returned.

IP filters apply only to RFC 2427-routed IP packets. Frames that do not contain IP packets will not be subject to the filter and will always be passed, even if the filter's default action is to drop.

The **no** form of this command removes any configured filter ID association with the SAP or IP interface. The filter ID itself is not removed from the system unless the scope of the created filter is set to local. To avoid deletion of the filter ID and only break the association with the service object, use **scope** command within the filter definition to change the scope to **local** or **global**. The default scope of a filter is **local**.

IPv6 filters are only supported by the 7450 ESS and 7750 SR but are not supported on a Layer 2 SAP that is configured with QoS MAC criteria. Also, MAC filters are not supported on a Layer 2 SAP that is configured with QoS IPv6 criteria.

Parameters

ip-filter-id

Specifies IP filter policy. The filter ID must already exist within the created IP filters.

Values 1 to 65535

ipv6-filter-id

Specifies the IPv6 filter policy for 7450 ESS or 7750 SR. The filter ID must already exist within the created IPv6 filters.

Values 1 to 65535

Full Context

configure service ies interface spoke-sdp ingress filter

configure service ies interface spoke-sdp egress filter

Description

This command associates an IP filter policy filter policy with an ingress or egress spoke SDP.

Filter policies control the forwarding and dropping of packets based on matching criteria.

MAC filters are only allowed on Epipe and Virtual Private LAN Service (VPLS) SAPs.

The **filter** command is used to associate a filter policy with a specified *ip-filter-id* with an ingress or egress spoke SDP. The *ip-filter-id* must already be defined in the **config>filter** context before the **filter** command is executed. If the filter policy does not exist, the operation fails and an error message returned.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

In general, filters applied to SAPs or spoke SDPs (ingress or egress) apply to all packets on the SAP or spoke SDPs. One exception is non-IP packets are not applied to IP match criteria, so the default action in the filter policy applies to these packets.

The **no** form of this command removes any configured filter ID association with the SAP or IP interface. The filter ID itself is not removed from the system unless the scope of the created filter is set to local. To avoid deletion of the filter ID and only break the association with the service object, use **scope** command within the filter definition to change the scope to **local** or **global**. The default scope of a filter is **local**.

Parameters

ip

Keyword indicating the filter policy is an IP filter.

ip-filter-id

The filter name acts as the ID for the IP filter policy. Allowed values are an integer in the range of 1 and 65535 that corresponds to a previously created IP filter policy. The filter ID must already exist within the created IP filters.

Platforms

All

filter

Context

[Tree] (config>service>vprn>log>log-id filter)

[Tree] (config>service>vprn>log filter)

Full Context

configure service vprn log log-id filter

configure service vprn log filter

Description

This command creates a context for an event filter. An event filter specifies whether to forward or drop an event or trap based on the match criteria.

Filters are configured in the **filter** *filter-id* context and then applied to a log in the **log-id** *log-id* context. Only events for the configured log source streams destined to the log ID where the filter is applied are filtered.

Changes made to an existing filter using any of the sub-commands are immediately applied to the destinations where the filter is applied.

By default, no event filters are defined. Event filters must be explicitly configured.

The **no** form of this command removes the filter association from log IDs, which causes those logs to forward all events.

Default

No event filters are defined.

Parameters

filter-id

Specifies the unique filter ID.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Values 1 to 1500

name filter-name

Configures an optional filter name, up to 64 characters, that can be used to refer to the filter after it is created.

Full Context

configure service pw-template ingress filter

configure service pw-template egress filter

Description

This command associates an IP filter policy or MAC filter policy on egress or ingress. Filter policies control the forwarding and dropping of packets based on IP or MAC matching criteria. There are two types of filter policies: IP and MAC. Only one type may be applied to a SAP at a time.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **filter** command is used to associate a filter policy with a specified *filter ID* with an ingress or egress SAP. The *filter ID* must already be defined before the **filter** command is executed. If the filter policy does not exist, the operation will fail and an error message returned.

This command is only supported in 'classic' configuration-mode (**configure system management-interface configuration-mode classic**). The **filter-name** command can be used in all configuration modes.

This command is mutually exclusive with the **filter-name** command. Only one or the other can be configured.

The **no** form of this command removes any configured filter ID association with the SAP or IP interface. The filter ID itself is not removed from the system unless the scope of the created filter is set to local. To avoid deletion of the filter ID and only break the association with the service object, use **scope** command within the filter definition to change the scope to **local** or **global**. The default scope of a filter is **local**.

Parameters

Full Context

configure filter md-auto-id filter-id-range

Description

This command specifies the range of IDs used by SR OS to automatically assign an ID to filters that are created in model-driven interfaces without an ID explicitly specified by the user or client.

A filter created with an explicitly-specified ID cannot use an ID in this range. In classic CLI and SNMP, the ID range cannot be changed while objects exist inside the previous or new range. In MD interfaces, the range can be changed, which causes any previously existing objects in the previous ID range to be deleted and re-created using a new ID in the new range.

The **no** form of this command removes the range values.

See the **config>filter md-auto-id** command for further details.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Default

no filter-id-range

Parameters

start *filter-id*

Specifies the lower value of the ID range. The value must be less than or equal to the **end** value.

Values 1 to 2147483647

end *filter-id*

Specifies the upper value of the ID range. The value must be greater than or equal to the **start** value.

[Tree] (config>service>pw-template>egress filter-name)

[Tree] (config>service>pw-template>ingress filter-name)

Full Context

configure service pw-template egress filter-name

configure service pw-template ingress filter-name

Description

This command associates an IP filter policy or MAC filter policy on egress or ingress. Filter policies control the forwarding and dropping of packets based on IP or MAC matching criteria. There are two types of filter policies: IP and MAC. Only one type may be applied to a SAP at a time.

The **filter-name** command is used to associate a filter policy with a specified *filter name* with an ingress or egress SAP. The *filter name* must already be defined before the **filter-name** command is executed. If the filter policy does not exist, the operation will fail and an error message returned.

This command is mutually exclusive with the **filter** command. Only one or the other can be configured.

The **no** form of this command removes any configured filter name association with the SAP or IP interface. The filter name itself is not removed from the system unless the scope of the created filter is set to local. To avoid deletion of the filter name and only break the association with the service object, use **scope** command within the filter definition to change the scope to **local** or **global**. The default scope of a filter is **local**.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

ip-name

Specifies the IP filter policy. The filter name must already exist within the created IP filters, up to 64 characters.

ipv6-name

Specifies the IPv6 filter policy. The filter name must already exist within the created IPv6 filters, up to 64 characters.

mac-name

Specifies the MAC filter policy. The specified filter name must already exist within the created MAC filters. The filter policy must already exist within the created MAC filters, up to 64 characters.

flags-tlv

Syntax

[no] flags-tlv

Context

[Tree] (config>router>fad>flex-algo flags-tlv)

Full Context

configure router flexible-algorithm-definitions flex-algo flags-tlv

Description

This command advertises the FAD Flags TLV to provide additional context on how the router must run a constrained SPF (cSPF). The IETF definition includes only the M-flag for use in the FAD Flags TLV. When

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

it is set, the M-flag specifies the use of a Flex-Algorithm specific prefix metric. The M-flag is important for inter-area or inter-domain routing support with Flex-Algorithms.

When a router advertises a FAD, it is optional to advertise the FAD Flags TLV. However, when a FAD that includes the FAD Flags TLV is received, then the router must decode the flags before participating in the Flex-Algorithm.

By default, the following considerations apply to the FAD Flags TLV.

- SR OS sets the M-flag and advertises the FAD Flags TLV.
- When a FAD Flags TLV is received, SR OS decodes the flags and modifies the cSPF computation based upon the M-flag status.

The **no** form of this command prevents the advertisement of the FAD Flags TLV within a FAD.

Default

flex-algo

Syntax

flex-algo *flex-algo*

no flex-algo

Context

[Tree] (config>router>static-route-entry>indirect>tunnel-next-hop flex-algo)

Full Context

configure router static-route-entry indirect tunnel-next-hop flex-algo

Description

This command instructs the tunnel towards the indirect static-route next-hop to use the specified flexible algorithm.

It is assumed that the router using this command is participating in the flexible algorithm. This command instructs the router to lookup the indirect next-hop using flexible algorithm tunnels. If flexible algorithm aware tunnel to the indirect next-hop does not exist, then the static-route is not activated.

The expected outcome of this command is that when the router receives an IP payload packet, that it is steered towards the indirect next-hop using a flexible algorithm aware segment-routing tunnel if such tunnel exists. If such tunnel does not exist, then the route is not active, and the received IP packet will be dropped, if no other Longest Prefix Match (LPM) route exists.

If the *flex-algo* parameter is specified, the resolution filter can only use matching flexible algorithm-aware segment routing tunnels created by flexible algorithm-aware routing protocols (for example, SR IS-IS).

The **no** form of this command disables flexible algorithm-aware indirect next-hop resolution.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Default

no flex-algo

Parameters

flex-algo

Configures or deconfigures tunnel-next-hop flexible algorithm for resolving indirect static-route-entry.

Values 128 to 255

Platforms

All

Syntax

flex-algo *fad-name* [**create**]

no flex-algo *fad-name*

Context

[Tree] (config>router>fad flex-algo)

Full Context

configure router flexible-algorithm-definitions flex-algo

Description

This command configures the definition context for a Flexible Algorithm Definition (FAD). Parameters, including the FAD priority, metric type, links to construct a flexible algorithm topology graph, and a description of the algorithm. Up to 256 local FADs can be configured on a router.

The FAD configuration parameters are grouped using the *fad-name* as the reference anchor. When an IGP is configured to use and advertise a local configured FAD, the *fad-name* is used as the reference anchor.

The **no** form of this command deletes the configured parameters and removes the defined FAD.

Default

no flex-algo

Parameters

fad-name

Specifies the name of the flexible algorithm, up to 32 characters, that is used as reference anchor for the configured parameters.

create

Specifies the mandatory keyword to create a router instance.

configure isa application-assurance-group flow-attribute

Description

This command enables the specified flow attribute.

The **no** form of this command disables the attribute.

Parameters

flow-attribute-name

Specifies the name of the flow attribute, up to 256 characters.

Values

video	This attribute specifies streaming or real-time video media traffic transferred between a sender and receiver. It does not differentiate adaptive and nonadaptive video streaming. Assigned to flows based on packet payload inspection (many protocols) or behavioral mechanisms, and may be used together with the RTC attribute to identify video call traffic.
abr_service	This attribute is assigned to adaptive bit rate traffic exchanges where the traffic rate or behavior can be automatically adjusted based on changes in network conditions. Assigned by application filter configuration or by behavioral mechanisms.
audio	This attribute is assigned to streaming or real-time audio media traffic transferred between a sender and receiver. Assigned to flows based on packet payload inspection or behavioral mechanisms, and may be used together with the RTC attribute to identify voice call traffic.
encrypted	This attribute is assigned to traffic exchanges where the initial payload or the entirety of the exchange is encrypted. Assigned to sessions based on packet payload inspection or by behavioral mechanisms.
download	This attribute is assigned to traffic that has a high likelihood of exchanging data predominantly in the network to subscriber direction over the lifetime of a session. May be assigned to sessions based on behavioral mechanisms.
upload	This attribute is assigned to traffic that has a high likelihood of exchanging data predominantly in the subscriber to network direction over the lifetime of the session. The upload and download attributes are mutually exclusive. Assigned to sessions based on behavioral mechanisms.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

real_time_ communication	This attribute is assigned to traffic that provides a low latency or real-time exchange of information between two or more communicating endpoints. Assigned by packet payload inspection of an RTP protocol being used or by behavioral mechanisms.
esni	This attribute is assigned to traffic that uses an encrypted server name indication (eSNI), as part of the TLS layer negotiation

configure application-assurance group policy app-qos-policy entry action flow-count-limit

Description

This command assigns an existing flow count limit policer as an action on flows matching this AQP entry.

The match criteria for the AQP entry must specify a uni-directional traffic direction before a policer action can be configured. If a policer is used in one direction in an AQP match entry the same policer name cannot be used by another AQP entry which uses a different traffic direction match criteria.

When multiple policers apply to a single flow, the final action on a packet is the worst case of all policer outcomes (for example, if one of the policers marks packet out of profile, the final marking will reflect that).

The **no** form of this command removes this flow policer from actions on flows matching this AQP entry.

Default

no flow-count-limit

Parameters

policer-name

Specifies the name of the existing flow setup rate policer for this application assurance profile. The *policer-name* is configured in the **config>app-assure>group>policer** context.

event-log-name

Specifies the name of the event log used when event logging is enabled, up to 32 characters, which is used when event logging is enabled.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

no flow-label

Context

[Tree] (config>system>security>mgmt-access-filter>ipv6-filter>entry flow-label)

Full Context

configure system security management-access-filter ipv6-filter entry flow-label

Description

This command configures flow label match conditions. Flow labeling enables the labeling of packets belonging to particular traffic flows for which the sender requests special handling, such as non-default quality of service or real-time service. This command only applies to the 7750 SR and 7950 XRS.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

value

Specifies the flow identifier in an IPv6 packet header that can be used to discriminate traffic flows (See RFC 3595, *Textual Conventions for IPv6 Flow Label*.)

Values 0 to 1048575

Platforms

All

Context

[Tree] (config>router>policy-options>policy-statement>entry>from flow-spec-dest)

Full Context

configure router policy-options policy-statement entry from flow-spec-dest

Description

This command enables route matching of BGP FlowSpec routes based on the destination IP prefix in the flow specification. An IPv4 FlowSpec route is matched if its NLRI contains a type 1 subcomponent encoding a prefix and prefix length that is covered by an entry in the referenced prefix list. An IPv6 FlowSpec route is matched if its NLRI contains a type 1 component encoding prefix-offset = 0 and a prefix and prefix length that is covered by an entry in the referenced prefix list.

This command has no effect when the policy is not applied as a BGP import or export policy.

The **no** form of this command disables route matching based on of the destination IP prefix.

Default

no flow-spec-dest

Parameters

prefix-list-name

Specifies the name of a prefix list containing IPv4 or IPv6 prefix entries, up to 64 characters.

Platforms

All

flow-timeout-on-switchover *percent*

Context

[Tree] (config>isa>nat-group>inter-chassis-redundancy flow-timeout-on-switchover)

Full Context

configure isa nat-group inter-chassis-redundancy flow-timeout-on-switchover

Description

This command configures an initial flow timeout on the newly activated node for the **nat-group** after a switchover. This timeout stays in effect only if there is no traffic present over this flow; otherwise, the first packet over the flow after the switchover resets the flow timeout to the originally configured value (under the NAT policy configuration).

This command configuration restricts the flow timeout to a portion of the originally configured value.

Default

flow-timeout-on-switchover 50

Parameters

percent

Specifies the percentage of the originally configured timeout value for the flow under the **nat-policy**.

Values 1 to 50

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

Full Context

configure service vprn interface sap ingress flowspec

configure service ies interface sap ingress flowspec

configure service ies interface spoke-sdp ingress flowspec

configure service vprn interface spoke-sdp ingress flowspec

Description

This command enables IPv4 FlowSpec filtering on an access IP interface associated with a VPRN or IES service. Filtering is based on all of the IPv4 FlowSpec routes that have been received and accepted by the corresponding BGP instance. Ingress IPv4 traffic on an interface can be filtered by both a user-defined IPv4 filter and FlowSpec. Evaluation proceeds in this order:

- user-defined IPv4 filter entries
- FlowSpec derived filter entries
- user-defined IPv4 filter default-action

The **no** form of this command removes IPv4 FlowSpec filtering from an IP interface.

Default

no flowspec. No access interfaces have IPv4 FlowSpec enabled.

configure router interface eth-cfm mep alarm-notification fng-alarm-time

Description

This command is used to configure the Fault Notification Generation time values for raising the alarm. This timer is used for network management processes and is not tied into delaying the notification to the fault management system on the network element. This timer does not affect fault propagation mechanisms.

Parameters

time

Specifies the time, in centiseconds (10ms intervals), that a defect condition at or above the **low-priority-defect** must be present before raising alarm.

Values 0, 250, 500, 1000

Default 0

Platforms

17.104 follow

follow

Syntax

follow router *router-instance* **pool** *name*

no follow

Context

[Tree] (config>router>nat>outside>pool>redundancy follow)

[Tree] (config>service>vprn>nat>outside>pool>redundancy follow)

Full Context

configure router nat outside pool redundancy follow

configure service vprn nat outside pool redundancy follow

Description

This command implicitly enables Pool Fate-Sharing Group (PFSG) which is required in case of multiple NAT policies per inside routing context. A NAT pool configured with this command will not advertise or monitor any route in order to change its (activity) state but instead it will directly follow the state of the lead pool in the PFSG. Once the lead pool changes its (activity) state, all the remaining pools following the lead pool will change their state accordingly.

Default

no follow

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

router *router-instance*

Specifies the routing instance where the lead pool resides.

Values <router-name> | <service-id>

router-name - Base

service-id - 1 to 2147483647

pool *name*

Specifies the pool whose activity state is being shared up to 32 characters in length.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

17.105 force-auth

force-auth

Syntax

force-auth [**cid-change**] [**rid-change**]

force-auth disabled

no force-auth

Context

[Tree] (config>service>ies>sub-if>grp-if>ipoe-session force-auth)

[Tree] (config>service>vprn>sub-if>grp-if>ipoe-session force-auth)

Full Context

configure service ies subscriber-interface group-interface ipoe-session force-auth

configure service vprn subscriber-interface group-interface ipoe-session force-auth

Description

By default, if the circuit-id/interface-id or remote-id in the IPoE session re-authentication trigger packet (such as a DHCP renewal) is not empty and different from the circuit-id/interface-id or remote-id stored in the IPoE session data, a forced re-authentication is performed, ignoring the configured **min-auth-interval**. This default behavior can be changed with this command.

The **no** form of this command reverts to the default behavior.

Default

force-auth cid-change rid-change force-auth disabled on wlan-gw group interfaces

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

cid-change

Perform a forced re-authentication upon a circuit-id/interface-id change. An empty circuit-id/interface-id is not considered a change.

rid-change

Perform a forced re-authentication upon a remote-id change. an empty remote-id is not considered a change. For DHCPv6, the enterprise number is excluded from the comparison.

disabled

Specifies that the **min-auth-interval** never is ignored. The system does not perform a forced re-authentication upon a circuit-id or interface-id or remote-id change.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

17.106 force-ipv6cp

force-ipv6cp

17.107 force-l2pt-boundary

force-l2pt-boundary

Syntax

force-l2pt-boundary [**cdp**] [**dtp**] [**pagp**] [**stp**] [**udld**] [**vtp**]

no force-l2pt-boundary

Context

[Tree] (config>service>vpls>sap force-l2pt-boundary)

Full Context

configure service vpls sap force-l2pt-boundary

Description

Enabling force-l2pt-boundary will force all SAPs managed by the specified m-vpls instance on the corresponding port to have l2pt-termination enabled. This command is applicable only to SAPs created under m-vpls regardless of the flavor of STP currently active. It is not applicable to spoke-SDPs.

The execution of this command will fail as soon as at least one of the currently managed SAPs (all SAPs falling within the specified managed-vlan-range) does not have l2pt-termination enabled regardless of its admin/operational status.

If force-l2pt-boundary is enabled on a specified m-vpls SAP, all newly created SAPs falling into the specified managed-vlan-range will have l2pt-termination enabled per default.

Extending or adding new range into a managed-vlan-range declaration will fail as soon as there is at least one SAPs falling into the specified vlan-range does not have l2pt-termination enabled.

Disabling l2pt-termination on currently managed SAPs will fail as soon as the force-l2pt-boundary is enabled under corresponding m-vpls SAP.

Parameters

cdp

Specifies the Cisco discovery protocol

dtp

Specifies the dynamic trunking protocol

pagp

Specifies the port aggregation protocol

stp

Specifies all spanning tree protocols: stp, rstp, mstp, pvst (default)

udld

Specifies unidirectional link detection

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

vtp

Specifies the virtual trunk protocol

configure service vpls bgp-evpn segment-routing-v6 force-qinq-vc-forwarding

configure service epipe spoke-sdp force-qinq-vc-forwarding

configure service vpls mesh-sdp force-qinq-vc-forwarding

Description

This command forces the datapath to push two VLAN tags at network egress when sending traffic on SDP bindings or EVPN destinations. The VLAN tag values are derived from the service-delimiting tags at the ingress, depending on the configured parameter. At network ingress this command, configured on EVPN-MPLS or the SDP-binding, pops two VLAN tags at most.

The **no** form of this command disables the datapath from pushing any VLAN tags in SDP bindings or EVPN, or from popping two VLAN tags.

Default

no force-qinq-vc-forwarding

Parameters

c-tag-c-tag

Specifies that the router pushes two tags with the same value derived from the inner service delimiting tag. At network ingress, two VLAN tags are extracted at most and the C-tag and S-tag p/de bits are propagated to the egress SAPs.

s-tag-c-tag

Specifies that the router pushes two tags that are copied from the QinQ service-delimiting VLAN values and may be different. At network ingress, two VLAN tags are extracted at most and the p/de bits are propagated to the egress SAP service-delimiting S-tag and C-tag respectively.

Syntax

[**no**] **force-qtag-forwarding**

Context

[Tree] (config>service>vpls>pbb force-qtag-forwarding)

Full Context

configure service vpls pbb force-qtag-forwarding

Description

This command forces the addition of a IEEE 802.1q tag after the Customer MAC (C-MAC) addresses when the PBB header is built, as it egresses a related BVPLS.

It is used to preserve the dot1q and DE bits from the customer domain when the service delimiting qtags are stripped when the packet is ingressing a PBB Epipe or an IVPLS. The VLAN value of the service delimiting qtag if one exists is used for the corresponding inserted dot1q field. If a service delimiting qtag does not exist, then the value of zero is used for all the inserted qtag bits.

The **no** form of this command sets default behavior.

Default

no force-qtag-forwarding

Context

[Tree] (debug>sync-if-timing force-reference)

Full Context

debug sync-if-timing force-reference

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command forces the system synchronous timing output to use a specific reference.

Note:
The list of available references may vary depending on the platform; all references are not supported on every platform.

Only use this command to test and debug problems. Network synchronization problems may appear if you leave network elements with this manual override setting. After forcing the system timing reference input, clear it using the **no force-reference** command.

This command also clears the Wait-to-Restore state of the reference so that the reference can be selected.

This command can also force the CPM clock to use a specific input reference.

When the command is executed, the CPM clock on the active CPM immediately switches its input reference to that specified by the command. If the specified input is not available (shutdown), or in a disqualified state, the CPM clock shall use the next qualified input reference based on the selection rules.

This command also affects the BITS output port on the active CPM. If the BITS output port selection is set to line-reference and the reference being forced is not the BITS input port, then the system uses the forced reference to generate the signal out the BITS output port. If the BITS output port selection is set to internal-clock, then the system uses the output of the CPM clock to generate the signal for the BITS output port.

On a CPM activity switch, the force command is cleared and normal reference selection is determined.

Debug configurations are not saved between reboots.

Parameters

ref1

Specifies that the clock uses the first timing reference.

ref2

Specifies that the clock uses the second timing reference.

bits

Specifies that the clock uses the external network interface on the active CPM to be the highest priority input.

bitsa

Specifies that the clock uses the bitsa timing reference, for redundant systems with a BITS port on each CPM.

bitsb

Specifies that the clock uses the bitsb timing reference, for redundant systems with a BITS port on each CPM.

gnss

Specifies that the clock uses the GNSS port as a timing reference. This keyword is supported only on 7750 SR single-slot platforms.

gnssa

Specifies that the clock uses the GNSS port on the CPM in slot A as a timing reference. This keyword is supported only on 7750 SR-2e platforms.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

gnssb

Specifies that the clock uses the GNSS port on the CPM in slot B as a timing reference. This keyword is supported only on 7750 SR-2e platforms.

ptp

Specifies that the clock uses the PTP timeReceiver as the timing reference. This keyword is supported on 7450 ESS and 7750 SR platforms.

synce

Specifies that the clock uses the SyncE/1588 timing reference on non-redundant systems.

syncea

Specifies that the clock uses the SyncE/1588 timing reference on CPM A of redundant systems.

synceb

Specifies that the clock uses the SyncE/1588 timing reference on CPM B of redundant systems.

admin redundancy force-switchover

Description

This command forces a switchover to the standby CPM card. The primary CPM reloads its software image and becomes the secondary CPM.

Parameters

now

Forces the switchover to the redundant CPM card immediately.

ignore-status

Forces a switchover despite any diagnostics or conditions on the standby. This is true even if the standby cannot reach the extension CPMs on the extension chassis of a 7950 XRS-40 via its local CPM interconnect ports.

This option is supported on 7950 XRS-20 and 7950 XRS-40 platforms only.

Full Context

configure router nat inside l2-aware force-unique-ip-addresses

configure service vprn nat inside l2-aware force-unique-ip-addresses

Description

This command enforces the uniqueness of IPv4 addresses of L2-aware subscribers in an inside routing context.

This functionality is required if multicast sourced from the inside routing context is enabled for L2-aware subscribers.

The **no** form of this command allows L2-aware subscribers to have overlapping IPv4 addresses.

Default

no force-unique-ip-addresses

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

configure service vpls bgp-evpn mpls force-vlan-vc-forwarding

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command enables the system to preserve the VLAN ID and 802.1p bits of the service-delimiting qtag in a new tag, which is sent in the customer frame to the EVPN destinations.

If this configuration is used in conjunction with the **sap ingress vlan-translation** command, the configured translated VLAN ID is the VLAN ID sent to the EVPN destinations, instead of the service-delimiting tag VLAN ID. If the ingress SAP or SDP binding is null-encapsulated, the output VLAN ID and p-bits are zero.

The **no** form of this command does not preserve the VLAN ID and 802.1p bits of the service-delimiting qtag.

Default

no force-vlan-vc-forwarding

Platforms

All

- configure service epipe bgp-evpn mpls force-vlan-vc-forwarding

[Tree] (config>filter>ipv6-filter>entry>action forward)

[Tree] (config>filter>ip-filter>entry>action forward)

Full Context

configure filter ipv6-filter entry action forward

configure filter ip-filter entry action forward

Description

This command sets the context for specific forward commands to be performed.

Parameters

connection-id

Specifies that the packet should be forwarded over the specified connection (specified by the connection ID under the bonding group interface), if that connect is available. Outside of a bonding egress context, the behavior of this filter is undefined.

Values 1, 2

esi service-id

Specifies that the packet matching the entry is forwarded to an ESI-identified first appliance in Nuage service chain using EVPN-resolved VXLAN tunnel in the specified VPLS service.

esi sf-ip vas-interface router

Specifies that the packet matching the entry is forwarded to ESI/SF-IP identified first appliance in Nuage service chain using EVPN-resolved VXLAN tunnel over the configured VAS interface in the specified VPRN service.

gre-tunnel-name

Specifies the GRE tunnel name up to 32 characters.

lsp

Specifies that the packet matching the entry is forwarded using the specified lsp.

mpls-policy

Specifies the redirection of the traffic to the programed instance of the MPLS FP specified by its endpoint IPv4 or IPv6 address. The behavior results in a simple forward if no policy exists, if no instance is programmed, and if the policy or instance is administratively down.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

next-hop

Specifies that the packet matching the entry is forwarded in the routing context of the incoming interface using direct or indirect IPv4 address in the routing lookup.

next-hop router

Specifies that the packet matching the entry is forwarded in the configured routing context using direct or indirect IPv4 address in the routing lookup.

redirect-policy

Specifies that the packet matching the entry is forwarded using forward next-hop or forward next hop router and the IP address of destination selected by the configured redirect policy. If no destination is selected, packets are subject to action forward.

router

Specifies that the packet matching the entry is routed in the configured routing instance and not in the incoming interface routing instance.

sap

Specifies that the packet matching the entry is forwarded using the configured SAP.

sdp

Specifies that the packet matching the entry is forwarded using the configured SDP.

srte-policy

Specifies the redirection of the traffic to the programed instance of the SR-TE policy specified by its endpoint IPv4 address or IPv6 address and color. The behavior results in a simple forward if no policy exists, if no instance is programmed, and if the policy or instance is administratively down.

color-id

Specifies the color identifier of the specified SR-TE policy.

Values 0 to 4294967295

vprn-target

Specifies that the packet matching the entry is redirected towards a designated BGP next-hop (**bgp-nh**). The user may specify an LSP (**lsp** *lsp-name*) to use towards that next-hop. If no LSP is specified, the system will automatically select one. The user must specify the routing context (**router** {*router-instance* | **service-name** *service-name*}) in which the system will perform the lookups in order to derive the proper VPRN service label. The user may specify an advertised prefix route (**adv-prefix** *ip-address/prefix-length*). This is needed in case label per VRF is not the label allocation method configured at the BGP peer.

esi

Specifies a 10-byte Ethernet Segment Identifier.

ip-address/mask

Specifies an IPv4 advertised route in the CIDR notation. The IPv4 address is in dotted decimal notation.

Values ip-address a.b.c.d (host bits must be 0)

mask: 0 to 32

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

ipv6-address/prefix-length

Specifies an IPv6 advertised route in the CIDR notation.

Values ipv6-address:

- x:x:x:x:x:x:x:x (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d, where "x" is [0..FFFF]H, and "d" is [0..255]

prefix-length: 0 to 128

bgp-nh ip-address

Specifies the IPv4 address (in dotted decimal notation) of the target BGP next-hop.

Values ip-address d.d.d.d

ipv6-address

Specifies the IPv6 address of a direct or indirect next hop to forward matching packets or of the service SID to use with the SRv6 policy.

interface-name

Specifies the (maximum 32-character) name of an egress R-VPLS IP interface used to forward the packets using ESI redirect for VPRN/IES service.

lsp-name

Specifies an existing RSVP-TE, MPLS-TP, or SR-TE LSP that supports LSP redirect.

policy-name

Specifies an IPv4 redirect policy configured in the config>filter>redirect-policy context.

sap-id

Specifies an existing VPLS Ethernet SAP.

sdp-id:vc-id

Specifies an existing VPLS SDP.

router-instance

Specifies "Base" or an existing VPRN service ID. For the **forward vprn-target bgp-nh** command, *router-instance* must specify an existing VPRN service ID.

service-name

Specifies an existing VPRN service name.

vpls-service-id

Specifies an existing VPLS service ID or service name.

[Tree] (config>service>template>vpls-template>stp forward-delay)

Full Context

configure service vpls stp forward-delay

configure service template vpls-template stp forward-delay

Description

RSTP, as defined in the IEEE 802.1D-2004 standards, will normally transition to the forwarding state via a handshaking mechanism (rapid transition), without any waiting times. If handshaking fails (foe example, on shared links, see below), the system falls back to the timer-based mechanism defined in the original STP (802.1D-1998) standard.

A shared link is a link with more than two nodes (for example, a shared 10/100BaseT segment). The port-type command is used to configure a link as point-to-point or shared.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

For timer-based transitions, the 802.1D-2004 standard defines an internal variable forward-delay, which is used in calculating the default number of seconds that a SAP or spoke-SDP spends in the discarding and learning states when transitioning to the forwarding state.

The value of the forward-delay variable depends on the STP operating mode of the VPLS instance:

- in rstp or mstp mode, but only when the SAP or spoke-SDP has not fallen back to legacy STP operation, the value configured by the hello-time command is used;
- in all other situations, the value configured by the forward-delay command is used.

Default

forward-delay 15

Parameters

seconds

The forward delay timer for the STP instance in seconds

Values 4 to 30

forwarding

Syntax

forwarding {**next-hop** *ip-address* | **interface** *interface-name* | **bypass-routing**}

no forwarding

Context

[Tree] (config>oam-pm>session>ip forwarding)

Full Context

configure oam-pm session ip forwarding

Description

This command influences the forwarding decision of the TWAMP Light packet. When this command is used, only one of the forwarding options can be enabled at any time.

The **no** form of this command removes the options and enables the default forwarding logic.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

ip-address

Specifies the IP address of the next hop on the path.

Values

ipv4-address:	a.b.c.d
ipv6-address:	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x: [0 to FFFF]H
	d: [0 to 255]D

interface-name

Specifies the name, up to 32 characters, to refer to the interface from which the packet is sent. The name must already exist in the **config>router>interface** context or within the appropriate **config>service** context.

bypass-routing

Specifies to send the packet to a host on a directly attached network, bypassing the routing table.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command determines the setting of the F bits in the GR and LLGR capabilities advertised by the router. When the F bit is set for an AFI/SAFI, it indicates that the advertising router was able to preserve forwarding state for the routes of that AFI/SAFI across the last restart. If a router restarts and does not set F=1, then when the session with a peer is re-established, the peer immediately deletes all LLGR stale routes it was preserving on behalf of the restarting router for the corresponding AFI/SAFI.

This command allows the F bits for all advertised AFI/SAFI to be set to 1, or only the F bits for non-forwarding AFI/SAFI to be set to 1. Non-forwarding AFI/SAFI are the following configuration-related address families: L2-VPN, route-target, flow-IPv4, and flow-IPv6.

Default

no forwarding-bits-set

Parameters

all

Specifies that the F bit for all AFI/SAFI should be set to 1.

non-fwd

Specifies that the F bit for only non-forwarding AFI/SAFI should be set to 1. These AFI/SAFI correspond to the following families: L2-VPN, route-target, flow-IPv4, and flow-IPv6.

Context

[Tree] (config>router>mpls>fwd-policies forwarding-policy)

Full Context

configure router mpls forwarding-policies forwarding-policy

Description

This command creates an MPLS forwarding policy.

There are two types of MPLS forwarding policy:

- endpoint policy
- label-binding policy

The endpoint policy allows the user to forward unlabeled packets over a set of user-defined direct (with option to push a label stack) or indirect next hops. Routes are bound to an endpoint policy when their next hop matches the endpoint address of the policy.

The label-binding policy provides the same capability for labeled packets. In this case, labeled packets matching the ILM of the policy binding label are forwarded over the set of next hops of the policy.

The data model of a forwarding policy represents each pair of {primary next hop, backup next hop} as a group and models the ECMP set as the set of Next-Hop Groups (NHGs). Flows of prefixes can be switched on a per-NHG basis from the primary next hop, when it fails, to the backup next hop without disturbing the flows forwarded over the other NHGs of the policy. The same can be performed when reverting back from a backup next hop to the restored primary next hop of the same NHG.

The MPLS forwarding policy supports two types of NHGs on a per policy basis:

- An NHG of resolution type indirect supported with the label-binding policy and in which forwarding over the primary/backup next hop is modeled as a swap operation from the binding label to an implicit-null label over multiple outgoing interfaces (multiple NHLFEs) corresponding to the resolved next hops of the indirect route.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Within a given NHG, the primary next hop is the preferred active path in the absence of any failure of the NHG of resolution type indirect.

The forwarding database tracks the primary or backup next hop in the routing table. A **route delete** of the primary indirect next hop causes the CPM to program the backup indirect next hop in the data path.

A **route modify** to the indirect primary or backup next hop causes the CPM to update the resolved next hops and to update the data path if it is the active indirect next hop.

When the primary indirect next hop is restored and is added back into the routing table, CPM waits for an amount of time equal to the user-programmed revert timer before updating the data path. However, if the backup indirect next hop fails while the timer is running, CPM updates the data path immediately.

- An NHG of resolution type direct is modeled as follows:
  - For a label-binding policy, forwarding over the primary or backup next hop is modeled as a swap operation from the binding label to the configured label stack or to an implicit-null label (if the **pushed-labels** command not configured) over a single outgoing interface to the next hop.
  - For an endpoint policy, forwarding over the primary or backup next hop is modeled as a push operation from the binding label to the configured label stack or to an implicit-null label (if the **pushed-labels** command not configured) over a single outgoing interface to the next hop.
  - The labels configured by the **pushed-labels** command are not validated.

  Within a given NHG, the primary next hop is the preferred active path in the absence of any failure of the NHG of resolution type direct.

  The NHG supports uniform failover. The forwarding policy database assigns a Protect-Group ID (PG-ID) to each of the primary next hop and the backup next hop and programs both of them in data path. A failure of the active path switches traffic to the other path following the uniform failover procedures.

  The forwarding database tracks the primary or backup next hop in the routing table. A **route delete** of the primary/backup direct next hop causes CPM to send the corresponding PG-ID switch to the data path.

  A **route modify** to the direct primary or backup next hop causes CPM to update the MPLS forwarding database and to update the data path since both next hops are programmed.

  When the primary direct next hop is restored and is added back into the routing table, CPM waits for an amount of time equal to the user programmed revert timer before activating it and updating the data path. However, if the backup direct next hop fails while the timer is running, CPM activates it and updates the data path immediately. The latter failover to the restored primary next hop is performed using the uniform failover procedure.

The forwarding policy database activates the best endpoint policy among the named policies sharing the same value of the endpoint parameter by selecting the lowest preference value policy. This policy is then programmed into the TTM and into the tunnel table in data path. If this policy goes down, then the forwarding policy database performs a re-evaluation and activates the named policy with the next lowest preference value for the same endpoint value. If a more preferred policy comes back up, the forwarding policy database reverts to it and activates it.

The forwarding policy database similarly activates the best label-binding policy among the named policies sharing the same binding label by selecting the lowest preference value policy. This policy is then programmed into the label FIB table in data path. If this policy goes down, then the forwarding policy database performs a re-evaluation and activates the names policy with the next lowest preference value for the same binding label value. If a more preferred policy comes back up, the forwarding policy database reverts to it and activates it.

Use subject to Terms available at: www.nokia.com/terms.

Ingress statistics can be enabled as is associated with binding label, that is the ILM of the forwarding policy, and provides aggregate packet and byte counters for packets matching the binding label.

The **no** form of the command deletes the named MPLS forwarding policy.

Parameters

name

Specifies the name of the MPLS forwarding policy, up to 64 characters.

Platforms

All

17.135 forwarding-set

forwarding-set

Syntax

forwarding-set policy *policy-name* **set** *set-id*

no forwarding-set

Context

[Tree] (config>router>mpls>lsp>class-forwarding forwarding-set)

[Tree] (config>router>mpls>lsp-template>class-forwarding forwarding-set)

Full Context

configure router mpls lsp class-forwarding forwarding-set

configure router mpls lsp-template class-forwarding forwarding-set

Description

This command configures the mapping of a class-forwarding policy and forwarding set ID to an LSP (RSVP-TE or SR-TE) or an LSP template.

An MPLS LSP can only map to one single class forwarding policy and forwarding set. Multiple LSPs can map to the same policy and set. If the LSPs form part of an ECMP set of next-hops for an IPv4 or IPv6 prefix resolved to IGP shortcuts, the prefix packets with a matching FC are mapped to this set and are sprayed over these LSPs. This behavior is based on a modulo operation of the output of the hash routine on the packet's headers and the number of LSPs in the set.

Parameters

policy-name

Specifies the name of the class forwarding policy, to a maximum of 32 characters.

set-id

Specifies the class forwarding set.

17.136 forwarding-tree-topology

forwarding-tree-topology

Syntax

forwarding-tree-topology unicast [**st** | **spf**]

Context

[Tree] (config>service>vpls>spb>level forwarding-tree-topology)

Full Context

configure service vpls spb level forwarding-tree-topology

Description

This command sets the unicast forwarding to follow the shortest path tree defined by the ECT algorithm shortest path forwarding (spf) or to follow a single tree. (st). Shortest path trees make use of more link resources.

Multicast traffic is defaulted to follow the single tree topology. A single tree unicast would make Multicast and unicast follow the same path.

Default

forwarding-tree-topology unicast spf

Parameters

spf

Follows the shortest path tree.

st

Follows a single tree.

17.137 fp

fp

Syntax

fp [*fp-number*]

Context

[Tree] (config>card fp)

Full Context

configure card fp

Description

This command enables access to the configuration of the forwarding planes on a card.

The default forwarding plane is 1. When entering the FP node, if the forwarding plane number is omitted, the system will assume forwarding plane number 1.

Commands can only be configured under **card>fp** if the hardware that the FP resides on (either a card or an XMA) is provisioned. Conversely, all commands under **card>fp** of the corresponding FPs are automatically removed when that hardware is unprovisioned.

Parameters

fp-number

Specifies that the FP number parameter is optional following the **fp** command.

Values 1 to 8

Default fp 1

Platforms

All

17.138 fp-redirect-group

fp-redirect-group

Syntax

fp-redirect-group *policer-type policer-id*

no fp-redirect-group *policer-type*

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Context

[Tree] (config>qos>network>ingress>fc fp-redirect-group)

Full Context

configure qos network ingress fc fp-redirect-group

Description

This command is used to redirect the FC of a broadcast packet received in a VPLS service over a PW or network IP interface to an ingress forwarding plane queue-group.

It defines the mapping of an FC to a policer-id and redirects the lookup of the policer of the same ID in some ingress forwarding plane queue-group instance. However, the queue-group name and instance are explicitly provided only at the time the network QoS policy is applied to the ingress context of a spoke or mesh SDP or a network IP interface.

The broadcast-policer statement is ignored when the network QoS policy is applied to any object other than a VPLS spoke or mesh SDP or a network IP interface.

The **no** form of this command removes the redirection of the FC.

Parameters

policer-type

The policer type to be used. The *policer-type* is ignored when the network QoS policy is applied to any object other than a VPLS spoke or mesh SDP or a network IP interface.

Values broadcast-policer | mcast-policer | policer | unknown-policer

policer-id

The specified *policer-id* must exist within the queue-group template applied to the ingress context of the forwarding plane.

Values 1 to 32

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, 7950 XRS, VSR

17.139 fp-resource-policy

fp-resource-policy

Syntax

fp-resource-policy *name*

no fp-resource-policy

Context

[Tree] (config>card>fp fp-resource-policy)

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Full Context

configure card fp fp-resource-policy

Description

This command configures the FP resource policy for the specified FP.

If the allocation configured within the FP resources policy is not achievable with the current ingress or egress queue consumption, the command fails. The configuration within the newly applied FP resource policy takes effect on the FP on which the FP resources policy is applied, and that includes removing an applied user created FP resource policy to return to the default policy, and causes the router to immediately reset the associated cards, XIOMs, and MDAs, except on the 7750 SR-1 where the configuration must be saved, and the router rebooted, immediately after committing the configuration transaction.

The **no** form of this command reverts to the default value by applying the default **fp-resource-policy** to the FP.

Default

no fp-resource-policy

Parameters

name

Specifies the FP resource policy name, up to 64 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-s, 7950 XRS

fp-resource-policy

Syntax

fp-resource-policy *policy-name* [**create**]

no fp-resource-policy *policy-name*

Context

[Tree] (config>qos fp-resource-policy)

Full Context

configure qos fp-resource-policy

Description

This command configures an FP resource policy that is used to manage resources on an FP4 forwarding plane.

A default policy is created by the system and applied to all FP4 FPs by default. If an FP resource policy is removed from an FP, the system automatically applies the default policy to that FP. The system prevents the modification or deletion of the default policy, and the deletion of any user created policy that is applied to an FP. The system supports a maximum of 15 FP resource policies.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **no** form of this command deletes the FP resources policy from the system.

Parameters

policy-name

Specifies the FP resource policy, up to 64 characters.

create

Creates the FP resource policy entry.

Platforms

7450 ESS, 7750 SR, 7750 SR-s, 7950 XRS

configure service vprn mvpn provider-tunnel inclusive umh-rate-monitoring fpe

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command specifies an FPE to use for the LAG interface of two monitoring IOMs for redundancy. A PXC port can be created on each IOM and added as a member to a per-link hashing LAG bundle. The FPE is used to create the interface on the LAG bundle with its own Martian IP address. On ingress to the Upstream Multicast Hop (UMH) IOMs, the P-Multicast Service Interfaces (PMSIs) traffic is forwarded to the active LAG IOM and, if there is a failure on the active LAG IOM, the PMSIs traffic is forwarded to the standby IOM.

The **no** form of this command removes the FPE association for the LAG interface.

Parameters

fpe-id

Specifies the FPE ID.

Values 1 to 64

Full Context

configure li li-filter li-ip-filter entry match fragment

Description

This command specifies match criterion for fragmented packets.

The **no** form of this command removes the match criterion.

Default

no fragment

Parameters

true

Specifies to match on all fragmented IP packets.

false

Specifies to match on all non-fragmented IP packets.

Platforms

All

fragment

Syntax

fragment {**true** | **false**}

no fragment

Context

[Tree] (config>qos>sap-egress>ip-criteria>entry>match fragment)

[Tree] (config>qos>sap-ingress>ip-criteria>entry>match fragment)

Full Context

configure qos sap-egress ip-criteria entry match fragment

configure qos sap-ingress ip-criteria entry match fragment

Description

This command configures fragmented or non-fragmented IP packets as a SAP QoS policy match criterion.

The **no** form of this command removes the match criterion and matches all packets regardless of whether they are fragmented or not.

Default

no fragment

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

true

Configures a match on all fragmented IP packets. A match will occur for all packets that have either the MF (more fragment) bit set or have the Fragment Offset field of the IP header set to a non-zero value.

false

Configures a match on all non-fragmented IP packets. Non-fragmented IP packets are packets that have the MF bit set to zero and have the Fragment Offset field also set to zero.

Platforms

All

fragment

Syntax

fragment {**true** | **false** | **first-only** | **non-first-only**}

no fragment

Context

[Tree] (config>qos>sap-ingress>ipv6-criteria>entry>match fragment)

Full Context

configure qos sap-ingress ipv6-criteria entry match fragment

Description

This command configures fragmented or non-fragmented IPv6 packets as a SAP ingress QoS policy match criterion.

The **no** form of this command removes the match criterion and matches all packets regardless of whether they are fragmented or not.

Default

no fragment

Parameters

true

Specifies to match on all fragmented IPv6 packets. A match will occur for all packets that contain an IPv6 Fragmentation Extension Header.

false

Specifies to match on all non-fragmented IP packets. Non-fragmented IPv6 packets are packets that do not contain an IPv6 Fragmentation Extension Header.

first-only

Matches if a packet is an initial fragment of the fragmented IPv6 packet.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

non-first-only

Matches if a packet is a non-initial fragment of the fragmented IPv6 packet.

[Tree] (config>filter>ip-filter>entry>match fragment)

Full Context

configure filter ipv6-filter entry match fragment

configure filter ip-filter entry match fragment

Description

This command specifies match criterion for fragmented packets.

Matches can be based on the presence of a fragmented packet (or otherwise) on the ingress or egress interface.

Matches can also be based on the presence of the first fragment of a packet, or on the presence of a fragment that is not the first fragment on the ingress interface.

The **no** form of the command removes the match criterion.

Default

no fragment

Parameters

true

Specifies to match on all fragmented packets.

false

Specifies to match on all non-fragmented packets.

first-only

Matches if a packet is an initial fragment of a fragmented packet.

non-first-only

Matches if a packet is a non-initial fragment of a fragmented packet.

Full Context

configure system security cpm-filter ip-filter entry match fragment

configure system security cpm-filter ipv6-filter entry match fragment

Description

This command specifies fragmented or non-fragmented IP packets as an IP filter match criterion.

Note:
An entry containing Layer 4 match criteria will not match non-initial (2nd, 3rd, etc) fragments of a fragmented packet since only the first fragment contains the Layer 4 information.

This command enables match on existence of IPv6 Fragmentation Extension Header in the IPv6 filter policy. To match first fragment of an IP fragmented packet, specify additional Layer 4 matching criteria in a filter policy entry. The **no** version of this command ignores IPv6 Fragmentation Extension Header presence/absence in a packet when evaluating match criteria of a given filter policy entry.

The **no** form of this command removes the match criterion.

This command enables match on existence of IPv6 Fragmentation Extension Header in the IPv6 filter policy. To match first fragment of an IP fragmented packet, specify additional Layer 4 matching criteria in a filter policy entry. The **no** version of this command ignores IPv6 Fragmentation Extension Header presence/absence in a packet when evaluating match criteria of a given filter policy entry.

Default

no fragment

Parameters

true

Specifies to match on all fragmented IP packets. A match will occur for all packets that have either the MF (more fragment) bit set or have the Fragment Offset field of the IP header set to a non-zero value. For IPv6, packet matches if it contains IPv6 Fragmentation Extension Header.

false

Specifies to match on all non-fragmented IP packets. Non-fragmented IP packets are packets that have the MF bit set to zero and have the Fragment Offset field also set to zero. For IPv6, packet matches if it does not contain IPv6 Fragmentation Extension Header.

Parameters

direction

Specifies the traffic direction.

Values from-sub, to-sub

create

Keyword used to create the TCA.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

17.147 fragments-per-packet

fragments-per-packet

Syntax

fragments-per-packet *number*

no fragments-per-packet

Context

[Tree] (config>isa>map-t-group fragments-per-packet)

Full Context

configure isa map-t-group fragments-per-packet

Description

This command configures the maximum number of fragments per packet in the downstream direction for non-resolved packets. If the number of fragments for non-resolved packets (packets for which the first fragment has not been received) exceeds this number, all the fragments from the packet are discarded, and the buffer is released.

The **no** form of this command reverts to the default.

Default

fragments-per-packet 5

Parameters

number

Specifies the maximum number of fragments per packet in the downstream direction.

Values 1 to 20

17.148 frame-based-accounting

frame-based-accounting

Syntax

[**no**] **frame-based-accounting**

Context

[Tree] (config>qos>scheduler-policy frame-based-accounting)

Full Context

configure qos scheduler-policy frame-based-accounting

Description

The frame-based-accounting command is used to enable frame-based accounting for both the children queues parented to the scheduling policy and for the schedulers within the scheduler policy.

When frame-based accounting is enabled on the policy, all queues associated with the scheduler (through the parent command on each queue) will have their rate and CIR values interpreted as frame-based values. When shaping, the queues will include the 12-byte Inter-Frame Gap (IFG) and 8 byte preamble for each packet scheduled out the queue. The profiling CIR threshold will also include the 20-byte frame encapsulation overhead. Statistics associated with the queue do not include the frame encapsulation overhead.

The scheduler policy's scheduler rate and CIR values will be interpreted as frame-based values.

The configuration of **parent-location** and **frame-based-accounting** in a scheduler policy is mutually exclusive to ensure consistency between the different scheduling levels. Packet byte offset settings are not included in the applied rate when frame-based accounting is configured; however, the offsets are applied to the statistics.

The **no** form of this command is used to return all schedulers within the policy and queues associated with the policy to the default packet-based accounting mode. If **frame-based-accounting** is not currently enabled for the scheduling policy, the **no frame-based-accounting** command has no effect.

configure port tdm e3 framing

Description

This command specifies E-3 framing for the associated E-3 port or channel.

Default

for E-3 non-ATM: framing g751 and cannot be changed. for E-3 ATM: framing g832 and cannot be changed.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

g751

Configures the E-3 port/channel for g751 framing.

g832

Configures the E-3 port/channel for g832 framing.

unframed-e3

Specifies e-3 unframed mode for E-3 interfaces. This parameter allows the configuration of an unstructured E-3 channel on a CES MDA.

Platforms

7450 ESS, 7750 SR-7/12/12e, 7750 SR-a, 7750 SR-e

17.160 frequency

frequency

Syntax

frequency *frequency*

no frequency

Context

[Tree] (config>port>dwdm frequency)

Full Context

configure port dwdm frequency

Description

This command configures the center frequency to use for a tunable DWDM optical interface. It replaces the **configure**>**port**>**dwdm**>**channel** command (used prior to Release 22.2.R1). The **frequency** command supports any frequency in the C band, but the actual operating frequency is dependent on the installed optic module.

Provisioning rules

The provisioned MDA type must have DWDM tunable optics (for example, p1-100g-tun-b) or the MDA must support the option of tunable DWDM optic modules. The following provisioning rules apply:

- The DWDM frequency must set to a non-zero value before the port is set to **no shutdown**.
- The port must be **shutdown** before changing the DWDM frequency.
- The port must be a physical port to set the DWDM frequency.

Default

frequency 0

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

frequency

Specifies the frequency in MHz.

Values 0, 191100000 to 196150000

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

Description

This command selects the source stream to be sent to a log destination.

One or more source streams must be specified. The source of the data stream must be identified using the **from** command before you can configure the destination using the **to** command. The **from** command can identify multiple source streams in a single statement (for example: **from main change debug-trace**).

Only one **from** command may be entered for a single *log-id*. If multiple **from** commands are configured, then the last command entered overwrites the previous **from** command.

The **no** form of this command removes all previously configured source streams.

Default

No source stream is configured.

Parameters

main

Instructs all events in the main event stream to be sent to the destination defined in the **to** command for this destination *log-id*. The main event stream contains the events that are not explicitly directed to any other event stream. To limit the events forwarded to the destination, configure filters using the **filter** command.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

security

Instructs all events in the security event stream to be sent to the destination defined in the **to** command for this destination *log-id*. The security event stream contains all events that pertain to attempts to breach system security. To limit the events forwarded to the destination, configure filters using the **filter** command.

change

Instructs all events in the user activity stream to be sent to the destination configured in the **to** command for this destination *log-id*. The change event stream contains all events that directly affect the configuration or operation of this node. To limit the events forwarded to the change stream destination, configure filters using the filter command.

debug-trace

Instructs all events in the debug-trace event stream to be sent to the destination defined in the **to** command for this destination *log-id*. The debug-trace event stream contains all events that pertain to trace or other debugging information. To limit the events forwarded to the destination, configure filters using the **filter** command.

Context

[Tree] (config>router>mpls>lsp-template from)

[Tree] (config>router>mpls>lsp from)

Full Context

configure router mpls lsp-template from

configure router mpls lsp from

Description

This optional command specifies the IP address of the ingress router for the LSP. When this command is not specified, the system IP address is used. IP addresses that are not defined in the system are allowed. If an invalid IP address is entered, LSP bring-up fails and an error is logged.

If an interface IP address is specified as the **from** address, and the egress interface of the LSP nexthop IP address is a different interface, the LSP is not signaled. As the egress interface changes due to changes in the routing topology, it is recommended to set the **from** IP address to the system IP address or to the address of a loopback interface to ensure the LSP recovers.

Only one **from** address can be configured.

Default

The system IP address

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

ip-address

Specifies the IP address of the ingress router. This can be either the interface, the system or a loopback interface IP address. If the IP address is local, the LSP must egress through that local interface which ensures local strictness. When the LSP type is **sr-te**, then an IPv6 address can be used.

Values ipv4-address — a.b.c.d

ipv6-address — x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x — 0 to FFFF (hexadecimal)

d — 0 to 255 (decimal)

Full Context

configure li log log-id from

Description

This command configures a bit mask that specifies the log event source stream(s) to be forwarded to the destination specified in the log destination (memory, session, SNMP). Events from more than one source can be forwarded to the log destination.

Parameters

li

Specifies the **li** event stream that contains all events configured for Lawful Intercept activities.

If the requester does not have access to the **li** context, the event stream will fail.

Full Context

configure oam-pm session mpls lsp rsvp-auto from

Description

One of three mandatory configuration statements that are required to identify automatically create RSVP LSPs, created using **config>router>mpls>lsp-template**. The **config>router>mpls>auto-lsp** *lsp-template* links three distinct functions. The **config>router>policy-options>prefix-list**, **config>router>policy-options>policy-statement>entry>from** and config>router>mpls> lsp-template. The from address under the test context is the same as the config>router>mpls>lsp-template>from address.

The three required identifiers are from, lsp-template and to, all under this container.

The **no** form of this command deletes the IP address from the configuration.

Parameters

ipv4-address

Specifies the IPv4 address.

Values a.b.c.d.

Platforms

Description

This command selects the source stream to be sent to a log destination.

One or more source streams must be specified. The source of the data stream must be identified using the **from** command before you can configure the destination using the **to** command. The **from** command can identify multiple source streams in a single statement (for example: **from main change debug-trace**).

Only one **from** command may be entered for a single *log-id*. If multiple **from** commands are configured, then the last command entered overwrites the previous **from** command.

The **no** form of this command removes all previously configured source streams.

Parameters

main

Instructs all events in the main event stream to be sent to the destination defined in the **to** command for this destination *log-id*. The main event stream contains the events that are not explicitly directed to any other event stream. To limit the events forwarded to the destination, configure filters using the **filter** command.

security

Instructs all events in the security event stream to be sent to the destination defined in the **to** command for this destination *log-id*. The security stream contains all events that affect attempts to breach system security such as failed login attempts, attempts to access MIB tables to which the user is not granted access or attempts to enter a branch of the CLI to which access has not been granted. To limit the events forwarded to the destination, configure filters using the **filter** command.

change

Instructs all events in the user activity stream to be sent to the destination configured in the **to** command for this destination *log-id*. The change event stream contains all events that directly affect the configuration or operation of this node. To limit the events forwarded to the change stream destination, configure filters using the **filter** command.

debug-trace

Instructs all debug-trace messages in the debug stream to be sent to the destination configured in the **to** command for this destination *log-id*. Filters applied to debug messages are limited to application and subject.

[**no**] **garp-flood-evpn**

Context

[Tree] (config>service>vpls>proxy-arp garp-flood-evpn)

Full Context

configure service vpls proxy-arp garp-flood-evpn

Description

This command controls whether the system floods GARP-requests and GARP-replies to the EVPN. The GARPs impacted by this command are identified by the sender's IP being equal to the target's IP and the MAC DA being broadcast.

The **no** form of the command only floods to local SAPs or binds but not to EVPN destinations.

Disabling this command is only recommended in networks where CEs are routers that are directly connected to the PEs. Networks using aggregation switches between the host/routers and the PEs should flood GARP messages in the EVPN to ensure that the remote caches are updated and the BGP does not miss the advertisement of these entries.

Full Context

debug ipsec gateway

Description

This command enables debugging for dynamic IPsec tunnels that terminate on the specified IPsec gateway.

The tunnel to be debugged can be specified by either its source address or source subnet. If a subnet is specified, the system will enable debugging for all tunnels with source addresses in the specified subnet.

Parameters

name

Specifies the name of the IPsec gateway up to 32 characters.

ip-address:port

Specifies the tunnel IP address of the remote peer and, optionally, the remote UDP port of IKE.

nat-ip:port

Specifies the inside IP address of the NAT tunnel and, optionally, the port.

detail

Specifies to display detailed debug information.

no-dpd-debug

Specifies to stop logging IKEv1 and IKEv2 DPD events during debug in order to produce less noise.

ip-prefix/ip-prefix-length

Specifies the subnet of the peer’s tunnel address.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

display-keys

Specifies the IKE-SA and CHILD-SA keys for inclusion in the debug output.

admin certificate gen-local-cert-req

Description

This command generates a PKCS#10 formatted certificate request by using a local existing key pair file.

Parameters

url-string

Specifies the name of the keyfile in cf3:\system-pki\key that is used to generate a certificate request.

Values

url-string	<local-url> [up to 99 characters]
local-url	<cflash-id>/<file-path>
cflash-id	cf1: | cf2: | cf3:

subject-dn

Specifies the distinguish name that is used as the subject in a certificate request, including:

- C-Country
- ST-State
- O-Organization name
- OU-Organization Unit name
- CN-common name

This parameter is formatted as a text string including any of the above attributes. The attribute and its value is linked by using "=", and "," is used to separate different attributes.

For example: C=US,ST=CA,O=ALU,CN=SR12

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Values attr1=val1,attr2=val2... where: attrN={C| ST| O| OU| CN}, 256 chars max

domain-name

Specifies a domain name string can be specified and included as the dNSName in the Subject Alternative Name extension of the certificate request.

ip-address

Specifies an IPv4 address string can be specified and included as the ipAddress in the Subject Alternative Name extension of the certificate request.

cert-req-file-url

Specifies the certificate URL. This URL could be either a local CF card path and filename to save the certificate request; or an FTP URL to upload the certificate request.

hash-algorithm

Specifies the hash algorithm to be used in a certificate request.

Values sha1, sha224, sha256, sha384, sha512

Platforms

18.6 general-port

general-port

Syntax

general-port *port-number*

no general-port

Context

[Tree] (config>system>snmp general-port)

Full Context

configure system snmp general-port

Description

This command configures the port number used to receive SNMP request messages and send replies.

For the port used for SNMP notifications, configure the **configure log snmp-trap-group trap-target port** command.

The **no** form of the command reverts to the default value.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Default

general-port 161

Parameters

port-number

Specifies the port number used to send SNMP traffic other than traps.

Values 1 to 65535

Platforms

All

18.7 generate-basic-fec-only

generate-basic-fec-only

Syntax

[**no**] **generate-basic-fec-only**

Context

[Tree] (config>router>ldp generate-basic-fec-only)

Full Context

configure router ldp generate-basic-fec-only

Description

This command configures mLDP to generate a basic FEC, even if the actual root node is resolved using BGP. This functionality is useful when a connected router does not support the mLDP recursive FEC type.

This command only supports recursive opaque type 7 FECs and non-recursive type 1 FECs.

The **no** form of this command causes mLDP to generate a recursive FEC when the actual root node is resolved using BGP.

Default

no generate-basic-fec-only

configure subscriber-mgmt diameter-application-policy gy include-avp ggsn-address

Description
The command includes the GGSN-Address AVP value in all Diameter DCCA CCR messages. The value is either the local IPv4 address or local IPv6 address used to set up the diameter peer.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **no** form of this command removes the GGSN-Address AVP from the Diameter DCCA CCR messages.

Parameters

ipv4 | ipv6

Specifies to include either the IPv4 or IPv6 address.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

18.16 gi-address

gi-address

Syntax

gi-address *ip-address*

no gi-address

Context

[Tree] (config>subscr-mgmt>loc-user-db>ipoe>host gi-address)

Full Context

configure subscriber-mgmt local-user-db ipoe host gi-address

Description

This command allows selection of GI addresses based on the host entry in LUDB.

The gi-address must be a valid address (associated with an interface) within the routing context that received the DHCP message on the access side.

The **no** form of this command reverts to the default.

Parameters

ip-address

Specifies the IPv4 gi-address.

Values a.b.c.d

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

configure service ies subscriber-interface group-interface dhcp gi-address

configure service ies subscriber-interface dhcp gi-address

configure service vprn subscriber-interface dhcp gi-address

configure service vprn interface dhcp gi-address

Description

This command configures the gateway interface address for the DHCP relay. A subscriber interface can include multiple group interfaces with multiple SAPs. The GI address is needed, when the router functions as a DHCP relay, to distinguish between the different subscriber interfaces and potentially between the group interfaces defined.

By default, the GI address used in the relayed DHCP packet is the primary IP address of a normal IES interface. Specifying the GI address allows the user to choose a secondary address. For group interfaces a GI address must be specified under the group interface DHCP context or subscriber-interface DHCP context in order for DHCP to function.

The **no** form of this command reverts to the default.

Parameters

ip-address

Specifies the host IP address to be used for DHCP relay packets.

Values a.b.c.d

src-ip-address

Specifies that this GI address is to be the source IP address for DHCP relay packets. This parameter is not applicable for PPPoE DHCP client messages (**dhcp client-applications ppp**).

18.17 global

global

Syntax

global *file-url*

no global

Context

[Tree] (config>system>login-control>login-scripts global)

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Full Context

configure system login-control login-scripts global

Description

This command enables an operator to define a common CLI script that executes when any user logs into a CLI session. This login exec script is executed when any user (authenticated by any means including local user database, TACACS+, or RADIUS) opens a CLI session. This allows a user, for example, to define a common set of CLI aliases that are made available on the router for all users. This global login exec script is executed before any user-specific login exec files that may be configured.

This CLI script executes in the context of the user who opens the CLI session. Any commands in the script that the user is not authorized to execute will fail.

The **no** form of this command disables the execution of a global login-script.

Default

no global

Parameters

file-url

The path or directory name.

Platforms

All

18.18 global-id

global-id

Syntax

global-id *global-id*

no global-id

Context

[Tree] (config>router>mpls>mpls-tp global-id)

Full Context

configure router mpls mpls-tp global-id

Description

This command configures the MPLS-TP Global ID for the node. This is used as the 'from' Global ID used by MPLS-TP LSPs originating at this node. If a value is not entered, the Global ID is taken to be Zero. This is used if the global-id is not configured. If an operator expects that inter-domain LSPs will be configured, then it is recommended that the global ID should be set to the local ASN of the node, as configured under

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

config>**system**. If two-byte ASNs are used, then the most significant two bytes of the global-id are padded with zeros.

In order to change the value of the **global-id**, **config**>**router**>**mpls**>**mpls-tp** must be in the shutdown state. This will bring down all of the MPLS-TP LSPs on the node. New values a propagated to the system when a no shutdown is performed.

Default

no global-id

Parameters

global-id

Specifies the global ID for the node.

Values 0 to 4294967295

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

18.19 global-sampling-rate

global-sampling-rate

Syntax

global-sampling-rate *sampling-rate*

no global-sampling-rate

Context

[Tree] (config>mirror global-sampling-rate)

Full Context

configure mirror global-sampling-rate

Description

This command configures the global sampling rate. The global sampling rate provides a higher sampling rate than the sampling rate specified on the mirror destination. The global sampling rate, when set, applies to all mirror destination services with the **use-global-sampling-rate** command configured.

The global sampling rate takes precedence over the sampling rate specified on a mirror destination. This means that when both the **global-sampling-rate** command and **configure mirror mirror-dest sampling-rate** command are configured under the same mirror destination, the system automatically samples using higher rate configured with the **global-sampling-rate** command and ignores the lower rate configured with the **sampling-rate** command.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **no** form of this command removes all mirror destinations associated with the global sampling rate and causes all mirror destinations to mirror at the full rate, which means every packet is mirrored unless a mirror destination rate is specified. You must first remove the **use-global-sampling-rate** configuration, before you remove the **global-sampling-rate** configuration.

Default

no global-sampling-rate

Parameters

sampling-rate

Specifies the global sampling rate. The highest global sampling rate is 1 out of 2 packets and the lowest rate is 1 out of 255. For example, when 2 is the configured rate, the mirror destination samples 1 out of every 2 packets, or equivalent to sampling 50% of packets.

Values 2 to 255

Platforms

All

18.20 global-sid-entries

global-sid-entries

Syntax

global-sid-entries *global-sid-entries*

Context

[Tree] (conf>router>sr>srv6>micro-segment global-sid-entries)

Full Context

configure router segment-routing segment-routing-v6 micro-segment global-sid-entries

Description

This command configures the maximum number of unique micro-segment locators that can be configured network wide. The value is expressed as the number of multiples of 1024 and must be the same on every platform network wide.

Default

global-sid-entries 16

Parameters

global-sid-entries

Specifies the maximum number of unique micro-segment locators.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Values 4 to 60 (in steps of 4)

18.49 gr-helper

gr-helper

Syntax

gr-helper [**enable** | **disable**]

Context

[Tree] (config>router>rsvp>if gr-helper)

Full Context

configure router rsvp interface gr-helper

Description

This command enables the RSVP Graceful Restart Helper feature.

The RSVP-TE Graceful Restart helper mode allows the SR OS based system (the helper node) to provide another router that has requested it (the restarting node) a grace period, during which the system will continue to use RSVP sessions to neighbors requesting the grace period. This is typically used when

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

another router is rebooting its control plane but its forwarding plane is expected to continue to forward traffic based on the previously available Path and Resv states.

The user can enable Graceful Restart helper on each RSVP interface separately. When the GR helper feature is enabled on an RSVP interface, the node starts inserting a new Restart_Cap Object in the Hello packets to its neighbor. The restarting node does the same and indicates to the helper node the required Restart Time and Recovery Time.

The GR Restart helper consists of a couple of phases. After it loses Hello communication with its neighbor, the helper node enters the Restart phase. During this phase, it preserves the state of all RSVP sessions to its neighbor and waits for a new Hello message.

After the Hello message is received indicating the restarting node preserved state, the helper node enters the recovery phase in which it starts refreshing all the sessions that were preserved. The restarting node activates all the stale sessions that are refreshed by the helper node. Any Path state that did not get a Resv message from the restarting node after the Recovery Phase time is over, is considered to have expired and is deleted by the helper node causing the correct Path Tear generation downstream.

The duration of the restart phase (recovery phase) is equal to the minimum of the neighbor's advertised Restart Time (Recovery Time) in its last Hello message and the locally configured value of the max-restart (max-recovery) parameter.

When GR helper is enabled on an RSVP interface, its procedures apply to the state of both P2P and P2MP RSVP LSP to a neighbor over this interface.

Default

disable

Platforms

gr-helper-time

Syntax

gr-helper-time max-recovery *recovery-interval* **max-restart** *restart-interval*

no gr-helper-time

Context

[Tree] (config>router>rsvp gr-helper-time)

Full Context

configure router rsvp gr-helper-time

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command configures the local values for the max-recovery and the max-restart intervals used in the RSVP Graceful Restart Helper feature.

The values are configured globally in RSVP but separate instances of the timers are applied to each RSVP interface that has the RSVP Graceful Restart Helper enabled.

The **no** version of this command re-instates the default value for the delay timer.

Default

gr-helper-time max-recovery 300 max-restart 120

Parameters

recovery-interval

Specifies the max recovery interval value in seconds.

Values 1 to 1800

restart-interval

Specifies the max restart interval value in seconds.

Values 1 to 300

18.52 grace-tx-enable

grace-tx-enable

Syntax

[**no**] **grace-tx-enable**

Context

[Tree] (config>system>ethernet>efm-oam grace-tx-enable)

[Tree] (config>port>ethernet>efm-oam grace-tx-enable)

Full Context

configure system ethernet efm-oam grace-tx-enable

configure port ethernet efm-oam grace-tx-enable

Description

Enables the sending of grace for all the enabled EFM-OAM sessions on the node. Disabled by default at the system level and enabled by default at the port level. The combination of the system level and port level configuration will determine if the grace function is enabled on the individual ports. Both the system level and the port level must be enabled in order to support grace on a specific port. If either level is disabled, grace is not enabled on those ports. Enabling grace during an active ISSU or soft reset does not invoke the grace function for the active event.

When both **grace-tx-enable** and **config>system>ethernet>efm-oam dying-gasp-tx-on-reset**, **config>port>ethernet>efm-oam dying-gasp-tx-on-reset** are active on the same port, **grace-tx-enable** takes precedence when a soft reset is invoked if the Peer Vendor OUI being received is 00:16:4d (ALU) or the configured **config>port>ethernet>efm-oam grace-vendor-oui** value. The **grace-tx-enable** command should not be configured if the Nokia Vendor Specific Grace TLV is not supported on the remote peer.

The **no** form of this command disables the sending of the Nokia Vendor Specific Grace TLV.

Default

config>system>ethernet>efm-oam>no grace-tx-enable

grace-tx-enable

Syntax

[**no**] **grace-tx-enable**

Context

[Tree] (config>eth-cfm>system grace-tx-enable)

Full Context

configure eth-cfm system grace-tx-enable

Description

This command enables ETH-CFM grace transmission at the system level when a soft reset message is received and processed by the ETH-CFM module. Individual MEP configuration determines which of the two supported grace functions, ETH-VSM or ETH-ED, is used to announce grace.

This command controls the overall capability to transmit grace and does not control which grace announcement to use. This command also has no impact on the reception and processing of grace-style PDUs.

The **no** form of this command disables ETH-CFM grace transmission at the system level.

Default

grace-tx-enable

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

18.53 grace-vendor-oui

grace-vendor-oui

Syntax

grace-vendor-oui *oui*

no grace-vendor-oui

Context

[Tree] (config>port>ethernet>efm-oam grace-vendor-oui)

Full Context

configure port ethernet efm-oam grace-vendor-oui

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This optional command configures an additional peer vendor OUI which indicates support for the Vendor Specific EFM-OAM Grace functionality, allowing grace to be preferred over dying gasp when both are configured. This is in addition to the Nokia Vendor OUI 00:16:4d.

When both **grace-tx-enable (config>system>ethernet>efm-oam grace-tx-enable**, **config>port>ethernet>efm-oam grace-tx-enable)** and **dying-gasp-tx-on-reset (config>system>ethernet>efm-oam dying-gasp-tx-on-reset**, **config>port>ethernet>efm-oam dying-gasp-tx-on-reset)** are active on the same port, **grace-tx-enable** takes precedence when a soft reset is invoked if the Peer Vendor OUI being received is 00:16:4d (ALU) or the configured **grace-vendor-oui** value. The **grace-tx-enable** command should not be configured if the Nokia Vendor Specific Grace TLV is not supported on the remote peer, including Nokia 7750 SR equipment prior to release 11.0 R4.

The **no** form of this command removes the additional Vendor OUI but does not remove the Nokia 00:16:4d value.

Default

no grace-vendor-oui

Parameters

oui

Hex value in the range 00:00:00 to FF:FF:FF.

graceful-restart

Syntax

[**no**] **graceful-restart**

Context

[Tree] (config>service>vprn>isis graceful-restart)

Full Context

configure service vprn isis graceful-restart

Description

This command enables IS-IS graceful restart (GR) to minimize service interruption. When the control plane of a GR-capable router fails or restarts, the neighboring routers (GR helpers) temporarily preserve IS-IS forwarding information. Traffic continues to be forwarded to the restarting router using the last known forwarding tables. If the control plane of the restarting router becomes operationally and administratively up within the grace period, the restarting router resumes normal IS-IS operation. If the grace period expires, then the restarting router is presumed inactive and the IS-IS topology is recalculated to route traffic around the failure.

The **no** form of this command disables graceful restart and removes the graceful restart configuration from the IS-IS instance.

Context

[Tree] (config>router>isis graceful-restart)

Full Context

configure router isis graceful-restart

Description

This command enables IS-IS graceful restart (GR) to minimize service interruption. When the control plane of a GR-capable router fails or restarts, the neighboring routers (GR helpers) temporarily preserve IS-IS forwarding information. Traffic continues to be forwarded to the restarting router using the last known forwarding tables. If the control plane of the restarting router becomes operationally and administratively up within the grace period, the restarting router resumes normal IS-IS operation. If the grace period expires, then the restarting router is presumed inactive and the IS-IS topology is recalculated to route traffic around the failure.

The **no** form of this command disables graceful restart and removes the graceful restart configuration from the IS-IS instance.

18.55 graceful-shutdown

graceful-shutdown

Syntax

[**no**] **graceful-shutdown**

Context

[Tree] (config>router>rsvp graceful-shutdown)

[Tree] (config>router>rsvp>interface graceful-shutdown)

Full Context

configure router rsvp graceful-shutdown

configure router rsvp interface graceful-shutdown

Description

This command initiates a graceful shutdown of the specified RSVP interface or all RSVP interfaces on the node if applied at the RSVP level. These are referred to as maintenance interface and maintenance node, respectively.

To initiate a graceful shutdown the maintenance node generates a PathErr message with a specific error sub-code of Local Maintenance on TE Link required for each LSP that is exiting the maintenance interface.

The node performs a single make-before-break attempt for all adaptive CSPF LSPs it originates and LSP paths using the maintenance interfaces. If an alternative path for an affected LSP is not found, then the LSP is maintained on its current path. The maintenance node also tears down and re-signals any detour LSP path using listed maintenance interfaces as soon as they are not active.

The maintenance node floods an IGP TE LSA/LSP containing Link TLV for the links under graceful shutdown with TE metric set to 0xffffffff and Unreserved Bandwidth parameter set to zero (0).

A head-end LER node, upon receipt of the PathErr message performs a single make-before-break attempt on the affected adaptive CSPF LSP. If an alternative path is not found, then the LSP is maintained on its current path.

A node does not take any action on the paths of the following originating LSPs after receiving the PathErr message:

a. An adaptive CSPF LSP for which the PathErr indicates a node address in the address list and the node corresponds to the destination of the LSP. In this case, there are no alternative paths which can be found.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

b. An adaptive CSPF LSP whose path has explicit hops defined using the listed maintenance interface(s)/ node(s).

c. A CSPF LSP with the adaptive option disabled and which current path is over the listed maintenance interfaces in the PathErr message. These are not subject to make-before-break.

d. A non CSPF LSP which current path is over the listed maintenance interfaces in the PathErr message.

The head-end LER node upon receipt of the updates IPG TE LSA/LSP for the maintenance interfaces updates the TE database. This information will be used at the next scheduled CSPF computation for any LSP which path may traverse any of the maintenance interfaces.

The **no** form of this command disables the graceful shutdown operation at the RSVP interface level or at the RSVP level. The configured TE parameters of the maintenance links are restored and the maintenance node floods the links.

18.57 granularity

granularity

Syntax

granularity {**percent** *percent-of-admin-pir* | **rate** *rate-in-kilobits-per-second*}

no granularity

Context

[Tree] (config>qos>adv-config-policy>child-control>bandwidth-distribution granularity)

Full Context

configure qos adv-config-policy child-control bandwidth-distribution granularity

Description

This command is used to create a step-like behavior where the operational PIR will round up to the nearest increment of the specified granularity before being applied to the child. The only exception is when the distributed bandwidth is less than 1% above a lower step value, in which case the lower step value is used.

This step-like behavior may be useful when the bandwidth used by an active child is well known. While the **above-offered-cap** command automatically adds a specified amount to the operational PIR of a child, the **granularity** command only increments the operational PIR to the next step value. While not expected to be used in conjunction, the **above-offered-cap** and **granularity** commands may be used simultaneously, in which case the above-offered-cap increase will be applied first, followed by the granularity rounding to the next step value.

If the **granularity** command is used with a percent-based value, the rounding up function of the configured PIR value on the policer or queue is based on the child's administrative PIR. In this case, care should be taken that the child is either configured with an explicit PIR rate (other than max) or the child's administrative PIR is defined using the percent-rate command with the local parameter enabled if an explicit value is not desired. When a maximum PIR is in use on the child, the system attempts to interpret the maximum child forwarding rate. This rate could be very large if the child is associated with multiple ingress or egress ports.

If the child's administrative PIR is modified while a percent-based granularity is in effect, the system automatically uses the new relative rounding value the next time the child's operational PIR is determined.

When this command is not specified or removed, the system makes no attempt to round up the child's determined operational PIR.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **no** form of this command is used to remove the operational PIR rounding behavior from all child policers and queues associated with the policy.

Parameters

percent-of-admin-pir

When the percent qualifier is used, the following percent-of-admin-pir parameter specifies the percentage of the child's administrative PIR that should be used as the rounding step value. If a value of 0 or 0.00 is used, the system will interpret this equivalent to no granularity.

Values 0.00 to 100.00

rate-in-kilobits-per-second

When the rate qualifier is used, the following rate-in-kilobits-per-second parameter specifies an explicit rate, in kb/s, that should be used as the child's rounding step value. If a rate step of 0 is specified, the system interprets this equivalent to no granularity.

Values 0 to 100,000,000

Platforms

All

granularity

Syntax

granularity {**percent** *percent-of-admin-pir* | **rate** *rate-in-kilobits-per-second*}

no granularity

Context

[Tree] (config>qos>adv-config-policy>child-control>offered-measurement granularity)

Full Context

configure qos adv-config-policy child-control offered-measurement granularity

Description

This command is used to adjust the sensitivity of the virtual scheduler to changes in the child offered rate. As the child offered rate is determined, it is compared to the previous offered rate. If the delta does not exceed the sensitivity threshold determined for the current offered rate, the change in offered rate is ignored for that iteration.

While it is assumed that changing the offered rate change sensitivity will be a rare occurrence, it may be prudent to react to smaller changes in the offered rate of a particular child policer or queue. Another possible reason for changing the sensitivity is that it may be desired to lower the impact of changes in offered rate on the virtual scheduler for a particular child by raising the granularity.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

A side effect of higher sensitivity (lower granularity) is that the virtual scheduler may need to adjust the distributed bandwidth between all children more often, resulting in the possibility of lowering resources available to other virtual scheduler instances on the slot.

A side effect of lower sensitivity (higher granularity) is that the parent virtual scheduler may distribute insufficient bandwidth to the child resulting in dropped packets.

If the granularity command is used with a percent-based value, the sensitivity is a function of the configured PIR value on the policer or queue. In this case, care should be taken that the child is either configured with an explicit PIR rate (other than max) or the child's administrative PIR is defined using the percent-rate command with the local parameter enabled if an explicit value is not desired. When a maximum PIR is in use on the child, the system attempts to interpret the maximum child forwarding rate. This rate could be very large if the child is associated with multiple ingress or egress ports.

Except for the overall cap on the offered input into the virtual scheduler, the child's administrative PIR has no effect on the calculated sensitivity if an explicit rate is specified.

If the child's administrative PIR is modified while a percent-based granularity is in effect, the system automatically uses the new relative sensitivity value the next time the child's offered rate is determined.

The **no** form of this command is used to restore the default offered rate sensitivity behavior to all child policers and queues associated with the policy.

Parameters

percent-of-admin-pir

When the percent qualifier is used, this parameter specifies the percentage of the child's administrative PIR that are used as the threshold sensitivity to the offered rate change. If a value of 0 or 0.00 is used, the system will interpret this equivalent to no granularity.

Values 1.00 to 100.00

rate-in-kilobits-per-second

When the rate qualifier is used, this parameter specifies an explicit rate, in kb/s, that are used as the child's offered rate change sensitivity value. If a rate sensitivity of 0 is specified, the system interprets this equivalent to no granularity.

Values 0 to 100,000,000

Description

Commands in this context add a static multicast group as a (*, G) or as one or more (S,G) records. When a static MLD or IGMP group is added, multicast data for that (*,G) or (S,G) is forwarded to the specific SAP or SDP without receiving any membership report from a host.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

grp-ip-address

Specifies an IGMP multicast group address that receives data on an interface. The IP address must be unique for each static group.

grp-ipv6-address

Specifies an MLD multicast group address that receives data on an interface. The IP address must be unique for each static group.

Values ipv6-address:

- x:x:x:x:x:x:x:x (eight 16-bit pieces)
- x:x:x:x:x:x:d.d.d.d
- x: [0 to FFFF]H
- d: [0 to 255]D

configure service vprn bgp group

Description

This command creates a context to configure a BGP peer group.

The **no** form of this command deletes the specified peer group and all configurations associated with the peer group. The group must be shut down before it can be deleted.

Parameters

name

Specifies the peer group name. Allowed values is a string up to 64 characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed between double quotes.

esm-dynamic-peer

Specifies that the given BGP group is used by BGP peers created dynamically based on subscriber-hosts pointing to corresponding BGP peering policy. There can be only one

Context

[Tree] (config>service>vprn>igmp>if>static group)

Full Context

configure service vprn igmp interface static group

Description

This command adds a static multicast group either as a (*,G) or one or more (S,G) records. Use IGMP static group memberships to test multicast forwarding without a receiver host. When IGMP static groups are enabled, data is forwarded to an interface without receiving membership reports from host members.

When static IGMP group entries on point-to-point links that connect routers to a rendezvous point (RP) are configured, the static IGMP group entries do not generate join messages toward the RP.

Parameters

grp-ip-address

Specifies an IGMP multicast group address that receives data on an interface. The IP address must be unique for each static group. The address must be in dotted decimal notation.

start *grp-ip-address*

Specifies the start multicast group address.

end *grp-ip-address*

Specifies the end multicast group address.

step *ip-address*

Specifies the step increment.

Platforms

All

group

Syntax

[**no**] **group** *group-name*

Context

[Tree] (config>service>vprn>msdp group)

Full Context

configure service vprn msdp group

Description

This command enables access to the context to create or modify a Multicast Source Discovery Protocol (MSDP) group. To configure multiple MSDP groups, include multiple group statements.

By default, the group's options are inherited from the global MSDP options. To override these global options, group-specific options within the group statement can be configured.

If the group name provided is already configured then this command only provides the context to configure the options pertaining to this group.

If the group name provided is not already configured, then the group name must be created and the context to configure the parameters pertaining to the group should be provided. In this case, the $ prompt to indicate that a new entity (group) is being created should be used.

For a group to be of use, at least one peer must be configured.

Default

no group

Parameters

group-name

Specifies a unique name for the MSDP group.

group

Syntax

[**no**] **group** *grp-ip-address*

Context

[Tree] (config>router>igmp>tunnel-interface>static group)

Full Context

configure router igmp tunnel-interface static group

Description

Commands in this context add a static multicast group either as a (*,G) or one or more (S,G) records.

The user can assign static multicast group joins to a tunnel interface associated with an RSVP P2MP LSP.

A given (*,G) or (S,G) can only be associated with a single tunnel interface.

A multicast packet which is received on an interface and which succeeds the RPF check for the source address will be replicated and forwarded to all OIFs which correspond to the branches of the P2MP LSP. The packet is sent on each OIF with the label stack indicated in the NHLFE of this OIF. The packets will also be replicated and forwarded natively on all OIFs which have received IGMP or PIM joins for this (S,G).

The multicast packet can be received over a PIM or IGMP interface which can be an IES interface, a spoke SDP terminated IES interface, or a network interface.

Parameters

grp-ip-address

Specifies a multicast group address that receives data on a tunnel interface. The IP address must be unique for each static group.

Platforms

All

group

Syntax

group

Syntax

[**no**] **group** *group-name*

Context

[Tree] (config>router>msdp group)

Full Context

configure router msdp group

Description

Commands in this context configure an MSDP group. Specifying a group name for the first time creates the group. To configure multiple MSDP groups, include multiple group statements.

By default, the group's options are inherited from the global MSDP options. To override these global options, configure the group-specific options within the **group** context.

For a group to function, at least one peer must be configured.

The **no** form of this command removes the specified group from the MSDP configuration.

Default

no group

Parameters

group-name

Specifies a MSDP group name, up to 32 characters.

Platforms

All

group

Syntax

group *group-id* **rate** *rate*

no group *group-id*

Context

[Tree] (config>qos>hs-scheduler-policy group)

Full Context

configure qos hs-scheduler-policy group

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command defines the maximum rate allowed for the scheduling classes mapped to the specified *group-id*. A group is a scheduling component used to combine up to six consecutive scheduling classes into a single strict priority level. Each scheduling class within the group has an associated weight. When the scheduler is servicing the strict level associated with the group, the ratio of bandwidth allocated to each scheduling class within the group during congestion is relative to the ratio of the weight of each active member.

The **no** form of the command reverts to the default.

Default

group 1 rate max

Parameters

group-id

Specifies the group ID. The group always exists and does not need to be created prior to defining group membership.

Values 1

rate

Specifies the maximum rate in megabits per second. When the **max** keyword follows the rate keyword, the bandwidth limitation is removed from the group. The **max** keyword and the *rate* parameter are mutually exclusive. Either **max** or a rate value must follow the **rate** keyword.

Values 1 to 100000, max

Platforms

7750 SR-7/12/12e

group

Syntax

group *name* [**create**]

no group *name*

Context

[Tree] (config>qos>port-scheduler-policy group)

Full Context

configure qos port-scheduler-policy group

Description

This command defines a weighted scheduler group within a port scheduler policy.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The port scheduler policy defines a set of eight priority levels. The weighted scheduler group allows for the application of a scheduling weight to groups of child queues competing at the same priority level of the port scheduler policy applied to a Vport defined in the context of the egress of an Ethernet port or applied to the egress of an Ethernet port.

Up to eight groups can be defined within each port scheduler policy. One or more levels can map to the same group. A group has a rate and, optionally, a cir-rate, and inherits the highest scheduling priority of its member levels. A group receives bandwidth from the port or from the Vport and distributes it within the member levels of the group according to the weight of each level within the group.

Each priority level will compete for bandwidth within the group based on its weight under a congestion situation. If there is no congestion, a priority level can achieve up to its rate (cir-rate) worth of bandwidth.

CLI will enforce that mapping of levels to a group are contiguous. A user would not be able to add a priority level to a group unless the resulting set of priority levels is contiguous.

The **no** form of this command removes the group from the port scheduler policy.

Parameters

name

Specifies the name of the weighted scheduler group and can be up to 32 ASCII characters.

create

This keyword is mandatory when creating the specified group.

Platforms

Full Context

configure service oper-group hold-time group

Description

The **group down** form of the command configures the number of seconds to wait before notifying clients monitoring this group when its operational status transitions from up to down.

The **group up** form of the command configures the number of seconds to wait before notifying clients monitoring this group when its operational status transitions from down to up. A value of zero indicates that transitions are reported immediately to monitoring clients. The up time option is a must to achieve fast convergence: when the group comes up, the monitoring MH site that tracks the group status may wait without impacting the overall convergence; there is usually a pair MH site that is already handling the traffic.

The **no** form of the command sets the values back to the default.

Default

group down 0

group up 4

Parameters

time

Specifies the group up or group down time value.

Values 0 to 3600

Full Context

configure subscriber-mgmt gtp apn-policy apn defaults group-interface

Description

This command configures the default group interface where the hosts of the GTP connection is enabled. The group interface must be of type **gtp**.

The **no** form of this command removes the default group interface. In this case, a group interface must be specified using authentication.

Default

no group-interface

Parameters

interface-name

Specifies the name of the group interface, up to 32 characters.

service-id

Specifies the ID of the service where the group interface resides.

Values

service-id: 1 to 2147483647

svc-name: up to 64 characters

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

configure service vprn igmp group-interface

Description

This command configures IGMP group interfaces.

The **no** form of this command reverts to the default.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

ip-int-name

Specifies the name of the IP interface. If the string contains special characters (#, ?, space), the entire string must be enclosed between double quotes.

fwd-service *service-id*

Specifies the service ID. This is only configured in the retailer VRF. This construct references the wholesaler service under which the group-interface (and the subscriber) is actually defined.

Values 1 to 2147483650, svc-name up to 64 characters

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

Context

[Tree] (config>router>igmp>if group-interface)

[Tree] (config>router>igmp group-interface)

Full Context

configure router igmp interface group-interface

configure router igmp group-interface

Description

This command enables IGMP on a group-interface in a VRF context. Activating IGMP under the group-interface is a prerequisite for subscriber replication. The group-interface is also needed so that MCAC can be applied and various IGMP parameters defined.

This command can be used in a regular, wholesaler or retailer type of VRF. The retailer VRF does not have the concept of group-interfaces under the subscriber-interface hierarchy. In the case that this command is applied to a retailer VRF instance, the optional **fwd-service** command must be configured. The **fwd-service** command is referencing the wholesaler VRF in which the traffic is ultimately replicated. Redirection in the retailer VRF is supported.

This command enables IGMP on a group-interface in the Global Routing Table (GRT). The group-interface in GRT is defined under the IES service. Activating IGMP under the group-interface is a prerequisite for subscriber replication. The group-interface is also needed so that MCAC can be applied and various IGMP parameters defined.

Parameters

ip-int-name

Specifies the name of the group interface.

Platforms

All

- configure router igmp interface group-interface

Full Context

configure router mld group-interface

Description

This command creates and enables the context to configure MLD group interface parameters.

The **no** form of this command removes the interface name from the MLD configuration.

Parameters

ip-int-name

Specifies the IP group interface name. Interface names must be unique within the group of defined IP interfaces for **config router interface** and **config service ies interface** commands. An interface name cannot be in the form of an IP address. Interface names can be any string up to 32 characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

18.75 group-name

group-name

Syntax

group-name *group-name* **value** *group-value*

no group-name *group-name*

Context

[Tree] (config>service>sdp-group group-name)

Full Context

configure service sdp-group group-name

Description

This command defines SDP administrative groups, referred to as SDP admin groups.

SDP admin groups provide a way for services using a pseudowire template to automatically include or exclude specific provisioned SDPs. SDPs sharing a specific characteristic or attribute can be made members of the same admin group. When users configure a pseudowire template, they can include and/or exclude one or more admin groups. When the service is bound to the pseudowire template, the SDP selection rules will enforce the admin group constraints specified in the **sdp-include** and **sdp-exclude** commands.

A maximum of 32 admin groups can be created. The group value ranges from zero (0) to 31. It is uniquely associated with the group name at creation time. If the user attempts to configure another group name for a group value that is already assigned to an existing group name, the SDP admin group creation is failed. The same happens if the user attempts to configure an SDP admin group with a new name but associates it to a group value already assigned to an existing group name.

The **no** option of this command deletes the SDP admin group but is only allowed if the group-name is not referenced in a PW template or SDP.

Parameters

group-name

Specifies the name of the SDP admin group. A maximum of 32 characters can be entered.

group-value

Specifies the group value associated with this SDP admin group. This value is unique within the system.

Values 0 to 31

Context

[Tree] (config>service>vprn>mvpn>rpf-select>core-mvpn group-prefix)

Full Context

configure service vprn mvpn rpf-select core-mvpn group-prefix

Description

This command configures multicast group IPv4 prefixes for the MVPN with per-group mapping extranet functionality. Multiple lines are allowed. Duplicate prefixes are ignored.

When the starg option is specified, extranet functionality is enabled for PIM ASM as for the specified group. When the option is not specified (not recommended with PIM ASM), the PIM ASM join will be mapped and data plane will be established, but the control plane will not be updated on SPT switchover, unless the switchover is driven by a CPE router on a receiver side.

The **no** form of this command deletes specified prefix from the list, or removes mapping of all prefixes if group-prefix any was specified.

Parameters

ip-address/mask

Specifies the IPv4 multicast address prefix with mask. Up to 8 addresses can be specified in a single statement.

Platforms

All

group-prefix

Syntax

group-prefix *ip-address*/*mask* [*ip-address*/*mask*...(up to 8 max)] [**starg**]

[Tree] (config>router>igmp>if>ssm-translate grp-range)

Full Context

configure router igmp ssm-translate grp-range

configure router igmp interface ssm-translate grp-range

Description

This command is used to configure group ranges which are translated to SSM (S,G) entries.

Parameters

start

An IP address that specifies the start of the group range.

end

An IP address that specifies the end of the group range. This value should always be greater than or equal to the value of the *start* value.

Platforms

All

grp-range

Syntax

[**no**] **grp-range** *start end*

Context

Full Context

configure router mld ssm-translate grp-range

configure router mld interface ssm-translate grp-range

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command is used to configure group ranges which are translated to SSM (S,G) entries.

The **no** form of this command removes the start and end ranges from the configuration.

Parameters

start

Specifies an IP address for the start of the group range.

end

Specifies an IP address for the end of the group range. This value should always be greater than or equal to the value of the *start* value.

configure application-assurance group policy app-qos-policy entry action gtp-filter

Description

This command assigns an existing GTP filter as an action on flows matching this AQP entry.

The **no** form of this command removes this GTP filter from actions on flows matching this AQP entry.

Default

no gtp-filter

Parameters

gtp-filter-name

Specifies the name of an existing GTP filter for this application assurance profile. The *gtp-filter-name* is configured in the **config>app-assure>group[:partition]>gtp>gtp-filter** context.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

gtp-filter

Syntax

gtp-filter *filter-name*

Context

[Tree] (config>app-assure>group>statistics>tca gtp-filter)

Full Context

configure application-assurance group statistics threshold-crossing-alert gtp-filter

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command configures TCA generation for a GTP filter.

Parameters

filter-name

Specifies the name of the GTP filter, up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

gtp-filter

Syntax

gtp-filter *gtp-filter-name* [**create**]

no gtp-filter *gtp-filter-name*

Context

[Tree] (config>app-assure>group>gtp gtp-filter)

Full Context

configure application-assurance group gtp gtp-filter

Description

This command allows AA to treat traffic on UDP port number 2152 as GTP-u. Without further specifying any other parameters within this GTP context, AA performs basic GTP-u header sanity checks and discards packets that are malformed. This GTP context allows the operator to configure various GTP filters (maximum of 128 GTP filters).

Parameters

gtp-filter-name

Specifies a GTP filter name, up to 32 characters.

create

Keyword used to create the GTP filter name and parameters.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

no gtp-in-gtp direction *direction*

Context

[Tree] (config>app-assure>group>statistics>tca>gtp-filter gtp-in-gtp)

Full Context

configure application-assurance group statistics threshold-crossing-alert gtp-filter gtp-in-gtp

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command configures a TCA for the counter capturing drops due to the GTP filter GTP-in-GTP packet check. A gtp-in-gtp drop TCA can be created for traffic generated from the subscriber side of AA (**from-sub**) or for traffic generated from the network toward the AA subscriber (**to-sub**). The **create** keyword is mandatory when creating a gtp-in-gtp TCA.

Parameters

direction

Specifies the traffic direction.

Values from-sub, to-sub

create

Keyword used to create the TCA.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

gtp-in-gtp

Syntax

gtp-in-gtp

Context

[Tree] (config>app-assure>group>gtp>gtp-fltr gtp-in-gtp)

Full Context

configure application-assurance group gtp gtp-filter gtp-in-gtp

Description

This command configures GTP-in-GTP packet filtering.

Default

gtp-in gtp permit

Parameters

permit | deny

Specifies the action to take for GTP packets that are encapsulated in GTP (GTP-in-GTP).

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

18.98 gtp-ping

gtp-ping

Syntax

gtp-ping *gtp-interface* [**router** *router-instance*] [**source** *ip-address*] **destination** *ip-address* **udp-port** *port-number* [**retry-count** *count*] [**time-out** *timeout*]

Context

[Tree] (oam gtp-ping)

Full Context

oam gtp-ping

Description

This command verifies whether a GTPv2 peer is reachable and correctly responds to GTPv2-C Echo Request messages. This command can be executed if no peering exists for the specified peer.

Parameters

gtp-interface

Specifies the GTP interface where the echo is sent.

Values s11, s1u, gnc, gnu, s2bc, s2bu, s2ac, s2au

router-instance

Specifies the router or VRF in which the GTP echo is sent.

Values *router-name* — Base, management

vprn-svc-id — 1 to 2147483647

Default Base

source ip-address

Specifies the source IP address to be used in the GTP ping.

Values a.b.c.d

destination ip-address

Specifies the destination IP address to be used in the GTP ping.

Values a.b.c.d

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

port-number

Specifies the port number to be used. Suggested port numbers are 2123 (GTP-C) or 2152 (GTP-U).

Values 1 to 65535

count

Specifies the number of echo message requests before the peer is considered unreachable.

Values 1 to 100

Default 1

timeout

Specifies the timeout, in seconds, of a single echo message.

Values 1 to 10

Default 5

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

18.99 gtp-sanity-drop

gtp-sanity-drop

Syntax

gtp-sanity-drop direction *direction* [**create**]

no gtp-sanity-drop direction *direction*

Context

[Tree] (config>app-assure>group>statistics>tca gtp-sanity-drop)

Full Context

configure application-assurance group statistics threshold-crossing-alert gtp-sanity-drop

Description

This command configures a TCA for the counter capturing drops due to basic GTP header sanity checks, such as validating that the GTP-U version is 1 and that the protocol bit is set to 1 for UDP traffic destined to port 2152. A GTP sanity drop TCA can be created for traffic generated from the subscriber side of AA (**from-sub**) or for traffic generated from the network toward the AA subscriber (**to-sub**). The **create** keyword is mandatory when creating a default action TCA.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

direction

Specifies the traffic direction.

Values from-sub, to-sub

create

Keyword used to create the TCA.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

18.100 gtp-traffic

gtp-traffic

Syntax

[**no**] **gtp-traffic**

Context

[Tree] (config>app-assure>group>policer gtp-traffic)

Full Context

configure application-assurance group policer gtp-traffic

Description

This command provides a mechanism to configure a policer to function at the GTP tunnel level. GTP tunnels are defined by a TEID and destination IP address as opposed to normal flows that are defined by IP 5 tuple values. By setting this value, the policer then can be used to limit GTP traffic (SeGW GTP firewall application).

The **no** form of this command resets policer behavior to act at the normal 5 tuple flow level and not at the GTP tunnel level.

Default

no gtp-traffic

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

gtp-tunnel-database

Context

[Tree] (config>app-assure>group>gtp>gtp-fltr gtp-tunnel-database)

Full Context

configure application-assurance group gtp gtp-filter gtp-tunnel-database

Description

Commands in this context configure GTP advanced firewall functions (such as validating GTP tunnels, sequence numbers, source IP addresses).

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

gtp-tunnel-database

Syntax

gtp-tunnel-database *size*

Context

[Tree] (config>isa>aa-grp>shr-res-pool gtp-tunnel-database)

Full Context

configure isa application-assurance-group shared-resources gtp-tunnel-database

Description

This command configures the allocation of memory resources required for stateful GTP firewall deployment on 3GPP S5/S8/Gn/Gp interfaces.

Default

gtp-tunnel-database 0

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

size

Specifies the percentage of allocated memory resources.

Values 0 to 100

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

18.102 gtp-u-ipv6-checksum

gtp-u-ipv6-checksum

Syntax

[**no**] **gtp-u-ipv6-checksum**

Context

[Tree] (config>subscr-mgmt>gtp gtp-u-ipv6-checksum)

Full Context

configure subscriber-mgmt gtp gtp-u-ipv6-checksum

Description

This command enables the calculation and insertion of a UDP checksum into the GTP-u tunneled traffic over IPv6 transport toward the RAN for 4G and 5G fixed-wireless access.

The **no** form of this command disables the calculation and insertion.

Default

no gtp-u-ipv6-checksum

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

18.103 gtp-user

gtp-user

Syntax

gtp-user

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Context

[Tree] (debug>oam>build-packet>packet>field-override>header gtp-user)

[Tree] (config>test-oam>build-packet>header gtp-user)

Full Context

debug oam build-packet packet field-override header gtp-user

configure test-oam build-packet header gtp-user

Description

This command causes the associated header to be defined as a GTP user header template and enables the context to define the GTP parameters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

18.104 gtp-user-name

gtp-user-name

Syntax

gtp-user-name {**imsi** | **imsi-apn** | **msisdn** | **msisdn-apn**}

no gtp-user-name

Context

[Tree] (config>subscr-mgmt>auth-plcy gtp-user-name)

Full Context

configure subscriber-mgmt authentication-policy gtp-user-name

Description

This command configures the username used to authenticate an FWA session. If a PAP message is present in the PCO IE of the Create Session request, the system uses that for authentication instead of the format specified for this command. If you specify a format that includes APN, the separator is an @ character; for example, msisdn@apn.

The **no** form of this command reverts to the default.

Default

gtp-user-name imsi

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

imsi

Specifies to use IMSI as the username.

imsi-apn

Specifies to use IMSI and APN as the username; for example, imsi@apn.

msisdn

Specifies to use MSISDN as the username.

msisdn-apn

Specifies to use MSISDN and APN as the username; for example, msisdn@apn.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

18.105 gtpc-inspection

gtpc-inspection

Syntax

[**no**] **gtpc-inspection**

Context

[Tree] (config>app-assure>group>gtp gtpc-inspection)

Full Context

configure application-assurance group gtp gtpc-inspection

Description

This command configures the inspection of GTP-C packets. This is relevant only when AA GTP FW is deployed on S8/S5/Gp/Gn interfaces. The **gtpc-inspection** command must be enabled before configuring related features, such as APN filtering, GTP tunnel validation, message-type-v2 filtering, sequence number validation, SRC IP validation.

The **no** form of this command disables GTP-C packet inspection.

Default

no gtpc-inspection

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

gtpv1-c

Syntax

gtpv1-c *type* **direction** {**ingress** | **egress**} **script** [*script*]

no gtpv1-c *type* **direction** {**ingress** | **egress**}

Context

[Tree] (config>python>py-policy gtpv1-c)

Full Context

configure python python-policy gtpv1-c

Description

This command configures a Python script for the specified GTPv1-C message type in the specified direction.

The **no** form of this command reverts to the default.

Parameters

type

Specifies the message type.

Values echo-request, echo-response, version-not-supported, create-pdp-context-request, create-pdp-context-response, delete-pdp-context-request, delete-pdp-context-response, error-indication

direction {ingress | egress}

Specifies if the message is incoming or outgoing.

script

Specifies the name of the Python script, up to 32 characters, that is used to handle the specified message.

Platforms

All

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

18.107 gtpv2-c

gtpv2-c

Syntax

gtpv2-c *type* **direction** {**ingress** | **egress**} **script** [*script*]

no gtpv2-c *type* **direction** {**ingress** | **egress**}

Context

[Tree] (config>python>py-policy gtpv2-c)

Full Context

configure python python-policy gtpv2-c

Description

This command configures a Python script for the specified GTPv2-C message type in the specified direction.

The **no** form of this command reverts to the default.

Parameters

type

Specifies the message type

Values echo-request, echo-response, version-not-supported, create-session-request, create-session-response, delete-session-request, delete-session-response, delete-bearer-request, delete-bearer-response, modify-bearer-request, modify-bearer-response, release-access-bearers-request, release-access-bearers-response, downlink-data-notification, downlink-data-notification-ack, change-notification-request, change-notification-response, stop-paging-indication

direction {ingress | egress}

Specifies if the message is incoming or outgoing.

script

Specifies the name of the Python script, up to 32 characters, that is used to handle the specified message.

no gw-address-range

Context

[Tree] (config>subscr-mgmt>isa-svc-chain>evpn>export gw-address-range)

Full Context

configure subscriber-mgmt isa-service-chaining evpn export gw-address-range

Description

This command specifies the address range to be used for the gateway IP address field in EVPN type-5 routes that are advertised for configured NAT pools, to the peer for service-chaining. The system allocates one address for each ISA in the NAT group out of the specified range.

The **no** form of this command removes the values from the configuration.

Parameters

start

Specifies the starting gateway address range (V4) for this EVPN service.

Values ipv4-address: a.b.c.d

end

Specifies the ending gateway address range (V4) for this EVPN service.

Values ipv4-address: a.b.c.d

Platforms

Description

This command specifies gateway endpoint address for the wlan-gw tunnel.

The **no** form of this command removes the gateway ipv4 or IPv6 endpoint address for the wlan-gw tunnel.

Parameters

ip-address

Specifies the IP address of the wlan-gw tunnels on this group interface.

Platforms

18.111 gw-mac

gw-mac

Syntax

gw-mac *mac-address*

no gw-mac

Context

[Tree] (config>service>vprn>sub-if>grp-if>srrp gw-mac)

Full Context

configure service vprn subscriber-interface group-interface srrp gw-mac

Description

This command overrides the default SRRP gateway MAC address used by the SRRP instance. Unless specified, the system uses the same base MAC address for all SRRP instances with the last octet overridden by the lower 8 bits of the SRRP instance ID. The same SRRP gateway MAC address should be in-use by both the local and remote routers participating in the same SRRP context.

One reason to change the default SRRP gateway MAC address is if two SRRP instances sharing the same broadcast domain are using the same SRRP gateway MAC. The system will use the SRRP instance ID to separate the SRRP messages (by ignoring the messages that does not match the local instance ID), but a unique SRRP gateway MAC is essential to separate the routed packets for each gateway IP address.

The **no** form of this command removes the explicit SRRP gateway MAC address from the SRRP instance. The SRRP gateway MAC address can only be changed or removed when the SRRP instance is shutdown.

Parameters

mac-address

Specifies a MAC address that is used to override the default SRRP base MAC address.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Values Any MAC address except all zeros, broadcast or multicast addresses. The offset is expressed in normal Ethernet MAC address notation. The defined gw-mac cannot be 00:00:00:00:00:00, ff:ff:ff:ff:ff:ff or any multicast address.

If not specified, the system uses the default SRRP gateway MAC address with the last octet set to the 8 least significant bits of the SRRP instance ID.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

Description

This command controls the instantiation of an internal category required for Diameter Gx session level Usage Monitoring (per IP-CAN session).

When configured, Gx session level Usage Monitoring can be enabled for sessions associated with this category map.

The internal category for Gx session level Usage Monitoring is counted against the maximum of sixteen categories that can be configured.

When not configured (default), then no internal category is instantiated and Gx session level Usage Monitoring cannot be enabled for sessions associated with this category map.

19 h Commands

19.1 half-life

half-life

Syntax

half-life *half-life* **max-suppress-time** *max-time*

Context

[Tree] (config>port>ethernet>dampening half-life)

Full Context

configure port ethernet dampening half-life

Description

This command configures the half-life decay time and the maximum period of time for which the port up state can be suppressed.

The *half-life* and *max-time* values must be set at the same time; the ratio of *max-time*/ *half-life* must be less than or equal to 49 and greater than or equal to 1.

Parameters

half-life

Specifies the required elapsed time, in seconds, before penalties decay to one-half the initial amount.

Values 1 to 2000

Default 5

max-time

Specifies the maximum suppression time, in seconds, which is the time it can take after the physical link comes up before the worst case accumulated penalties have decayed to the reuse threshold. The maximum penalty is derived from the maximum suppression time, half-life, and reuse threshold, using the following equation:

maximum penalty = (reuse threshold) X 2 expo:(max-time/half-life)

Values 1 to 43200

Default 20

Platforms

All

half-life

Syntax

half-life *minutes*

no half-life

Context

[Tree] (config>router>policy-options>damping half-life)

Full Context

configure router policy-options damping half-life

Description

This command configures the **half-life** parameter for the route damping profile.

The half-life value is the time, expressed in minutes, required for a route to remain stable in order for the Figure of Merit (FoM) value to be reduced by one half; for example, if the half-life value is 6 (minutes) and the route remains stable for 6 minutes, then the new FoM value is 3 (minutes). After another 3 minutes pass and the route remains stable, the new FoM value is 1.5 (minutes).

When the FoM value falls below the **config>router>policy-options>damping reuse** threshold, the route is once again considered valid and can be reused or included in route advertisements.

The **no** form of this command removes the half life parameter from the damping profile.

Default

no half-life

Parameters

minutes

Specifies the half-life in minutes expressed as a decimal integer.

Values 1 to 45

Description

This command enables the use of the hash label on a VLL, VPRN or VPLS service bound to any MPLS type encapsulated SDP, as well as to a VPRN service that is using the **auto-bind-tunnel** with the

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

resolution-filter set to any MPLS tunnel type. This feature is not supported on a service bound to a GRE SDP or for a VPRN service using the autobind mode with the gre option. This feature is also not supported on multicast packets forwarded using RSVP P2MP LSP or mLDP LSP in both the base router instance and in the multicast VPN (mVPN) instance. It is, however, supported when forwarding multicast packets using an IES/VPRN spoke-interface.

When this feature is enabled, the ingress data path is modified such that the result of the hash on the packet header is communicated to the egress data path for use as the value of the label field of the hash label. The egress data path appends the hash label at the bottom of the stack (BoS) and sets the S-bit to one (1).

To allow applications where the egress LER infers the presence of the hash label implicitly from the value of the label, the Most Significant Bit (MSB) of the result of the hash is set before copying into the Hash Label. This means that the value of the hash label will always be in the range [524,288 - 1,048,575] and will not overlap with the signaled/static LSP and signaled/static service label ranges. This also guarantees that the hash label will not match a value in the reserved label range.

The (unmodified) result of the hash continues to be used for the purpose of ECMP and LAG spraying of packets locally on the ingress LER. Note, however, that for VLL services, the result of the hash is overwritten and the ECMP and LAG spraying will be based on service-id when ingress SAP shared queuing is not enabled. However, the hash label will still reflect the result of the hash such that an LSR can use it to perform fine grained load balancing of VLL pseudowire packets.

Packets generated in CPM and that are forwarded labeled within the context of a service (for example, OAM packets) must also include a Hash Label at the BoS and set the S-bit accordingly.

The TTL of the hash label is set to a value of 0.

The user enables the signaling of the hash-label capability under a VLL spoke-sdp, a VPLS spoke-sdp or mesh SDP, or an IES/VPRN spoke interface by adding the **signal-capability** option. In this case, the decision whether to insert the hash label on the user and control plane packets by the local PE is solely determined by the outcome of the signaling process and can override the local PE configuration. The following are the procedures:

- The local PE will insert the flow label interface parameters sub-TLV with F=1 in the PW ID FEC element in the label mapping message for that spoke SDP or mesh SDP.
- If the remote PE includes this sub-TLV with F=1 or F=0, then local PE must insert the hash label in the user and control plane packets.
- If remote PE does not include this sub-TLV (for example, it does not support it, or it is supported but the user did not enable the **hash-label** option or the **signal-capability** option), then the local PE establishes the PW but must not insert the hash label in the user and control packets over that spoke SDP or mesh SDP. If the remote PE does not support the **signal-capability** option, then there are a couple of possible outcomes:
  - If the **hash-label** option was enabled on the local configuration of the spoke SDP or mesh SDP at the remote PE, the PW packets received by the local PE will have the hash label included. These packets must be dropped. The only way to solve this is to disable the signaling capability option on the local node which will result in the insertion of the hash label by both PE nodes.
  - If the **hash-label** option is not supported or was not enabled on the local configuration of the spoke SDP or mesh SDP at the remote PE, the PW received by the local PE will not have the hash label included.
- The user can enable or disable the signal-capability option in CLI as needed. When doing so, the 7450 ESS or 7750 SR must withdraw the label it sent to its peer and send a new label mapping message with the new value of the F bit in the flow label interface parameters sub-TLV of the PW ID FEC element.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Full Context

configure service vprn pim rp bsr-candidate hash-mask-len

Description

This command is used to configure the length of a mask that is to be combined with the group address before the hash function is called. All groups with the same hash map to the same RP. For example, if this value is 24, only the first 24 bits of the group addresses matter. This mechanism is used to map one group or multiple groups to an RP.

Default

hash-mask-len 30

Parameters

hash-mask-length

The hash mask length.

Values 0 to 32

Platforms

All

hash-mask-len

Syntax

hash-mask-len *hash-mask-length*

no hash-mask-len

Context

[Tree] (config>service>vprn>pim>rp>ipv6>bsr-candidate hash-mask-len)

Full Context

configure service vprn pim rp ipv6 bsr-candidate hash-mask-len

Description

This command is used to configure the length of a mask that is to be combined with the group address before the hash function is called. All groups with the same hash map to the same RP. For example, if this value is 24, only the first 24 bits of the group addresses matter. This mechanism is used to map one group or multiple groups to an RP.

Default

hash-mask-len 126

hash-weight-threshold

Syntax

hash-weight-threshold *weight* [**action** *action*] [**cost** *static-cost*]

no hash-weight-threshold

Context

[Tree] (config>lag hash-weight-threshold)

Full Context

configure lag hash-weight-threshold

Description

This command controls the operational status of the LAG or the IGP cost based on the sum of the **hash-weight** values for the active links in the LAG.

The **no** form of this command disables the hash weight threshold.

Parameters

weight

Specifies the value for the sum of all the active LAG ports **hash-weight** at or below which the configured action is invoked. If the sum of **hash-weight** for operational LAG links exceeds the **hash-weight-threshold** value, then no action is taken.

Values 1 to 6400000

action

Specifies the action to take if the sum of the **hash-weight** for active links in the LAG is equal or below the threshold value.

Values **down —** Specifies that the LAG is operationally DOWN. The LAG is only considered as UP once the number of **hash-weight** for the active links exceeds the configured threshold value.

dynamic-cost — Specifies that dynamic cost is activated. The LAG remains operationally UP with a link cost relative to the number of operational links. The link is only considered as operationally DOWN when all links in the LAG are down.

static-cost — Specifies that static cost is activated. The LAG remains operationally UP with the configured cost, regardless of the number of

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

operational links. The link is only considered as operationally DOWN when all links in the LAG are down. If this parameter is used with an IGP, its **reference-bandwidth** must also be configured.

static-cost

Specifies the decimal integer static cost of the LAG.

Values 1 to 16777215

Platforms

19.10 head-end

head-end

Syntax

head-end local

head-end *ipv4-address*

no head-end

Context

[Tree] (conf>router>segment-routing>sr-policies>policy head-end)

Full Context

configure router segment-routing sr-policies static-policy head-end

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command associates a head-end location with a statically-defined segment-routing policy. The head-end identifies the router that is the target to install the policy. This is a mandatory parameter and configuration command for enabling the segment-routing policy; if the head-end parameter value is not configured, the execution of the **no shutdown** command on the static segment routing policy fails.

To associate a static policy with the local router as head-end, the keyword **local** must be specified. The static policy is associated with another (non-local) router, if the head-end parameter is set to any IPv4 address. When a non-local, static segment routing policy that originates as a BGP route is imported into BGP, the configured head-end address is converted to an IPv4-address specific route-target extended community that is automatically added to the route.

The **no** form of this command removes the head-end association.

Default

no head-end

Parameters

local

Keyword indicating that the policy is intended to be used by the local router and not advertised to other BGP routers.

ipv4-address

Specifies the IP address of the target head-end router.

Values ipv4-address: a.b.c.d

health-check

Syntax

[**no**] **health-check** [**interval** *interval*]

Context

[Tree] (config>system>security>password health-check)

Full Context

configure system security password health-check

Description

This command enables health check monitoring of the RADIUS, TACACS+, and LDAP servers by sending authentication requests for an unknown user at regular intervals. If a response is not received, the operational status of the server is changed to down. The operational status is changed to up when responses are received.

When RADIUS over TLS is configured, Status-Server packets are sent at 30-second intervals as specified in *RFC 3539*, regardless of whether health checks are enabled.

The **no** form of this command disables health monitoring of RADIUS, TACACS+, and LDAP servers. In this case, the operational status for the server is up if a response was received for the last user request.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Default

health-check interval 30

Parameters

interval

Specifies the polling interval for RADIUS, TACACS+, and LDAP servers.

Values 6 to 1500

Default 30

configure router ldp targeted-session ipv6 hello

configure router ldp interface-parameters ipv6 hello

configure router ldp interface-parameters ipv4 hello

configure router ldp targeted-session peer hello

configure router ldp targeted-session peer-template hello

configure router ldp interface-parameters interface ipv4 hello

Description

This command configures the time interval to wait before declaring a neighbor down. The **factor** parameter derives the Hello interval.

The **config**>**router**>**ldp**>**if-params**>**ipv6**>**hello** and **config**>**router**>**ldp**>**targ-session**>**ipv6**>**hello** commands are not supported on the 7450 ESS.

Hold time is local to the system and sent in the Hello messages to the neighbor. Hold time cannot be less than three times the Hello interval. The hold time can be configured globally (applies to all LDP interfaces) or per interface. The most specific value is used.

When LDP session is being set up, the hold down time is negotiated to the lower of the two peers. Once an operational value is agreed upon, the Hello factor is used to derive the value of the Hello interval.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **no** form of the command at the interface-parameters and targeted-session level sets the **hello timeout** and the **hello factor** to the default values.

The **no** form of the command, at the interface level, sets the **hello timeout** and the **hello factor** to the value defined under the interface-parameters level.

The **no** form of this command, at the peer level, sets the **hello timeout** and the **hello factor** to the value defined under the targeted-session level.

The session must be flapped for the new settings to operate.

Default

Table 49: Hello Timeout Factors lists the default values.

Table 49: Hello Timeout Factors

Context	Timeout	Factor
config>router>ldp>if-params	15	3
config>router>ldp>targ-session	45	3
config>router>ldp>if-params>if	Inherits values from interface-parameters context.	
config>router>ldp>targ-session>peer	Inherits values from targeted-session context.	

Parameters

timeout

Configures the time interval, in seconds, that LDP waits before a neighbor down.

Values 1 to 65535

factor

Specifies the number of keepalive messages that should be sent on an idle LDP session in the Hello timeout interval.

Values 1 to 255

[Tree] (config>service>vprn>isis>if hello-authentication-key)

Full Context

configure service vprn isis interface level hello-authentication-key

configure service vprn isis interface hello-authentication-key

Description

This command configures the authentication key (password) for Hello PDUs. Neighboring routers use the password to verify the authenticity of Hello PDUs sent from this interface. Both the Hello authentication key and the Hello authentication type on a segment must match. The **hello-authentication-type** must be specified.

To configure the Hello authentication key in the interface context use the **hello-authentication-key** in the **config>router>isis>if** context.

To configure or override the Hello authentication key for a specific level, configure the **hello-authentication-key** in the **config>router>isis>if>level** context.

If both IS-IS and hello-authentication are configured, Hello messages are validated using Hello authentication. If only IS-IS authentication is configured, it will be used to authenticate all IS-IS (including Hello) protocol PDUs.

When the Hello authentication key is configured in the **config>router>isis>if** context, it applies to all levels configured for the interface.

The **no** form of this command removes the authentication-key from the configuration.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Default

no hello-authentication-key — No Hello authentication key is configured.

Parameters

authentication-key

The Hello authentication key (password). The key can be any combination of ASCII characters up to 254 characters in length (un-encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

hash-key

The hash key. The key can be any combination of ASCII characters up to 342 characters in length (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided.

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

custom

Specifies the custom encryption to management interface.

configure router isis interface level hello-authentication-key

Description

This command configures the authentication key (password) for Hello PDUs. Neighboring routers use the password to verify the authenticity of Hello PDUs sent from this interface. Both the Hello authentication key and the Hello authentication type on a segment must match. The **hello-authentication-type** must be specified.

To configure the Hello authentication key in the interface context, use the **hello-authentication-key** in the **config>router>isis>interface** context.

To configure or override the Hello authentication key for a specific level, configure the **hello-authentication-key** in the **config>router>isis>interface>level** context.

If both IS-IS and hello-authentication are configured, Hello messages are validated using Hello authentication. If only IS-IS authentication is configured, it will be used to authenticate all IS-IS (including Hello) protocol PDUs.

When the Hello authentication key is configured in the **config>router>isis>interface** context, it applies to all levels configured for the interface.

The **no** form of this command removes the authentication-key from the configuration.

Parameters

authentication-key

Specifies the Hello authentication key (password). The key can be any combination of ASCII characters, up to 254 characters (un-encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

hash-key

Specifies the hash key. The key can be any combination of ASCII characters, up to 342 characters (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided.

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

[Tree] (config>service>vprn>isis>if>level hello-interval)

Full Context

configure router isis interface level hello-interval

configure service vprn isis interface level hello-interval

Description

This command configures the interval between IS-IS Hello PDUs issued on the interface at this level. The **hello-interval**, along with the **hello-multiplier**, is used to calculate a hold time, which is communicated to a neighbor in a Hello PDU.

Note:
The neighbor hold time is (hello multiplier X hello interval) on non-designated intermediate system broadcast interfaces and point-to-point interfaces and is (hello multiplier X hello interval / 3) on designated intermediate system broadcast interfaces. Hello values can be adjusted for faster convergence, but the hold time should always be > 3 to reduce routing instability.

The **no** form of this command reverts to the default value.

Default

3 – for designated intermediate system interfaces

9 – for non-designated intermediate system interfaces and point-to-point interfaces

Parameters

seconds

The Hello interval in seconds expressed as a decimal integer.

Values 1 to 20000

Platforms

All

configure service vprn ospf3 area virtual-link hello-interval

configure service vprn ospf area interface hello-interval

configure service vprn ospf area sham-link hello-interval

configure service vprn ospf area virtual-link hello-interval

Description

This command configures the interval between OSPF Hello messages issued on the interface, virtual link, or sham-link.

The Hello interval, in combination with the dead-interval, is used to establish and maintain the adjacency. Use this parameter to edit the frequency that Hello packets are sent.

Reducing the interval, in combination with an appropriate reduction in the associated **dead-interval**, allows for faster detection of link and/or router failures at the cost of higher processing costs.

The **no** form of this command reverts to the default value.

Default

hello-interval 10 — a 10-second Hello interval

Parameters

seconds

The Hello interval in seconds expressed as a decimal integer.

Values 1 to 65535

Full Context

configure service vprn isis interface level hello-padding

configure service vprn isis level hello-padding

configure service vprn isis interface hello-padding

configure service vprn isis hello-padding

Description

This command enables the IS-IS Hello (IIH) message padding to ensure that IS-IS LSPs can traverse the link. When this option is enabled, IS-IS Hello messages are padded to the maximum LSP MTU value, which can be set with the **lsp-mtu-size** command. If link MTU is greater than the maximum LSP MTU value, padding to the link MTU is applied.

The **no** form of this command disables IS-IS Hello message padding at this level. However, the router may still perform Hello padding if it was set at a higher level in the configuration. To ensure that Hello message padding is disabled, set all levels of configuration to **no hello-padding**.

Default

no hello-padding

Parameters

adaptive

Specifies the adaptive padding option; this option is able to detect MTU asymmetry from one side of the connection but uses more overhead than loose padding.

- point-to-point interface—Hello PDUs are padded until the sender declares an adjacency on the link to be in the state up. If the implementation supports RFC 3373/5303, *Three-Way Handshake for IS-IS Point-to-Point Adjacencies*, then this is when the three-way state is up. If the implementation uses the "classic” algorithm described in ISO 10589, this is when the adjacency state is up. If the neighbor does not support the adjacency state TLV, then padding continues.
- broadcast interface—Padding starts until at least one adjacency is up on the interface.

loose

Specifies the loose padding option; the loose padding may not be able to detect certain conditions such as asymmetrical MTUs between the routing devices.

- point-to-point interface—the Hello packet is padded from the initial detection of a new neighbor until the adjacency transitions to the INIT state
- broadcast interface—padding starts until at least one adjacency (broadcast only has up/down) is up on the interface

none

Specifies that the Hello message padding is not enabled at this level, even if it is configured at one of the parent levels.

strict

Specifies the strict padding option.

- point-to-point interface—padding is done for all adjacency states, and is continuous. Strict padding has the most overhead but detects MTU issues on both sides of a link

© 2025 Nokia.

configure router ldp targeted-session peer-template hello-reduction

configure router ldp targeted-session ipv6 hello-reduction

Description

This command enables the suppression of periodic targeted Hello messages between LDP peers once the targeted LDP session is brought up.

The **config**>**router**>**ldp**>**targ-session**>**ipv6**>**hello-reduction** command is not supported on the 7450 ESS.

When this feature is enabled, the target Hello adjacency is brought up by advertising the Hold-Time value the user configured in the " **hello** timeout" parameter for the targeted session. The LSR node will then start advertising an exponentially increasing Hold-Time value in the Hello message as soon as the targeted LDP session to the peer is up. Each new incremented Hold-Time value is sent in a number of Hello messages equal to the value of the argument *factor*, which represents the dampening factor, before the next exponential value is advertised. This provides time for the two peers to settle on the new value. When the Hold-Time reaches the maximum value of 0xffff (binary 65535), the two peers will send Hello messages at a frequency of every [(65535-1)/local helloFactor] seconds for the lifetime of the targeted-LDP session (for example, if the local Hello Factor is three (3), then Hello messages will be sent every 21844 seconds.

The LSR node continues to compute the frequency of sending the Hello messages based on the minimum of its local Hold-time value and the one advertised by its peer as in RFC 5036. Thus for the targeted LDP session to suppress the periodic Hello messages, both peers must bring their advertised Hold-Time to the maximum value. If one of the LDP peers does not, the frequency of the Hello messages sent by both peers will continue to be governed by the smaller of the two Hold-Time values.

When the user enables the Hello reduction option on the LSR node while the targeted LDP session to the peer is operationally up, the change will take effect immediately. In other words, the LSR node will start advertising an exponentially increasing Hold-Time value in the Hello message, starting with the current configured Hold-Time value.

When the user disables the Hello reduction option while the targeted LDP session to the peer is operationally up, the change in the Hold-Time from 0xffff (binary 65535) to the user configured value for this peer will take effect immediately. The local LSR will immediately advertise the value of the user configured Hold-Time value and will not wait until the next scheduled time to send a Hello to make sure the peer adjusts its local hold timeout value immediately.

In general, any configuration change to the parameters of the T-LDP Hello adjacency (modifying the Hello adjacency Hello Timeout or factor, enabling/disabling Hello reduction, or modifying Hello reduction factor) will cause the LSR node to trigger immediately an updated Hello message with the updated Hold Time value without waiting for the next scheduled time to send a Hello.

The **no** form of this command disables the Hello reduction feature.

Default

no hello-reduction

Parameters

factor

Specifies the integer that specifies the Hello reduction dampening factor.

Full Context

configure service template vpls-template stp hello-time

configure service vpls stp hello-time

Description

This command configures the Spanning Tree Protocol (STP) Hello time for the Virtual Private LAN Service (VPLS) STP instance.

The Hello time parameter defines the default timer value that controls the sending interval between BPDU configuration messages by this bridge, on ports where this bridge assumes the designated role.

The active Hello time for the spanning tree is determined by the root bridge (except when the STP is running in RSTP mode, then the Hello time is always taken from the locally configured parameter).

The configured **hello-time** can also be used to calculate the forward delay. See **auto-edge** (**config>service>vpls>sap>stp auto-edge, config>service>template>vpls-sap-template>stp auto-edge, config>service>vpls>spoke-sdp>stp auto-edge**).

The **no** form of this command returns the Hello time to the default value.

Default

hello-time 2

Parameters

hello-time

The Hello time for the STP instance in seconds.

Full Context

configure service vprn isis graceful-restart helper-disable

Description

This command disables helper support for IS-IS graceful restart (GR).

When **graceful-restart** is enabled, the router can be a helper (that is, the router is helping a neighbor to restart), a restarting router, or both. The router only supports the helper mode. It will not act as a restarting router, because the high availability feature set already preserves IS-IS forwarding information such that this functionality is not needed.

Note:
This command is a historical command and should not be disabled. Configuring **helper-disable** has the effect of disabling graceful restart, because the router only supports helper mode.

The **no helper-disable** command enables helper support and is the default when graceful restart is enabled.

[Tree] (config>service>vprn>ospf>graceful-restart helper-disable)

Full Context

configure service vprn ospf3 graceful-restart helper-disable

configure service vprn ospf graceful-restart helper-disable

Description

This command disables helper support for OSPF graceful restart (GR).

When **graceful-restart** is enabled, the router can be a helper (that is, the router is helping a neighbor to restart), a restarting router, or both. The router only supports helper mode. It will not act as a restarting router, because the high availability feature set already preserves OSPF forwarding information such that this functionality is not needed.

configure service vprn bgp graceful-restart long-lived helper-override-restart-time

configure service vprn bgp group graceful-restart long-lived helper-override-restart-time

Description

This command overrides the restart-time advertised by a peer (in its GR capability) with a locally-configured value. This override applies only to AFI/SAFI that were included in the GR capability of the peer. The restart-time is always zero for AFI/SAFI not included in the GR capability. This command is useful if the local router wants to force LLGR phase to begin after a set time for all protected AFI/SAFI.

By default, the restart time for all AFI/SAFI in the GR capability is the value signaled by the peer.

Default

no helper-override-restart-time

Parameters

seconds

The locally-imposed restart time for all AFI/SAFI included in the peer's GR capability.

Values 0 to 4095

Full Context

configure card fp hi-bw-mcast-src

Description

This command designates the forwarding plane as a high-bandwidth IP multicast source, expecting the ingress traffic to include high-bandwidth IP multicast traffic. When configured, the system attempts to allocate a dedicated multicast switch fabric plane (MSFP) to the forwarding plane. If a group is specified,

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

all FPs in the group will share the same MSFP. If the alarm parameter is specified and the system cannot allocate a dedicated MSFP to the new group or FP, the FPs will be brought online and generate an event (SYSTEM: 2052 - tmnxChassisHiBwMulticastAlarm). Similarly, if during normal operation there is a failure or removal of resources, an event will be generated if the system cannot maintain separation of MSFPs for the MDAs.

The **no** form of this command removes the high-bandwidth IP multicast source designation from the forwarding plane.

Default

no hi-bw-mcast-src

Parameters

alarm

Enables event generation if the MDA is required to share an MSFP with another MDA that is in a different group. MDAs within the same group sharing an MSFP will not cause this alarm.

group-id

Specifies the logical MSFP group for the MDA. MDAs configured with the same *group-id* will be placed on the same MSFP.

Values 0 to 32 (A value of 0 removes the MDA from the group).

Default By default, "none" is used, and the system will attempt to assign a unique MSFP to the MDA.

default-paths-only

When this parameter is specified the system will only attempt to allocate the two default paths (one high priority and one low priority) to dedicated MSFPs.

Full Context

configure application-assurance group tcp-optimizer high-cpu-backoff

Description

This command configures AA to stop optimizing TCP sessions when the CPU capacity is limited.

AA implements the following CPU utilization thresholds:

- level 1 – 75%
- level 2 – 85%
- level 3 – 90%

The following describes the functionality of the preceding thresholds:

- **early random bypass stage (level 1)**

  When the CPU utilization is between level 1 and level 2, AA randomly optimizes or bypasses new TCP sessions proportional to the position of the CPU utilization within the range between level 1 and level 2.
- **stop optimization of new flows stage (level 2)**

  When the CPU utilization is at or above level 2, AA stops optimizing new TCP sessions.
- **abandon stage (level 3)**

  When the CPU utilization is at or above level 3, AA abandons existing optimized TCP sessions.

Note: The CPU utilization is measured once per second in each core or worker. The CPU utilization may differ between cores.

Default

no high-cpu-backoff

Full Context

configure subscriber-mgmt sla-profile egress qos queue high-prio-only

configure subscriber-mgmt sla-profile ingress qos queue high-prio-only

Description

This command configures the value of the percentage of buffer space for the queue, used exclusively by high priority packets. The specified value overrides the default value for the context.

The priority of a packet can only be set in the SAP ingress QoS policy and is only applicable on the ingress queues for a SAP. The **high-prio-only** parameter is used to override the default value derived from the **network-queue** command.

The defined **high-prio-only** value cannot be greater than the MBS size of the queue. Attempting to change the MBS to a value smaller than the high priority reserve will generate an error and fail execution. Attempting to set the **high-prio-only** value larger than the current MBS size will also result in an error and fail execution.

The **no** form of this command returns high-prio-only to the size as configured in the QoS policy.

Parameters

percent

The *percent* parameter is the percentage reserved for high priority traffic on the queue. If a value of 10KBytes is desired, enter the value 10. A value of 0 specifies that none of the MBS of the queue is reserved for high priority traffic. This does not affect RED slope operation for packets attempting to be queued.

Values 0 to 100, default

19.39 high-rate-hold-time

high-rate-hold-time

Syntax

high-rate-hold-time *seconds* [**active-min-only**]

no high-rate-hold-time

Context

[Tree] (config>qos>adv-config-policy>child-control>offered-measurement high-rate-hold-time)

Full Context

configure qos adv-config-policy child-control offered-measurement high-rate-hold-time

Description

This command sets a time period that the current offered rate should be maintained for a child policer or queue when it is seen that the offered rate is decreasing. The offered measurement that triggers the hold time is used when the hold timer expires, unless a higher offered rate is seen in the interim. When a higher rate is observed, the hold timer is canceled and the higher offered rate is used immediately.

A possible reason to define a hold timer for an offered rate is to allow a child queue is to dampen the effects of a child with a fluctuating rate on the virtual scheduler. This works similar to the max-decrement in that the child holds on to bandwidth from the virtual scheduler in case it may be needed in the near future.

This parameter has no effect on an increase to the child's offered rate. If the rate increase is above the change sensitivity, the new offered rate is immediately used.

When this command is not specified or removed, the virtual scheduler immediately reacts to measured decreases in offered load.

The **no** form of this command is used to remove any currently configured hold time for all child policers and queues associated with the policy. When the hold time is removed, any current hold timers for child policers are automatically canceled.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

seconds

The hold time configured must be specified in seconds. A value of 0 is equivalent to no high-rate-hold-time.

Default 0

Values 0 to 60

active-min-only

When this optional parameter is specified, the **high-rate-hold-time** command will accept the optional **active-min-only** parameter. Attempting to remove the active-min-only parameter from the **add** command, or removing the **add** command itself, will fail while **active-min-only** is enabled on the **high-rate-hold-time** command. When specified, the respective rate or percentage is treated as the minimum offered rate for a queue, only when the queue has an actual non-zero offered rate. This is intended to limit the artificial increase in offered rate to queues that are currently active. When a queue's measured offered rate drops to zero, the system stops enforcing the minimum value.

Platforms

All

19.40 high-slope

high-slope

Syntax

[**no**] **high-slope**

Context

[Tree] (config>qos>slope-policy high-slope)

Full Context

configure qos slope-policy high-slope

Description

The **high-slope** context contains the commands and parameters for defining the high Random Early Detection (RED) slope graph. Each buffer pool supports a high RED slope for managing access to the shared portion of the buffer pool for in-profile packets.

The **high-slope** parameters can be changed at any time and the affected buffer pool high RED slopes will be adjusted appropriately.

The **no** form of this command restores the high slope configuration commands to the default values. If the commands within **high-slope** are set to the default parameters, the **high-slope** node will not appear in save config and show config output unless the detail parameter is present.

[Tree] (config>oam-pm>session>ethernet>slm>loss-events hli-event)

[Tree] (config>oam-pm>session>ethernet>lmm>loss-events hli-event)

Full Context

configure oam-pm session ip twamp-light loss-events hli-event

configure oam-pm session ethernet slm loss-events hli-event

configure oam-pm session ethernet lmm loss-events hli-event

Description

This command sets the high loss interval (HLI) threshold to be monitored and the associated thresholds using the counter of the specified direction. The aggregate is a function of summing forward and backward. This value is only used as a threshold mechanism and is not part of the stored statistics. If the optional **clear** *clear-threshold* parameter is not specified, the traffic crossing alarm is stateless. Stateless means the state is not carried forward to other measurement intervals. Each measurement interval is analyzed independently and regardless of any previous window. Each unique event can only be raised once within measurement interval. If the optional **clear** *clear-threshold* parameter is specified, the traffic crossing alarm uses stateful behavior. Stateful means each unique previous event state is carried forward to following measurement intervals. If a threshold crossing event is raised another is raised until a measurement interval completes and the clear threshold has not been exceeded. A clear event is raised under that condition.

The **no** form of this command removes the event threshold for frame loss ratio. The direction must be included with the **no** command.

Default

no hli-event forward

no hli-event backward

no hli-event aggregate

Parameters

forward

Specifies the threshold is applied to the forward direction count.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

backward

Specifies the threshold is applied to the backward direction count.

aggregate

Specifies the threshold is applied to the aggregate count (sum of forward and backward).

raise-threshold

Specifies the rising threshold that determines when the event is to be generated, when the percentage of loss value is reached.

Values 1 to 864000

clear-threshold

Specifies an optional value used for stateful behavior that allows the operator to configure a percentage of loss value lower than the rising percentage to indicate when the clear event should be generated.

Values 0 to 863999

A value of zero means that the HLI counter must be 0.

configure vrrp policy priority-event port-down hold-clear

configure vrrp policy priority-event host-unreachable hold-clear

configure vrrp policy priority-event mc-ipsec-non-forwarding hold-clear

Description

This command configures the hold clear time for the event. The *seconds* parameter specifies the hold-clear time, the amount of time in seconds by which the effect of a cleared event on the associated virtual router instance is delayed.

The hold-clear time is used to prevent black hole conditions when a virtual router instance advertises itself as a master before other conditions associated with the cleared event have had a chance to enter a forwarding state.

Default

no hold-clear

Parameters

seconds

Specifies the amount of time in seconds by which the effect of a cleared event on the associated virtual router instance is delayed.

Values 0 to 86400

Platforms

All

- configure vrrp policy priority-event lag-port-down hold-clear

hold-down-time

Syntax

hold-down-time *seconds*

no hold-down-time

Context

[Tree] (config>service>sdp>keep-alive hold-down-time)

Full Context

configure service sdp keep-alive hold-down-time

Description

This command configures the minimum time period the SDP will remain in the operationally down state in response to SDP keepalive monitoring.

This parameter can be used to prevent the SDP operational state from "flapping” by rapidly transitioning between the operationally up and operationally down states based on keepalive messages.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

When an SDP keepalive response is received that indicates an error condition or the **max-drop-count** keepalive messages receive no reply, the *sdp-id* will immediately be brought operationally down. If a keepalive response is received that indicates the error has cleared, the *sdp-id* will be eligible to be put into the operationally up state only after the **hold-down-time** interval has expired.

The **no** form of this command reverts the **hold-down-time seconds** *value* to the default setting.

Default

hold-down-time 10

Parameters

seconds

Specifies time, in seconds, expressed as a decimal integer. The SDP ID will remain in the operationally down state before it is eligible to enter the operationally up state. A value of 0 indicates that no **hold-down-time** will be enforced for SDP ID.

Values 0 to 3600

Platforms

All

19.51 hold-down-timer

hold-down-timer

Syntax

hold-down-timer *hold-down-timer*

no hold-down-timer

Context

[Tree] (config>router>segment-routing>maintenance-policy hold-down-timer)

Full Context

configure router segment-routing maintenance-policy hold-down-timer

Description

This command configures the hold down timer for SR policy candidate paths.

This command is intended to prevent bouncing of the SR policy path state if one or more S-BFD sessions associated with segment lists flap and therefore cause the threshold to be repeatedly crossed in a short period of time. It is started when the number of up S-BFD sessions drops below the threshold. The SR policy path is not considered to be up again until the hold down timer has expired and the number of up S-BFD sessions equals or exceeds the threshold and the internal hold timer is not running.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Note:
If the revert timer is also configured, the revert timer is not started until after the number of S-BFD sessions that are up ≥ threshold and the hold down timer for the primary candidate path has expired.

The **no** form of this command reverts to the default.

Default

hold-down-timer 0

Parameters

hold-down-timer

Specifies the hold-down timer, in deciseconds, in 10ms steps.

Values 0 to 5000

Full Context

configure redundancy multi-chassis peer mc-lag hold-on-neighbor-failure

Description

This command specifies the interval that the standby node will wait for packets from the active node before assuming a redundant-neighbor node failure. This delay in switch-over operation is required to accommodate different factors influencing node failure detection rate, such as IGP convergence, or HA switch-over times and to prevent the standby node to act prematurely.

The **no** form of this command reverts to the default.

Default

hold-on-neighbor-failure 3

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

multiplier

Specifies the time interval that the standby node waits for packets from the active node before assuming a redundant-neighbor node failure.

Values 2 to 25

Platforms

All

hold-on-neighbor-failure

Syntax

hold-on-neighbor-failure *multiplier*

no hold-on-neighbor-failure

Context

[Tree] (config>redundancy>multi-chassis>peer>mc-ep hold-on-neighbor-failure)

Full Context

configure redundancy multi-chassis peer mc-endpoint hold-on-neighbor-failure

Description

This command specifies the number of keep-alive intervals that the local node will wait for packets from the MC-EP peer before assuming failure. After this time interval passed the all the mc-endpoints configured under services will revert to single chassis behavior, activating the best local pseudowire.

The **no** form of this command sets the multiplier to default value

Default

no hold-on-neighbor-failure

Parameters

multiplier

Specifies the hold time applied on neighbor failure.

Values 2 to 25

Platforms

All

configure vrrp policy priority-event mc-ipsec-non-forwarding hold-set

configure vrrp policy priority-event route-unknown hold-set

configure vrrp policy priority-event lag-port-down hold-set

Description

This command specifies the amount of time that must pass before the set state for a VRRP priority control event can transition to the cleared state to dampen flapping events. A flapping event continually transitions between clear and set.

The **hold-set** command is used to dampen the effect of a flapping event. The **hold-set** value is loaded into a hold-set timer that prevents a set event from transitioning to the cleared state until it expires.

Each time an event transitions between cleared and set, the timer is loaded and begins a countdown to zero. When the timer reaches zero, the event is allowed to enter the cleared state. Entering the cleared state is dependent on the object controlling the event, conforming to the requirements defined in the event itself. It is possible, on some event types, to have another set action reload the hold-set timer. This extends the amount of time that must expire before entering the cleared state.

Once the hold-set timer expires and the event meets the cleared state requirements or is set to a lower threshold, the current set effect on the virtual router instances in-use priority can be removed. As with **lag-port-down** events, this may be a decrease in the set effect if the *clearing* amounts to a lower set threshold.

The **hold-set** command can be executed at any time. If the hold-set timer value is configured larger than the new *seconds* setting, the timer is loaded with the new **hold-set** value.

The **no** form of the command disables the hold timer so that event transitions are processed immediately.

Default

no hold-set

Parameters

seconds

The number of seconds that the hold-set timer waits after an event enters a set state or enters a higher threshold set state, depending on the event type.

The value of 0 disables the hold-set timer, preventing any delay in processing lower set thresholds or cleared events.

Values 0 to 86400

hold-time

Syntax

hold-time *seconds*

no hold-time

Context

[Tree] (config>subscr-mgmt>bgp-prng-plcy hold-time)

Full Context

configure subscriber-mgmt bgp-peering-policy hold-time

Description

This command configures the BGP hold time, expressed in seconds.

The BGP hold time specifies the maximum time BGP waits between successive messages (either keepalive or update) from its peer, before closing the connection.

Even though the router OS implementation allows setting the keepalive time separately, the configured keepalive timer is overridden by the hold-time value under the following circumstances:

If the specified hold-time is less than the configured keepalive time, then the operational keepalive time is set to a third of the hold-time; the configured keepalive time is not changed.

If the hold-time is set to zero, then the operational value of the keepalive time is set to zero; the configured keepalive time is not changed. This means that the connection with the peer is up permanently and no keepalive packets are sent to the peer.

The **no** form of this command reverts to the default.

Parameters

seconds

Specifies the hold-time, in seconds, expressed as a decimal integer. A value of 0 indicates the connection to the peer is up permanently.

Values 0, 3 to 65535

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

hold-time

Syntax

hold-time *time-value*

no hold-time

Context

[Tree] (config>port>ethernet>efm-oam hold-time)

Full Context

configure port ethernet efm-oam hold-time

Description

This command configures efm-oam operational transition dampening timers which reduce the number of efm-oam state transitions reported to upper layers.

Default

no hold-time

Parameters

time-value

Indicates the number of seconds that the efm-oam protocol will wait before going back to the operational state after leaving the operational state. Note that the hold-time does not apply if efm-oam moved from operational to link-fault.

A hold-time value of zero indicates that there should be no delay in transitioning to the operational state. A non-zero value will cause the efm-oam protocol to attempt to negotiate with a peer if possible, but it will remain in the send-local-remote-ok state until the hold time has expired if negotiation is successful.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

If efm-oam is administratively shutdown while it was in the operational state and then re-enabled when a non-zero hold time is configured, efm-oam will attempt transition to the operational state immediately.

The **no** form of this command reverts the value to the default.

Values 0 to 50

Default 0

Platforms

no hold-time

Context

[Tree] (config>port>ethernet hold-time)

Full Context

configure port ethernet hold-time

Description

This command configures port link dampening timers which reduce the number of link transitions reported to upper layer protocols. The **hold-time** value dampens interface transitions.

When an interface transitions from an up state to a down state, it is immediately advertised to the rest of the system if the hold-time down interval is zero, but if the hold-time down interval is greater than zero, interface down transitions are not advertised to upper layers until the hold-time down interval has expired. Likewise, an interface is immediately advertised as up to the rest of the system if the hold-time up interval is zero, but if the hold-time up interval is greater than zero, up transitions are not advertised until the hold-time up interval has expired.

For ESM SRRP setup, MCS synchronizes subscriber information between the two chassis. After a chassis recovers from a power reset/down, MCS immediately synchronizes all subscriber information at once. The longer the host list, the longer it will take to synchronize the chassis. In a fully populated chassis, it is recommended to allow at least 45 minutes for MCS synchronization. It is also recommended to hold the port down, facing the subscriber, on the recovering chassis for 45 minutes before it is allowed to forward traffic again.

The **no** form of this command reverts to the default values.

Default

down 0 seconds — No port link down dampening is enabled; link down transitions are immediately reported to upper layer protocols.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

up 0 seconds — No port link up dampening is enabled; link up transitions are immediately reported to upper layer protocols.

Parameters

hold-time-up

The delay, in seconds or centiseconds, after which to notify the upper layers when an interface transitions from a down state to an up state.

Values 0 to 36000 seconds, 0 or 10 to 3600000 centiseconds in 5 centisecond increments

hold-time-down

The delay, in seconds or centiseconds, after which to notify the upper layers when an interface transitions from an up state to a down state.

Values 0 to 36000 seconds, 0 or 10 to 3600000 centiseconds in 5 centisecond increments

seconds | centiseconds

Specifies the hold time units as **seconds** or **centiseconds**.

Platforms

All

hold-time

Syntax

hold-time down *hold-down-time*

no hold-time

Context

[Tree] (config>lag hold-time)

Full Context

configure lag hold-time

Description

This command specifies the timer, in tenths of seconds, which controls the delay between detecting that a LAG is down (all active ports are down) and reporting it to the higher levels.

A non-zero value can be configured, for example, when active/standby signaling is used in a 1:1 fashion to avoid informing higher levels during the small time interval between detecting that the LAG is down and the time needed to activate the standby link.

Default

no hold-time

Use subject to Terms available at: www.nokia.com/terms.

Parameters

hold-down-time

Specifies the hold-time for event reporting.

Values 0 to 2000

Platforms

All

hold-time

Syntax

hold-time *value*

no hold-time

Context

[Tree] (config>service>vpls>mrp>mvrp hold-time)

Full Context

configure service vpls mrp mvrp hold-time

Description

This command enables the dampening timer and applies to both types of provisioned SAPs – end-station and UNI. When a value is configured for the timer, it controls the delay between detecting that the last provisioned SAP in VPLS goes down and reporting it to the MVRP module. The CPM will wait for the time specified in the value parameter before reporting it to the MVRP module. If the SAP comes up before the hold-timer expires, the event will not be reported to MVRP module.

The non-zero hold-time does not apply for SAP transition from down to up, This kind of transition is reported immediately to MVRP module without waiting for hold-time expiration. Also this parameter applies only to the provisioned SAPs. It does not apply to the SAPs configured with the **vpls-sap-template** command. Also when end-station QinQ SAPs are present only the "no hold-time" configuration is allowed.

The **no** form of this command disables tracking of the operational status for the last active SAP in the VPLS. MVRP will stop declaring the VLAN only when the last provisioned customer (UNI) SAP associated locally with the service is deleted. Also MVRP will declare the associated VLAN attribute as soon as the first provisioned SAP is created in the associated VPLS instance, regardless of the operational state of the SAP.

Default

no hold-time

Parameters

value

Specifies the hold time in minutes

[Tree] (config>service>vprn>bgp>group>neighbor hold-time)

Full Context

configure service vprn bgp hold-time

configure service vprn bgp group hold-time

configure service vprn bgp group neighbor hold-time

Description

This command configures the BGP hold time, expressed in seconds.

The BGP hold time specifies the maximum time BGP waits between successive messages (either keepalive or update) from its peer, before closing the connection. This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in group) or neighbor level (only applies to specified peer). The most specific value is used.

Even though the router OS implementation allows setting the **keepalive** (**config>service>vprn>bgp keepalive**, **config>service>vprn>bgp>group keepalive**, **config>service>vprn>bgp>group>neighbor keepalive**) time separately, the configured **keepalive** timer is overridden by the **hold-time** value under the following circumstances:

- If the specified hold-time is less than the configured **keepalive** time, then the operational **keepalive** time is set to a third of the **hold-time**; the configured **keepalive** time is not changed.
- If the **hold-time** is set to zero, then the operational value of the **keepalive** time is set to zero; the configured **keepalive** time is not changed. This means that the connection with the peer is up permanently and no **keepalive** packets are sent to the peer.

The **no** form of this command used at the global level reverts to the default value.

The **no** form of this command used at the group level reverts to the value defined at the global level.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Default

hold-time 90

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

seconds

Specifies the hold-time, in seconds, expressed as a decimal integer. A value of 0 indicates the connection to the peer is up permanently.

Values 0, 3 to 65535

seconds2

Specifies the minimum hold-time that is accepted for the session. If the peer proposes a hold-time lower than this value the session attempt is rejected.

no hold-timer

Context

[Tree] (config>router>mpls hold-timer)

Full Context

configure router mpls hold-timer

Description

This command specifies the amount of time that the ingress node holds before programming its data plane and declaring the LSP up to the service module. This occurs anytime the ingress node brings up an LSP path or switches traffic from a working path to another working path of the same LSP.

The **no** form of this command reverts to the default value.

Default

no hold-timer

Parameters

seconds

Specifies the time (in seconds), for which the ingress node holds before programming its data plane and declaring the LSP up to the service module.

Values 0 to 1000

Default 1

configure system security user-template home-directory

configure system security user home-directory

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command configures the home directory of the user for file access. Files can be accessed locally by CLI **file** commands and output modifiers such as **>** (file redirect), or remotely via FTP and SCP. If the home directory does not exist, a warning message is displayed when the user logs in.

When **restricted-to-home** is configured, file access is denied unless the **home-directory** is configured and the directory is created by an administrator.

The **no** form of this command removes the configured home directory of the user. The directory must be also removed by the administrator.

Default

no home-directory

Parameters

url-prefix [directory] [directory/directory ..]

Specifies the local home directory URL prefix of the user and directory structure, up to 200 characters.

hop *hop-index* **sid-label** *sid-value*

no hop *hop-index*

Context

[Tree] (config>router>mpls>path hop)

Full Context

configure router mpls path hop

Description

This command specifies the hops that the LSP should traverse on its way to the egress router. When specified, the IP address can be the interface IP address, a loopback interface address, or the system IP address. If a loopback interface or the system IP address is specified then the LSP can choose the best available interface.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

When an IPv6 hop is specified, the interface IP address must be a global unicast IPv6 address. A link-local address is not allowed and is rejected in the configuration if attempted.

Optionally, the LSP ingress and egress IP address can be included as the first and the last hop. A hop list can include the ingress interface IP address, the system IP address, and the egress IP address of any of the hops being specified.

When the **sid-label** parameter is specified, this command specifies an MPLS label value for a hop in the path of an SR-TE LSP. The label value implied by the SID is only used when the path is used by an SR-TE LSP.

The **no** form of this command deletes hop list entries for the path. All the LSPs currently using this path are affected. Additionally, all services actively using these LSPs are affected. The path must be shutdown first in order to delete the hop from the hop list. The **no hop** *hop-index* command will not result in any action except a warning message on the console indicating that the path is administratively up.

Parameters

hop-index

Specifies the hop index is used to order the hops specified. The LSP always traverses from the lowest hop index to the highest. The hop index does not need to be sequential.

Values 1 to 1024

ip-address

Specifies a loopback interface, the system or network interface IP address of the transit router. An interface IPv6 address must be a global unicast address.

Values ipv4-address — a.b.c.d

ipv6-address — x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x — 0 to FFFF (hexadecimal)

d — 0 to 255 (decimal)

loose

This keyword specifies that the route taken by the LSP from the previous hop to this hop can traverse through other routers. Multiple hop entries with the same IP address are flagged as errors. Either the **loose** *or* **strict** keyword must be specified.

strict

This keyword specifies that the LSP must take a direct path from the previous hop router to this router. No transit routers between the previous router and this router are allowed. If the IP address specified is the interface address, then that is the interface the LSP must use. If there are direct parallel links between the previous router and this router and if system IP address is specified, then any one of the available interfaces can be used by the LSP. The user must ensure that the previous router and this router have a direct link. Multiple hop entries with the same IP address are flagged as errors. Either the **loose** *or* **strict** keyword must be specified.

sid-value

Specifies the SID value. The *sid-value* can be any valid MPLS/SR label value. It is not restricted by any locally-defined label ranges since these may be different on the remote node or adjacency for which the SID is defined.

© 2025 Nokia.

Values 32 to 1048575

Platforms

All

hop

Syntax

hop *hop-index ip-address*

no hop *hop-index*

Context

[Tree] (config>service>pw-routing>path hop)

Full Context

configure service pw-routing path hop

Description

This command configures each hop on an explicit path that can be used by one or more dynamic MS-PWs. It specifies the IP addresses of the hops that the MS-PE should traverse. These IP addresses can correspond to the system IP address of each S-PE, or the IP address on which the T-LDP session to a given S-PE terminates.

The **no** form of this command deletes hop list entries for the path. All the MS-PWs currently using this path are unaffected. Additionally, all services actively using these MS-PWs are unaffected. The path must be shutdown first in order to delete the hop from the hop list. The ' **no hop hop-index**' command will not result in any action, except for a warning message on the console indicating that the path is administratively up.

Default

no hop

Parameters

hop-index

Specifies a locally significant numeric identifier for the hop. The hop index is used to order the hops specified. The LSP always traverses from the lowest hop index to the highest. The hop index does not need to be sequential.

Values 1 to 1024

ip-address

Specifies the system IP address or terminating IP address for the T-LDP session to the S-PE corresponding to this hop. For a given IP address on a hop, the system will choose the appropriate SDP to use.

configure router mpls lsp-template fast-reroute hop-limit

configure router mpls lsp fast-reroute hop-limit

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

For fast reroute, how many more routers a detour is allowed to traverse compared to the LSP itself. For example, if an LSP traverses four routers, any detour for the LSP can be no more than ten router hops, including the ingress and egress routers.

The **no** form of this command reverts to the default value.

Default

hop-limit 16

Parameters

limit

Specify the maximum number of hops.

Values 0 to 255

Platforms

All

hop-limit

Syntax

hop-limit *number*

no hop-limit

Context

[Tree] (config>router>mpls>lsp>primary-p2mp-instance hop-limit)

[Tree] (config>router>mpls>lsp hop-limit)

Full Context

configure router mpls lsp primary-p2mp-instance hop-limit

configure router mpls lsp hop-limit

Description

This command specifies the maximum number of hops that an LSP can traverse, including the ingress and egress routers. An LSP is not set up if the hop limit is exceeded. This value can be changed dynamically for an LSP that is already set up with the following implications.

If the new value is less than the current number of hops of the established LSP, the LSP is brought down. The software then tries to re-establish the LSP within the new **hop-limit** number. If the new value is equal to or greater than the current number hops of the established LSP, the LSP is not affected.

The **config**>**router**>**mpls**>**lsp**>**primary-p2mp-instance**> **hop-limit** command is not supported on the 7450 ESS.

The **no** form of this command returns the parameter to the default value.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Default

hop-limit 255

Parameters

number

Specifies the number of hops the LSP can traverse, expressed as an integer.

Values 2 to 255

Platforms

All

hop-limit

Syntax

hop-limit *number*

no hop-limit

[Tree] (config>router>mpls>lsp>secondary hop-limit)

[Tree] (config>router>mpls>lsp>primary hop-limit)

Full Context

configure router mpls lsp secondary hop-limit

configure router mpls lsp primary hop-limit

Description

This optional command overrides the **config>router>mpls>lsp** *lsp-name***>hop-limit** command. This command specifies the total number of hops that an LSP traverses, including the ingress and egress routers.

This value can be changed dynamically for an LSP that is already set up with the following implications:

If the new value is less than the current hops of the established LSP, the LSP is brought down. MPLS then tries to re-establish the LSP within the new hop-limit number. If the new value is equal or more than the current hops of the established LSP then the LSP will be unaffected.

The **no** form of this command reverts the values defined under the LSP definition using the **config>router>mpls>lsp** *lsp-name***>hop-limit** command.

Default

no hop-limit

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

number

Specifies the number of hops the LSP can traverse, expressed as an integer.

Values 2 to 255

Platforms

[Tree] (config>subscr-mgmt>loc-user-db>ipoe host)

Full Context

configure subscriber-mgmt local-user-db ppp host

configure subscriber-mgmt local-user-db ipoe host

Description

This command creates an IPoE or PPP host entry in the local user database. A host entry in the local user database is matched based on the specified match-list criteria and an optional mask that is applied to the host-identification parameters.

A default host entry can be created without host-identification parameters which is used when no other host entries match. Note that creating a default host entry also requires a match-list to be specified.

The **no** form of this command removes the host entry from the local user database.

Parameters

host-name

Specifies a unique host name, up to 32 characters. The *host-name* **default** creates a special match-all host entry that should not have host-identification parameters and is used when no other host entries match.

create

Keyword used to create the host name. The **create** keyword requirement can be enabled or disabled in the **environment>create** context.

Context

[Tree] (config>subscr-mgmt>acct-plcy host-accounting)

Full Context

configure subscriber-mgmt radius-accounting-policy host-accounting

Description

This command enables per-host accounting. In host accounting mode, the acct-session-id is generated per host. This acct-session-id is uniformly included in all accounting messages (START/INTERIM-UPDATE/STOP) and it can be included in RADIUS Access-Request message.

Accounting counters are based on the queue counters and as such are aggregated for all host sharing the queues within an sla-profile instance. CoA and LI is supported based on the acct-session-id of the host.

The **no** form of this command reverts to the default.

Parameters

interim-update

Specifies that no interim-update messages are sent for the related subscriber hosts when the session is deleted. Without this keyword, only START and STOP accounting messages are generated when the host is established or terminated. This is equivalent to a time-based accounting where only the duration of the session is required.

configure service vpls sap host-connectivity-verify

configure service vpls host-connectivity-verify

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command enables subscriber host connectivity verification on a given VPLS SAP or within a VPLS service.

This tool will periodically scan all known hosts (from dhcp-state) and perform a UC ARP request. The subscriber host connectivity verification will maintain state (connected vs. not-connected) for all hosts.

The **no** form of this command reverts to the default.

Parameters

ip-address

Specifies an unused IP address in the same network for generation of subscriber host connectivity verification packets.

ieee-address

Specifies the source MAC address to be used for generation of subscriber host connectivity verification packets.

interval

The interval, in minutes, which specifies the time interval in which all known sources should be verified. The actual rate is then dependent on number of known hosts and interval.

Values 1 to 6000 Note that a zero value can be used by the SNMP agent to disable host-connectivity-verify.

action {remove | alarm}

Defines the action taken on a subscriber host connectivity verification failure for a given host. The **remove** keyword raises an alarm and removes the dhcp-state and releases all allocated resources (queues, table entries, and so on). A DHCP release is signaled to corresponding DHCP server. The static host is never removed. The **alarm** keyword raises an alarm indicating that the host is disconnected.

retry-timeout

Specifies the time, in seconds, to wait before a SAP that has been disabled after exceeding the maximum relearn rate is re-enabled.

Values 0 to 120

count

Specifies the number of connectivity check retransmissions.

Values 10 to 60 seconds

Specifies the retry timeout.

Values 10 to 60 seconds

count

Specifies the number of retry requests.

Values 2 to 29

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

family

Allows the host connectivity checks to be performed for IPv4 endpoint, IPv6 endpoint or both. With family IPv6 configured, host connectivity checks is performed on the global unicast address (assigned via SLAAC or DHCPv6 IA_NA) and link-local address of a Layer 3 RG or bridged hosts. In case of SLAAC assignment, host connectivity can only be performed if the /128 is known (via downstream ND). DHCPv6 PD assigned prefixes is removed if link-local address is determined to be unreachable via host connectivity check" Reachability checks for GUA and link-local address is done simultaneously.

Description

This command enables subscriber host connectivity verification for all hosts on this interface. This tool periodically scans all known hosts (from dhcp-state) and perform UC ARP requests. The subscriber host connectivity verification maintains state (connected vs. not-connected) for all hosts.

The **no** form of this command reverts to the default.

Parameters

source {vrrp | interface}

Specifies the source to be used for generation of subscriber host connectivity verification packets. The **vrrp** keyword specifies that the VRRP state should be used to select proper IP and MAC (active uses VRID, back-up uses interface addresses). The **interface** keyword forces the use of the interface mac and ip addresses.

Note:
There are up to 256 possible subnets on a given interface, therefore, the subscriber host connectivity verification tool always uses an address of the

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

subnet to which the given host is pertaining. For group-interfaces, one of the parent subscriber interface subnets (depending on host's address) is used.

action {remove | alarm}

Defines the action taken on a subscriber host connectivity verification failure for a given host. The **remove** keyword raises an alarm and removes dhcp-state and releases all allocated resources (queues, table entries, and so on). The **alarm** keyword raises an alarm indicating that the host is disconnected.

interval

Specifies the interval, expressed in minutes, which specifies when all known sources should be verified. The actual rate is then dependent on number of known hosts and interval.

Values 1 to 6000

Note:
A zero value can be used by the SNMP agent to disable host-connectivity-verification.

Use subject to Terms available at: www.nokia.com/terms.

Full Context

configure router policy-options policy-statement entry from host-ip

Description

This command specifies a prefix list host IP address as a match criterion for the route policy-statement entry.

Default

no host-ip

Parameters

prefix-list-name

Specifies the prefix-list name. Allowed values are any string up to 64 characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

The *prefix-list-name* is defined in the **config>router>policy-options>prefix-list** context.

Platforms

19.71 host-key

host-key

Syntax

host-key {**mac**}

no host-key

Context

[Tree] (config>subscr-mgmt>host-lockout-plcy host-key)

Full Context

configure subscriber-mgmt host-lockout-policy host-key

Description

This command specifies the parameters used in host identification for lockout on a given SAP or capture SAP.

no host-key – include (MAC address, Circuit-Id, Remote-Id)

host-key mac – include MAC address only

"host-key mac" should be used in DHCPv4 scenarios where Circuit-Id and Remote-Id are changed with "dhcp option action replace" configuration: a host lockout context is created with the replaced Circuit-Id/

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Remote-Id; with the default host-key (including Circuit-Id and Remote-Id), lockout does not kick in on the original trigger packet when it is retransmitted by the client.

Changing the host-key to mac should be used with care: all hosts with the same MAC address on a given SAP or capture SAP are identified as a single host with respect to host-lockout.

This command cannot be changed when the **host-lockout-policy** is referenced (configured under a SAP context).

The **no** form of this command reverts to the default value.

Parameters

mac

Specifies to use the MAC address only for host identification for lockout.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

Description

This command selects an existing host lockout policy. The **host-lockout-policy** *policy-name* is created in the **config>subscr-mgmt** context.

The **no** form of this command removes the policy name from the SAP configuration.

Parameters

policy-name

Specifies an existing host lockout policy, up to 32 characters, to associate with the SAP.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

host-lockout-policy

Syntax

host-lockout-policy *policy-name* [**create**]

no host-lockout-policy *policy-name*

Context

[Tree] (config>subscr-mgmt host-lockout-policy)

Full Context

configure subscriber-mgmt host-lockout-policy

Description

This command creates a host lockout policy. The policy contains set of host lockout configuration parameters. It is applied to SAP or MSAPs (by a MSAP-policy). Any change does not impact existing locked-out hosts, but only new incoming hosts that enter lockout.

The **no** form of this command removes the policy name from the configuration. The policy must not be associated with any entity.

Parameters

policy-name

Specifies an existing host lockout policy to associate with the SAP.

create

Specifies the keyword required to create the host lockout policy. The **create** keyword requirement can be enabled or disabled in the **environment>create** context.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

[Tree] (config>port>ethernet>access>egress>vport host-match)

Full Context

configure port ethernet access egress vport host-match

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command specifies the destination and organization strings to be used for matching subscriber hosts with this Vport.

The parent Vport of a subscriber host queue, which has the port-parent option enabled, is determined by matching the destination string **dest** string associated with the subscriber and the organization string org string associated with the subscriber host with the strings defined under a Vport on the port associated with the subscriber.

If a given subscriber host queue does not have the port-parent option enabled, it will be foster-parented to the Vport used by this subscriber and which is based on matching the dest string and org string. If the subscriber could not be matched with a Vport on the egress port, the host queue will not be bandwidth controlled and will compete for bandwidth directly based on its own PIR and CIR parameters.

By default, a subscriber host queue with the port-parent option enabled is scheduled within the context of the port's port scheduler policy.

Parameters

description-string

The destination character string. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

[Tree] (config>subscr-mgmt host-tracking-policy)

Full Context

configure subscriber-mgmt sub-profile host-tracking-policy

configure subscriber-mgmt host-tracking-policy

Description

This command configures a host tracking policy. IGMP host tracking is an option in the subscriber profile that allows the factoring in of a subscriber's (multicast) video traffic by reducing the unicast operational egress aggregate rate or the rate of the scheduler specified in the ANCP policy to account for a subscriber's multicast traffic. If no ANCP policy is defined, the egress aggregate rate configured in the subscriber profile is reduced. If an ANCP policy is defined, the **rate-modify** command in the policy specifies whether the egress aggregate rate or the rate of the egress policer specified in the policy is to be reduced to account for the subscriber's multicast traffic.

The **no** form of this command reverts to the default value.

Parameters

policy-name

Specifies a host tracking policy name up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

19.79 host-unreachable

host-unreachable

Syntax

[**no**] **host-unreachable** *ip-address*

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

[**no**] **host-unreachable** *ipv6-address*

Context

[Tree] (config>vrrp>policy>priority-event host-unreachable)

Full Context

configure vrrp policy priority-event host-unreachable

Description

This command creates the context to configure a host unreachable priority control event to monitor the ability to receive ICMP echo reply packets from an IP host address.

A host unreachable priority event creates a continuous ICMP echo request (ping) probe to the specified *ip-address*. If a ping fails, the event is considered to be set. If a ping is successful, the event is considered to be cleared.

Multiple unique (different *ip-address*) **host-unreachable** event nodes can be configured within the **priority-event** node to a maximum of 32 events.

The **host-unreachable** command can reference any valid local or remote IP address. The ability to ARP a local IP address or find a remote IP address within a route prefix in the route table is considered part of the monitoring procedure. The **host-unreachable** priority event operational state tracks ARP or route table entries dynamically appearing and disappearing from the system. The operational state of the **host-unreachable** event are listed in Table 50: Host Unreachable Operational States.

Table 50: Host Unreachable Operational States

Host Unreachable Operational State	Description
Set – no ARP	No ARP address found for *ip-addr* for **drop-count** consecutive attempts; only applies when IP address is considered local
Set – no route	No route exists for *ip-addr* for **drop-count** consecutive attempts; only when IP address is considered remote
Set – host unreachable	ICMP host unreachable message received for **drop-count** consecutive attempts
Set – no reply	ICMP echo request timed out for **drop-count** consecutive attempts
Set – reply received	Last ICMP echo request attempt received an echo reply but historically not able to clear the event
Cleared – no ARP	No ARP address found for *ip-addr* - not enough failed attempts to set the event
Cleared – no route	No route exists for *ip-addr* - not enough failed attempts to set the event
Cleared – host unreachable	ICMP host unreachable message received - not enough failed attempts to set the event

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Host Unreachable Operational State	Description
Cleared – no reply	ICMP echo request timed out - not enough failed attempts to set the event
Cleared – reply received	Event is cleared - last ICMP echo request received an echo reply

Unlike other priority event types, the **host-unreachable** priority event monitors a repetitive task. A historical evaluation is performed on the success rate of receiving ICMP echo reply messages. The operational state takes its cleared and set orientation from the historical success rate. The informational portion of the operational state is derived from the last attempt's result. It is possible for the previous attempt to fail while the operational state is still cleared due to an insufficient number of failures to cause it to become set. It is also possible for the state to be set while the previous attempt was successful.

When an event transitions from clear to set, the set is processed immediately and must be reflected in the associated virtual router instances in-use priority value. As the event transitions from clear to set, a hold-set timer is loaded with the value configured by the events **hold-set** command. This timer prevents the event from clearing until it expires, damping the effect of event flapping. If the event clears and becomes set again before the hold-set timer expires, the timer is reset to the **hold-set** value, extending the time before another clear can take effect.

The hold-set timer be expired and the historical success rate must be met prior to the event operational state becoming cleared.

The **no** form of the command deletes the specific IP host monitoring event. The event may be deleted at any time. When the event is deleted, the in-use priority of all associated virtual router instances must be reevaluated. The event's **hold-set** timer has no effect on the removal procedure.

Default

no host-unreachable — No host unreachable priority events are created.

Parameters

ip-address

The IP address of the host for which the specific event will monitor connectivity. The *ip-addr* can only be monitored by a single event in this policy. The IP address can be monitored by multiple VRRP priority control policies. The IP address can be used in one or multiple **ping** requests. Each VRRP priority control **host-unreachable** and **ping** destined to the same *ip-addr* is uniquely identified on a per message basis. Each session originates a unique identifier value for the ICMP echo request messages it generates. This allows received ICMP echo reply messages to be directed to the appropriate sending application.

Values The following values apply to the 7450 ESS:

ipv4-address: a.b.c.d

Values The following values apply to the 7750 SR and 7950 XRS:

ipv4-address: a.b.c.d

ipv6-address: x:x:x:x:x:x:x:x[-interface]

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

x:	[0..FFFF]H
interface:	32 chars maximum, mandatory for link local addresses

The link-local IPv6 address must have an interface name specified. The global IPv6 address must not have an interface name specified.

Context

[Tree] (config>service>vpls>proxy-nd host-unsolicited-na-flood-evpn)

Full Context

configure service vpls proxy-nd host-unsolicited-na-flood-evpn

Description

This command controls whether the system floods host unsolicited Neighbor Advertisements to the EVPN. The NA messages impacted by this command are NA messages with the following flags: S=0 and R=0.

The **no** form of the command will only flood to local SAPs/binds but not to the EVPN destinations. This is only recommended in networks where CEs are routers that are directly connected to the PEs. Networks using aggregation switches between the host/routers and the PEs should flood unsolicited NA messages in the EVPN to ensure that the remote caches are updated and the BGP does not miss the advertisement of these entries.

Context

[Tree] (config>subscr-mgmt>sla-profile>egress hs-agg-rate-limit)

Full Context

configure subscriber-mgmt sla-profile egress hs-agg-rate-limit

Description

This command configures high scale (HS) aggregate rate limit of the SLA profile instance (SPI) associated with the subscriber in expanded SLA mode. The aggregate rate of the subscriber (the primary shaper) is configured in the **config>subscr-mgmt>sub-profile>egress>hs-agg-rate-limit** context.

The **no** form of this command removes the value from the configuration.

Parameters

kilobits-per-second

Specifies the HS egress aggregate rate limit.

Values 1 to 100000000

Platforms

7750 SR-7/12/12e

hs-agg-rate-limit

Syntax

hs-agg-rate-limit *kilobits-per-second* [**min-resv-bw** *min-rate*]

hs-agg-rate-limit max [**min-resv-bw** *min-rate*]

no hs-agg-rate-limit

Context

[Tree] (config>subscr-mgmt>sub-profile>egress hs-agg-rate-limit)

Full Context

configure subscriber-mgmt sub-profile egress hs-agg-rate-limit

Description

This command configures the HS aggregate rate limit for the subscriber in single SLA mode. In single SLA mode, the **hs-aggregate-rate-limit** command under the **config>subscr-mgmt>sla-profile** context should not be configured.

When both, **sub-profile>egress>hs-agg-rate-limit** and **sla-profile>egress>hs-agg-rate-limit** are configured, the system takes the minimum of the two to program the subscriber's aggregate rate.

The **no** form of this command removes the value from the configuration.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

kilobits-per-second

Specifies the HS egress aggregate rate limit.

Values 1 to 100000000

min-rate

Specifies the minimum rate of the minimum reserved bandwidth for unicast data traffic. Since minimum rate can oversubscribe subscriber bandwidth to guarantee a minimum bandwidth for unicast traffic, care must be taken in QoS provisioning to prioritize packets accordingly (downstream network elements such as the access node or aggregation nodes) when congestion occurs.

Values 0 to 100000000

max

Specifies that the egress aggregate rate limit for the subscriber is unlimited. Scheduling for the subscriber queues will only be governed by the individual queue parameters and any congestion on the port relative to each queues scheduling priority.

19.88 hs-attachment-policy

hs-attachment-policy

Syntax

hs-attachment-policy *policy-name* [**create**]

no hs-attachment-policy *policy-name*

Context

[Tree] (config>qos hs-attachment-policy)

Full Context

configure qos hs-attachment-policy

Description

This command specifies how the queues within an HSQ queue group associated with the SAP egress policy instance, egress queue group instance, or egress network queue policy instance attaches to the HSQ scheduling classes managed by the port scheduler. On the HSQ IOM, eight queues are allocated per egress SAP or subscriber SLA profile instance (SPI), or per egress (access or network) queue group instance, or per egress network port, numbered 1 through 8. The port scheduler maintains six scheduling classes numbered from 1 through 6 (6 being the highest relative priority and 1 being the lowest). The set of eight queues may also be placed into one of two local Weighted Round Robin (WRR) groups which collapse the member queues into a single scheduling class while providing a weighted fair distribution of scheduling opportunities per member. The attachment policy contains the **attachment** commands that map the queue IDs and WRR groups to the scheduling classes. The attachment policy also defines the mapping of the scheduling classes to the queue's aggregate shapers low and high burst limit thresholds.

The **no** form of the command deletes the HS attachment policy from the system, which is only possible if the policy is not being referenced.

Parameters

policy-name

Specifies an existing attachment policy, up to 32 characters. Each HS attachment policy must be uniquely named within the system.

create

This keyword is required when first creating the configuration context. After the context is created, it is possible to navigate into the context without the **create** keyword.

hs-attachment-policy

Syntax

hs-attachment-policy *policy-name*

no hs-attachment-policy

Context

[Tree] (config>qos>network-queue hs-attachment-policy)

Full Context

configure qos network-queue hs-attachment-policy

Description

This command associates an existing HS attachment policy with the network queue QoS policy. The HS attachment policy controls how the network queues are attached to scheduler classes or WRR groups, and how WRR groups are attached to the scheduler classes. It also defines the mapping of the scheduling classes to the queues' aggregate shaper's low and high burst limit thresholds.

Only one HS attachment policy can be associated with a network queue policy.

The **no** form of the command removes the policy name from the configuration and reapplies the default HS attachment policy.

Parameters

policy-name

Specifies an existing attachment policy up, to 32 characters. Each HSQ attachment policy must be uniquely named within the system.

hs-attachment-policy

Syntax

hs-attachment-policy *src-name dst-name* [**overwrite**]

Context

[Tree] (config>qos>copy hs-attachment-policy)

Full Context

configure qos copy hs-attachment-policy

Description

This command copies existing QoS policy entries for a QoS policy ID to another QoS policy ID.

The **copy** command is a configuration-level maintenance tool used to create new policies using existing policies. It also allows bulk modifications to an existing policy with the use of the **overwrite** keyword.

Parameters

src-name dst-name

Indicates that the source policy ID and the destination policy ID are HS policy IDs. Specify the source policy ID that the copy command attempts to copy from and specify the destination policy ID to which the command copies a duplicate of the policy.

overwrite

Specifies to replace the existing destination policy. Everything in the existing destination policy is overwritten with the contents of the source policy. If **overwrite** is not specified, an error occurs if the destination policy ID exists.

Example:

```
   – SR>config>qos# copy hs-pool-policy policy1 policy2
   – MINOR: CLI Destination "policy2" exists use {overwrite}.
   – SR>config>qos# copy hs-pool-policy policy1 policy2
overwrite
```

19.90 hs-fixed-high-thresh-delta

hs-fixed-high-thresh-delta

Syntax

hs-fixed-high-thresh-delta *size-in-bytes*

no hs-fixed-high-thresh-delta

Context

[Tree] (config>card>fp>egress hs-fixed-high-thresh-delta)

Full Context

configure card fp egress hs-fixed-high-thresh-delta

Description

This command specifies the egress aggregate shaper high burst limit threshold delta for this HSQ IOM FP. An aggregate rate can be applied to each egress HSQ queue group, HS secondary shaper and (for subscribers configured with HS SLA expanded mode) primary shaper which manages the maximum burst limit over a specified shaping rate. Each aggregate shaper supports two thresholds which are used in conjunction with the low burst class setting. The system utilizes the lowest value attainable for each low threshold aggregate burst limit without causing shaper under run conditions. The high burst limit threshold is determined by adding the configured value of this command to the aggregate's low burst limit threshold value. This configured value should be set to at least two times the maximum frame size to prevent lower threshold class forwarding from also affecting the higher threshold classes when forwarding larger packet sizes. An insufficient high threshold delta defeats the intended purpose of mapping classes to the higher threshold.

The configured value for this command can be changed at any time. Modifying the setting causes all aggregate shapers on this FP to reconfigure the low and high burst limit thresholds to reflect the new value.

The **no** form of this command reverts this parameter to the default.

Default

hs-fixed-high-thresh-delta 4000

Parameters

size-in-bytes

Specifies high threshold data in bytes.

Values 0 to 65536

Platforms

7750 SR-7/12/12e

19.91 hs-low-burst-max-class

hs-low-burst-max-class

Syntax

hs-low-burst-max-class *class*

no hs-low-burst-max-class

Context

[Tree] (config>subscr-mgmt>sub-prof>egress hs-low-burst-max-class)

Full Context

configure subscriber-mgmt sub-profile egress hs-low-burst-max-class

Description

This command specifies which scheduling classes map to the low burst limit threshold of an egress HS primary shaper. The HS primary shaper is used to manage aggregate bandwidth of the subscriber with multiple SLA profile instances (expanded SLA mode).

Each HS primary shaper supports two burst thresholds, a low burst limit threshold and a high burst limit threshold. The two thresholds allow separation of burstiness between low and high scheduling classes.

When the low burst threshold of the HS primary shaper is reached, the lower scheduling classes, up to the scheduling class configured by this command, stops being served. Traffic on higher scheduling classes still goes through until the high burst threshold is reached. When the high burst threshold is exceeded, all scheduling classes associated with the HS primary shaper and stops being serve, which effectively shuts off the traffic flow.

Typically, the queues associated with higher scheduling classes are individually rate-limited so that their aggregate allowed throughput is less than the configured rate of the HS primary shaper. Determining the **hs-low-burst-max-class** *class* value involves anticipating the proper dividing line between the low and high scheduling classes by evaluating the forwarding behavior and SLA enforcement of each class.

By default, all scheduling classes are mapped to the low burst limit threshold. When mapping scheduling classes to the high burst limit threshold, an adequate value for the **config>card>fp>egress>hs-fixed-high-thresh-delta** should be specified (by default, it is set to 4000 bytes). This is because the queues associated with the lower scheduling classes may burst over the lower threshold during normal operation due to the scheduler forwarding whole packets. The **hs-fixed-high-thresh-delta** value should be set to at least two times the maximum frame size to prevent lower threshold class forwarding from also affecting the higher threshold classes when forwarding larger packet sizes. An insufficient high threshold delta defeats the intended purpose of mapping classes to the higher threshold.

The system uses the lowest value attainable for each low threshold aggregate burst limit without causing shaper underrun conditions. The high burst limit threshold is determined by adding the **hs-fixed-high-thresh-delta** value to the aggregate low burst limit threshold value.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **hs-low-burst-max-class** value for HS primary shaper can be changed at any time in the subscriber profile (sub-profile).

The **no** form of this command restores the low burst limit threshold of the scheduling classes to the default value. This causes all scheduling classes associated with the HS primary shaper to be mapped to the low burst limit threshold.

Default

hs-low-burst-max-class 6

Parameters

class

Specifies the highest scheduling class that is associated with the low burst limit threshold of the HS primary shaper. Scheduling classes that are higher than the scheduling class ID are associated with the high burst limit threshold.

Values 1 to 6

hs-pool-policy

Syntax

hs-pool-policy *policy-name* [**create**]

no hs-pool-policy *policy-name*

Context

[Tree] (config>qos hs-pool-policy)

Full Context

configure qos hs-pool-policy

Description

Commands in this context create HS pool policy parameters. The policy can be assigned to an egress forwarding plane of an HSQ IOM. The policy contains the required parameters to create and size root and mid-tier buffer pools on an HSQ IOM, and apply a slope policy to each. The HS pool policy can be applied using the **hs-pool-policy** command within the **config>card>fp** *fp-number* **egress** context.

The system supports 63 HS pool policies including the default HS pool policy.

- HSQ IOM System Reserved Buffers — The HSQ IOM maintains two types of queues; provisioned queues and system reserved queues. The HSQ IOM ensures that provisioned queues cannot consume buffers that must be available for internal system queues required for correct operating behavior. To prevent buffer starvation between the two types of queues, the system divides the available buffers into two portions. The first portion is given to system root pools and is allocated to HSQ queues reserved for internal functions. The second portion is given to the provisioned or user-defined root pools and is available for egress service queues, network queues, queue-group queues or subscriber queues. By default, 5% of the total buffers available are given to the system root pools leaving 95% for the provisioned root pools.

  The default separation between the system and the provisioned root pools can be overridden using the **system-reserve** command.

- Root Pools — Root pools are the buffer pools at the bottom of the buffer allocation hierarchy. Two sets of root pools exist: the system root pools and the provisioned root pools. The system root pools cannot be managed by the HS pool policy; only the total number of buffers given to the system root pools can be adjusted by using the **system-reserve** command.

  The HS pool policy manages sixteen provisioned root pools defined under the **root-tier** context and specified as root-pool 1 through 16. Each root pool accepts a weight command that defines the relative quantity of buffers that are allocated to each root pool. Root pools are deactivated by defining a weight equal to 0. Root pools with a non-zero weight are sized based on the pool's weight divided by the sum of all root pool weights, multiplied by the available buffer space. In this manner, all buffers not reserved for system use are distributed between the provisioned root pools without oversubscription. The lack of oversubscription prevents buffer starvation between the root pools allowing root pools, to act as protected buffer space between different types of traffic (best-effort, expedited, or real-time). Root pools allocate buffers to the FP-level mid-tier pools.

- Mid-Tier Pools — Mid-tier pools are the buffer pools that act as aggregators for port-class pools. Multiple mid-tier pools can be mapped to a single root pool and each mid-tier pool is assigned a percentage of that root pool's buffer space. The sum of the percentages may exceed 100%,

Use subject to Terms available at: www.nokia.com/terms.

allowing for oversubscription of the root pool's buffer space. Due to statistical multiplexing principles, oversubscribing the root pool's buffer allocation may allow more efficient use of the available buffers as not all mid-tier pools are expected to use their fair share simultaneously. Examples of a multiple mid-tier pool application are multiple assured forwarding (AF) or best-effort classes being grouped together in the same root pool. The HS pool policy manages the sixteen mid-tier pools on an HSQ IOM, defined under the **mid-tier** context and specified as mid-pool 1 through 16.

- Port Class Pools — The HSQ IOM maintains two sets of scheduler class pools per port: a standard (or default) set and an alternate set. Each set contains six pools, one for each scheduler class serviced by the HSQ IOM port scheduler. Each queue or WRR group is mapped to a scheduling class based on the HS attachment policy defined within the policy or template used to create the queue. Within the SAP egress policy, network queue policy and egress queue group template, an **alt-port-class-pool** command specifies whether the queues created through the policy use the standard or alternate set of port class pools on the physical port. Further, the scheduling class servicing the queue defines which port-class pool (1 through 6) within the set allocate buffers to the queue.

  Port-class pools are defined within the **hs-port-pool-policy**, which is applied to each physical port. Further information on HSQ IOM port-class pools is contained in the HS port pool policy section.

- HSQ Stable Pool Sizing Equivalency — Stable pool sizing is a feature supported on ingress and on non-HSQ egress forwarding planes. By default, the system tries to make all buffers available to active ports (provisioned and equipped). This leads to a condition where an IOM may have only a single MDA populated and the users on that MDA receive all available buffers. At a later date, the second MDA can be populated, causing the buffer space to be fragmented between the users on each MDA. The users on the earlier populated MDA may perceive a degradation in service based on the change in available buffers. The stable pool sizing feature mitigates this potential issue by segregating the buffer space per MDA.

  The HSQ IOM can be made to operate in this stable buffer allocation mechanism by utilizing per-MDA buffer pools. This is accomplished by performing the following steps:

  1. Create two sets of root-pools and two sets of mid-pools in the **hs-pool-policy** applied to the IOM's FP egress CLI context. The first set of mid-pools should be parented to the first set of root-pools. The second set of mid-pools should be parented to the second set of root-pools.
  2. Create two distinct HS port pool policies. One is applied to the ports on the first MDA and has the port-class pools parented to the first set of mid-tier pools from the FP level policy. The second HS port pool policy is applied to the ports on the second MDA (when it is provisioned) and has the port-class pools parented to the second set of mid-tier pools from the FP level policy. This provides deterministic pool sizing independent of MDA equipping events.
  3. Configure further control at the port-class level by utilizing **explicit-percent** based port-class pool sizing, which eliminates the effect of changing port states, including bandwidth changes.

- HSQ Queue Buffer Allocation — As each packet arrives at an HSQ queue, the queue must obtain buffers to admit the packet on the queue. The queue first checks the depth of the queue relative to the packet's congestion priority (based on the in, out, or exceed profile) to determine if the packet should be discarded based on early congestion detection or based on the MBS threshold. If the packet is allowed into the queue, the HSQ IOM continues to determine buffer availability using checks to the queue's port-class pool, the port-class pool's mid-tier pool, and the mid-tier pool's root pool. The same RED slope type used at the queue (high, low, or exceed) is used within each buffer pool. If a buffer is available, the buffer can be allocated, and given to the queue.

- Default HSQ Pool Policy — An HSQ pool policy with the name **default** always exists on the system and does not need to be created. The default pool policy cannot be changed and is used by all HSQ IOMs within the system unless an explicitly created **hs-pool-policy** is associated with a forwarding plane.

hs-pool-policy

Syntax

hs-pool-policy *src-name dst-name* [**overwrite**]

Context

[Tree] (config>qos>copy hs-pool-policy)

Full Context

configure qos copy hs-pool-policy

Description

This command copies existing QoS policy entries for a QoS policy ID to another QoS policy ID.

The **copy** command is a configuration-level maintenance tool used to create new policies using existing policies. It also allows bulk modifications to an existing policy with the use of the **overwrite** keyword.

Parameters

src-name dst-name

Indicates that the source policy ID and the destination policy ID are HS policy IDs. Specify the source policy ID that the copy command attempts to copy from and specify the destination policy ID to which the command copies a duplicate of the policy.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

overwrite

Specifies to replace the existing destination policy. Everything in the existing destination policy is overwritten with the contents of the source policy. If **overwrite** is not specified, an error occurs if the destination policy ID exists.

Example:

```
   – SR>config>qos# copy hs-pool-policy policy1 policy2
   – MINOR: CLI Destination "policy2" exists use {overwrite}.
   – SR>config>qos# copy hs-pool-policy policy1 policy2
overwrite
```

Context

[Tree] (config>qos hs-port-pool-policy)

Full Context

configure qos hs-port-pool-policy

Description

This command creates an HS port buffer pool policy. The policy can be assigned to an egress port on an HSQ IOM. The policy contains the required commands to define and size port-class buffer pools on an HSQ IOM. The policy can be applied using the **hs-port-pool-policy** command within the **config>port>ethernet>egress** context.

SR OS supports 2047 HS port pool policies including the default HS port pool policy.

HSQ IOM port buffer pools provide buffer control for queues based on the queue's scheduling class. Two sets of scheduling class pools exist per port: a standard (or default) set and an alternative set. The SAP egress policy, network queue policy, and egress queue group template have a parameter (**alt-port-class-pool**) that specifies that the queues created by the policy or template uses the alternate port-class pools, as opposed to the default standard port-class pools. Each set has six pools, one for each scheduling class. Based on the **alt-port-class-pool** setting and the queue's scheduling class (based on the HS attachment policy configuration), each queue is mapped to a specific port-class pool.

The HS port pool policy defines how each of these pools are parented (mapped) to an FP level mid-pool and how each pool is sized.

The system allows two separate mechanisms to size each port-class pool:

- dynamic sizing based on port bandwidth, relative to bandwidth of other ports
- explicit sizing based on a percentage of the port-class pool's parent mid-pool

Dynamic Port-Class Pool Sizing — Dynamic port-class pool sizing is a mechanism that provides a fair share of a mid-pool's size to each of the port-class pools based on the potential bandwidth represented by each port. To understand port-class pool sizing, consider the following:

- Each port's bandwidth is the minimum of the port's line rate, the port's configured **egress-rate**, and the port's **hs-scheduler-policy** *max-rate*.
- The port's bandwidth can be further modified by the port's **egr-percentage-of-rate** command, which increases or decreases the port's bandwidth derived by the specified percent. This parameter allows the port to have a higher or lower bandwidth-derived weight based on how the port is actually being used instead of bandwidth alone.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- Because the port-class pools are user mapped to the mid-pools, not every port has a port-class pool associated with a mid-pool, requiring that the system perform the relative bandwidth calculations separately per mid-pool.
- Each port's portion of a specified mid-pool's size is calculated based on:

  Port_Portion = (Port_Adj_Bw / Sigma_Mid_Pool_Ports_Adj_Bw) * Mid_Pool_Size

  where Sigma_Mid_Pool_Ports_Adj_Bw is the sum of the adjusted bandwidths for all ports with port-class pools mapped to the mid-pool that are not sized using explicit-percent.
- A port without any port-class pools associated with a given mid-pool has a port portion of zero for that mid-pool.
- Multiple port-class pools on the same port can be mapped to the same mid-pool, requiring a mechanism to distribute the portion of the mid-pool given to the port between multiple port-class pools. Each mid-pool's **port-bw-weight** parameter is used to determine how much of the port's mid-pool portion is given to each port-class pool associated with mid-pool. Port-class pools sized using an **explicit-percent** value instead of port bandwidth are assumed to have a **port-bw-weight** equal to 0, causing those port-class pools to not participate in the port portion distribution. It is expected (but not required) that one of port bandwidth-based sizing or explicit percent-based sizing is used and any concurrent use of both mechanisms is transitory in nature.
- The port bandwidth weighting mechanism allocates 100% of the mid-pool size to the associated port-class pools. To allow the port-class pools to oversubscribe the parent mid-pool, a mid-pool **port-bw-oversub-factor** parameter is supported that allows the port-class pools sized by dynamic port bandwidth to increase in size by the specified oversubscription factor. This oversubscription factor can provide a more efficient use of the mid-pool's available buffers because it is not expected that all port-class pools are utilizing their allotted size simultaneously.

Explicit Port-Class Pool Sizing — The port-class pool's allocation **explicit-percent** *percent-of-parent-pool* command is used to override the dynamic pool sizing mechanism for a given mid-pool. The specified percentage value is applied to the port-class's parent mid-pool's size to derive the port-class pool size.

Explicit and Dynamic Sizing from the Same Mid-Pool Parent — If explicit and dynamic pool sizing are used simultaneously for port-class pools parented to the same mid-pool, unexpected contention or underutilization of the mid-pool's available buffers may result. While this is not a proscribed condition, it is expected most instances of dual-sizing mechanisms are transitory, based on moving between the two mechanisms.

Port-Class Pool Slope Policy Association — The HS port pool policy also provides the ability to specify a slope policy on each port-class pool. The slope policy is used to define the high, low, and exceed slope parameters used to manage contention within the port-class pool.

Default HS Port Pool Policy — An HS port pool policy with the name **default** always exists on the system and does not need to be created. The default port pool policy cannot be changed and is used by all HSQ IOMs within the system unless an explicitly created **hs-port-pool-policy** is associated with an HSQ egress port.

The default policy contains the following parameters:

Standard Port-Class Pools

Full Context

configure qos hs-scheduler-policy

Description

This command configures an HS scheduler policy. The HS scheduler policies are applied to egress HSQ ports in the **config>port>ethernet>egress** context. The policy contains the required commands to provision the scheduling behavior of the HSQ scheduler classes. When assigned to an HSQ egress port, the policy is used to define the scheduling behavior for all queues associated with the egress port. The values defined in the policy can be overridden on each scheduler instance using the **config>port>ethernet>egress>hs-scheduler-overrides** command.

HSQ Queue Groups — A fundamental concept on an HSQ IOM is the queue group. Queue groups are not directly managed by the provisioning. Instead, they are indirectly assigned when creating SAPs or subscribers on an HSQ port. A queue group has eight queue members, numbered from 1 through 8. When creating a SAP or subscriber associated on an HSQ egress port, a queue group is allocated to the object. Within the SAP egress policy, network queue policy and egress queue group template, provisioned queue IDs 1 through 8 correspond directly to queue group queue IDs 1 through 8. Each group also allows each queue to be dynamically placed in a scheduling class or on one of two WRR groups local to the queue group.

Each queue within the group has three RED slopes (managed by associating a slope policy to the queue), an MBS defined in bytes, a packet byte offset parameter used to add or subtract bytes to or from each packet handled by the queue for accounting purposes, and a PIR shaper used to rate limit the queue. An HSQ attachment policy associated with the queue group defines how each queue maps either directly to a scheduling class or one of the WRR groups within the queue group. The attachment policy also defines the scheduling class attachments for the WRR groups.

The queue group supports an aggregate shaper used to manage an aggregate rate limit for all queues within the group. Scheduling for queues within the queue group is stopped and started based on the rate set on the shaper.

Scheduling Classes and Scheduling Priorities — HSQ supports six scheduler classes (1 through 6). The scheduler class should not be confused with a QoS policy forwarding class. Forwarding classes within the system are used between the ingress and egress forwarding complexes and help the system to map a packet to per-hop and per-domain behavior. Scheduling classes are slices of scheduling opportunity within a port-scheduling context. Each port scheduler maintains six strict priority levels, where 6 is the highest priority and 1 is the lowest. As a rule, the scheduler services all active queues associated with priority level 6 before moving to queues on priority level 5. This strict behavior continues through priority level 1. Scheduling classes are mapped either to their corresponding scheduling priority level (scheduling class 1 mapped to priority level 1 through scheduling class 6 mapped to priority level 6) or to a single port level WRR group. The WRR group allows collapsing up to 6 of the scheduling classes into a single scheduling priority. The WRR group provides a weighted fair scheduling behavior for its member scheduling classes at that strict priority level.

Strict Priority Level PIR — The scheduler supports a strict scheduling level PIR that limits the amount of bandwidth allowed for the level. The rate is defined in increments of megabits per second and can be set to **max** (the default setting) which disables the shaping function. The scheduler includes the full Ethernet frame encapsulation overhead when updating the priority level PIR, including the 12-byte inter-frame gap and the 8-byte preamble.

Scheduler Maximum Rate — A maximum scheduling rate can be defined for the scheduler. The rate is specified in megabits per second and the default rate is **max** which allows the scheduler to operate without a set limit. When the HS scheduling policy is applied to an egress port, the maximum scheduling rate can be used to define a rate less than the available line rate of the port. The scheduler includes the full

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Ethernet frame encapsulation overhead when updating the scheduler level PIR, including the 12-byte inter-frame gap and the 8-byte preamble.

HS Scheduler Policy Overrides — After an HS scheduler is applied to an egress port, the various parameters can be overridden, allowing an HS scheduler policy to be adapted to changing needs on a port without requiring a new policy to be created.

Default HS Scheduling Policy — An HS scheduling policy with the name **default** always exists on the system and does not need to be created. The default policy cannot be modified or deleted.

The default policy contains the following parameters:

Table 51: HS Scheduler Policy Parameter Defaults

Parameter	Sub-Parameter	Default
max-rate	—	max
scheduling-class 1 through 6	rate	max
	group	—
	weight	—
group 1	rate	max

Default

The **no** form of the command removes an HS scheduler policy from the system. If the HS scheduler policy is currently associated with an egress port, the command fails.

Parameters

policy-name

Specifies the HS scheduler policy up to 32 characters. Each HS scheduler policy must be uniquely named within the system.

create

This keyword is required when first creating the configuration context. After the context is created, it is possible to navigate into the context without the **create** keyword.

configure port ethernet egress hs-secondary-shaper

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command specifies an HS secondary shaper on the port egress. HS secondary shapers are used to apply an aggregate rate and per-scheduling class rates to the set of SAP egress HSQ queue groups which reference them using the SAP egress queue-override **hs-secondary-shaper** command.

By default, the **hs-secondary-shaper** default is applied to each port egress on all HSQ ports and the settings under it can be modified.

Multiple HS secondary shapers are supported per port egress, up to the number supported per-HSQ FP, which is 4096 HS secondary shapers. The number of HS secondary shapers allocated on an HSQ FP can be seen using the **tools dump resource-usage card** *slot-number* **fp** *fp-number* command.

Non-default HS secondary shapers are only configurable on access or hybrid mode ports.

This command is only applicable to the HSQ IOM (iom4-e-hs) and will fail if configured on all other card types.

The **no** form of this command removes the HS secondary shaper from the port egress configuration. An HS scheduler policy cannot be removed when HS scheduler overrides exist on the port egress.

Default

hs-secondary-shaper default

Parameters

Context

[Tree] (config>service>vprn>if>sap>egress>queue-override hs-secondary-shaper)

Full Context

configure service vprn interface sap egress queue-override hs-secondary-shaper

Description

This command configures the HS secondary shaper to be used to apply an aggregate rate and per-scheduling class rates to the SAP egress HSQ queue group.

The **no** form of this command removes the HS secondary shaper override from the configuration, returning the SAP egress HSQ queue group to the default HS secondary shaper on that port.

Parameters

policy-name

Specifies the secondary shaper name, up to 32 characters.

Platforms

7750 SR-7/12/12e

19.99 hs-sla-mode

hs-sla-mode

Syntax

hs-sla-mode {**expanded** | **single**}

no hs-sla-mode

Context

[Tree] (config>subscr-mgmt>sub-prof hs-sla-mode)

Full Context

configure subscriber-mgmt sub-profile hs-sla-mode

Description

This command specifies the SLA profile handling mode for the subscriber if on an HS board.

The **no** form of this command reverts to the default.

Parameters

expanded

Specifies the expanded SLA profile handling mode for the subscriber if on an HS board.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

single

Specifies a single SLA profile handling mode for the subscriber if on an HS board.

Platforms

19.100 hs-turbo

hs-turbo

Syntax

[**no**] **hs-turbo**

Context

[Tree] (config>port>ethernet>access>egress>queue-group hs-turbo)

[Tree] (config>port>ethernet>network>egress>queue-group hs-turbo)

Full Context

configure port ethernet access egress queue-group hs-turbo

configure port ethernet network egress queue-group hs-turbo

Description

This command enables HS turbo queues which allows the corresponding HSQ queue group queues to achieve a higher throughput. The **hs-turbo** command is not applicable to 10G ports and is ignored when configured under a queue group instance on a 10G port.

This command is only applicable to the HSQ IOM (iom4-e-hs) and will fail if configured on all other card types.

The **no** form of this command disables the command.

Platforms

7750 SR-7/12/12e

configure system security pki est-profile http-auth

Description

This command configures HTTP authentication parameters. HTTP authentication is used by a client when requested by the server. When disabled, there is no HTTP-level client authentication.

The **no** form of the command reverts to the default value.

Default

no http-auth

Parameters

password

Specifies a text string containing the password. Allowed values are any string up to 64 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

user-name

Specifies the name of the user to authenticate, up to 32 characters.

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, cleartext form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be

configure application-assurance group http-error-redirect http-host

Description

This command refers to the http host name of the landing server (Barefruit or Xerocole). It is used in the HTTP GET operation from the client (which is being redirected) to the redirect search landing server. It must contain a valid IP address or HTTP host name / URI for the HTTP GET from the client to the landing server to work.

The **no** form of this command removes the HTTP host string from the configuration.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Default

no http-host

Parameters

http-host

Specifies a string of 255 chars max length, that refers to the HTTP host name of the landing server (barefruit or xerocole).

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

19.111 http-host-recorder

http-host-recorder

Syntax

[**no**] **http-host-recorder**

Context

[Tree] (debug>app-assure>group http-host-recorder)

Full Context

debug application-assurance group http-host-recorder

Description

This command enables the http-host-recorder feature on a particular group:partition.

The **no** form of the command disables the http-host-recorder feature.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

19.112 http-listening-port

http-listening-port

Syntax

http-listening-port *http-listening-port*

no http-listening-port

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Context

[Tree] (config>service>upnp>upnp-policy http-listening-port)

Full Context

configure service upnp upnp-policy http-listening-port

Description

This command specifies the listening port of UPnP server.

The **no** form of the command reverts to the default.

Default

http-listening-port 5000

Parameters

http-listening-port

Specifies the HTTP TCP port this UPnP IGD listens to.

Values 1 to 65535

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

19.113 http-match-all-requests

http-match-all-requests

Syntax

[**no**] **http-match-all-requests**

Context

[Tree] (config>app-assure>group http-match-all-requests)

[Tree] (config>app-assure>group>policy>app-filter>entry http-match-all-requests)

Full Context

configure application-assurance group http-match-all-requests

configure application-assurance group policy app-filter entry http-match-all-requests

Description

This command enables HTTP matching for all requests for a given HTTP expression.

The **no** form of this command restores the default (removes http-match-all-request for this particular expression) by this app-filter entry.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Default

no http-match-all-requests

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

19.114 http-notification

http-notification

Syntax

http-notification *http-notification-name* [**create**]

no http-notification *http-notification-name*

Context

[Tree] (config>app-assure>group http-notification)

Full Context

configure application-assurance group http-notification

Description

This command configures an http-notification object for subscriber in browser notification.

The **no** form of this command removes the http notification policy from the configuration.

Parameters

http-notification-name

Specifies the name of the HTTP Notification policy.

create

Specifies the mandatory keyword to create the policy.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

http-notification

Syntax

http-notification *http-notification*

no http-notification

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Context

[Tree] (config>app-assure>group>policy>aqp>entry>action http-notification)

Full Context

configure application-assurance group policy app-qos-policy entry action http-notification

Description

This command configures an HTTP notification action for flows matching this entry.

Default

no http-notification

Parameters

http-notification

specifies the Application-Assurance HTTP Notification that will be applied as defined in the tmnxBsxHttpNotifTable. If no string is configured then no HTTP notification will occur.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

19.115 http-port

http-port

Syntax

http-port {**eq** | **neq**} *port-num*

http-port {**eq** | **neq**} **port-list** *port-list-name*

no http-port

Context

[Tree] (config>app-assure>group>policy>app-filter>entry http-port)

Full Context

configure application-assurance group policy app-filter entry http-port

Description

This command specifies an HTTP server TCP or UDP port number or port list to use in the application definition.

The **no** form of this command restores the default by removing the HTTP port or port list from the application criteria defined by this app-filter entry.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Default

no http-port

Parameters

eq

Specifies that the value configured and the value in the flow are equal.

neq

Specifies that the value configured differs from the value in the flow.

port-list-name

Specifies the name of the port list containing a set or range of ports, up to 32 characters.

port-num

Specifies a valid server port number.

Values 0 to 65535

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

19.116 http-redirect

http-redirect

Syntax

http-redirect *redirect-name* [**create**]

no http-redirect *redirect-name*

Context

[Tree] (config>app-assure>group http-redirect)

Full Context

configure application-assurance group http-redirect

Description

This command configures an HTTP redirect.

The **no** form of this command removes the HTTP redirect policy from the configuration.

Parameters

redirect-name

Specifies the HTTP redirect that will be applied. If no redirect name is specified, then HTTP redirect is not enabled.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

create

Keyword to create the HTTP redirect policy.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

http-redirect

Syntax

http-redirect *http-redirect–name* **flow-type** *flow-type*

no http-redirect

Context

[Tree] (config>app-assure>group>policy>aqp>entry>action http-redirect)

Full Context

configure application-assurance group policy app-qos-policy entry action http-redirect

Description

This command assigns an existing http redirect policy as an action on flows matching this AQP entry.

The redirect only takes effect if the matching flows are HTTP and the condition specified after the **http-redirect** command, admitted flows or dropped-flows, is met. The condition specified by "dropped-flows" means the flow is dropped due to an AQP actions such as "flow rate/count policers" or "drop" actions. HTTP Policy Redirect on admitted-flows allows the operator to redirect HTTP traffic to a web portal while allowing non-HTTP matching the same AQP rule to be forwarded.

No HTTP redirect will take place if HTTP redirect action and a "drop/flow-police" action are part of the default AQP policy, because in this case, any flow drop actions will take place before identification of the application/application-group.

The **no** form of this command removes http redirect from actions on flows matching this AQP entry.

Default

no http-redirect

Parameters

http-redirect-name

Specifies the name of the existing http policy redirect for this application assurance profile. The HTTP redirect name is configured in the **config>app-assure>group>http-redirect** context.

flow-type

Specifies the flow type.

Values **admitted-flows** — Redirect HTTP flows matching the AQP criteria.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

dropped-flows — Redirects those HTTP flows that are dropped due to an AQP action.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

http-redirect

Syntax

http-redirect *http-redirect-name*

Context

[Tree] (config>app-assure>group>sess-fltr>entry>action http-redirect)

Full Context

configure application-assurance group session-filter entry action http-redirect

Description

This command configures a session filter entry action to HTTP redirect the subscriber flows. The HTTP redirect policy referenced within this session filter entry is configured for captive redirect with the appropriate VLAN id assigned.

Parameters

http-redirect-name

Specifies the name of the http-redirect-policy.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

http-redirect

Syntax

http-redirect *http-redirect-name*

no http-redirect

[Tree] (config>app-assure>group>url-filter>local-filtering>deny-list http-redirect)

Full Context

configure application-assurance group url-filter web-service http-redirect

configure application-assurance group url-filter icap http-redirect

configure application-assurance group url-filter local-filtering deny-list http-redirect

Description

This command creates or modifies an HTTP redirect policy.

Default

no http-redirect

The **no** form of this command removes the HTTP redirect policy from the configuration.

Parameters

http-redirect-name

Specifies the name of the HTTP redirect policy, up to 32 characters.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

http-redirect

Syntax

http-redirect *rdr-url-string* [**allow-radius-override**]

http-redirect url-from-cpf

Context

[Tree] (config>filter>ipv6-filter>entry>action http-redirect)

[Tree] (config>filter>ip-filter>entry>action http-redirect)

Full Context

configure filter ipv6-filter entry action http-redirect

configure filter ip-filter entry action http-redirect

Description

This command sets the filter entry action to **http-redirect** and specifies the redirect URL.

Parameters

rdr-url-string

Specifies the HTTP redirect URL, up to 255 characters. This option can be used for any session.

Values The following macro substitutions may be used:

$URL — request-URI in the HTTP GET request received

$MAC — a string that represents the MAC address of the subscriber host

$IP — a string that represents the IP address of the subscriber host

$SUB — a string that represents the subscriber ID

$SAP — a string that represents a SAP ID

$SAPDESC — description string configured on the SAP

$CID — a string that represents the circuit ID or interface ID of the subscriber host (hexadecimal format)

$RID — a string that represents the remote ID of the subscriber host (hexadecimal format)

allow-radius-override

Specifies that the HTTP redirect URL configured by *rdr-url-string* can be optionally overridden by a URL returned by the RADIUS server; this does not apply for the **url-from-cpf** option.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

url-from-cpf

Specifies that the HTTP redirect URL is from the BNG CUPS CPF. This option can be used for BNG CUPS ESM sessions only.

Platforms

All

http-redirect

Syntax

http-redirect *url*

Context

[Tree] (config>filter>mac-filter>entry>action http-redirect)

Full Context

configure filter mac-filter entry action http-redirect

Description

This command sets the MAC filter entry action to HTTP redirect.

Parameters

url

Specifies the URL, up to 255 characters.

Platforms

All

19.117 http-redirect-policy

http-redirect-policy

Syntax

http-redirect-policy *policy-name*

no http-redirect-policy

Context

[Tree] (config>subscr-mgmt http-redirect-policy)

© 2025 Nokia.

Full Context

configure service ies subscriber-interface group-interface wlan-gw vlan-tag-ranges range http-redirect-policy

configure service vprn subscriber-interface group-interface wlan-gw vlan-tag-ranges range http-redirect-policy

Description

This command specifies http redirect policy on ISA to redirect http traffic to the URL specified in the policy.

The **no** form of this command reverts to the default.

Parameters

policy-name

Specifies the name of the http redirect policy under subscriber-management context.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

19.118 http-request-filtering

http-request-filtering

Syntax

http-request-filtering {**all** | **first**}

Context

[Tree] (config>app-assure>group>url-filter http-request-filtering)

Full Context

configure application-assurance group url-filter http-request-filtering

Description

HTTP Filtering can either be enabled for all HTTP request within a flow or limited to the first HTTP request in a flow.

Default

http-request-filtering all

Parameters

all

Specifies all HTTP Request within a flow.

first

Specifies the first HTTP Request within a flow.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

19.119 http-response-timeout

Full Context

configure qos queue-group-templates egress queue-group hw-agg-shaper-queues

configure qos sap-egress hw-agg-shaper-queues

Description

This command configures the pool of queue-set sizes or non-shaper queues from which the objects using this egress queue-group template draw their queues.

Default

no hw-agg-shaper-queues

Parameters

queue-set-size

Specifies the queue-set size to use for a specific egress queue-group template.

Values 2 to 8

non-shaper-queues

Keyword to use non-shaper queues for a specific egress queue-group template.

Platforms

7750 SR-1, 7750 SR-s

19.123 hw-agg-shaper-scheduler-policy

hw-agg-shaper-scheduler-policy

Syntax

hw-agg-shaper-scheduler-policy *policy-name*

configure port ethernet access egress vport hw-agg-shaper-scheduler-policy

configure port ethernet egress hw-agg-shaper-scheduler-policy

Description

This command assigns a hardware aggregate shaper scheduler policy to the specified vport.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **no** form removes the policy from the vport.

Parameters

policy-name

Specifies the policy name.

Platforms

7750 SR-1, 7750 SR-s

hw-agg-shaper-scheduler-policy

Syntax

hw-agg-shaper-scheduler-policy *policy-name* **[create]**

no hw-agg-shaper-scheduler-policy

Context

[Tree] (config>qos hw-agg-shaper-scheduler-policy)

Full Context

configure qos hw-agg-shaper-scheduler-policy

Description

This command configures the name of the hardware aggregate shaper scheduler policy.

The **no** form removes the policy.

Parameters

policy-name

Specifies the policy name, up to 64 characters.

create

Creates a new policy.

Platforms

7750 SR-1, 7750 SR-s

19.124 hw-agg-shapers

hw-agg-shapers

Syntax

hw-agg-shapers [subscribers] [saps] [queue-groups]

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

no hw-agg-shapers

Context

[Tree] (config>qos>fp-resource-policy>aggregate-shapers hw-agg-shapers)

Full Context

configure qos fp-resource-policy aggregate-shapers hw-agg-shapers

Description

This command enables the use of hardware aggregate shapers for subscribers, SAPs, or queue groups on the specified FP.

The **no** form of this command disables the use of hardware aggregate shapers on the specified FP.

Default

no hw-agg-shapers

Parameters

subscribers

Keyword to enable hardware aggregate shapers for subscribers.

saps

Keyword to enable hardware aggregate shapers for SAPs.

queue-groups

Keyword to enable hardware aggregate shapers for queue groups.

Platforms

7750 SR-1, 7750 SR-s

19.125 hybrid-buffer-allocation

[Tree] (config>filter>ipv6-filter>entry>match icmp-code)

Full Context

configure filter ipv6-exception entry match icmp-code

configure filter ip-exception entry match icmp-code

configure filter ip-filter entry match icmp-code

configure filter ipv6-filter entry match icmp-code

Description

Configures matching on /ICMPv6 code field in the /ICMPv6 header of an IPv4 or IPv6 packet as a filter match criterion or configures matching on the ICMP code field in the ICMP header of an IPv4 packet as an exception filter match criterion. An entry containing Layer 4 non-zero match criteria will not match non-initial (for example, 2nd, 3rd) fragments of a fragmented packet because only the first fragment contains the Layer 4 information. Similarly an entry containing " **icmp-code** 0" match criterion, may match non-initial fragments when the Layer 4 header is not present in a packet fragment and other match criteria are also met.

The **no** form of the command removes the criterion from the match entry.

Default

no icmp-code

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

icmp-code

Specifies the /ICMPv6 code value that must be present to match. Value can be expressed as a decimal integer, as well as in hexadecimal or binary format, or even using keywords. The following value shows decimal integer only.

Values 0 to 255

Platforms

VSR

- configure filter ip-exception entry match icmp-code
- configure filter ipv6-exception entry match icmp-code

All

- configure filter ip-filter entry match icmp-code
- configure filter ipv6-filter entry match icmp-code

Syntax

icmp-code *icmp-code*

no icmp-code

Context

[Tree] (cfg>sys>sec>cpm>ipv6-filter>entry>match icmp-code)

[Tree] (cfg>sys>sec>cpm>ip-filter>entry>match icmp-code)

Full Context

configure system security cpm-filter ipv6-filter entry match icmp-code

configure system security cpm-filter ip-filter entry match icmp-code

Description

This command configures matching on ICMP code field in the ICMP header of an IP packet as an IP filter match criterion.

Note:
An entry containing Layer 4 match criteria will not match non-initial (2nd, 3rd, and so on) fragments of a fragmented packet because only the first fragment contains the Layer 4 information.

The behavior of the **icmp-code** value is dependent on the configured **icmp-type** value, therefore, a configuration with only an **icmp-code** value specified will have no effect. To match on the **icmp-code**, an associated **icmp-type** must also be specified.

The **no** form of this command removes the criterion from the match entry.

Default

no icmp-code

Parameters

icmp-code

Specifies the ICMP code values that must be present to match.

icmp-echo-reply

Syntax

[**no**] **icmp-echo-reply**

Context

[Tree] (config>router>nat>outside>pool icmp-echo-reply)

[Tree] (config>service>vprn>nat>outside>pool icmp-echo-reply)

Full Context

configure router nat outside pool icmp-echo-reply

configure service vprn nat outside pool icmp-echo-reply

Description

IPv4 addresses in a NAT pool can be configured to respond to ICMP Echo Requests (PINGs). The configuration can be toggled online while the pool is in use.

In L2-aware NAT when **port-block-extensions** is disabled, the reply from an outside IP address is generated only when this IP address has at least one host (binding) behind it.

In L2-aware NAT when **port-block-extensions** is enabled, the reply from an outside IP address is generated regardless if a binding is present.

In LSN, the reply from an outside IP address is generated regardless if a binding is present.

The **no** form of the command disables ICMP echo replies.

Default

no icmp-echo-reply

20.9 icmp-ping

icmp-ping

Syntax

icmp-ping {*ip-address* | *dns-name*} [{**bypass-routing** | {**interface** *interface-name*} | {**next-hop** *ip-address*}}] [**count** *requests*] [**do-not-fragment**] [**fc** *fc-name*] [**interval** { *centisecs* | *secs*}] [**pattern** *pattern*] [**rapid**] [{ **router** *router-or-service* | **router-instance** *router-instance* | **service-name** *service-name*}] [**size** *bytes*] [**source** *ip-address*] [**timeout** *timeout*] [**tos** *type-of-service*] [**ttl** *time-to-live*]

Context

[Tree] (config>saa>test>type icmp-ping)

Full Context

configure saa test type icmp-ping

Description

This command configures an ICMP traceroute test.

Parameters

ip-address* | *dns-name

Specifies the far-end IP address or DNS name to which to send the **svc-ping** request message in dotted-decimal notation.

Values

ipv4-address:	a.b.c.d	
ipv6-address:	x:x:x:x:x:x:x:x	
	x:x:x:x:x:x:d.d.d.d	
	x:	[0 to FFFF]H
	d:	[0 to 255]D
	interface	up to 32 characters. This is mandatory for link local addresses.
dns-name	up to 128 characters	

bypass-routing

Specifies whether to send the ping request to a host on a directly attached network bypassing the routing table.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

interface-name

Specifies the name used to refer to the interface, up to 32 characters. The name must already exist in the **config>router>interface** context.

next-hop *ip-address*

Displays only static routes with the specified next-hop IP address.

Values

ipv4-address:	a.b.c.d (host bits must be 0)
ipv6-address:	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x: [0 to FFFF]H
	d: [0 to 255]D

requests

Specifies the number of times to perform an OAM ping probe operation. Each OAM echo message request must either time out or receive a reply before the next message request is sent.

Values 1 to 100000

Default 5

do-not-fragment

Sets the DF (Do Not Fragment) bit in the ICMP ping packet (does not apply to ICMPv6).

fc-name

Specifies the forwarding class of the SAA.

Values be, l2, af, l1, h2, ef, h1, nc

Default nc

interval {*centisecs* | *secs*}

Specifies the minimum amount of time, in seconds, that must expire before the next message request is sent. If the **rapid** parameter is configured, this value is measured in centiseconds (hundredths of a second) instead of seconds.

Values 1 to 10000

Default 1

pattern

Specifies the date portion in a ping packet is filled with the pattern value specified. If not specified, a system-generated sequential pattern is used.

Values 0 to 65535

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

rapid

Configures the *interval* parameter to use centiseconds (hundredths of a second) instead of seconds.

router-or-service

Specifies the numerical reference to the router instance or service. Well known router names "Base", "management", "vpm-vr-name", and " vpls-management" are allowed for convenience, but are mapped numerically.

Values {*router-name* | *vprn-svc-id*}

router-name: Base, management, cmp-vr-name, vpls-management

vprn-svc-id: 1 to 2147483647

cpm-vr-name: Up to 32 characters

The parameter *router-instance* is preferred for specifying the router or service.

Default Base

router-instance

Specifies the preferred method for entering a service name. Stored as the service name. Only the service linking function is allowed for both mixed-mode and model-driven configuration modes.

Values *router-name*, *vprn-svc-name*

router-name: Base, management, vpls-management, *cpm-vr-name*

vprn-svc-name: up to 64 characters

cpm-vr-name: up to 32 characters

service-name

Specifies the alias function that allows the service name to be used, converted and stored as a service ID, up to 64 characters.

The *router-instance* parameter is preferred for specifying the router or service.

bytes

Specifies the request packet size in bytes, expressed as a decimal integer.

Values 0 to 16384

Default 56

source *ip-address*

Specifies the IP address to be used.

Values

ipv4-address: a.b.c.d

ipv6-address: x:x:x:x:x:x:x:x

x:x:x:x:x:x:d.d.d.d

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

x: [0 to FFFF]H

d: [0 to 255]D

timeout

Specifies the override time that the router waits for a message reply after sending the last probe for a specific test. Upon the expiration of the time out, the test is marked complete and no more packets are processed for any of those request probes.

Values 1 to 10

Default 5

type-of-service

Specifies the service type.

Values 0 to 255

Default 0

time-to-live

Specifies the TTL value for the MPLS label, expressed as a decimal integer.

Values 1 to 128

Default 64

Platforms

configure service nat nat-policy timeouts icmp-query

Description

This command configures the timeout applied to an ICMP query session.

Default

icmp-query min 1

Parameters

min *minutes*

Specifies the timeout, in minutes, applied to an ICMP query session.

Values 1 to 4

Default 1

sec *seconds*

Specifies the timeout, in seconds, applied to an ICMP query session.

Values 1 to 59

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

20.11 icmp-trace

icmp-trace

Syntax

icmp-trace [*ip-address* | *dns-name*] [**router** *router-or-service* | **router-instance** *router-instance* | **service-name** *service-name*] [**source** *ip-address*] [**tos** *type-of-service*] [**ttl** *ttl*] [**wait** *milliseconds*]

configure saa test type icmp-trace

Description

This command configures an ICMP traceroute test.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

ip-address

Specifies the far-end IP address to which to send the **svc-ping** request message in dotted-decimal notation.

Values

ipv4-address:	a.b.c.d	
ipv6-address:	x:x:x:x:x:x:x:x	
	x:x:x:x:x:x:d.d.d.d	
	x:	[0 to FFFF]H
	d:	[0 to 255]D
dns-name	up to 63 characters	

dns-name

Specifies the DNS name of the far-end device to which to send the **svc-ping** request message, up to 63 characters.

router-instance

Specifies the preferred method for entering a service name. Stored as the service name. Only the service linking function is allowed for both mixed-mode and model-driven configuration modes.

Values {*router-name* | *vprn-svc-name*}

router-name: Base, management, vpls-management, *cpm-vr-name*

vprn-svc-name: up to 64 characters

cpm-vr-name: up to 32 characters

Default Base

router-or-service

Specifies the numerical reference to the router instance or service. Well known router names "Base", "management" and " vpls-management" are allowed for convenience, but are mapped numerically.

Values {*router-name* | *vprn-svc-id*}

router-name: Base, management, vpls-management

vprn-svc-id: 1 to 2147483647

The parameter *router-instance* is preferred for specifying the router or service.

Default Base

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

service-name

Specifies the alias function that allows the service name to be used, converted and stored as service ID, up to 64 characters.

The parameter *router-instance* is preferred for specifying the router or service.

source *ip-address*

Specifies the IP address to be used.

Values

ipv4-address:	a.b.c.d
ipv6-address:	x:x:x:x:x:x:x:x
	x:x:x:x:x:x:d.d.d.d
	x: [0 to FFFF]H
	d: [0 to 255]D

type-of-service

Specifies the service type.

Values 0 to 255

Default 0

ttl

Specifies the TTL value for the MPLS label, expressed as a decimal integer.

Values 1 to 255

Default 30

milliseconds

Specifies the time, in milliseconds, to wait for a response to a probe, expressed as a decimal integer.

Values 10 to 60000

Default 5000

Platforms

All

20.12 icmp-tunneling

icmp-tunneling

Syntax

[**no**] **icmp-tunneling**

Context

[Tree] (config>router icmp-tunneling)

Full Context

configure router icmp-tunneling

Description

This command enables the tunneling of ICMP reply packets over MPLS LSP at a LSR node as per RFC 3032.

The LSR part of this feature consists of crafting the reply ICMP packet of type=11- 'time exceeded', with a source address set to a local address of the LSR node, and appending the IP header and leading payload octets of the original datagram. The system skips the lookup of the source address of the sender of the label TTL expiry packet, which becomes the destination address of the ICMP reply packet. Instead, CPM injects the ICMP reply packet in the forward direction of the MPLS LSP the label TTL expiry packet was received from. The TTL of pushed labels should be set to 255.

The source address of the ICMP reply packet is determined as follows. The LSR uses the address of the outgoing interface for the MPLS LSP. With LDP LSP or BGP LSP multiple ECMP next-hops can exist and in such a case the first outgoing interface is selected. If that interface does not have an address of the same family (IPv4 or IPv6) as the ICMP packet, then the system address of the same family is selected. If one is not configured, the packet is dropped.

When the packet is received by the egress LER, it performs a regular user packet lookup in the data path in the GRT context for BGP shortcut, 6PE, and BGP label route prefixes, or in VPRN context for VPRN and 6VPE prefixes. It then forwards it to the destination, which is the sender of the original packet which TTL expired at the LSR.

If the egress LER does not have a route to the destination of the ICMP packet, it drops the packets.

The rate of the tunneled ICMP replies at the LSR can be directly or indirectly controlled by the existing IOM level and CPM levels mechanisms. Specifically, the rate of the incoming UDP traceroute packets received with a label stack can be controlled at ingress IOM using the distributed CPU protection feature. The rate of the ICMP replies by CPM can also be directly controlled by configuring a system wide rate limit for packets ICMP replies to MPLS expired packets which are successfully forwarded to CPM using the command 'configure system security vprn-network-exceptions'. While this command's name refers to VPRN service, this feature rate limits ICMP replies for packets received with any label stack, including VPRN and shortcuts.

The 7450 ESS, 7750 SR, and 7950 XRS implementation supports appending to the ICMP reply of type Time Exceeded the MPLS label stack object defined in RFC 4950. It does not include it in the ICMP reply type of Destination unreachable.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The new MPLS Label Stack object permits an LSR to include label stack information including label value, EXP, and TTL field values, from the encapsulation header of the packet that expired at the LSR node. The ICMP message continues to include the IP header and leading payload octets of the original datagram.

In order to include the MPLS Label Stack object, SR OS implementation adds support of RFC 4884 which defines extensions for a multi-part ICMPv4/v6 message of type Time Exceeded.

The **no** form of command disables the tunneling of ICMP reply packets over MPLS LSP at a LSR node.

Default

20.16 icmp6-query

icmp6-query

Syntax

icmp6-query [**min** *minutes*] [**sec** *seconds*]

no icmp6-query

Context

[Tree] (config>service>nat>firewall-policy>timeouts icmp6-query)

Full Context

configure service nat firewall-policy timeouts icmp6-query

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command configures the timeout interval for ICMPv6 query mappings.

The **no** form of the command reverts the timeout interval to the default of 1 minute.

Default

icmp6-query min 1

Parameters

minutes

Specifies the number of minutes in the ICMP query mapping timeout interval.

Values 1 to 4

seconds

Specifies the number of seconds in the ICMP query mapping timeout interval.

Values 0 to 59

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

20.17 id

id

Syntax

[**no**] **id** *service-id*

Context

[Tree] (debug>service id)

Full Context

debug service id

Description

This command enables debugging for the specified service ID.

The **no** form of this command disables the debugging.

Parameters

service-id

The ID that uniquely identifies a service.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Values service-id: 1 to 214748364
svc-name: A string up to 64 characters in length

Platforms

All

20.18 id-permission

id-permission

Syntax

id-permission {**chassis**}

no id-permission

Context

[Tree] (cfg>eth-cfm>domain>assoc>bridge id-permission)

Full Context

configure eth-cfm domain association bridge-identifier id-permission

Description

This command allows the operator to include the sender-id TLV information that was specified under the **config>eth>system>sender-id** configuration for service MEPs and MIPs. When this option is present under the maintenance association, the specific MPs in the association includes the **sender-id** TLV information in ETH-CFM PDUs. MEPs include the **sender-id** TLV for CCM (not sub second CCM enabled MEPs), LBM/LBR, and LTM/LTR. MIPs includes this value in the LBR and LTR PDUs.

Note:
LBR functions reflect all TLVs received in the LBM unchanged including the SenderID TLV. Transmission of the Management Domain and Management Address fields are not supported in this TLV.

Parameters

chassis

Sends the configured chassis information defined under in the **eth-cfm>system>sender-id** context.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

id-permission

Syntax

id-permission {**chassis** | **defer**}

no id-permission

Context

[Tree] (config>eth-cfm>default-domain>bridge-identifier id-permission)

Full Context

configure eth-cfm default-domain bridge-identifier id-permission

Description

This command enables the inclusion of the Sender ID TLV information specified under the **config**>**eth**>**system**>**sender-id** command for installed MEPs and MIPs. The inclusion of the Sender ID TLV is based on the configured value. The Sender ID TLV is supported for ETH-CC, ETH-LB, and ETH-LB PDUs.

Note: LBR functions reflect back all TLVs received in the LBM, unchanged, including the Sender ID TLV. Transmission of the Management Domain and Management Address fields are not supported in this TLV.

The **no** form of this command disables the inclusion of the Sender ID TLV.

Default

id-permission defer (config>eth-cfm>default-domain>bridge-identifier)

no id-permission (config>eth-cfm>domain>association>bridge)

Parameters

chassis

Keyword to include the Sender ID TLV with a value equal to the *sender-id* configured under the eth-cfm>system context.

defer

Keyword to specify that **id-permission** will inherit the value from the global read-only system values.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

20.19 identification-strings

identification-strings

Syntax

identification-strings *option-number* [**create**]

no identification-strings

Context

[Tree] (config>subscr-mgmt>loc-user-db>ppp>host identification-strings)

[Tree] (config>subscr-mgmt>loc-user-db>ipoe>host identification-strings)

Full Context

configure subscriber-mgmt local-user-db ppp host identification-strings

configure subscriber-mgmt local-user-db ipoe host identification-strings

Description

This command specifies identification strings for the subscriber. This is useful when the server is centralized with Enhanced Subscriber Management (ESM) in a lower level in the network. These strings are parsed by a downstream Python script or they can be used literally if the **strings-from-option** option in the **config>subscr-mgmt>sub-ident-policy** context is set to this option number. In this case, the option number may be set to any allowed number (between 224 and 254 is suggested, as these are not dedicated to specific purposes). If the option number is not given, a default value of 254 is used. For PPPoE only, if the local user database is attached to the PPPoE node under the group interface and not to a local DHCP server, the strings are used internally so the option number is not used.

The **no** form of this command returns to the default.

Parameters

option-number

Specifies identification strings for the subscriber.

Values 1 to 254

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

20.20 identifier

identifier

Syntax

identifier *identifier*

no identifier

Context

[Tree] (config>system>bluetooth>module identifier)

Full Context

configure system bluetooth module identifier

Description

This command configures an identifier string used to advertise the Bluetooth module during pairing operations.

If no identifier is specified by the user, the default is derived from the platform type, the CPM slot, and the serial number of the chassis.

For example, a device with a platform field of 7750, SR-12 chassis, and a CPM serial number of NS23456 would have a Bluetooth identifier of "7750-SR-12-CPM-A-NS23456." for the CPM in slot A.

The **no** form of this command resets the identifier back to the default.

Parameters

identifier

Specifies string, up to 32 characters, using the values in the range 0-9, a-z, or A-Z.

Platforms

7750 SR-1, 7750 SR-s, 7950 XRS-20e

idi string-type *string-type* **string-value** *string-value*

no idi

Context

[Tree] (config>ipsec>client-db>client>client-id idi)

Full Context

configure ipsec client-db client client-identification idi

Description

This command specifies a match criteria that uses the peer's identification initiator (IDi) as the input, only one IDi criteria can be configured for a given client entry. This command supports the following matching methods:

- **idi any**: Matches any type of IDi with any value.
- **idi ipv4-prefix**: Matches an IDi with the type ID_IPV4_ADDR. If the **any** parameter is specified, then it will match any IPv4 address. If an IPv4 prefix is specified, then it will match an IPv4 address that is within the specified prefix.
- **idi ipv6-prefix**: Matches an IDi with the type ID_IPV6_ADDR. If the **any** parameter is specified, then it will match any IPv6 address. If an IPv6 prefix is specified, then it will match an IPv6 address that is within the specified prefix.
- **idi string-type**: Supports following type of IDi:
  - FQDN: Either a full match or a suffix match
  - RFC822: Either a full match or a suffix match

The **no** form of this command reverts to the default.

Default

no idi

Parameters

any

Matches any type of IDi with any value.

ipv4-prefix/ipv4-prefix-length

Matches any IPv4 address and prefix.

ipv6-prefix/ipv6-prefix-length

Matches any IPv6 address and prefix.

string-type

Matches the type of IDi value for this IPsec client entry.

Values fqdn, fqdn-suffix, rfc822, rfc822-suffix, regexp

string-value

Matches the IDi value within the client ID for this IPsec client entry up to 256 characters.

© 2025 Nokia.

Full Context

configure port tdm ds3 idle-cycle-flag

configure port tdm e3 idle-cycle-flag

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command configures the value that the HDLC TDM DS-0, E-3, or DS-3 interface transmits during idle cycles. For ATM ports/channels/channel-groups, the configuration does not apply and only the no form is accepted.

The **no** form of this command reverts the idle cycle flag to the default value.

Default

flags (0x7E)

no flags (ATM)

Parameters

flags

Specifies that 0x7E is used as the idle cycle flag.

ones

Specifies that 0xFF is used as the idle cycle flag.

Platforms

7450 ESS, 7750 SR-7/12/12e, 7750 SR-a, 7750 SR-e

idle-signal-fill

Syntax

idle-signal-fill {**all-ones**}

idle-signal-fill pattern *pattern*

no idle-signal-fill

Context

[Tree] (config>port>tdm>ds1>channel-group idle-signal-fill)

[Tree] (config>port>tdm>e1>channel-group idle-signal-fill)

Full Context

configure port tdm ds1 channel-group idle-signal-fill

configure port tdm e1 channel-group idle-signal-fill

Description

This command defines the signaling pattern to be transmitted when the circuit emulation service is not operational or temporarily experiences under-run conditions. This command is only valid for cesopsn-cas circuit emulation services. It is blocked with a warning for unstructured (satop) and basic cesopsn circuit emulation services.

Default

idle-signal-fill all-ones

Parameters

all-ones

Defines the 8 bit value to be transmitted as 11111111.

pattern

Transmits a user-defined pattern.

Values 0 to 15, accepted in decimal, hex or binary

Platforms

7450 ESS, 7750 SR-7/12/12e, 7750 SR-a, 7750 SR-e

Full Context

configure service vprn subscriber-interface group-interface wlan-gw vlan-tag-ranges range idle-timeout

configure service ies subscriber-interface group-interface wlan-gw vlan-tag-ranges range idle-timeout

Description

This command specifies idle-timeout behavior for DSM UEs and UEs undergoing (ISA-based) portal authentication. This knob only specifies the desired action, idle-timeout is activated by RADIUS on a per-UE basis.

The **no** form of this command resets the idle-timeout to its default.

Default

idle-timeout action remove

Parameters

action

Specifies which action to perform when the idle-timeout timer goes off.

Values remove, shcv

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

idle-timeout

Syntax

idle-timeout {*minutes* | **disable**}

no idle-timeout

Context

[Tree] (config>system>login-control idle-timeout)

Full Context

configure system login-control idle-timeout

Description

This command configures the idle timeout for console, FTP, Telnet, and SSH sessions before the session is terminated by the system.

By default, each idle console, FTP, Telnet, and SSH session times out after 30 minutes of inactivity.

The **no** form of this command reverts to the default value.

Default

idle-timeout 30

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

minutes

Specifies the idle timeout in minutes. Allowed values are 1 to 1440.

Values 1 to 1440

disable

When the **disable** option is specified, a session will never timeout. To re-enable idle timeout, enter the command without the disable option.

Platforms

All

20.27 idle-timeout-action

idle-timeout-action

Syntax

idle-timeout-action {**shcv-check** | **terminate**}

no idle-timeout-action

Context

[Tree] (config>subscr-mgmt>sla-prof>cat-map>category idle-timeout-action)

Full Context

configure subscriber-mgmt sla-profile category-map category idle-timeout-action

Description

This command defines the action to be executed when the idle-timeout is reached. The action is performed for all hosts associated with the sla-profile instance.

The **no** form of this command reverts to the default.

Default

idle-timeout-action terminate

Parameters

shcv-check

Performs a subscriber host connectivity verification check (IPoE hosts only).

Note:
Host connectivity verification must be enabled on the group-interface where the host is connected.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

If the check is successful, the hosts are not disconnected and the idle-timeout timer is reset.

If the check fails, the hosts are deleted, similar as for **idle-timeout-action terminate**.

terminate

Deletes the subscriber host from the system: for PPP hosts, a terminate request is send; for IPoE hosts a DHCP release is send to the DHCP server.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

20.28 ies

ies

Syntax

ies *service-id* [**customer** *customer-id*] [**create**] [**vpn** *vpn-id*] [**name** *name*]

no ies *service-id*

Context

[Tree] (config>service ies)

Full Context

configure service ies

Description

This command creates or edits an IES service instance.

The **ies** command creates or maintains an Internet Ethernet Service (IES). If the *service-id* does not exist, a context for the service is created. If the *service-id* exists, the context for editing the service is entered.

IES services allow the creation of customer facing IP interfaces in the same routing instance used for service network core routing connectivity. IES services require that the IP addressing scheme used by the subscriber must be unique between it and other addressing schemes used by the provider and potentially the entire Internet.

IP interfaces defined within the context of an IES service ID must have a SAP created as the access point to the subscriber network. This allows a combination of bridging and IP routing for redundancy purposes.

When a service is created, the **customer** keyword and *customer-id* must be specified and associates the service with a customer. The *customer-id* must already exist having been created using the **customer** command in the service context. Once a service has been created with a customer association, it is not possible to edit the customer association. The service must be deleted and recreated with a new customer association.

Once a service is created, the use of the **customer** *customer-id* is optional for navigating into the service configuration context. Attempting to edit a service with the incorrect *customer-id* specified results in an error.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Multiple IES services are created to separate customer owned IP interfaces. More than one IES service may be created for a single customer ID. More than one IP interface may be created within a single IES service ID. All IP interfaces created within an IES service ID belongs to the same customer.

By default, no IES service instances exist until they are explicitly created.

The **no** form of this command deletes the IES service instance with the specified *service-id*. The service cannot be deleted until all the IP interfaces defined within the service ID have been shut down and deleted.

Parameters

service-id

Specifies the unique service identification number identifying the service in the service domain. This ID must be unique to this service and may not be used for any other service of any type. The *service-id* must be the same number used for every router on which this service is defined.

Values *service-id*: 1 to 214748364

svc-name: A string up to 64 characters

customer-id

Specifies the customer ID number to be associated with the service. This parameter is required on service creation and optional for service editing or deleting.

Values 1 to 2147483647

vpn-id

Specifies the VPN ID number used to identify virtual private networks (VPNs) by a VPN identification number.

Values 1 to 2147483647

Default **null** (0)

create

Keyword used to create the service ID. The **create** keyword requirement can be enabled or disabled in the **environment>create** context.

name

This parameter configures an optional service name, up to 64 characters, which adds a name identifier to a given service to then use that service name in configuration references as well as display and use service names in show commands throughout the system. This helps the service provider or administrator to identify and manage services within the SR OS platforms.

All services are required to assign a service ID to initially create a service. However, either the service ID or the service name can be used to identify and reference a given service once it is initially created.

If a name is not specified at creation time, then SR OS assigns a string version of the service-id as the name.

Service names may not begin with an integer (0 to 9).

Values *name*: up to 64 characters

Context

[Tree] (config>cflowd>collector>exp-filter>if-list>svc ies)

Full Context

configure cflowd collector export-filter interface-list service ies

Description

This command configures the IES service interface flow data sent to this collector.

The **no** form of this command removes the values from the configuration.

Parameters

service-id

Specifies the unique service ID number or string identifying the service in the service domain. This ID must be unique to this service and may not be used for any other service of any type. The *service-id* must be the same number for every SR OS on which this service is defined.

Values *service-id*: 1 to 2147483647

svc-name: 64 characters maximum

interface *ip-int-name*

Specifies the name of the IP interface. Interface names must be unique within the group of defined IP interfaces for **configure router interface** and **configure service ies interface** commands. An interface name cannot be in the form of an IP address. Interface names can be from 1 to 32 alphanumeric characters and must start with a letter. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

subscriber-interface *ip-int-name*

Specifies the interface name of a subscriber interface. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes and must start with a letter.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

group-interface *ip-int-name*

Specifies the interface name of a group interface. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes and must start with a letter.

ingress

Keyword to specify that ingress flows are sent to the associated Cflowd Collector.

Default both

egress

Keyword to specify that egress flows are sent to the associated Cflowd Collector.

Default both

both

Keyword to specify that both ingress and egress flows are sent to the associated Cflowd Collector.

Default both

configure router mpls interface mpls-tp-mep if-num-validation

Description

The if-num-validation command is used to enable or disable validation of the if-num in LSP Trace packet against the locally configured if-num for the interface over which the LSP Trace packet was received at the egress LER. This is because some third-party implementations may not perform interface validation for unnumbered MPLS-TP interfaces and instead set the if-num in the DSMAP TLV to 0. If the value is **enable**, the node performs the validation of the ingress and egress if-nums received in the LSP echo request messages that ingress on this MPLS-interface. It validates that the message arrives on the interface as identified by the ingress if-num, and is forwarded on the interface as identified by the egress if-num.

If the value is **disable**, no validation is performed for the ingress and egress if-nums received in the LSP echo request messages that ingress on this MPLS-interface.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Default

if-num-validation enable

Parameters

enable

Enables interface number validation.

disable

Disables interface number validation.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

if-policy

Syntax

if-policy *mcac-if-policy-name*

no if-policy

Context

[Tree] (config>subscr-mgmt>msap-policy>vpls-only>igmp-snp>mcac if-policy)

Full Context

configure subscriber-mgmt msap-policy vpls-only-sap-parameters igmp-snooping mcac if-policy

Description

This command assigns an existing MCAC interface policy to this MSAP policy.

The **no** form of this command removes the MCAC interface policy association.

Parameters

mcac-if-policy-name

Specifies an existing MCAC interface policy up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

Context

[Tree] (config>router igmp)

Full Context

configure router igmp

Description

This command enables the Internet Group Management Protocol (IGMP) context. When the context is created, the IGMP protocol is enabled.

The Internet Group Management Protocol (IGMP) is used by IPv4 systems (hosts and routers) to report their IP multicast group memberships to neighboring multicast routers. An IP multicast router can be a member of one or more multicast groups, in which case it performs both the "multicast router part" of the protocol which collects the membership information needed by its multicast routing protocol, and the "group member part" of the protocol which informs itself and other neighboring multicast routers of its memberships.

The **no** form of the command disables the IGMP instance. To start or suspend execution of IGMP without affecting the configuration, use the **no shutdown** command.

Platforms

All

igmp

Syntax

[**no**] **igmp**

Context

configure subscriber-mgmt igmp-policy

Description

This command configures an IGMP policy.

The **no** form of this command reverts to the default value.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

policy-name

Specifies the policy name up to 32 characters.

create

Keyword used to create the IGMP policy. The **create** keyword requirement can be enabled or disabled in the **environment>create** context.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

igmp-policy

Syntax

igmp-policy *policy-name*

no igmp-policy

Context

[Tree] (config>subscr-mgmt>sub-prof igmp-policy)

Full Context

configure subscriber-mgmt sub-profile igmp-policy

Description

This command will enable IGMP processing per subscriber host. Without this command IGMP states will not be maintained per subscriber hosts. The referenced policy is defined under the **configure>subscr-mgmt** context and can be only applied via the sub-profile.

The referenced policy contains entries such as:

- description statement
- import statement — IGMP filters
- egress-rate-modify statement—HQoS Adjustment
- mcast-redirection statement—redirection to alternate interface
- static statement—definition of static IGMP groups
- version statement —IGMP version
- fast-leave statement
- max-num-groups statement—the maximum number of multicast groups allowed

The **no** form of this command reverts to the default.

Parameters

policy-name

Specifies the name of the IGMP policy for the subscriber. The policy itself is defined under the **configure>sub-mgmt** context.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

configure service vpls ignore-l2vpn-mtu-mismatch

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command enables the router to bring up a VPLS service, regardless of any MTU mismatch. The router does not check the value of the Layer 2 MTU in the Layer 2 Info Extended Community received in a BGP update message or the value of the MTU interface parameter received in a LDP label mapping message against the local service MTU or locally signaled MTU.

The **no** form of this command disables the functionality. When this functionality is disabled, the router does not bring up a VPLS service if an MTU mismatch occurs.

Default

no ignore-l2vpn-mtu-mismatch

Full Context

configure router isis ignore-lsp-errors

configure service vprn isis ignore-lsp-errors

Description

This command specifies that for this VPRN instance, ISIS will ignore LSP packets with errors. When enabled, IS-IS LSP errors will be ignored and the associated record will not be purged.

This command enables ISIS to ignore the ATT bit and therefore suppress the installation of default routes.

The **no** form of this command specifies that ISIS will not ignore LSP errors.

configure router dhcp6 server pool failover ignore-mclt-on-takeover

configure service vprn dhcp6 local-dhcp-server failover ignore-mclt-on-takeover

Description

With this flag enabled, the remote IP address or prefix can be taken over immediately upon entering the PARTNER-DOWN state of the intercommunication link, without having to wait for the Maximum Client Lead Time (MCLT) to expire. By setting this flag, the lease times of the existing DHCP clients, while the intercommunication link is in the PARTNER-DOWN state, will still be reduced to the MCLT over time and all new lease times are set to MCLT. This behavior remains the same as originally intended for MCLT.

Some deployments require that the remote IP address/prefix range starts delegating new IP addresses and prefixes upon the failure of the intercommunication link, without waiting for the intercommunication link to transition from the COMM-INT state into the PARTNER-DOWN state and the MCLT to expire while in PARTNER-DOWN state.

This can be achieved by enabling the **ignore-mclt-on-takeover** flag and by configuring the **partner-down-delay** to 0.

Enabling this functionality must be exercised with caution. One needs to keep in mind that the partner-down-delay and MCLT timers were originally introduced to prevent IP address duplication in cases where DHCP redundant nodes transition out-of-sync due to the failure of intercommunication link. These timers (**partner-down-delay** and MCLT) would ensure that during their duration, the new IP addresses and prefixes are delegated only from one node, the one with local IP address-range/prefix. This causes the new IP address delegation to be delayed and the service is impacted.

If it can be assured that the intercommunication link is always available, then the DHCP nodes would stay in sync and the two timers would not be needed. Therefore, it is important that in this mode of operation, the intercommunication link is well protected by providing multiple paths between the two DHCP nodes. The only event that should cause intercommunication link to fail is the entire nodal failure. This failure is acceptable since in this case only one DHCP node is available to provide new IP addresses and prefixes.

The **no** form of this command reverts to the default.

[Tree] (config>router>mpls>lsp igp-shortcut)

Full Context

configure router mpls lsp-template igp-shortcut

configure router mpls lsp igp-shortcut

Description

This command enables the use of a specific RSVP LSP by IS-IS and OSPF routing protocols as a shortcut or as a forwarding adjacency for resolving IGP routes.

When the **igp-shortcut** or the **advertise-tunnel-link** option is enabled at the IGP instance level, all RSVP LSPs originating on this node are eligible by default as long as the destination address of the LSP, as configured in **config>router>mpls>lsp>to**, corresponds to a router-id of a remote node.

The **lfa-protect** option allows an LSP to be included in both the main SPF and the Loop-Free Alternate (LFA) SPF. For a given prefix, the LSP can be used either as a primary next-hop or as an LFA next-hop, but not both. If the main SPF computation selected a tunneled primary next-hop for a prefix, the LFA SPF will not select an LFA next-hop for this prefix and the protection of this prefix will rely on the RSVP LSP FRR protection. If the main SPF computation selected a direct primary next-hop, then the LFA SPF will select an LFA next-hop for this prefix but will prefer a direct LFA next-hop over a tunneled LFA next-hop.

The **lfa-only** option allows an LSP to be included in the LFA SPF only such that the introduction of IGP shortcuts does not impact the main SPF decision. For a given prefix, the main SPF always selects a direct primary next-hop. The LFA SPF selects an LFA next-hop for this prefix but will prefer a direct LFA next-hop over a tunneled LFA next-hop.

When the **relative-metric** option is enabled, IGP will apply the shortest IGP cost between the endpoints of the LSP plus the value of the offset (instead of the LSP operational metric) when computing the cost of a prefix which is resolved to the LSP. The offset value is optional and it defaults to zero. The minimum net cost for a prefix is one (1) after applying the offset. The TTM continues the show the LSP operational metric as provided by MPLS. In other words, applications such as LDP-over-RSVP (when IGP shortcut is disabled) and BGP and static route shortcuts will continue to use the LSP operational metric.

The **relative-metric** option is mutually exclusive with the **lfa-protect** or the **lfa-only** options. In other words, an LSP with the **relative-metric** option enabled cannot be included in the LFA SPF, and vice-versa, when the **igp-shortcut** option is enabled in the IGP.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Finally, the **relative-metric** option is ignored when forwarding adjacency is enabled in IS-IS or OSPF. In this case, IGP advertises the LSP as a point-to-point unnumbered link along with the LSP operational metric as returned by MPLS and capped to maximum link metric allowed in that IGP. Both the main SPF and the LFA SPFs will use the local IGP database to resolve the routes.

When the router performs local SPF, the SR-TE LSP is used as an eligible IGP shortcut for SRv4 or SRv6 only if the LSP is explicitly allowed using the **allow-sr-over-srte** option when the top SID in the SR-TE LSP is an adjacency SID.

The **no** form of this command disables the use of a specific RSVP LSP by IS-IS and OSPF routing protocols as a shortcut or a forwarding adjacency for resolving IGP routes.

Default

igp-shortcut. All RSVP LSPs originating on this node are eligible by default as long as the destination address of the LSP corresponds to a router-id of a remote node.

Parameters

lfa-protect

Specifies an LSP is included in both the main SPF and the LFA SPF.

lfa-only

Specifies an LSP is included in the LFA SPF only.

relative-metric [*offset*]

Specifies the shortest IGP cost between the endpoints of the LSP plus the configured offset, instead of the LSP operational metric returned by MPLS, is used when calculating the cost of prefix resolved to this LSP. The offset parameter is an integer and is optional. An offset value of zero is used when the relative-metric option is enabled without specifying the offset parameter value.

Values [-10, +10]

allow-sr-over-srte

Specifies that the LSP or LSP template is eligible as an IGP shortcut.

Context

[Tree] (config>router>isis igp-shortcut)

Full Context

configure router isis igp-shortcut

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command enables the use of an RSVP-TE or SR-TE shortcut for resolving IGP routes by OSPF or IS-IS routing protocols.

This command instructs IGP to include RSVP LSPs and SR-TE LSPs originating on this node and terminating on the router ID of a remote node as direct links with a metric equal to the metric provided by MPLS.

During the IP reach calculation to determine the reachability of nodes and prefixes, LSPs are overlaid and the LSP metric is used to determine the subset of paths that are equal lowest cost to reach a node or a prefix. If the user enabled the **relative-metric** option for this LSP, IGP will apply the shortest IGP cost between the endpoints of the LSP plus the value of the offset, instead of the LSP operational metric, when computing the cost of a prefix that is resolved to the LSP.

When a prefix is resolved to a tunnel next-hop, the packet is sent labeled with the label stack corresponding to the NHLFE of the RSVP-TE or SR-TE LSP, as well as the explicit-null IPv6 label at the bottom of the stack in the case of an IPv6 prefix. Any network event causing one or more IGP shortcuts to go down will trigger a full SPF computation, which may result in installing a new route over an updated set of tunnel next-hops and IP next-hops.

When **igp-shortcut** is enabled at the IGP instance level, all RSVP-TE and SR-TE LSPs originating on this node are eligible by default as long as the destination address of the LSP, as configured in **config>router>mpls>lsp>to**, corresponds to a router ID of a remote node. LSPs with a destination corresponding to an interface address or any other loopback interface address of a remote node are automatically not considered by IGP. The user can, however, exclude a specific RSVP-TE or SR-TE LSP from being used as a shortcut for resolving IGP routes by entering the **config>router>mpls>lsp>no igp-shortcut** command.

The SPF in IGP only uses RSVP LSPs as forwarding adjacencies, IGP shortcuts, or as endpoints for LDP-over-RSVP. These applications of RSVP LSPs are mutually exclusive at the IGP instance level. If two or more options are enabled in the same IGP instance, then forwarding adjacency takes precedence over the shortcut application, which takes precedence over the LDP-over-RSVP application.

The SPF in IGP uses SR-TE LSPs as IGP shortcuts only.

When ECMP is enabled on the system and multiple equal-cost paths exist for a prefix, the following selection criteria are used to pick up the set of tunnel and IP next-hops to program in the data path.

- Where a destination is a tunnel-endpoint (including external prefixes with tunnel-endpoint as the next-hop), the tunnel with lowest tunnel-index is selected (the IP next-hop is never used in this case).
- Where a destination is not a tunnel-endpoint:
  - LSPs with metric higher than underlying IGP cost between the endpoint of the LSP are excluded
  - Tunnel next-hops are preferred over IP next-hops
  - Within tunnel next-hops, the following priority applies to selection:
    1. The lowest endpoint-to-destination cost is selected
    2. If the endpoint-to-destination costs are the same, the lowest endpoint node router ID is selected
    3. If the router IDs are the same, the lowest tunnel index is selected
  - Within IP next-hops, the following priority applies to selection:
    1. The lowest downstream router ID is selected
    2. If the downstream router IDs are the same, the lowest interface-index is selected

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Note:
Although ECMP is not performed across both the IP and tunnel next-hops, the tunnel endpoint may lie in one of the shortest IGP paths for that prefix. In that case, the tunnel next-hop is always selected as long as the prefix cost using the tunnel is equal to or lower than the IGP cost.

When both RSVP-TE and SR-TE IGP shortcuts are available, the IP reach calculation, in the unicast routing table, will first follow the above ECMP tunnel and IP next-hop selection rules when resolving a prefix over IGP shortcuts. After the set of ECMP tunnel and IP next-hops have been selected, the preference of tunnel type is then applied based on the user setting for prefix family resolution. If the user enabled resolution of the prefix family to both RSVP-TE and SR-TE tunnel types, the TTM tunnel preference value is used to select one type for the prefix. In other words, an RSVP-TE LSP type is preferred to an SR-TE LSP type on a per-prefix basis.

The ingress IOM sprays the packets for this prefix over the set of tunnel next-hops and IP next-hops based on the hashing routine currently supported for IPv4 packets.

This feature provides IGP with the capability to populate the multicast RTM with the prefix IP next-hop when both the **igp-shortcut** and the **multicast-import** options are enabled in IGP. The unicast RTM can still use the tunnel next-hop for the same prefix. The SPF keeps track of both the direct first hop and the tunneled first hop of a node, which is added to the Dijkstra tree.

between the endpoints of the LSP plus the value of the offset, instead of the LSP operational metric, when computing the cost of a prefix that is resolved to the LSP.

When a prefix is resolved to a tunnel next hop, the packet is sent labeled with the label stack corresponding to the NHLFE of the RSVP-TE or SR-TE LSP, as well as the explicit-null IPv6 label at the bottom of the stack in the case of an IPv6 prefix. Any network event causing one or more IGP shortcuts to go down will trigger a full SPF computation, which may result in installing a new route over an updated set of tunnel next-hops and IP next-hops.

When **igp-shortcut** is enabled at the IGP instance level, all RSVP-TE and SR-TE LSPs originating on this node are eligible by default as long as the destination address of the LSP, as configured in **config>router>mpls>lsp>to**, corresponds to a router ID of a remote node. LSPs with a destination corresponding to an interface address or any other loopback interface address of a remote node are automatically not considered by IGP. The user can, however, exclude a specific RSVP-TE or SR-TE LSP from being used as a shortcut for resolving IGP routes by entering the **config>router>mpls>lsp>no igp-shortcut** command.

The SPF in IGP only uses RSVP LSPs as forwarding adjacencies, IGP shortcuts, or as endpoints for LDP-over-RSVP. These applications of RSVP LSPs are mutually exclusive at the IGP instance level. If two or more options are enabled in the same IGP instance, then forwarding adjacency takes precedence over the shortcut application, which takes precedence over the LDP-over-RSVP application.

The SPF in IGP uses SR-TE LSPs as IGP shortcuts only.

When ECMP is enabled on the system and multiple equal-cost paths exist for a prefix, the following selection criteria are used to pick up the set of tunnel and IP next-hops to program in the data path.

- Where a destination is a tunnel-endpoint (including external prefixes with tunnel-endpoint as the next hop), the tunnel with lowest tunnel-index is selected (the IP next hop is never used in this case).
- Where a destination is not a tunnel-endpoint:
  - LSPs with metric higher than underlying IGP cost between the endpoint of the LSP are excluded
  - Tunnel next-hops are preferred over IP next-hops
  - Within tunnel next-hops:
    1. The lowest endpoint-to-destination cost is selected
    2. If the endpoint-to-destination costs are the same, the lowest endpoint node router ID is selected
    3. If the router IDs are the same, the lowest tunnel index is selected
  - Within IP next-hops:
    1. The lowest downstream router ID is selected
    2. If the downstream router IDs are the same, the lowest interface-index is selected

Note:
Although ECMP is not performed across both the IP and tunnel next-hops, the tunnel endpoint may lie in one of the shortest IGP paths for that prefix. In that case, the tunnel next hop is always selected as long as the prefix cost using the tunnel is equal or lower than the IGP cost.

When both RSVP-TE and SR-TE IGP shortcuts are available, the IP reach calculation, in the unicast routing table, will first follow the above ECMP tunnel and IP next hop selection rules when resolving a prefix over IGP shortcuts. After the set of ECMP tunnel and IP next-hops have been selected, the preference of tunnel type is then applied based on the user setting of the resolution of the family of the prefix. If the user enabled resolution of the prefix family to both RSVP-TE and SR-TE tunnel types, the

Use subject to Terms available at: www.nokia.com/terms.

TTM tunnel preference value is used to select one type for the prefix. In other words, the RSVP-TE LSP type is preferred to an SR-TE LSP type on a per-prefix basis.

The ingress IOM sprays the packets for this prefix over the set of tunnel next-hops and IP next-hops based on the hashing routine currently supported for IPv4 packets.

This feature provides IGP with the capability to populate the multicast RTM with the prefix IP next hop when both the **igp-shortcut** and the **multicast-import** options are enabled in IGP. The unicast RTM can still make use of the tunnel next hop for the same prefix. This change is made possible with the enhancement by which SPF keeps track of both the direct first hop and the tunneled first hop of a node which is added to the Dijkstra tree.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Default

ike-auth-algorithm sha1

Parameters

auth-algorithm

Specifies the values used to identify the hashing algorithm

Values **md5** — Configures the use of the hmac-md5 algorithm for authentication

sha1 — Configures the use of the hmac-sha1 algorithm for authentication

sha256 — Configures the use of the hmac-sha256 algorithm for authentication.

sha384 — Configures the use of the hmac-sha384 algorithm for authentication

sha512 — Configures the use of the hmac-sha512 algorithm for authentication.

aes-xcbc — Configures the use of aes-xcbc (RFC 3566, *The AES-XCBC-MAC-96 Algorithm and Its Use With IPsec*) algorithm for authentication.

Platforms

Context

[Tree] (config>ipsec>ike-transform ike-encryption-algorithm)

Full Context

configure ipsec ike-transform ike-encryption-algorithm

Description

This command specifies the IKE encryption algorithm to be used in the IKE transform instance.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Default

ike-encryption-algorithm aes128

Parameters

encryption-algorithm

Specifies the IKE encryption algorithm.

Values **des** — Configures the 56-bit des algorithm for encryption. This is an older algorithm with relatively weak security. While better than nothing, it should only be used where a strong algorithm is not available on both ends at an acceptable performance level.

3des — Configures the 3-des algorithm for encryption. This is a modified application of the des algorithm which uses multiple des operations to make information more secure.

aes128 — Configures the aes algorithm with a block size of 128 bits. This is a mandatory implementation size for aes. This is a very strong algorithm choice.

aes192 — Configures the aes algorithm with a block size of 192 bits. This is a stronger version of aes.

aes256 — Configures the aes algorithm with a block size of 256 bits. This is the strongest available version of aes.

aes128-gcm8 - Configures ESP to use aes-gcm with a 128-bit key size and an 8-byte ICV for encryption and authentication.

aes128-gcm16 - Configures ESP to use aes-gcm with a 128-bit key size and a 16-byte ICV for encryption and authentication.

aes256-gcm8 - Configures ESP to use aes-gcm with a 256-bit key size and an 8-byte ICV for encryption and authentication.

aes256-gcm16 - This parameter configures ESP to use aes-gcm with a 256-bit key size and a 16-byte ICV for encryption and authentication.

20.75 implicit-generation

implicit-generation

Syntax

[**no**] **implicit-generation**

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Context

[Tree] (config>subscr-mgmt>auto-sub-id-key implicit-generation)

Full Context

configure subscriber-mgmt auto-sub-id-key implicit-generation

Description

By default, the system automatically generates a subscriber identifier, using the characters A to Z and 0 to 9, that is used when a subscriber ID is not provided during the authentication of a subscriber host or session and when no explicit default **def-sub-id** is configured at the SAP or in the MSAP policy.

A subscriber ID obtained from authentication sources can conflict with the format of an implicit, automatically generated subscriber ID. When this happens, the subscriber host or session setup fails and generates the following message: "Non auto-generated sub-id 4574233754 with an auto sub-id format not allowed". Therefore, when implicit subscriber ID generation is enabled (the default behavior), a 10-character string containing characters A to Z and 0 to 9 should not be returned from authentication sources.

The **no** form of this command disables the implicit automatic generation of subscriber IDs. When a subscriber ID is not provided in authentication and no explicit **def-sub-id** is configured, then the host or session setup fails and generates the following message: "Missing subscriber id". A 10-character (A to Z and 0 to 9) subscriber ID format can be returned from authentication sources without the risk of conflicts.

Disabling the implicit automatic generation of subscriber IDs fail when there are active subscribers with an implicit automatically generated subscriber ID.

Enabling the implicit automatic generation of subscriber IDs fails when there are active subscribers.

Default

implicit-generation

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

All

implicit-null-label

Syntax

[**no**] **implicit-null-label**

Context

[Tree] (config>router>rsvp implicit-null-label)

Full Context

configure router rsvp implicit-null-label

Description

This command enables the use of the implicit null label.

Signaling the IMPLICIT NULL label value for all RSVP LSPs can be enabled for which this node is the egress LER. RSVP must be shut down before being able to change this configuration option.

The egress LER does not signal the implicit null label value on P2MP RSVP LSPs. However, the Penultimate Hop Popping (PHP) node can honor a Resv message with the label value set to the implicit null.

The **no** form of this command disables the signaling of the implicit null label.

Default

no implicit-null-label

Platforms

All

implicit-null-label

Syntax

implicit-null-label [**enable** | **disable**]

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

no implicit-null-label

Context

[Tree] (config>router>rsvp>interface implicit-null-label)

Full Context

configure router rsvp interface implicit-null-label

Description

This command enables the use of the implicit null label over a specific RSVP interface.

All LSPs for which this node is the egress LER and for which the path message is received from the previous hop node over this RSVP interface will signal the implicit null label. This means that if the egress LER is also the merge-point (MP) node, then the incoming interface for the path refresh message over the bypass dictates if the packet will use the implicit null label or not. The same for a 1-to-1 detour LSP.

The user must shut down the RSVP interface before being able to change the implicit null configuration option.

The **no** form of this command returns the RSVP interface to use the RSVP level configuration value.

Default

no implicit-null-label

Parameters

enable

Enables the implicit null label.

disable

Disables the implicit null label.

Full Context

configure subscriber-mgmt local-user-db ipoe host mld-parameters import

configure subscriber-mgmt local-user-db ppp host mld-parameters import

Description

This command configures an MLD import policy.

The LUDB allows a list of up to 14 MLD import policies per host. The MLD policy also allows the configuration of an additional import policy, providing a total of 15 MLD import policies per host. The import policy inside the MLD policy is always applied last, which determines if the list is a black list or a white list. To configure an MLD white list, the import policies in the LUDB should all be allowed or forward entries and the import policy in the MLD policy should have a default action to deny all. To configure a black list, the import policies inside the LUDB should drop entries and the MLD policy import policy default action should be to forward all. The 15 import policies can be configured to be a mixed white and black list. Since it is difficult to control the order of the import policies within the LUDB, it is recommended to provision the import policy inside the MLD policy first for deterministic behavior.

The **no** form of this command removes the specified import policy.

Parameters

policy-name

Specifies the MLD import policy, up to 32 characters, used to control the multicast group accessible for the subscriber host.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

[Tree] (config>subscr-mgmt>bgp-prng-plcy import)

Full Context

configure subscriber-mgmt bgp-peering-policy import

Description

This command specifies the import policies to be used to control routes advertised to BGP neighbors. Route policies are configured in the **config>router>policy-options** context. When multiple policy names are specified, the policies are evaluated in the order they are specified. The first policy that matches is applied.

The **no** form of this command removes all route policy names from the import list.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Default

no import — BGP accepts all routes from configured BGP neighbors. Import policies can be used to limit or modify the routes accepted and their corresponding parameters and metrics.

Parameters

policy

Specifies route policy statement name, up to 32 characters. Up to five policies can be specified.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

configure service vprn bgp group neighbor import

configure service vprn bgp group import

configure service vprn bgp import

Description

This command is used to specify route policies that control the handling of inbound routes received from certain peers. Route policies are configured in the **config>router>policy-options** context.

This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in a peer-group) or neighbor level (only applies to the specified peer). The most specific level is used

The **import** command can reference up to 15 objects, where each object is either a policy logical expression or the name of a single policy. The objects are evaluated in the specified order to determine the modifications of each route and the final action to accept or reject the route.

Only one of the 15 objects referenced by the **import** command can be a policy logical expression consisting of policy names (enclosed in square brackets) and logical operators (AND, OR, NOT). The first of the 15 objects has a maximum length of 255 characters while the remaining 14 objects have a maximum length of 64 characters each.

When multiple **import** commands are issued, the last command entered overrides the previous command.

When an import policy is not specified, BGP routes are accepted by default.

The **no** form of this command removes the policy association.

Default

no import

Parameters

plcy-or-long-expr

Specifies the route policy name (up to 64 characters) or a policy logical expression (up to 255 characters).

plcy-or-expr

Specifies the route policy name (up to 64 characters) or a policy logical expression (up to 255 characters).

configure service vprn isis import

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command applies one or more (up to five) route polices as IS-IS import policies.

When a prefix received in an IS-IS LSP is accepted by an entry in an IS-IS import policy, it is installed in the routing table, if it is the most preferred route to the destination.

When a prefix received in an IS-IS LSP is rejected by an entry in an IS-IS import policy, it is not installed in the routing table, even if it has the lowest preference value among all the routes to that destination.

The flooding of LSPs is unaffected by IS-IS import policy actions.

The **no** form of this command removes all policies from the configuration.

Default

no import

Parameters

policy-name

Identifies the export route policy name. Allowed values are any string up to 32 characters, composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed between double quotes. The specified name(s) must already be defined.

configure service vprn pim import

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command specifies the import route policy to be used for determining which routes are accepted from peers. Route policies are configured in the **config>router>policy-options** context. When an import policy is not specified, BGP routes are accepted by default.

The **no** form of this command removes the policy association from the IGMP instance.

Default

no import join-policy

no import register-policy

Parameters

join-policy

Use this command to filter PIM join messages which prevents unwanted multicast streams from traversing the network.

register-policy

This keyword filters register messages. PIM register filters prevent register messages from being processed by the RP. This filter can only be defined on an RP. When a match is found, the RP immediately sends back a register-stop message.

policy-name

Specifies the route policy name. Allowed values are any string up to 32 characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed between double quotes. Route policies are configured in the **config>router>policy-options** context.

admin certificate import

Description

This command converts an input file (key/certificate/CRL) to a system format file. The following list summarizes the formats supported by this command:

- Certificate
  - PKCS #12
  - PKCS #7 PEM encoded
  - PKCS #7 DER encoded
  - PEM
  - DER
- Key
  - PKCS #12
  - PEM
  - DER
- CRL
  - PKCS #7 PEM encoded
  - PKCS #7 DER encoded
  - PEM
  - DER

Note:
If there are multiple objects with the same type in the input file, only the first object is extracted and converted.

Parameters

input *url-string*

Specifies the URL for the input file. This URL could be either a local CF card URL file or a FP URL to download the input file.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Values	url-string	<local-url> up to 99 characters
	local-url	<cflash-id>/<file-path>
	cflash-id	cf1:| cf2:| cf3:

output *filename*

Specifies the name of output file up to 95 characters. The output directory depends on the file type like following:

- Key: cf3:\system-pki\key
- Cert: cf3:\system-pki\cert
- CRL: cf3:\system-pki\CRL

type

The type of input file.

Values cert, key, crl

format

Specifies the format of input file.

Values pkcs12, pkcs7-der, pkcs7-pem, pem, der

password

Specifies the password to decrypt the input file in case that it is an encrypted PKCS#12 file.

configure router bgp group neighbor import

Description

This command specifies route policies that control the handling of inbound routes received from certain peers. Route policies are configured in the **config>router>policy-options** context.

This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). The most specific level is used.

The **import** command can reference up to 15 objects, where each object is either a policy logical expression or the name of a single policy. The objects are evaluated in the specified order to determine the modifications of each route and the final action to accept or reject the route.

Only one of the 15 objects referenced by the **import** command is allowed to be a policy logical expression consisting of policy names (enclosed in square brackets) and logical operators (AND, OR, NOT). The first of the 15 objects has a maximum length of 255 characters; the remaining 14 objects have a maximum length of 64 characters each.

When multiple **import** commands are issued, the last command entered overrides the previous command.

When an import policy is not specified, BGP routes are accepted by default.

The **no** form of this command removes the policy association.

Default

no import

Parameters

plcy-or-long-expr

Specifies the route policy name (up to 64 characters long) or a policy logical expression (up to 255 characters long). Allowed values are any string up to 255 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

plcy-or-expr

Specifies the route policy name (up to 64 characters long) or a policy logical expression (up to 64 characters long). Allowed values are any string up to 64 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

Full Context

configure router isis import

Description

This command specifies up to five route polices as IS-IS import policies.

When a prefix received in an IS-IS LSP is accepted by an entry in an IS-IS import policy, it is installed in the routing table, if it is the most preferred route to the destination.

When a prefix received in an IS-IS LSP is rejected by an entry in an IS-IS import policy, it is not installed in the routing table, even if it has the lowest preference value among all the routes to that destination.

The flooding of LSPs is unaffected by IS-IS import policy actions.

The **no** form of this command removes all policies from the configuration.

Default

no import

Parameters

policy-name

Specifies the import route policy name. Allowed values are any string up to 32 characters, composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes. The specified names must already be defined.

Description

This command applies one or more (up to 5) route polices as OSPF import policies. When a prefix received in an OSPF LSA is accepted by an entry in an OSPF import policy, it is installed in the routing table if it is the most preferred route to the destination. When a prefix received in an OSPF LSA is rejected by an entry in an OSPF import policy, it is not installed in the routing table, even if it has the lowest preference value among all the routes to that destination. The flooding of LSAs is unaffected by OSPF import policy actions. The **no** form of this command removes all policies from the configuration.

Default

no import

Parameters

policy-name

Specifies up to 5 export route policy names. Allowed values are any string up to 32 characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes. The specified names must already be defined.

configure router rip group import

configure router ripng group neighbor import

configure router rip import

configure router rip group neighbor import

configure router ripng group import

Description

This command configures import route policies to determine which routes are accepted from RIP neighbors. If no import policy is specified, RIP accepts all routes from configured RIP neighbors. Import policies can be used to limit or modify the routes accepted and their corresponding parameters and metrics.

If multiple policy names are specified, the policies are evaluated in the order they are specified. The first policy that matches is applied. If multiple import commands are issued, the last command entered will override the previous command. A maximum of five policy names can be specified.

The **no** form of the command removes all policies from the configuration.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Default

no import

Parameters

policy-name

Specifies up to five import route policy names. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

The specified names must already be defined.

All

import

Syntax

import {**ignore** | **accept** | **drop**}

Context

[Tree] (config>service>vprn>bgp-ipvpn>attribute-set import)

Full Context

configure service vprn bgp-ipvpn attribute-set import

Description

This command configures the reception behavior for ATTR_SETs in received VPN-IP routes.

Default

import ignore

Parameters

accept

Keyword to configure BGP to accept and process ATTR_SETs in received unicast VPN-IP routes (MPLS or SRv6) when they are imported into the VPRN. The path attributes contained inside the ATTR_SET are used for best-path selection within the VPRN, instead of the outer-path attributes attached to the imported VPN-IP route. The path attributes inside the ATTR_SET determine the path attributes of BGP routes advertised to PE-CE peers of the VPRN. However, the ATTR_SET is removed at the time of advertisement. VPRN BGP routes with attributes derived from **accept** processing are only advertised to EBGP peers and IBGP route reflector client peers. VPRN BGP routes are not advertised to BGP confederation peers. If the origin AS in the ATTR_SET attribute does not match the configured ASN, VPRN BGP routes with attributes derived from **accept** processing are advertised to IBGP peers that are not covered by a cluster configuration.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

drop

Keyword to configure BGP to ignore and silently discard ATTR_SETs in received VPN-IP routes when they are imported into the VPRN. The path attributes contained inside the ATTR_SET are not used for best path selection within the VPRN. If a VPRN is not involved in an independent domain Layer 3 VPN service, Nokia recommends configuring the **import** command to **drop**.

ignore

Keyword to configure BGP to ignore ATTR_SETs in received VPN-IP routes when they are imported into the VPRN. The path attributes contained inside the ATTR_SET are not used for best-path selection within the VPRN. With the **ignore** parameter, the ATTR_SET attribute is transmitted unchanged to the CE. Nokia does not recommend configuring the **import** command to **ignore** in most deployments.

Platforms

All

20.78 import-grt

import-grt

Syntax

import-grt *plcy-or-long-expr* [*plcy-or-expr*]

no import-grt

Context

[Tree] (config>service>vprn>grt import-grt)

Full Context

configure service vprn grt-lookup import-grt

Description

This command associates policies to control the leaking of GRT routes into the associated VPRN.

The GRT route must have first been leaked by a **leak-export** policy defined under the **config>router** context. Then the route must match a route entry in the specified **import-grt** policy with an accept action. Refer to the *IP Router Configuration Command Reference* section in the *7750 SR Extensible Routing System Virtualized Service Router*.

The **no** form of this command removes route leaking policy associations and disables the leaking of GRT routes into the local VPRN.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

plcy-or-long-expr

Specifies route policy names, up to 64 characters, or a policy logical expression, up to 255 characters.

Values *plcy-or-long-expr*: *policy-name* | *long-expr*

policy-name: up to 64 characters

long-expr: up to 255 characters

plcy-or-expr

Specifies up to four route policy names, up to 64 characters, or a policy logical expression, up to 64 characters.

Values *plcy-or-expr*: *policy-name* | *expr*

policy-name: up to 64 characters

expr: up to 64 characters

Context

[Tree] (config>router>ldp>session-params>peer import-prefixes)

Full Context

configure router ldp session-parameters peer import-prefixes

Description

This command configures the import FEC prefix policy to determine which prefixes received from this LDP peer are imported and installed by LDP on this node. If resolved these FEC prefixes are then re-distributed to other LDP and T-LDP peers. A FEC prefix that is filtered out (deny) will not be imported. A FEC prefix that is filtered in (accept) will be imported.

If no import policy is specified, the node will import all prefixes received from this LDP/T-LDP peer. This policy is applied in addition to the global LDP policy and targeted session policy.

Policies are configured in the **config>router>policy-options** context. A maximum of five policy names can be specified. Peer address has to be the peer LSR-ID address.

The **no** form of the command removes the policy from the configuration.

Default

no import-prefixes - no import route policy is specified

Parameters

policy-name

Specifies up to five import-prefix route policy names. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters excluding double quotes. If the string contains spaces, use double quotes to delimit the start and end of the string. The specified name(s) must already be defined.

configure router ldp targeted-session import-prefixes

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command configures the import route policy to determine which FEC prefix label bindings are accepted from targeted LDP neighbors into this node. A label binding that is filtered out (deny) will not be imported. A route that is filtered in (accept) will be imported.

If no import policy is specified, this node session will accept all bindings from configured targeted LDP neighbors. This policy is applied in addition to the global LDP policy.

Policies are configured in the **config>router>policy-option**s context. A maximum of five policy names can be specified.

The **no** form of this command removes the policy from the configuration.

Parameters

policy-name

Specifies up to five import policy names. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

20.82 import-tunnel-table

import-tunnel-table

Syntax

import-tunnel-table *policy-name* [*policy-name*]

no import-tunnel-table

Context

[Tree] (config>router>ldp import-tunnel-table)

Full Context

configure router ldp import-tunnel-table

Description

This command controls the import, in the tunnel table, of LDP tunnels to non-host prefixes. This command is only intended for importing tunnels; it cannot be used for preventing the import of any specific prefix and only non-host prefixes will be considered when evaluating this policy in this context. The LDP tunnels to these non-host prefixes must be created before they can be imported.

This command does not affect the automatic import of LDP tunnels to host prefixes.

The **no** version of this command removes all of the import policies and, by consequence, any tunnels to non-host prefixes from the tunnel table. If a non-host prefix tunnel is currently being used for forwarding, disabling this command may be service-impacting.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Default

no import-tunnel-table

Parameters

policy-name

Specifies up to five import route policy names. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

The specified policy names must already be defined.

improved-assert

Syntax

[**no**] **improved-assert**

Context

[Tree] (config>service>vprn>pim>if improved-assert)

Full Context

configure service vprn pim interface improved-assert

Description

This command enables improved assert processing on this interface. The PIM assert process establishes a forwarder for a LAN and requires interaction between the control and forwarding planes.

The assert process is started when data is received on an outgoing interface. This could impact performance if data is continuously received on an outgoing interface.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

When enabled, the PIM assert process is done entirely on the control-plane with no interaction between the control and forwarding plane.

Default

improved-assert

Platforms

All

improved-assert

Syntax

[**no**] **improved-assert**

Context

[Tree] (config>router>pim>interface improved-assert)

Full Context

configure router pim interface improved-assert

Description

This command enables improved assert processing. The PIM assert process establishes a forwarder for a LAN and requires interaction between the control and forwarding planes. The assert process is started when data is received on an outgoing interface meaning that duplicate traffic is forwarded to the LAN until the forwarder is negotiated among the routers.

When the **improved-assert** command is enabled, the PIM assert process is done entirely in the control plane. The advantages are that it eliminates duplicate traffic forwarding to the LAN. It also improves performance since it removes the required interaction between the control and data planes.

Note:
improved-assert is still fully interoperable with the RFC 4601, *Protocol Independent Multicast - Sparse Mode (PIM-SM): Protocol Specification (Revised)* and RFC 2362, *Protocol Independent Multicast-Sparse Mode (PIM-SM)*, implementations. However, there may be conformance tests that may fail if the tests expect control-data plane interaction in determining the assert winner. Disabling the **improved-assert** command when performing conformance tests is recommended.

Full Context

configure router mpls mpls-tp transit-path forward-path in-label

configure router mpls mpls-tp transit-path reverse-path in-label

Description

This command configures the label mapping associated with a forward path or reverse path of an MPLS-TP transit path to be configured.

The incoming label, outgoing label and outgoing interface must be configured, using the **in-label**, **out-label** and **out-link** parameters. If the out-link refers to a numbered IP interface, the user may optionally configure the **next-hop** parameter and the system will determine the interface to use to reach the configured next-hop, but will check that the user-entered value for the *out-link* corresponds to the link returned by the system. If they do not correspond, then the path will not come up.

Default

no in-label

Parameters

in-label

Specifies the in label.

Values 32 to 16415

out-label

Specifies the out label.

Values 32 to 16415

if-name

Specifies the name of the outgoing interface use for the path.

next-hop

Specifies the next-hop.

Values a.b.c.d

20.101 in-remark

in-remark

Syntax

in-remark {**dscp** *dscp-name* | **prec** *ip-prec-value*}

no in-remark

Context

[Tree] (config>qos>sap-ingress>fc in-remark)

Full Context

configure qos sap-ingress fc in-remark

Description

This command is used in a SAP ingress QoS policy to define an explicit in-profile remark action for a forwarding class or subclass. While the SAP ingress QoS policy may be applied to any SAP, the remarking functions are only enforced when the SAP is associated with an IP or subscriber interface (in an IES or VPRN). When the policy is applied to a Layer 2 SAP (i.e., Epipe or VPLS), the remarking definitions are silently ignored.

In the case where the policy is applied to a Layer 3 SAP, the in-profile remarking definition will be applied to packets that have been classified to the forwarding class or subclass. It is possible for a packet to match a classification command that maps the packet to a particular forwarding class or subclass, only to have a more explicit (higher priority match) override the association. Only the highest priority match forwarding class or subclass association will drive the in-profile marking.

The in-remark command is only applicable to ingress IP routed packets that are considered in-profile. The profile of a SAP ingress packet is affected by either the explicit in-profile/out-of-profile definitions or the ingress policing function applied to the packet. Table 52: Effect of In-Remark Command on Received SAP

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Ingress Packets shows the effect of the in-remark command on received SAP ingress packets. Within the in-profile IP packet's ToS field, either the six DSCP bits or the three precedence bits are remarked.

Table 52: Effect of In-Remark Command on Received SAP Ingress Packets

SAP Ingress Packet State	in-remark Command Effect
Non-Routed, Policed In-Profile	No Effect (non-routed packet)
Non-Routed, Policed Out-of-Profile	No Effect (non-routed packet)
Non-Routed, Explicit In-Profile	No Effect (non-routed packet)
Non-Routed, Explicit Out-of-Profile	No Effect (non-routed packet)
IP Routed, Policed In-Profile	in-remark value applied to IP header ToS field
IP Routed, Policed Out-of-Profile	No Effect (out-of-profile packet)
IP Routed, Explicit In-Profile	in-remark value applied to IP header ToS field
IP Routed, Explicit Out-of-Profile	No Effect (out-of-profile packet)

The **no** form of this command disables ingress remarking of in-profile packets classified to the forwarding class or subclass.

Parameters

dscp *dscp-name*

Specifies that the matching packet's DSCP bits should be overridden with the value represented by dscp-name.

The *dscp-name* parameter is a 6-bit value. It must be one of the predefined DSCP names defined on the system.

Values be, cp1, cp2, cp3, cp4, cp5, cp6, cp7, cs1, cp9, af11, cp11, af12, cp13, af13, cp15, cs2, cp17, af21, cp19, af22, cp21, af23, cp23, cs3, cp25, af31, cp27, af32, cp29, af33, cp31, cs4, cp33, af41, c p35, af42, cp37, af43, cp39, cs5, cp41, cp42, cp43, cp44, cp45, ef, cp47, nc1, cp49, cp50, cp51, cp52, cp53, cp54, cp55, nc2, cp57, cp58, cp59, cp60, cp61, cp62, cp63

prec *ip-prec-value*

Specifies that the matching packet's precedence bits should be overridden with the value represented by *ip-prec-value*.

Values 0 to 7

20.102 inactive-flow-timeout

inactive-flow-timeout

Syntax

inactive-flow-timeout *seconds*

no inactive-flow-timeout

Context

[Tree] (config>cflowd inactive-flow-timeout)

Full Context

configure cflowd inactive-flow-timeout

Description

This command specifies the length of time, in seconds, that must elapse without a packet matching a flow before the flow is considered inactive.

The **no** form of this command resets the inactive flow timeout back to the default of 15 seconds.

Existing flows do not inherit the new **inactive-flow-timeout** value if this parameter is changed while **cflowd** is active. The **inactive-flow-timeout** value for a flow is set when the flow is first created in the active cache table and does not change dynamically.

Default

inactive-flow-timeout 15

Parameters

seconds

Specifies the length of time, in seconds, without a packet matching a flow before the flow is considered inactive.

Values 10 to 600

Platforms

All

Syntax

inactivity-timeout *seconds*

no inactivity-timeout

Context

[Tree] (config>test-oam>twamp>twamp-light inactivity-timeout)

Full Context

configure test-oam twamp twamp-light inactivity-timeout

Description

This command configures the length of time to maintain stale state on the session reflector. Stale state is test data that has not been refreshed or updated by newly arriving probes for that specific test in a predetermined length of time. Any single reflector can maintain up state for a maximum of 12000 tests. If the maximum value is exceeded, the session reflector lacks memory to allocate to new tests.

The **no** form of this command returns the value to the default.

Default

inactivity-timeout 100

Parameters

seconds

Specifies the value in seconds for maintaining stale state.

Values 10 to 100

© 2025 Nokia.

configure eth-cfm slm inactivity-timer

Description

The time the responder keeps a test active. Should the time between packets exceed this values within a test the responder will mark the previous test as complete. It will treat any new packets from a peer with the same test-id, source-mac and MEP-ID as a new test responding with the sequence number one.

The **no** form of the command reverts the timeout to the default value.

Default

inactivity-timer 100

Parameters

timer

Specifies the amount of time in seconds.

Values 10 100

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

Context

[Tree] (config>system>security>vprn-aaa-server inband)

Full Context

configure system security vprn-aaa-server inband

Description

This command configures TACACS+ or RADIUS servers in a VPRN to be used for AAA by that VPRN and by sessions in the Base routing instance.

The **no** form of this command disables the use of servers for in-band management.

Default

no inband

Parameters

service-id

Specifies the VPRN server for AAA to use for in-band sessions.

Values *service-id*: 1 to 2147483648

svc-name: 64 characters maximum

Platforms

All

20.107 inband-collector-export-only

inband-collector-export-only

Syntax

[**no**] **inband-collector-export-only**

Context

[Tree] (config>cflowd inband-collector-export-only)

Full Context

configure cflowd inband-collector-export-only

Description

This command, when the **inband-collector-export-only** command is enabled, allows only collectors that are reachable through inband interfaces and enables a higher flow export rate.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **no** form of this command, the default, re-enables the use of the out-of-band management Ethernet port.

20.108 inbound-max-sessions

inbound-max-sessions

Syntax

inbound-max-sessions *number-of-sessions*

no inbound-max-sessions

Context

[Tree] (config>system>login-control>ftp inbound-max-sessions)

Full Context

configure system login-control ftp inbound-max-sessions

Description

This command configures the maximum number of concurrent inbound FTP sessions.

This value is the combined total of inbound and outbound sessions.

The **no** form of this command reverts to the default value.

Default

inbound-max-sessions 3

Parameters

value

Specifies the maximum number of concurrent FTP sessions on the node.

Values 0 to 5

Platforms

All

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

inbound-max-sessions

Syntax

inbound-max-sessions *number-of-sessions*

no inbound-max-sessions

Context

[Tree] (config>system>login-control>telnet inbound-max-sessions)

[Tree] (config>system>login-control>ssh inbound-max-sessions)

Full Context

configure system login-control telnet inbound-max-sessions

configure system login-control ssh inbound-max-sessions

Description

This parameter limits the number of inbound Telnet and SSH sessions. A maximum of 30 telnet and ssh connections can be established to the router. The local serial port cannot be disabled.

Telnet and SSH maximum sessions can also use the combined total of both inbound sessions (SSH +Telnet). While it is acceptable to continue to internally limit the combined total of SSH and Telnet sessions to N, either SSH or Telnet sessions can use the inbound maximum sessions, if so required by the Operator.

The **no** form of this command reverts to the default value.

Default

inbound-max-sessions 5

Parameters

number-of-sessions

The maximum number of concurrent inbound Telnet sessions, expressed as an integer.

Values 0 **to** 50 (default = 5) or 0 **to** N where N is the new total number of SSH +Telnet sessions if they are scaled

20.109 incl-mcast-l2-attributes-advertisement

incl-mcast-l2-attributes-advertisement

Syntax

[**no**] **incl-mcast-l2-attributes-advertisement**

Context

[Tree] (config>service>vpls>bgp-evpn incl-mcast-l2-attributes-advertisement)

Full Context

configure service vpls bgp-evpn incl-mcast-l2-attributes-advertisement

Description

This command triggers the advertisement of the Layer 2 attributes extended community including:

- the service MTU in the Layer 2 MTU field
- the F bit, which is set to 1 if the **hash-label** command is set to true (in the **configure service vpls bgp-evpn mpls** context); otherwise, the F bit is set to 0
- the C bit, which is set to 1 if the **control-word** command is set to true (in the **configure service vpls bgp-evpn mpls** context); otherwise, the C bit is set to 0

The router compares the received Layer 2 MTU from a peer with the local service MTU. If there is a mismatch, the operation state of the EVPN destination is set to down, except if the **configure service vpls bgp-evpn ignore-mtu-mismatch** command is enabled.

A mismatch between the received C bit and the local **control-word** setting (in the **configure service vpls bgp-evpn mpls** context) results in the operational state of the EVPN destination being set to down.

A mismatch between the received F bit and the local F bit (via the hash label configuration) results in the operational state of the EVPN destination being set to down.

The **no** form of this command prevents the router from advertising the Layer 2 attributes extended community along with the IMET route for the service.

Default

no incl-mcast-l2-attributes-advertisement

Platforms

All

Use subject to Terms available at: www.nokia.com/terms.

20.110 incl-mcast-orig-ip

incl-mcast-orig-ip

Syntax

incl-mcast-orig-ip *ip-address*

no incl-mcast-orig-ip

Context

[Tree] (config>service>vpls>bgp-evpn incl-mcast-orig-ip)

Full Context

configure service vpls bgp-evpn incl-mcast-orig-ip

Description

The IP address configured by the user in the **incl-mcast-orig-ip** command is encoded in the **originating-ip** field of EVPN Inclusive Multicast Routes with tunnel type Ingress Replication (value 6), mLDP (2), and Composite IR and mLDP (130).

The configured address does not need to be reachable in the base router or have an interface in the base router. The originating-ip address is used solely for BGP route-key selection.

The originating-ip is never changed for Inclusive Multicast Routes with tunnel type AR (Assisted Replication, value 10).

The **no** version of the command withdraws the affected Inclusive Multicast Routes and re-advertises it with the default system-ip address in the originating-ip field.

Default

incl-mcast-orig-ip 1

Parameters

ip-address

Specifies the IPv4 address value.

Values a.b.c.d

Platforms

All

Full Context

configure router mpls lsp secondary include

configure router mpls lsp-template include

configure router mpls lsp primary-p2mp-instance include

configure router mpls lsp primary include

configure router mpls lsp include

Description

This command specifies the admin groups to be included when an LSP is set up. Up to five groups per operation can be specified, up to 32 maximum. The **include** statement instructs the CSPF algorithm to pick TE links among the links which belong to one or more of the specified admin groups. A link that does not belong to at least one of the specified admin groups is excluded and thus pruned from the TE database before the CSPF computation. However, a link can still be selected if it belongs to one of the groups in a **include** statement but also belongs to other groups which are not part of any **include** statement in the LSP or primary/secondary path configuration. In other words, the **include** statements implements the "include-any" behavior.

The **config**>**router**>**mpls**>**lsp**>**primary-p2mp-instance**> **include** command is not supported on the 7450 ESS.

The **no** form of this command deletes the specified groups in the specified context.

Default

no include

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

group-name

Specifies admin groups to be included when an LSP is set up.

20.116 include-group

include-group

Syntax

include-group *ip-admin-group-name* [**pref** *preference*]

no include-group *ip-admin-group-name*

Context

[Tree] (config>router>route-next-hop-policy>template include-group)

Full Context

configure router route-next-hop-policy template include-group

Description

This command configures the admin group constraint into the route next-hop policy template.

Each group is entered individually. The **include-group** statement instructs the LFA SPF selection algorithm to pick up a subset of LFA next-hops among the links which belong to one or more of the specified admin groups. A link which does not belong to at least one of the admin-groups is excluded. However, a link can still be selected if it belongs to one of the groups in a include-group statement but also belongs to other groups which are not part of any include-group statement in the route next-hop policy.

The **pref** option is used to provide a relative preference for the admin group to select. A lower preference value means that LFA SPF will first attempt to select a LFA backup next-hop which is a member of the corresponding admin group. If none is found, then the admin group with the next higher preference value is evaluated. If no preference is configured for a given admin group name, then it is supposed to be the least preferred, that is, numerically the highest preference value.

When evaluating multiple **include-group** statements within the same preference, any link which belongs to one or more of the included admin groups can be selected as an LFA next-hop. There is no relative preference based on how many of those included admin groups the link is a member of.

The **exclude-group** statement simply prunes all links belonging to the specified admin group before making the LFA backup next-hop selection for a prefix.

If the same group name is part of both include and exclude statements, the exclude statement will win. It other words, the exclude statement can be viewed as having an implicit preference value of 0.

The admin-group criteria are applied before running the LFA next-hop selection algorithm.

The **no** form deletes the admin group constraint from the route next-hop policy template.

© 2025 Nokia.

20.120 inclusive

inclusive

Syntax

inclusive

Context

[Tree] (config>service>vpls>provider-tunnel inclusive)

Full Context

configure service vpls provider-tunnel inclusive

Description

Commands in this context configure the use of a P2MP LSP as the default tree for forwarding Broadcast, Unknown unicast, and Multicast (BUM) packets of a VPLS or B-VPLS instance. The P2MP LSP is referred to, in this case, as the Inclusive Provider Multicast Service Interface (I-PMSI).

When enabled, this feature relies on BGP Auto-Discovery (BGP-AD), BGP-VPLS or BGP-EVPN to discover the PE nodes participating in a specified VPLS/B-VPLS instance. In the case of BGP-AD or BGP-VPLS, the BGP route contains the information required to signal both point-to-point (P2P) PWs used to forward unicast known Ethernet frames, and the RSVP or mLDP P2MP LSP used to forward the BUM frames. In the case of BGP-EVPN, the EVPN IMET route contains the information to set up the mLDP P2MP LSP and may also contain the information that enables the remote leaf-only nodes to setup an EVPN destination to the sending PE.

Note:
The provider-tunnel for a specified service must be configured with an owner protocol (BGP-AD, BGP-VPLS or BGP-EVPN); only one owner must be configured. Use the **owner {bgp-ad|bgp-vpls|bgp-evpn-mpls}** command to configure an owner.

With an mLDP I-PMSI, each leaf node will initiate the signaling of the mLDP P2MP LSP upstream using the P2MP FEC information in the I-PMSI tunnel information discovered through the BGP.

If IGMP or PIM snooping are configured on the VPLS/B-VPLS instance, multicast packets matching an L2 multicast Forwarding Information Base (FIB) record will also be forwarded over the P2MP LSP.

Use the **mldp** command to enable the use of an LDP P2MP LSP as the I-PMSI for forwarding Ethernet BUM and IP multicast packets in a VPLS instance:

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

config>service>vpls [b-vpls]>provider-tunnel>inclusive>mldp

When a **no shutdown** is performed under the context of the inclusive node and the expiration of a delay timer, BUM packets will be forwarded over an automatically signaled mLDP P2MP LSP.

Use the **root-and-leaf** command to configure the node to operate as both root and leaf in the VPLS instance:

config>service>vpls [b-vpls]>provider-tunnel>inclusive>root-and-leaf

The node behaves as a leaf-only node by default. For the I-PMSI of type mLDP, the leaf-only node will join I-PMSI rooted at other nodes it discovered but will not include a PMSI Tunnel Attribute in BGP route update messages. This way a leaf-only node will forward packets to other nodes in the VPLS/B-VPLS using the point-to-point spoke-SDPs in the case of BGP-AD or BGP-VPLS, or using EVPN destinations in the case of BGP-EVPN.

Note:
Either BGP-AD/VPLS or BGP-EVPN must be enabled in the VPLS/B-VPLS instance otherwise the execution of the **no shutdown** command under the context of the inclusive node will fail and the I-PMSI will not come up.

If the P2MP LSP instance goes down, the VPLS/B-VPLS immediately reverts the forwarding of BUM packets to the P2P PWs or EVPN destinations (in the case of BGP-EVPN). Performing a shutdown under the context of the inclusive node will allow the user to restore BUM packet forwarding over the P2P PWs or EVPN destinations.

This feature is supported with VPLS and B-VPLS; it is not supported with I-VPLS. Although Routed VPLS is supported, routed traffic cannot be sent over the I-PMSI tree.

[Tree] (config>router>ospf3>timers incremental-spf-wait)

[Tree] (config>router>ospf>timers incremental-spf-wait)

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Full Context

configure router ospf3 timers incremental-spf-wait

configure router ospf timers incremental-spf-wait

Description

This command sets the delay before an incremental SPF calculation is performed when LSA types 3, 4, 5, or 7 are received. This allows multiple updates to be processed in the same SPF calculation. Type 1 or type 2 LSAs are considered a topology change and will always trigger a full SPF calculation.

The **no** form of this command resets the timer value back to the default value.

Note:
The timer granularity is 10 ms if the value is less than 500 ms, and 100 ms if the value is ≥ 500 ms. Timer values are rounded down to the nearest granularity, for example a configured value of 550 ms is internally rounded down to 500 ms.

Default

incremental-spf-wait 1000

Parameters

incremental-spf-wait

Specifies the OSPF incremental SPF calculation delay, in milliseconds.

Values 0 to 1000

Platforms

All

20.123 index

index

Syntax

index *index* [**create**]

no index *index*

Context

[Tree] (config>service>dynsvc>ladb>user index)

Full Context

configure service dynamic-services local-auth-db user-name index

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command creates an index entry containing authentication data for a dynamic service SAP. Up to 32 indexes can be created per user name entry, representing up to 32 dynamic service SAPs that can be instantiated with a single dynamic service data trigger. One of the dynamic service SAPs must be the data trigger SAP.

The **no** form of this command removes the index entry from the user name entry in the local authentication database configuration.

Parameters

index

Specifies the index entry identifier.

Values 1 to 32

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

index

Syntax

index *index-id* **instance-id** *instance-value*

no index *index-id*

Context

[Tree] (config>router>p2mp-sr-tree>p2mp-policy>candidate-path>instances index)

Full Context

configure router p2mp-sr-tree p2mp-policy candidate-path path-instances index

Description

This command configures the candidate path instance for the P2MP SR tree as primary or secondary, and the instance identifier.

The **no** form of this command removes the candidate path instance.

Parameters

index-id

Specifies the instance as primary (1) or secondary (2).

Values 1, 2

instance-value

Specifies the instance identifier.

Values 1 to 4294967295

21 i Commands – Part II

21.1 indirect

indirect

Syntax

[**no**] **indirect** *ip-address*

Context

[Tree] (config>service>vprn>static-route-entry indirect)

Full Context

configure service vprn static-route-entry indirect

Description

This command specifies that the route is indirect and specifies the next hop IP address used to reach the destination.

The configured *ip-addr*ess is not directly connected to a network configured on this node. The destination can be reached via multiple paths. The indirect address can only be resolved from dynamic routing protocol. Another static route cannot be used to resolve the indirect address.

The *ip-address* configured here can be either on the network side or the access side and is typically at least one hop away from this node.

Default

no indirect

Parameters

ip-address

The IP address of the IP interface.

Values

ipv4-address	a.b.c.d
ipv6-address	x:x:x:x:x:x:x:x-[interface]

Platforms

All

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

indirect

Syntax

[**no**] **indirect** *ip-address*

Context

[Tree] (config>router>static-route-entry indirect)

Full Context

configure router static-route-entry indirect

Description

This command specifies that the route is indirect and specifies the next hop IP address used to reach the destination.

The configured *ip-addr*ess is not directly connected to a network configured on this node. The destination can be reached via multiple paths. The indirect address can only be resolved from dynamic routing protocol. Another static route cannot be used to resolve the indirect address.

The *ip-address* configured here can be either on the network side or the access side and is typically at least one hop away from this node.

Default

no indirect

Parameters

ip-address

Specifies the IP address of the IP interface.

Values

ipv4-address	a.b.c.d
ipv6-address	x:x:x:x:x:x:x:x-[interface]

Platforms

All

Use subject to Terms available at: www.nokia.com/terms.

21.2 ine-identifier

ine-identifier

Syntax

ine-identifier *identifier*

no ine-identifier

Context

[Tree] (config>li>x-interfaces ine-identifier)

Full Context

configure li x-interfaces ine-identifier

Description

This command configures the Intercepting Network Element (INE).

The **no** form of this command reverts to the default.

Parameters

identifier

Specifies the INE name, up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

info [**detail**] [**objective**] **operational**

Context

[Tree] (info)

Full Context

info

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command displays the running configuration for the configuration context where it is entered and all branches below that context level. It can be used in any branch under configure, but not with **configure** itself.

By default, the command only enters the configuration parameters that vary from the default values.

The **detail** keyword causes all configuration parameters to be displayed. The **include-dynamic** objective keyword includes configuration parameters from dynamic sources such as dynamic data services Python scripts. These dynamic configuration parameters are not saved in the configuration file.

The **operational** keyword is available in edit-cfg mode only, in which case the keyword is mandatory when using the **info** command.

Example:

```
A:ALA-48>config>router>if-attr# info
----------------------------------
            admin-group "green" value 15
            admin-group "red" value 25
            admin-group "yellow" value 20
A:ALA-48>config>router>mpls# info

Parameters

detail

Displays all configuration parameters including parameters at their default values.

objective

Provides an output objective that controls the configuration parameters to be displayed.

Values **include-dynamic**: includes configuration parameters from dynamic sources such as dynamic data services Python scripts.

Platforms

All

21.4 info-notification

info-notification

Syntax

info-notification

Context

[Tree] (config>port>ethernet>efm-oam>link-mon>local-sf-action info-notification)

Full Context

configure port ethernet efm-oam link-monitoring local-sf-action info-notification

Description

The context allows the operator to set different flags in the Information OAM PDU. The flags can be used to notify the peer that a local signal failure threshold has been exceeded within the configured window. This is useful when the local node supports the link monitoring function, but the remote peer does not support this capability. Information OAM PDUs are sent on the interval where the Event Notification OAM PDU is typically only sent on the initial sf-threshold crossing event. It is strongly suggested one of the Information OAM PDU Flag fields used to continually communicate current monitor state to the peer.

Interactions: The signal failure threshold will trigger these actions.

Platforms

All

21.6 ing-percentage-of-rate

ing-percentage-of-rate

Syntax

ing-percentage-of-rate *ing-rate-percentage*

no ing-percentage-of-rate

Context

[Tree] (config>port>modify-buffer-allocation-rate ing-percentage-of-rate)

Full Context

configure port modify-buffer-allocation-rate ing-percentage-of-rate

Description

This command increases or decreases the active bandwidth associated with the ingress port that affects the amount of ingress buffer space managed by the port. Changing a port's active bandwidth using the **ing-percentage-of-rate** command is an effective means of artificially lowering the buffers managed by one ingress port and giving them to other ingress ports on the same MDA.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **ing-percentage-of-rate** command accepts a percentage value that increases or decreases the active bandwidth based on the defined percentage. A value of 50% causes the active bandwidth to be reduced by 50%. A value of 150% causes the active bandwidth to be increased by 50%. Values from 1 to 1000 percent are supported.

A value of 100 (the default value) is equivalent to executing the **no ing-percentage-of-rate** command and restores the ingress active rate to the normal value.

The **no** form of this command removes any artificial increase or decrease of the ingress active bandwidth used for ingress buffer space allocation to the port. The **no ing-percentage-of-rate** command sets the ingress rate percentage to 100%.

Parameters

ing-rate-percentage

The *ing-rate-percentage* parameter is required and specifies the percentage value used to modify the current ingress active bandwidth of the port. This does not actually change the bandwidth available on the port in any way. The defined *ing-rate-percentage* parameter is multiplied by the ingress active bandwidth of the port. A value of 150 results in an increase of 50% (1.5 x Rate).

Values 1 to 1000

Default 100 (no change to active rate)

Platforms

All

21.7 ing-weight

ing-weight

Syntax

ing-weight access *access-weight* **network** *network-weight*

no ing-weight

Context

[Tree] (config>port>hybrid-buffer-allocation ing-weight)

Full Context

configure port hybrid-buffer-allocation ing-weight

Description

This command configures the sharing of the ingress buffers allocated to a hybrid port among the access and network contexts. By default, it is split equally between network and access.

The **no** form of this command reverts to the default values for the ingress access and network weights.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

access-weight

Specifies the access weight as an integer.

Values 0 to 100

Default 50

network-weight

Specifies the network weight as an integer.

Values 0 to 100

Default 50

ingress

Syntax

ingress

Context

[Tree] (config>qos>network ingress)

Full Context

configure qos network ingress

Description

This command is used to enter the CLI node that creates or edits policy entries that specify the DiffServ code points-to-forwarding class mapping for all IP packets and define the MPLS EXP bits-to-forwarding class mapping for all labeled packets.

When premarked IP or MPLS packets ingress on a network port, they get a Per Hop Behavior (that is, the QoS treatment through the router, based on the mapping defined under the current node).

Platforms

21.9 ingress-buffer-allocation

ingress-buffer-allocation

Syntax

ingress-buffer-allocation *percentage*

no ingress-buffer-allocation

Context

[Tree] (config>card>fp ingress-buffer-allocation)

Full Context

configure card fp ingress-buffer-allocation

Description

This command allows the user to configure an ingress buffer allocation percentage per forwarding plane from 20.00% to 80.00%. Ingress buffer allocation applies to user-accessible buffers (total buffers less those reserved for system use).

The ingress buffer allocation percentage determines how much of the user-accessible buffers will be available for ingress purposes. The remaining buffers will be available for egress purposes.

This command is supported on all 50G FP2-based and 100G/200G FP3-based hardware. It is not supported on other FP2 or FP3-based hardware, nor on FP4-based hardware.

The **no** form of this command reverts the ingress buffer allocation to the default value.

Default

ingress-buffer-allocation 50.00

Parameters

percentage

Specifies the buffer allocation percentage.

Values 20.00 to 80.00

Platforms

7450 ESS, 7750 SR-7/12/12e, 7750 SR-a, 7750 SR-e, 7950 XRS

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

21.10 ingress-counter-map

ingress-counter-map

Syntax

ingress-counter-map policer *policer-id* **traffic-type** { **unicast** | **multicast** | **broadcast**} [**create**]

ingress-counter-map queue *queue-id* **traffic-type** { **unicast** | **multicast** | **broadcast**} [**create**]

no ingress-counter-map policer *policer-id*

no ingress-counter-map queue *queue-id*

Context

[Tree] (config>sflow ingress-counter-map)

Full Context

configure sflow ingress-counter-map

Description

This command configures the ingress counter map for sFlow. The map must be configured so sFlow agent understands how to interpret data collected against SAP queues and policers. Multiple queues/policers can be mapped to the same **traffic-type** using separate line entries.

The **no** form of this command deletes a SAP policy queue/policer from the map.

Parameters

policer-id

Specifies the policer ID in a SAP ingress QoS policy. If the SAP policy does not have a policer with the specified ID, the map entry will be ignored for this SAP.

Values 1 to 32

queue-id

Specifies the queue ID in a SAP ingress QoS policy. If the SAP policy does not have a queue with the specified ID, the map entry will be ignored for this SAP.

Values 1 to 32

Platforms

7750 SR, 7750 SR-s, 7950 XRS

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

21.13 ingress-label

ingress-label

Syntax

ingress-label *label* [*label*]

no ingress-label [*label*]

Context

[Tree] (debug>mirror-source ingress-label)

Full Context

debug mirror-source ingress-label

Description

This command enables ingress mirroring based on MPLS labels with the following limitations.

- The ingress label provisioned must be a MPLS transport label and can be at any label stack as long as it is known by the system. Transport label distributed by LDP, RSVP, and segment routing are supported. For BGP-specific label distribution mirroring, the following are supported.
  - BGP label-unicast (RFC 8277, *Using BGP to Bind MPLS Labels to Address Prefixes*)
  - VPN service labels distributed by BGP for Carrier Supporting Carrier (CSC) VPNs (RFC 4364, *BGP/MPLS IP Virtual Private Networks (VPNs)*)
  - VPN service labels distributed by BGP in an ASBR (inter-as-option-B)
  - VPN service labels distributed by BGP in a route reflector with next-hop-self (RR + NHS)
- VPN service label mirroring is not supported in a provider edge (PE) router.
- The ingress label can only be mirrored to a single mirror destination. If the same label is defined with multiple mirror destinations, an error is generated and the original mirror destination remains unchanged.

The ingress label mirror source overrides all other mirror source definitions. The MPLS frame is mirrored to the mirror destination as it is received on the ingress network port. The router MPLS label space is global for the system. A specific label is mirrored to a mirror destination regardless of the ingress interface. In addition to mirroring known labels, debug also allows pre-provisioning label values which are yet to be known by the system. Be aware that debug mirroring requires provisioning of static label values while

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

labels distributed by label distribution protocols are dynamic in nature. Therefore, when label values change due to network changes, labels provisioned in debug mirroring must be changed or deleted manually.

By default, no ingress MPLS frames are mirrored. The **ingress-label** command must be executed to start mirroring on a specific MPLS label.

Parameters

label

Specifies up to eight transport labels received on ingress to be mirrored. Each label can only be mirrored to a single mirror destination.

If the label does not exist on any ingress network ports, no packets are mirrored for that label. An error will not occur. Once the label exists on a network port, ingress mirroring begins for that label.

Values 0 to 1048575

The local MPLS stack may not support portions of this range.

Platforms

All

21.14 ingress-percent-of-total

ingress-percent-of-total

Syntax

ingress-percent-of-total *percent-of-total-queues*

no ingress-percent-of-total

Context

[Tree] (config>qos>fp-resource-policy>queues ingress-percent-of-total)

Full Context

configure qos fp-resource-policy queues ingress-percent-of-total

Description

This command configures the percentage of the total number of queues on the FP on which the policy is applied that are allocated to ingress, with the remainder allocated to egress. The ingress and egress buffer pool sizes are not affected by the queue allocation.

The allocation is performed in sets of 8192 queues, with a minimum of 8192 queues at ingress and 8192 queues at egress. If the percentage configured results in the queue allocation not being a multiple of 8192, the number of queues at ingress is rounded down to the next 8192 boundary, and consequently the

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

number of queues at egress is rounded up to the next 8192 boundary, both while respecting the minimum at ingress and egress.

If the FP resources policy being applied to any FP and the updated allocation is not achievable with the current ingress or egress queue consumption on any of the related FPs, then the command fails.

The configuration of **ingress-percent-of-total** command, including removing this parameter to return to its default configuration, causes the router to immediately reset the associated cards, XIOMs, and MDAs, except on the 7750 SR-1 where the configuration must be saved, and the router rebooted, immediately after committing the configuration transaction.

The **no** form of this command reverts the percentage of ingress queues, and consequently egress queues, to their default allocation.

Default

ingress-percent-of-total 50.00

Parameters

percent-of-total-queues

Specifies the percentage of total ingress queues as two fraction digits.

Values 4.00 to 97.00

Platforms

7450 ESS, 7750 SR, 7750 SR-s, 7950 XRS

21.15 ingress-policer

ingress-policer

Syntax

ingress-policer *policer-name*

no ingress-policer

Context

[Tree] (config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range>dsm ingress-policer)

[Tree] (config>service>ies>sub-if>grp-if>wlan-gw>ranges>range>dsm ingress-policer)

Full Context

configure service vprn subscriber-interface group-interface wlan-gw vlan-tag-ranges range distributed-sub-mgmt ingress-policer

configure service ies subscriber-interface group-interface wlan-gw vlan-tag-ranges range distributed-sub-mgmt ingress-policer

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command specifies the ingress policer applied to all UEs corresponding to default vlan-range (such as group-interface) or the specified vlan-range. The policer can be created in the **config>subscr-mgmt>isa-policer** context. The ingress policer can be overridden per UE from RADIUS via access-accept or COA.

The **no** form of this command reverts to the default.

Parameters

policer-name

Specifies the identifier of the distributed-sub-mgmt policer for ingress traffic.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

21.16 ingress-rate

ingress-rate

Syntax

ingress-rate *sub-rate*

no ingress-rate

Context

[Tree] (config>port>ethernet ingress-rate)

Full Context

configure port ethernet ingress-rate

Description

This command configures the maximum amount of ingress bandwidth that this port can receive with the configured sub-rate using packet-based accounting.

The **no** form of this command returns the value to the default.

Default

no ingress-rate

Parameters

sub-rate

Specifies the ingress rate, in Mb/s.

Values 1 to 400000

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Platforms

All

21.17 ingress-repl-inc-mcast-advertisement

ingress-repl-inc-mcast-advertisement

Syntax

[**no**] **ingress-repl-inc-mcast-advertisement**

Context

[Tree] (config>service>vpls>bgp-evpn ingress-repl-inc-mcast-advertisement)

Full Context

configure service vpls bgp-evpn ingress-repl-inc-mcast-advertisement

Description

This command enables and disables the advertisement of the Inclusive Multicast Ethernet Tag route (IMET route) with tunnel-type Ingress-Replication in the PMSI Tunnel Attribute, or with the tunnel-type Composite Point-to-Multipoint and Ingress-Replication (P2MP+IR) in the root-and-leaf nodes. The following must be considered:

- When **no ingress-repl-inc-mcast-advertisement** is configured, no IMET routes will be sent for the service unless the **provider-tunnel** is configured with **owner bgp-evpn-mpls** and **root-and-leaf**, in which case, an IMET-P2MP route is sent.
- When **ingress-repl-inc-mcast-advertisement** and **provider-tunnel** are configured for **bgp-evpn-mpls** with **root-and-leaf**, the system will send an IMET-P2MP-IR route, that is, an IMET route with a composite P2MP+IR tunnel type.
- When **no ingress-repl-inc-mcast-advertisement** and **assisted-replication replicator** are configured, the system will send IMET-AR routes, but IMET-IR routes will not be sent.

Default

ingress-repl-inc-mcast-advertisement

Platforms

All

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

21.18 ingress-replication-bum-label

ingress-replication-bum-label

Syntax

[**no**] **no-ingress-replication-bum-label**

Context

[Tree] (config>service>vpls>bgp-evpn>mpls ingress-replication-bum-label)

Full Context

configure service vpls bgp-evpn mpls ingress-replication-bum-label

Description

This command allows the user to configure the system so that a separate label is sent for BUM (Broadcast, Unknown unicast and Multicast) traffic in a specified service. By default (**no ingress-replication-bum-label**), the same label is used for unicast and flooded BUM packets when for-warding traffic to remote PEs.

When saving labels, this might cause transient traffic duplication for all-active multihoming. By enabling **ingress-replication-bum-label**, the system will advertise two labels per EVPN VPLS instance, one for unicast and one for BUM traffic. The ingress PE will use the BUM label for flooded traffic to the advertising egress PE, so that the egress PE can determine if the unicast traffic has been flooded by the ingress PE. Depending on the scale required in the network, the user may choose between saving label space or avoiding transient packet duplication sent to an all-active multihomed CE for certain macs.

Default

no ingress-replication-bum-label

Platforms

All

21.19 ingress-statistics

ingress-statistics

21.24 init-extract-prio-mode

init-extract-prio-mode

Syntax

init-extract-prio-mode {**uniform** | **l3-classify**}

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Context

[Tree] (config>card>fp init-extract-prio-mode)

Full Context

configure card fp init-extract-prio-mode

Description

This command determines the scheme used to select the initial drop priority of extracted control plane traffic. The initial drop priority of extracted packets can be either low or high priority. The drop priority of the extracted packets can be subsequently altered by mechanisms such as CPU protection. High-priority traffic receives preferential treatment in control plane congestion situations over low-priority traffic.

Default

init-extract-prio-mode uniform

Parameters

uniform

Initializes the drop priority of all extracted control traffic as high priority. Drop priority can then be altered (marked low priority) by distributed CPU protection (DCP) or centralized CPU protection rate-limiting functions in order to achieve protocol and interface isolation.

l3-classify

Initializes the drop priority of Layer 3 extracted control traffic (BGP and OSPF) based on the QoS classification of the packets. This is useful in networks where the DSCP and EXP markings can be trusted as the primary method to distinguish, protect, and isolate good terminating protocol traffic from unknown or potentially harmful protocol traffic instead of using the rate-based DCP and centralized CPU protection traffic marking/coloring mechanisms (for example, **out-profile-rate** and **exceed-action low-priority**).

For network interfaces, the QoS classification profile result selects the drop priority (in = high priority, out = low priority) for extracted control traffic, and the default QoS classification maps different DSCP and EXP values to different in/out profile states.

For access interfaces, the QoS classification priority result typically selects the drop priority for extracted control traffic. The default access QoS classification (**default-priority**) maps all traffic to **low**. If the queues in the access QoS policy are configured as **profile-mode** queues (rather than the default **priority-mode**) extracted traffic will use the QoS classification profile value configured against the associated FC (rather than the priority result) to select the drop priority.

Layer 2 extracted control traffic (ARP or ETH-CFM) and protocols that cannot always be QoS-classified, such as IS-IS, are initialized as low drop priority in order to protect Layer 2 protocol traffic on uniform interfaces (which would typically be subject to centralized CPU protection). Alternately, DCP can be used (by configuring a non-zero rate with **exceed-action** of **low-priority** for the **all-unspecified** protocol) to mark some of this traffic as high priority.

21.25 init-ss-threshold

init-ss-threshold

Syntax

init-ss-threshold *init-ss-threshold*

Context

[Tree] (config>app-assure>group>tcp-optimizer init-ss-threshold)

Full Context

configure application-assurance group tcp-optimizer init-ss-threshold

Description

This command configures the initial Slow Start (SS) threshold for a given TCP optimizer policy. Nokia recommends to set the threshold close to the access network Bandwidth Delay Product (BDP).

Default

1000000

Parameters

init-ss-threshold

Specifies the initial SS threshold value in kilobytes.

Values auto, 0 to 1000000

The auto value instructs the system to use an intelligent mechanism to set the optimum value for the initial SS threshold to dynamically track the BDP of the access network.

Platforms

Full Context

configure service vprn subscriber-interface group-interface wpp initial-app-profile

configure service ies subscriber-interface group-interface wpp initial-app-profile

configure subscriber-mgmt local-user-db ipoe host wpp initial-app-profile

Description

This command specifies the initial app-profile for the hosts created on the group-interface. This initial app-profile is replaced after hosts pass web portal authentication.

The **no** form of this command reverts to the default.

Default

no initial-app-profile

Parameters

app-profile-name

Specifies the initial application profile, up to 32 characters, to be used during the WPP authentication phase of the IPoE hosts.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

initial-hold-time [**min** *min*] [**sec** *sec*]

no initial-hold-time

Context

[Tree] (config>subscr-mgmt>vrgw>brg>brg-profile initial-hold-time)

Full Context

configure subscriber-mgmt vrgw brg brg-profile initial-hold-time

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This hold time applies to BRG instances that are created without any hosts; for example, triggered due to proxy authentication. During this initial hold-time the BRG is not deleted and no connectivity-verification is started. When this timer expires, connectivity verification is started. If connectivity verification is disabled and no hosts are associated with the BRG upon expiry, the regular hold time is started and the BRG instance will be removed.

This command allows an operator to have fast BRG removal (no connectivity-verification and **no hold-time**) but still use BRG proxy authentication. Without an initial hold time the BRG would be removed immediately after creation.

This command does not apply to BRG instances that are created through host setup.

The **no** form of this command reverts to the default.

Default

initial-hold-time min 5

Parameters

seconds

Specifies the initial time, in seconds, to hold on to a BRG after the system considered it down.

Values 0 to 900

min

Specifies the initial time in minutes.

Values 1 to 15

sec

Specifies the initial time in seconds.

Values 1 to 59

Platforms

21.30 initial-registration

initial-registration

Syntax

initial-registration ca *ca-profile-name* **key-to-certify** *key-filename* **protection-alg** {**password** *password* **reference** *ref-number* | **signature** [**cert** *cert-file-name* [**send-chain** [**with-ca** *ca-profile-name*]]] [**protection-key** *key-file-name*] [**hash-alg** {**md5** | **sha1** | **sha224** | **sha256** | **sha384** | **sha512**}]} **subject-dn** *dn* [**domain-name** *domain-names*] [**ip-addr** *ip-address* | *ipv6-address*] **save-as** *save-path-of-result-cert*

Context

[Tree] (admin>certificate>cmpv2 initial-registration)

Full Context

admin certificate cmpv2 initial-registration

Description

This command request initial certificate from CA by using CMPv2 initial registration procedure.

The **ca** parameter specifies a CA-profile which includes CMP server information.

The **key-to-certify** is an imported key file to be certified by the CA.

The protection-key is an imported key file used to for message protection if protection-alg is signature.

The request is authenticated either of following methods:

- A password and a reference number that pre-distributed by CA via out-of-band means.
- The specified password and reference number are not necessarily in the cmp-keylist configured in the corresponding CA-Profile
- A signature signed by the protection-key or key-to-certify, optionally along with the corresponding certificate. If the protection-key is not specified, system will use the key-to-certify for message protection. The hash algorithm used for signature is depends on key type:
- DSA key: SHA1

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- RSA key: MD5/SHA1/SHA224 | SHA256 | SHA384 | SHA512, by default is SHA1

Optionally, the system could also send a certificate or a chain of certificates in extraCerts field. Certificate is specified by the "cert" parameter, it must include the public key of the key used for message protection.

Sending a chain is enabled by specify the **send-chain** parameter.

subject-dn specifies the subject of the requesting certificate.

save-as specifies full path name of saving the result certificate.

In some cases, CA may not return certificate immediately, due to reason like request processing need manual intervention. In such cases, the **admin certificate cmpv2** poll command could be used to poll the status of the request. If key-list is not configured in the corresponding **ca-profile**, then the system will use the existing password to authenticate the CMPv2 packets from server if it is in password protection.

If key-list is configured in the corresponding **ca-profile** and server does not send SenderKID, then the system will use lexicographical first key in the key-list to authenticate the CMPv2 packets from server in case it is in password protection.

Parameters

ca-profile-name

Specifies a ca-profile name which includes CMP server information up to 32 characters.

key-filename

Specifies the file name of the key to certify up to 95 characters.

password

Specifies an ASCII string up to 64 characters.

ref-number

Specifies the reference number for this CA initial authentication key up to 64 characters.

cert-file-name

specifies the certificate file up to 95 characters.

ca-profile-name

Specifies to send the chain.

key-file-name

Specifies the protection key associated with the action on the CA profile.

hash-algorithm

Specifies the hash algorithm for RSA key.

Values md5,sha1,sha224,sha256,sha384,sha512

dn

Specifies the subject of the requesting certificate up to 256 characters.

Values attr1 equals val1

attr2 equals val2 where: attrN equals {C | ST | O | OU | CN}

save-path-of-result-cert

Specifies the save full path name of saving the result certificate up to 200 characters.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

domain-name *domain-names*

Specifies FQDNs for SubjectAltName of the requesting certificate, separated by commas, up to 512 characters.

ip-address* | *ipv6-address

Specifies an IPv4 or IPv6 address for SubjectAtName of the requesting certificate.

21.35 initiation-message

initiation-message

Syntax

initiation-message [*initiation-message*]

no initiation-message

Context

[Tree] (config>bmp>station initiation-message)

Full Context

configure bmp station initiation-message

Description

This command configures a free-form initiation message for a type 0 TLV to be sent to the BMP monitoring station. The message is transmitted when a BMP monitoring station establishes a connection to the device. Information can be provided to the BMP station system administrator (for example, a contact phone number). The initiation message includes a type 1 TLV containing the SNMP sysDescr value specified in RFC 1213, *Management Information Base for Network Management of TCP/IP-based internets: MIB-II*, and a type 2 TLV containing the SNMP sysName value also from RFC 1213. The string in the initiation-message is UTF-8 encoded.

The **no** form of this command removes initiation message from the configuration and causes a free-form message to be included in the type 0 information TLV and the corresponding tlv-length is made 0.

Parameters

initiation-message

Specifies an initiation message up to 256 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

Platforms

All

21.36 inner-tag

inner-tag

Syntax

inner-tag *value* [*vid-mask*]

no inner-tag

Context

[Tree] (config>qos>sap-ingress>mac-criteria>entry>match inner-tag)

Full Context

configure qos sap-ingress mac-criteria entry match inner-tag

Description

This command configures the matching of the second tag that is carried transparently through the service. The inner tag on ingress is the second tag on the frame if there are no service delimiting tags. The inner tag is the second tag before any service delimiting tags on egress but is dependent in the ingress configuration and may be set to 0 even in cases where additional tags are on the frame. This allows matching VLAN tags for explicit filtering or QoS setting when using default or null encapsulations.

The inner tag is not applicable in ingress on dot1Q SAPs. The inner tag may be populated on egress depending on the ingress SAP type.

On QinQ SAPs of null and default that do not strip tags, the inner-tag will contain the second tag (which is still the second tag carried transparently through the service.) On ingress SAPs that strip any tags, the inner tag will contain 0 even if there are more than two tags on the frame.

The optional vid_mask is defaulted to 4095 (exact match) but may be specified to allow pattern matching. The masking operation is ((value and vid-mask) = = (tag and vid-mask)). A value of 6 and a mask of 7 would match all VIDs with the lower 3 bits set to 6.

For QoS, the VID type cannot be specified on the default QoS policy.

The default vid-mask is set to 4095 for exact match.

21.39 insert

insert

Syntax

insert [*line*]

Context

[Tree] (candidate insert)

Full Context

candidate insert

Description

This command inserts the contents of the temporary buffer (populated by a previous copy or delete command) into the candidate configuration. The contents are inserted by default after the current edit point. Optional parameters allow the insertion after some other point of the candidate. The contents of the temporary buffer are deleted when the operator exits candidate edit mode.

Insertions are context-aware. The temporary buffer always stores the CLI context (such as the current CLI branch) for each line deleted or copied. If the lines to be inserted are supported at the context of the insertion point then the lines are simply inserted into the configuration. If the lines to be inserted are not supported at the context of the insertion point, then the context at the insertion point is first closed using multiple exit statements, the context of the lines to be inserted is built (added) into the candidate at the insertion point, then the lines themselves are added, the context of the inserted lines is closed using exit statements and finally the context from the original insertion point is built again leaving the context at the same point as it was before the insertion.

Parameters

line

Indicates where to insert the line starting at the point indicated by the following options.

Values line, offset, **first**, **edit-point**, **last**

line	absolute line number
offset	relative line number to current edit point. Prefixed with '+' or '-'
first	keyword - first line
edit-point	keyword - current edit point
last	keyword - last line that is not 'exit'

[Tree] (config>router>policy-options>policy-statement>default-action install-backup-path)

Full Context

configure router policy-options policy-statement entry action install-backup-path

configure router policy-options policy-statement default-action install-backup-path

Description

When the best BGP route for an IPv4 or IPv6 prefix is matched by a policy entry or policy default action with this command, BGP attempts to find and install a preprogrammed backup path for the prefix in order to provide BGP fast reroute protection.

The **install-backup-path** command overrides and has no dependency on commands such as the BGP instance **backup-path** command or the VPRN-level **enable-bgp-vpn-backup** command, which enable BGP fast reroute for an entire address family. The **install-backup-path** command provides more precise control over which IP prefixes are supported with preprogrammed backup paths.

In VPRN, if the best path for an IP prefix is provided by a VPRN BGP route, the backup path can be provided by another VPRN BGP route or an imported VPN-IP route. If the best path for an IP prefix is provided by an imported VPN-IP route, the backup path can be provided by another VPN-IP route.

The **install-backup-path** command is supported only in BGP and VRF import policies and has no effect on other types. The **install-backup-path** command applies only to the following types of matched routes: IPv4, IPv6, label-IPv4, label-IPv6, VPN-IPv4, and VPN-IPv6.

The **no** form of this command disables the install-backup-path functionality.

Default

no install-backup-path

[Tree] (config>service>vprn>aaa>rmt-srv>tacplus interactive-authentication)

Full Context

configure system security tacplus interactive-authentication

configure service vprn aaa remote-servers tacplus interactive-authentication

Description

This configuration instructs the SR OS to send no username nor password in the TACACS+ start message, and to display the *server_msg* in the GETUSER and GETPASS response from the TACACS+ server. Interactive authentication can be used to support a One Time Password scheme (such as an S/Key). An example flow (such as with a telnet connection) is as follows:

- The SR OS sends an authentication start request to the TACACS+ server with no username nor password.
- TACACS+ server replies with TAC_PLUS_AUTHEN_STATUS_GETUSER and a *server_msg*.
- The SR OS displays the *server_msg*, and collects the username.
- The SR OS sends a continue message with the username.
- TACACS+ server replies with TAC_PLUS_AUTHEN_STATUS_GETPASS and a *server_msg*.
- The SR OS displays the *server_msg* (which may contain, for example, an S/Key for One Time Password operation), and collects the password.
- The SR OS sends a continue message with the password.
- TACACS+ server replies with PASS or FAIL.

When interactive-authentication is disabled, the SR OS will send the username and password in the *tacplus* start message. An example flow (such as with a telnet connection) is as follows:

- TAC_PLUS_AUTHEN_TYPE_ASCII.
  - the login username in the "user" field.
  - the password in the *user_msg* field (while this is non-standard, it does not cause interoperability problems).
- TACACS+ server ignores the password and replies with TAC_PLUS_AUTHEN_STATUS_GETPASS.
- The SR OS sends a continue packet with the password in the *user_msg* field.
- TACACS+ server replies with PASS or FAIL.

When interactive-authentication is enabled, tacplus must be the first method specified in the authentication-order configuration.

[Tree] (config>li>li-source>nat>dslite-lsn-sub intercept-id)

[Tree] (config>li>li-source>nat>ethernet-header intercept-id)

[Tree] (config>li>li-source>nat>classic-lsn-sub intercept-id)

[Tree] (config>li>li-source>nat>l2-aware-sub intercept-id)

[Tree] (config>li>li-source>nat>nat64-lsn-sub intercept-id)

Full Context

configure li li-source nat dslite-lsn-sub intercept-id

configure li li-source nat ethernet-header intercept-id

configure li li-source nat classic-lsn-sub intercept-id

configure li li-source nat l2-aware-sub intercept-id

configure li li-source nat nat64-lsn-sub intercept-id

Description

This command configures the intercept-id that is inserted into the packet header for all mirrored packets of the associated **li-source** entry. This **intercept-id** can be used (for example by a downstream LI gateway) to identify the particular LI session to which the packet belongs.

For nat mirroring (a **nat li-source** entry type), when the mirror service is not configured with any routable encap (for example, no ip-udp-shim or ip-gre configured under **config>mirror>mirror-dest>encap**), the presence of a configured intercept-id against an li-source (nat) entry will cause the insertion of the intercept-id after a configurable mac-da, mac-sa and etype (configured under **li-source>nat>ethernet-header**), at the front of each packet mirrored for that particular li-source entry. If there is no **intercept-id** configured (for a **nat** entry using a mirror service without routable encap), then a configurable mac-da and mac-sa are added to the front of the packets (but no intercept-id). In both cases a non-configurable etype is also added immediately before the mirrored customer packet. Note that routable encapsulation configured in the mirror-dest takes precedence over the ethernet-header configuration in the li-source nat entries. If

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

routable encapsulation is configured, then the ethernet-header config is ignored and no mac header is added to the packet (the encap is determined by the mirror-dest in this case).

For all types of **li-source** entries (filter, nat, sap, subscriber), when the mirror service is configured with **ip-udp-shim** routable encap, an intercept-id field (as part of the routable encap) is always present in the mirrored packets. If there is no intercept ID configured for an li-source entry, then the default value will be inserted. When the mirror service is configured with ip-gre routable encap, no intercept-id is inserted and none should be specified against the **li-source** entries.

The **no** form of this command removes the value from the configuration.

Default

no intercept-id (an id of 0, or no id)

Parameters

id

Specifies the intercept ID value to insert into the header of the mirrored packets.

Values 1 to 4294967295 (32b) For nat li-source entries that are using a mirror service that is not configured with routable encap

Values 1 to 1,073,741,824 (30b) For all types of li-source entries that are using a mirror service with routable ip-udp-shim encap and no direction-bit.

Values 1 to 536,870,912 (29b) For all types of li-source entries that are using a mirror service with routable ip-udp-shim encap and with the direction-bit enabled.

interconnect

Syntax

interconnect {**ring-id** *ring-index* | **vpls**}

no interconnect

Context

[Tree] (config>eth-ring>sub-ring interconnect)

Full Context

configure eth-ring sub-ring interconnect

Description

This command links the G.8032 sub-ring to a ring instance or to a VPLS instance. The ring instance must be a complete ring with two paths but may itself be a sub-ring or a major ring (declared by its configuration on another node).

When the interconnection is to another node, the sub-ring may have a virtual link or a non-virtual-link.

When the sub-ring is configured with a non-virtual link, the sub ring may be alternatively connected to a VPLS service.

This command is only valid on the interconnection node where a single sub-ring port connects to a major ring or terminates on a VPLS service.

The **no** form of this command removes the interconnect node.

Default

no interconnect

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

ring-id

Specifies the identifier for the ring instance of the connection ring for this sub-ring on this node.

Values 0 to 128

vpls

Specifies that the sub-ring is connected to the VPLS instance that contains the sub-ring SAP.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

Context

[Tree] (config>service>ies interface)

[Tree] (config>service>vprn interface)

Full Context

configure service ies interface

configure service vprn interface

Description

This command creates a logical IP routing interface. Once created, attributes like an IP address and service access point (SAP) can be associated with the IP interface.

The **interface** command, under the context of services, is used to create and maintain IP routing interfaces within service IDs. The **interface** command can be executed in the context of a service ID. The IP interface created is associated with the service core network routing instance and default routing table. The typical use for IP interfaces created in this manner is for subscriber Internet access. An IP address cannot be assigned to an IES interface. Multiple SAPs can be assigned to a single group interface.

Interface names are case sensitive and must be unique within the group of defined IP interfaces defined for **config>router>interface**, **config>service>ies>interface** and **config>service>vprn>interface** (that is, the network core router instance). Interface names must not be in the dotted decimal notation of an IP address. For example, the name "1.1.1.1” is not allowed, but "int-1.1.1.1” is allowed. Show commands for router interfaces use either interface names or the IP addresses. Use unique IP address values and IP

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

address names to maintain clarity. It could be unclear to the user if the same IP address and IP address name values are used. Although not recommended, duplicate interface names can exist in different router instances.

When a new name is entered, a new logical router interface is created. When an existing interface name is entered, the user enters the router interface context for editing and configuration.

By default, there are no default IP interface names defined within the system. All IP interfaces must be explicitly defined. Interfaces are created in an enabled state.

The **no** form of this command removes IP the interface and all the associated configuration. The interface must be administratively shut down before issuing the **no interface** command.

The IP interface must be shut down before the SAP on that interface may be removed. IES and VPRN services do not have the **shutdown** command in the SAP CLI context. The service SAPs rely on the interface status to enable and disable them.

Parameters

ip-int-name

Specifies the name of the IP interface. Interface names must be unique within the group of defined IP interfaces for **config router interface** and config service vprn interface commands. An interface name cannot be in the form of an IP address. Interface names can be from 1 to 32 alphanumeric characters. If the string contains special characters (#, ?, space), the entire string must be enclosed between double quotes.

If *ip-int-name* already exists within the service ID, the context will be changed to maintain that IP interface. If *ip-int-name* already exists within another service ID or is an IP interface defined within the **config router** commands, an error will occur and context will not be changed to that IP interface. If *ip-int-name* does not exist, the interface is created and context is changed to that interface for further command processing.

tunnel

Specifies that the interface is configured as tunnel interface, which could be used to terminate IPsec or GRE runnels in the private service.

create

Creates the IPsec interface instance. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

Platforms

Full Context

configure router igmp interface

Description

Commands in this context configure an IGMP interface. The interface is a local identifier of the network interface on which reception of the specified multicast address is to be enabled or disabled.

The **no** form of the command deletes the IGMP interface. The **shutdown** command in the **config>router>igmp>interface** context can be used to disable an interface without removing the configuration for the interface.

Default

no interface

Parameters

ip-int-name

The IP interface name. Interface names must be unique within the group of defined IP interfaces for **config router interface** and **config service ies interface** commands. An interface name cannot be in the form of an IP address. Interface names can be any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

If the IP interface name does not exist or does not have an IP address configured an error message will be returned.

If the IP interface exists in a different area it will be moved to this area.

configure router mld interface

Description

Commands in this context configure an Multicast Listener Discovery (MLD) interface. The interface is a local identifier of the network interface on which reception of the specified multicast address is to be enabled or disabled.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **no** form of this command deletes the MLD interface. The **shutdown** command in the **config>router>mld>interface** context can be used to disable an interface without removing the configuration for the interface.

Default

no interface — No interfaces are defined.

Parameters

ip-int-name

Specifies the IP interface name. Interface names must be unique within the group of defined IP interfaces for **config>router>interface** and **config>service>ies>interface** commands. An interface name cannot be in the form of an IP address. Interface names can be any string up to 32 characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

If the IP interface name does not exist or does not have an IP address configured an error message will be returned.

If the IP interface exists in a different area it will be moved to this area.

configure router radius-proxy server interface

configure service vprn radius-proxy server interface

Description

This command configures the IP interface the RADIUS-proxy server will bind to. One RADIUS-proxy server could bind to multiple interfaces.

Parameters

ip-int-name

Specifies the name of an IP interface.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

interface

Syntax

interface router *router-instance* **name** *interface-name*

no interface

Context

[Tree] (config>subscr-mgmt>pfcp-association interface)

Full Context

configure subscriber-mgmt pfcp-association interface

Description

This command configures the interface from which PFCP messages are sent and on which PFCP messages are received.

The **no** form of this command removes the interface.

Default

no interface

Parameters

router-instance

Specifies the router instance.

© 2025 Nokia.

Values *router-name* | *vprn-svc-id*

router-name: Base Default - Base

vprn-svc-id: 1 to 2147483647

interface-name

Specifies the interface name, up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

interface

Syntax

[**no**] **interface** *ip-int-name*

Context

[Tree] (config>service>vpls interface)

Full Context

configure service vpls interface

Description

This command creates a logical IP routing interface for a VPLS service. Once created, attributes such as IP address and service access points (SAP) can be associated with the IP interface.

The interface command, under the context of services, is used to create and maintain IP routing interfaces within the VPLS service IDs. The IP interface created is associated with the VPLS management routing instance. This instance does not support routing.

Interface names are case-sensitive and must be unique within the group of defined IP interfaces defined for the network core router instance. Interface names in the dotted decimal notation of an IP address are not allowed. For example, the name "1.1.1.1” is not allowed, but "int-1.1.1.1” is allowed. Show commands for router interfaces use either interface names or the IP addresses. Use unique IP address values and IP address names to maintain clarity. Duplicate interface names can exist in different router instances.

Enter a new name to create a logical router interface. When an existing interface name is entered, the user enters the router interface context for editing and configuration.

By default, no default IP interface names are defined within the system. All VPLS IP interfaces must be explicitly defined in an enabled state.

The no form of this command removes the IP interface and the entire associated configuration. The interface must be administratively shut down before issuing the no interface command.

For VPLS services, the IP interface must be shut down before the SAP on that interface is removed.

For VPLS service, ping and traceroute are the only applications supported.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

ip-int-name

Specifies the name of the IP interface. Interface names must be unique within the group of defined IP.

An interface name:

- Should not be in the form of an IP address.
- Can be from 1 to 32 alphanumeric characters.
- If the string contains special characters (such as #,$,spaces), the entire string must be enclosed within double quotes.

If ip-int-name already exists within the service ID, the context changes to maintain that IP interface. If ip-int-name already exists within another service ID, an error occurs and the context does not change to that IP interface. If ip-int-name does not exist, the interface is created and the context is changed to that interface for further command processing.

configure router ldp interface-parameters interface

Description

This command enables LDP on the specified IP interface.

The **no** form of the command deletes the LDP interface and all configuration information associated with the LDP interface.

The LDP interface must be disabled using the **shutdown** command before it can be deleted.

The user can configure different parameters for IPv4 and IPv6 LDP interfaces by entering **ipv4** or **ipv6** as the next command.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

ip-int-name

Specifies the name of an existing interface. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

dual-stack

This optional keyword allows the user to explicitly indicate if this interface should create the IPv4 context automatically or not. With the introduction of LDP IPv6, the creation of the interface does not automatically mean it is to be used for IPv4 like with legacy IPv4 only LDP interface. Thus the dual-stack keyword is an indication to the system that user will manually enable the IPv4, IPv6, or the dual-stack IPv4/IPv6 contexts manually.

The following are some of the key points for this keyword:

- If the keyword is provided, then IPv4 interface context will not be created automatically. If it is not provided, the IPv4 interface context will be created like in the legacy single stack LDP IPv4 interface behavior.
- This new keyword will always show in a configuration.
- When entering an already configured interface, there is no need to provide the keyword, but it will be ignored if provided.
- When deleting a configured interface, the keyword will not be accepted in the **no** version of the **interface** command.

configure router mpls srlg-database router-id interface

Description

This command allows the operator to manually enter the SRLG membership information for any link in the network, including links on this node, into the user SRLG database.

An interface can be associated with up to five SRLG groups for each execution of this command. The operator can associate an interface with up to 64 SRLG groups by executing the command multiple times.

CSPF will not use entered SRLG membership if an interface is not validated as part of a router ID in the routing table.

The **no** form of this command deletes a specific interface entry in this user SRLG database. The *group-name* must already exist in the config>router>if-attribute>srlg-group context.

Parameters

ip-address

Specifies the IPv4 address in a.b.c.d

srlg-group group-name

Specifies the SRLG group name. Up to 1024 group names can be defined in the config>router>if-attribute context. The SRLG group names must be identical across all routers in a single domain.

configure router pim interface

Description

This command creates a PIM interface.

Interface names are case-sensitive and must be unique within the group of defined IP interfaces defined for **config>router>interface**, **config>service>ies>interface**, and **config>service>ies>subscriber-interface>group-interface**. Interface names must not be in the dotted decimal notation of an IP address. For example, the name "1.1.1.1" is not allowed, but "int-1.1.1.1" is allowed. Show commands for router interfaces use either the interface names or the IP addresses. Ambiguity can exist if an IP address is used as an IP address and an interface name. Duplicate interface names can exist in different router instances, although this is not recommended because it may be confusing.

By default, no interfaces or names are defined within PIM.

The **no** form of this command removes the IP interface and all the associated configurations.

Parameters

ip-int-name

Specifies the name of the IP interface, up to 32 characters. Interface names must be unique within the group of defined IP interfaces for **config router interface**, **config service ies interface**, and **config service ies subscriber-interface group-interface**

Context

[Tree] (config>router interface)

Full Context

configure router interface

Description

This command creates a logical IP routing or unnumbered MPLS-TP interface. Once created, attributes like IP address, port, or system can be associated with the IP interface.

Interface names are case-sensitive and must be unique within the group of IP interfaces defined for **config router interface** and **config service ies interface**. Interface names must not be in the dotted decimal notation of an IP address.; for example, the name "1.1.1.1” is not allowed, but "int-1.1.1.1” is allowed. Show commands for router interfaces use either the interface names or the IP addresses. Ambiguity can exist if an IP address is used as an IP address and an interface name. Duplicate interface names can exist in different router instances, although this is not recommended because it is confusing. Nokia recommends that names are meaningful and unique to remove ambiguity when displaying the state associated with IP interfaces through show commands.

When a new name is entered, a new logical router interface is created. When an existing interface name is entered, the user enters the router interface context for editing and configuration.

Although not a keyword, the ip-int-name "**system**” is associated with the network entity (such as a specific router), not a specific interface. The system interface is also referred to as the loopback address.

An unnumbered MPLS-TP interface is a special type of interface that is only intended for MPLS-TP LSPs. IP routing protocols are blocked on interfaces of this type. If an interface is configured as unnumbered-mpls-tp, then it can only be associated with an Ethernet port or VLAN, using the port command, then either a unicast, multicast, or broadcast remote MAC address may be configured. Only static ARP is supported.

The control-tunnel parameter creates a loopback interface representing a GRE tunnel. One IP tunnel can be created in this interface.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Only the primary IPv4 interface address and only one IP tunnel per interface are allowed. Multiple tunnels can be configured using up to four controlTunnel loopback interfaces. A static route can take the new controlTunnel interface as a next hop.

The **no** form of this command removes the IP interface and all the associated configurations. The interface must be administratively shut down before issuing the **no interface** command.

Parameters

interface-name

Specifies the name of the IP interface. Interface names must be unique within the group of defined IP interfaces for **config router interface** and **config service ies interface** commands. An interface name cannot be in the form of an IP address. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

Values 1 to 32 alphanumeric characters

If the *ip-int-name* already exists, the context is changed to maintain that IP interface. If *ip-int-name* already exists within another service ID or is an IP interface defined within the **config router** commands, an error will occur and the context will not be changed to that IP interface. If *ip-int-name* does not exist, the interface is created and the context is changed to that interface for further command processing.

unnumbered-mpls-tp

Specifies that an interface is an unnumbered MPLS-TP. An unnumbered MPLS-TP interface is a special type of interface that is only intended for MPLS-TP LSPs. IP routing protocols are blocked on interfaces of this type. If an interface is configured as **unnumbered-mpls-tp**, then it can only be associated with an Ethernet port or VLAN, using the **port** command. A unicast, multicast, or broadcast remote MAC address can be configured using the **static-arp** command. Only static ARP is supported.

pdn

Specifies that the interface is a PDN.

interface

Syntax

[**no**] **interface** *ip-int-name*

Context

[Tree] (config>router>bgp>group>dynamic-neighbor interface)

Full Context

configure router bgp group dynamic-neighbor interface

Description

Commands in this context configure an unnumbered base router network interface for dynamic neighbors.

If this interface connects to a network with other BGP routers, sessions with the other routers can be set up automatically without explicitly configuring them as BGP neighbors. The interface must be IPv6 enabled, but because the interface is considered unnumbered, it does not require an IPv4 address or a global-unicast IPv6 address. The sessions are set up using IPv6 link-local addresses.

The BGP unnumbered feature supports all address families that allow IPv6 link-local BGP next-hop addresses. This includes IPv4 with the use of RFC 8950 extensions.

When an interface is added to the list of dynamic-neighbor interfaces, an outgoing connection attempt is initiated toward any directly connected router on the interface that announces itself using an ICMPv6 router advertisement message. The session attempt is unsuccessful if the peer type is not EBGP, the reported AS number of the peer does not match one of the allowed values, or the maximum session limit of the interface would be exceeded.

The **no** form of this command removes the interface from the list of dynamic-neighbor interfaces.

Parameters

ip-int-name

Specifies the name of a base router IP interface, up to 32 characters.

Platforms

All

Full Context

configure service vprn bgp group dynamic-neighbor interface

Description

Commands in this context configure an unnumbered VPRN access IP interface for dynamic neighbors.

If this interface connects to a network with other BGP routers, sessions with the other routers can be set up automatically without explicitly configuring them as BGP neighbors. The interface must be IPv6 enabled, but because the interface is considered unnumbered, it does not require an IPv4 address or a global-unicast IPv6 address. The sessions are set up using IPv6 link-local addresses.

The BGP unnumbered feature supports all address families that allow IPv6 link-local BGP next-hop addresses. This includes IPv4 with the use of RFC 8950 extensions.

When an interface is added to the list of dynamic-neighbor interfaces, an outgoing connection attempt is initiated toward any directly connected router on the interface that announces itself using an ICMPv6 router advertisement message. The session attempt is unsuccessful if the peer type is not EBGP, the reported AS number of the peer does not match one of the allowed values, or the maximum session limit of the interface would be exceeded.

The **no** form of this command removes the interface from the list of dynamic-neighbor interfaces.

Parameters

ip-int-name

Specifies the name of a VPRN access IP interface, up to 32 characters.

Full Context

configure router dhcp6 local-dhcp-server interface-id-mapping

configure service vprn dhcp6 local-dhcp-server interface-id-mapping

Description

This command enables the behavior where unique /64 prefix is allocated per interface-id, and all clients having the same interface-id get an address allocated out of this /64 prefix for DHCP6. This is relevant for bridged clients behind the same local-loop (and same SAP), where sharing the same prefix allows communication between bridged clients behind the same local-loop to stay local. For SLAAC based assignment, downstream neighbor-discovery is automatically enabled to resolve the assigned address.

The **no** form of this command reverts to the default.

21.66 interface-subnets

interface-subnets

Syntax

interface-subnets [**service** *service-id*] *interface-name*

no interface-subnets

Context

[Tree] (config>router>policy-options>policy-statement>entry>from interface-subnets)

Full Context

configure router policy-options policy-statement entry from interface-subnets

Description

This command configures the applied router instance and interfaces that are used as matching condition within each policy-statement entry. A maximum of 10 *interface-name* entries is supported, and all entries must belong to the same routing context (either **base** or **service**). The interface subnet policy-statement match criterion is applied to the following unicast use case contexts:

- **export**, when used with OSPFv2, OSPFv3, IS-IS, RIP, RIPng, and BGP
- **route-table-import**, when used with BGP
- **vrf-export**, when used with MP-BGP

The **no** form of this command removes all policies from the configuration.

Default

no interface-subnets

Parameters

service

Specifies the context in which the configured interface exists. By default, the base routing instance is assumed. However, the configured service context is used only when the service is configured.

service-id

Specifies the service ID of the service to match.

Values *service-id* — 1 to 2147483647

svc-name — 64 characters maximum

interface-name

Specifies the interface name, up to 32 characters, to match when exporting the IP address of the associated interface to a routing protocol.

configure service vpls mesh-sdp eth-cfm mep ais-enable interface-support-enable

Description

This command enables the AIS function to consider the operational state of the entity on which it is configured. With this command, ETH-AIS on DOWN MEPs are triggered and cleared based on the operational status of the entity on which it is configured. If CCM is also enabled, then transmission of the AIS PDU is based on either the non-operational state of the entity or on any CCM defect condition. AIS generation ceases if both the operational state is UP and the CCM has no defect conditions. If the MEP is not CCM-enabled then the operational state of the entity is the only consideration, assuming this command is present for the MEP. By default, AIS is not generated or stopped based on the state of the entity on which the DOWN MEP is configured.

The **no** form of this command disables the AIS function to consider the operational state of the entity on which it is configured.

Default

no interface-support-enabled

Platforms

no interface-type

Context

[Tree] (config>service>vprn>isis>if interface-type)

Full Context

configure service vprn isis interface interface-type

Description

This command configures the IS-IS interface type as either broadcast or point-to-point.

Use this command to set the interface type of an Ethernet link to point-to-point to avoid having to carry the designated IS-IS overhead if the link is used as a point-to-point.

If the interface type is not known at the time the interface is added to IS-IS and subsequently the IP interface is bound (or moved) to a different interface type, then this command must be entered manually.

The **no** form of this command reverts to the default value.

Default

point-to-point — For IP interfaces on SONET channels.

broadcast — For IP interfaces on Ethernet or unknown type physical interfaces.

Parameters

broadcast

Configures the interface to maintain this link as a broadcast network.

point-to-point

Configures the interface to maintain this link as a point-to-point link.

Platforms

All

Full Context

configure service vprn ospf area interface interface-type

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

configure service vprn ospf3 area interface interface-type

Description

This command configures the interface type to:

- broadcast
- non-broadcast
- point-to-point
- point-to-multipoint on a link without broadcast or multicast support

Use this command to set the interface type of an Ethernet link to point-to-point to avoid having to carry the broadcast adjacency maintenance overhead if the Ethernet link provided the link is used as a point-to-point.

For subscriber interfaces, configure the adjacent interface (CPE) with interface type point-to-point. For subscriber interfaces, when the interface is configured as P2MP-NBMA, the subscriber interface becomes an active OPSF interface, allowing it to both send and receive OSPF LSAs. For all other interface types, subscriber interfaces remain as passive OSPF interfaces by default.

The **no** form of this command reverts to the default value.

Default

point-to-point — If the physical interface is SONET.

broadcast — If the physical interface is Ethernet or unknown.

Parameters

broadcast

Specifies the interface as a broadcast network. To significantly improve adjacency forming and network convergence, configure the network as point-to-point if only two routers are connected, even if the network is a broadcast media such as Ethernet.

point-to-point

Specifies the interface as a point-to-point link. Set the interface type of an Ethernet link to point-to-point to avoid having to carry the broadcast adjacency maintenance overhead if the Ethernet link provided is used as a point-to-point.

non-broadcast

Specifies the interface as a non-broadcast network.

p2mp-nbma

Specifies the interface as a point-to-multipoint on a link without broadcast or multicast support. No designated router or backup designated router is elected on this type of interface and all OSPF neighbors connect through individual point-to-point links. Only VPRN and IES services interfaces support this interface type.

configure system sync-if-timing bits interface-type

Description

This command configures the Building Integrated Timing Source (BITS) timing reference.

The **no** form of the command reverts to the default configuration.

Default

interface-type ds1 esf

Parameters

ds1 esf

Specifies Extended Super Frame (ESF). This is a framing type used on DS1 circuits that consists of 24 192-bit frames, The 193rd bit provides timing and other functions.

ds1 sf

Specifies Super Frame (SF), also called D4 framing. This is a common framing type used on DS1 circuits. SF consists of 12 192-bit frames. The 193rd bit provides error checking and other functions. ESF supersedes SF.

e1 pcm30crc

Specifies the pulse code modulation (PCM) type. PCM30CRC uses PCM to separate the signal into 30 user channels with CRC protection.

e1 pcm31crc

Specifies the pulse code modulation (PCM) type. PCM31CRC uses PCM to separate the signal into 31 user channels with CRC protection.

interface-type broadcast (if the physical interface is Ethernet or unknown)

Parameters

broadcast

Specifies the interface as a broadcast network. To significantly improve adjacency forming and network convergence, configure a network as point-to-point if only two routers are connected, even if the network is a broadcast media such as Ethernet.

point-to-point

Specifies the interface as a point-to-point link. Set the interface type of an Ethernet link to point-to-point to avoid having to carry the broadcast adjacency maintenance overhead if the Ethernet link provided is used as a point-to-point.

non-broadcast

Specifies the interface as a non-broadcast network.

p2mp-nbma

Specifies the interface as a point-to-multipoint on a link without broadcast or multicast support. No designated router or backup designated router is elected on this type of interface and all OSPF neighbors connect through individual point-to-point links. Only VPRN and IES services interfaces support this interface type.

interface-type

Syntax

interface-type {**client-facing** | **network-facing**}

no interface-type

Context

[Tree] (config>service>vpls>sap>dhcp6>ldra interface-type)

Full Context

configure service vpls sap dhcp6 ldra interface-type

Description

This command configures LDRA interface type as either client or network facing.

The **no** form of this command reverts to the default value.

Default

no interface-type

Parameters

client-facing

Configures the SAP as an untrusted client-facing interface. Only DHCPv6 client messages are accepted and encapsulated in a Relay-Forward message. It is mandatory to configure an interface ID for client-facing SAPs. Relay-Forward, Relay-Reply, and DHCPv6 server messages are silently dropped when received on a client-facing SAP

network-facing

Configures the SAP as a network-facing interface. Only Relay-Reply messages are accepted: the server message is extracted from the Relay-Reply message and forwarded in the VPLS. All other DHCPv6 message types are silently dropped when received on a network-facing SAP.

[Tree] (config>router>wlan-gw>mobility-triggered-acct interim-update)

Full Context

configure service vprn wlan-gw mobility-triggered-acct interim-update

configure router wlan-gw mobility-triggered-acct interim-update

Description

This command enables the inclusion of counters with a **hold-down** time option in mobility-triggered interim updates. When enabled, to disable the inclusion of counters, interim updates must be disabled and then re-enabled without the **include-counters** keyword. By default, the **hold-down** time is not imposed.

The **no** form of this command disables generation of flash interim accounting updates to RADIUS when change in location of the UE is detected.

Default

no interim-update

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

include-counters

Specifies the inclusion of counters in mobility-triggered interim updates.

seconds

Specifies the time, in seconds, that must elapse after a mobility-triggered interim with counters sent for the next mobility-triggered interim with counters to be sent.

Values 60 to 864000

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

21.72 interleave

interleave

Syntax

[**no**] **interleave**

Context

[Tree] (config>service>vprn>l2tp>group>mlppp interleave)

[Tree] (config>router>l2tp>group>mlppp interleave)

Full Context

configure service vprn l2tp group mlppp interleave

configure router l2tp group mlppp interleave

Description

This command is applicable only to LNS. Interleaving is supported only on MLPPPoX bundles that contain a single member link. If more than one link is present in the MLPPPoX bundle, interleaving is automatically disabled and a TRAP/log (tmnxMlpppBundleIndicatorsChange) is generated.

The minimum supported rate of the link on which interleaving is performed is 1 kb/s.

If configured at this level, interleaving is enabled on all tunnels within the group, unless it is explicitly disable per tunnel.

The **no** form of this command reverts to the default.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s

interleave

Syntax

interleave {**always** | **never**}

no interleave

Context

[Tree] (config>service>vprn>l2tp>group>tunnel>mlppp interleave)

[Tree] (config>router>l2tp>group>tunnel>mlppp interleave)

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Full Context

configure service vprn l2tp group tunnel mlppp interleave

configure router l2tp group tunnel mlppp interleave

Description

This command configures the user of link fragmentation and interleaving and is applicable only to LNS. Interleaving is supported only on MLPPPoX bundles that contain a single member link. If more than one link is present in the MLPPPoX bundle, interleaving is automatically disabled and a TRAP/log (tmnxMlpppBundleIndicatorsChange) is generated.

The minimum supported rate of the link on which interleaving is performed is 1 kb/s.

Interleaving configured on this level overwrites the configuration option under the group hierarchy. If the **no** form of this command is configured for interleaving at this level, the interleaving configuration inherits the configuration option configured under the L2TP group.

The **no** form of this command reverts to the default.

Parameters

always

Always perform interleaving on single linked MLPPPoX sessions within this tunnel, regardless of the configuration option for interleaving under the group level.

never

Never perform interleaving on single linked MLPPPoX sessions within this tunnel, regardless of the configuration option for interleaving under the group level.

21.80 intersite-shared

intersite-shared

Syntax

intersite-shared [**persistent-type5-adv**] [**kat-type5-adv-withdraw**]

no intersite-shared

Context

[Tree] (config>service>vprn>mvpn intersite-shared)

Full Context

configure service vprn mvpn intersite-shared

Description

This command specifies whether to use inter-site shared C-trees or not. Optional parameters allow enabling additional inter-site shared functionality. Not specifying an optional parameter when executing the command disables that parameter.

Default

n/a

Parameters

persistent-type5-adv

When specified for inter-site shared trees enabled, this parameter ensures that Type 5 SA routes are generated for the multicast source even if no joins are present for that source. When the parameter is not specified, the Type 5 SA routes are withdrawn where the prune from the last receiver is received for the multicast source.

kat-type5-adv-withdraw

When specified for inter-site shared trees, this parameter allows operators to enable KeepAlive Timers (KAT) on source PEs for ng-MVPN inter-site shared deployments. On a multicast source failure, a KAT expiry on source PEs will trigger a withdrawal of Type-5 Source-Active (S-A) route and switch from (C-S,C-G) to (C-*,C-G). When receiver PEs process reflected Type-5 S-A route withdrawals, they will withdraw their Type-7 ng-MVPN routes to the failed multicast source. The following conditions apply:

- KAT must only be enabled on source PEs.
- Functionality is supported with mLDP and RSVP-TE in the P-instance.
- Local receiver per (C-S, C-G) must be configured on source PEs running KAT.

Full Context

configure subscriber-mgmt diameter-application-policy gy ccrt-replay interval

configure subscriber-mgmt diameter-application-policy gx ccrt-replay interval

Description

This command specifies the interval at which CCR-T messages for Diameter Gx or Gy sessions that belong to the Diameter application policy are replayed, until a valid CCA-t response is received or until the configured **max-lifetime** period expires.

The **no** form of this command resets the interval to the default setting.

Default

interval 3600

Parameters

seconds

Specifies the interval at which the CCR-T messages are replayed for a gx session. The messages are replayed until a valid CCA-t response is received or until a 24 hour period expires, whichever comes first.

Values 60 to 86400

Default 3600

[Tree] (config>oam-pm>session>ethernet>lmm interval)

Full Context

configure oam-pm session ethernet dmm interval

configure oam-pm session ethernet lmm interval

Description

This command defines the message period or probe spacing for the transmission of the DMM or LMM frame.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **no** form of this command sets the interval to the default. If an LMM test is in **no shutdown** state, it always has timing parameters, whether default or operator configured.

Parameters

milliseconds

Specifies the number of milliseconds between the transmission of the DMM or LMM frames. The default value for the DMM or LMM interval is different than the default interval for SLM. This is intentional.

Values 50, 100, 200, 300, 400, 500, 600, 700, 800, 900, 1000, 10000

Default 1000

21.82 intervals-stored

intervals-stored

Syntax

intervals-stored *intervals*

no intervals-stored

Context

[Tree] (config>oam-pm>session>meas-interval intervals-stored)

Full Context

configure oam-pm session meas-interval intervals-stored

Description

This command defines the number of completed measurement intervals per session to be stored in volatile system memory. The entire block of memory is allocated for the measurement interval when the test is active (**no shutdown**) to ensure memory is available. The numbers are increasing from 1 to the configured value + 1. The active pm data is stored in the interval number 1 and older runs are stored, in order, to the upper most number with the oldest rolling off when the number of completed measurement intervals exceeds the configured value+1. As new test measurement intervals complete for the session, the stored intervals are renumbered to maintain the described order. Use caution when setting this value. There must be a balance between completed runs stored in volatile memory and the use of the write-to-flash function of the accounting policy.

The **5-mins** and **15-mins** measurement intervals share the same (1 to 96) retention pool. In the event that both intervals are required, the sum total of both intervals cannot exceed 96. The **1-hour** and **1-day** measurement intervals utilize their own ranges.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

If this command is omitted when configuring the measurement interval, the default value is used.

The **no** form of the command reverts to the default.

Default

intervals-stored 1

Parameters

intervals

Specifies the number of measurement intervals.

Values **5-mins**: 1 to 96
15-mins: 1 to 96
1-hour: 1 to 24
1-day: 1

Default **5-mins**: 32
15-mins: 32
1-hour: 8
1-day: 1

iom

Syntax

iom *slot-number* **type** {[**load-balancer**] [**ue-anchor**]}

no iom *slot-number*

Context

[Tree] (config>isa>wlan-gw-group iom)

Full Context

configure isa wlan-gw-group iom

Description

This command designates the specified IOM as a WLAN-GW IOM. Each WLAN-GW IOM must be provisioned with two ISA-BB modules on a hardware chassis and with an ISA-BB module in the first MDA slot in the VSR.

The **no** form of this command removes the IOM from the configuration.

Parameters

slot-number

Indicates the IOM slot to be used in the WLAN-GW group.

Values 1 to 10

type {[load-balancer] [ue-anchor]}

This parameter is supported on the VSR only. It determines if an IOM slot is used for load-balancing or UE anchoring and processing, or both. When the **wlan-gw-group** has only a single IOM, it is required to put this IOM in both modes at the same time.

Platforms

Description

This command configures back-up IPv4 or IPv6 destination address for the sFlow agent to send sFlow datagrams to. Optionally a destination port can also be configured (by default port 6343 is used).

The **no** form of this command deletes backup sFlow receiver destination.

Parameters

ip-address

Specifies the IPv4 or IPv6 address to send the sFlow datagrams to.

Values

a.b.c.d	(IPv4)

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

x:x:x:x:x:x:x:x	(IPv6)
[x:x:x:x:x:x:x:x]	(IPv6)
x - [0 to FFFF]H	

port

Specifies the UDP destination port to send the sFlow datagrams to.

Values 1 to 65535

Platforms

7750 SR, 7750 SR-s, 7950 XRS

21.88 ip-addr-primary

ip-addr-primary

Syntax

ip-addr-primary *ip-address*[:*port*]

no ip-addr-primary

Context

[Tree] (config>sflow>receiver ip-addr-primary)

Full Context

configure sflow receiver ip-addr-primary

Description

This command configures primary IPv4 or IPv6 destination address for the sFlow agent to send sFlow datagrams to. Optionally a destination port can also be configured (by default port 6343 is used).

The **no** form of this command deletes primary sFlow receiver destination.

Parameters

ip-address

Specifies the IPv4 or IPv6 address to send the sFlow datagrams.

Values

a.b.c.d	(IPv4)
x:x:x:x:x:x:x:x	(IPv6)
[x:x:x:x:x:x:x:x]	(IPv6)

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

x - [0..FFFF]H

port

Specifies the UDP destination port to send the sFlow datagrams.

Values 1 to 65535

Platforms

7750 SR, 7750 SR-s, 7950 XRS

21.89 ip-addr1

ip-addr1

Syntax

ip-addr1 {**eq** | **neq**} *ip-address*

no ip-addr1

21.91 ip-address

ip-address

Syntax

ip-address *ipv6-address*

no ip-address

Context

[Tree] (conf>router>segment-routing>sr-policies>policy>srv6>binding-sid ip-address)

Full Context

configure router segment-routing sr-policies static-policy segment-routing-v6 binding-sid ip-address

Description

This command configures an SRv6 binding SID for a remote SRv6 policy. It cannot be used with a local head-end location (defined with the **head-end local** command in the **conf>router>segment-routing>sr-policies>policy**).

This command and the **locator** or **micro-segment-locator** command in the **conf>router>segment-routing>sr-policies>policy>srv6>binding-sid** context are mutually exclusive.

If the remote head-end is an SR OS system, the binding SID can either be regular or uSID and, in the latter case, must be configured with the node ID in the following format: <block><uN><uB6>::.

The **no** form of this command removes the configuration.

Parameters

ipv6-address

Specifies the SRv6 binding SID as a 128 bit IPv6 address.

Values x:x:x:x:x:x:x:x (16 eight-bit pieces) or x:x:x:x:x:x:d:d:d:d

Context

[Tree] (config>subscr-mgmt>wlan-gw>ue-query>state ip-assigned-authorized)

Full Context

configure subscriber-mgmt wlan-gw ue-query state ip-assigned-authorized

Description

This command enables matching on UEs in an IP-assigned and authorized state, meaning that the UE already has an IP assigned and is authorized, but is not yet promoted to a final state such as ESM or DSM. This applies to UEs authenticated by distributed RADIUS proxy without **auth-on-dhcp** configured. UEs move to this state upon DHCP completion and continue to a more final state (such as DSM, ESM, or portal) upon receiving the first data packet.

The **no** form of this command disables matching on UEs in an IP-assigned and authorized state, unless all state matching is disabled.

Default

no ip-assigned-authorized

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

21.97 ip-criteria

ip-criteria

Syntax

[**no**] **ip-criteria**

Context

[Tree] (config>qos>sap-ingress ip-criteria)

[Tree] (config>qos>sap-egress ip-criteria)

Full Context

configure qos sap-ingress ip-criteria

configure qos sap-egress ip-criteria

Description

IP criteria-based SAP ingress or egress policies are used to select the appropriate ingress or egress queue or policer and corresponding forwarding class and packet profile for matched traffic.

This command is used to enter the context to create or edit policy entries that specify IP criteria such as IP quintuple lookup or DiffServ code point.

The software implementation will exit on the first match found and execute the actions in accordance with the accompanying action command. For this reason, entries must be sequenced correctly from most to least explicit.

The **no** form of this command deletes all the entries specified under this node. When IP criteria entries are removed from a SAP ingress or egress policy, the IP criteria is removed from all services where that policy is applied.

Platforms

All

ip-criteria

Syntax

[**no**] **ip-criteria**

[Tree] (config>qos>network>ingress ip-criteria)

[Tree] (config>qos>network>egress ip-criteria)

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Full Context

configure qos network ingress ip-criteria

configure qos network egress ip-criteria

Description

IP criteria-based network ingress and egress policies are used to select the appropriate ingress or egress queue or policer, and the corresponding forwarding class and packet profile for matched traffic. This command is used to enter the context to create or edit policy entries that specify IP criteria such as IP quintuple lookup or DSCP.

The 7750 SR OS implementation will exit on the first match found and execute the actions in accordance with the accompanying action command. Entries must be sequenced correctly from most to least explicit.

The ingress classification only applies to the outer IP header of non-tunneled traffic. The only exception is for traffic received on a Draft Rosen tunnel, for which only classification on the outer IP header is supported.

Attempting to apply a network QoS policy containing an **ip-criteria** statement to any object except a network IP interface will result in an error.

The **no** form of this command deletes all entries specified under this node. When IP criteria entries are removed from a network policy, the IP criteria are removed from all network interfaces to which that policy is applied.

Full Context

configure router interface group-encryption ip-exception

Description

This command associates an IP exception filter policy with an NGE-enabled router interface to allow packets matching the exception criteria to transit the NGE domain as clear text.

When an exception filter is added for inbound traffic, packets matching the criteria in the IP exception filter policy are allowed to be received in clear text even if an inbound key group is configured. If no inbound key group is configured, then associated inbound IP exception filter policies will be ignored.

When an exception filter is added for outbound traffic, packets matching the criteria in the IP exception filter policy are not encrypted when sent out of the router interface even if an outbound key group is configured. If no outbound key group is configured, then associated outbound IP exception filter policies will be ignored.

The **no** form of this command removes the IP exception filter policy from the specified direction.

Default

no ip-exception direction inbound

no ip-exception direction outbound

Parameters

filter-id

Specifies the IP exception filter policy. The IP exception ID or exception name must have already been created.

Values 1 to 6553, *filter-name* (64 characters maximum)

inbound

Binds the exception filter policy in the inbound direction.

outbound

Binds the exception filter policy in the outbound direction.

Context

[Tree] (config>router ip-fast-reroute)

Full Context

configure router ip-fast-reroute

Description

This command enables IP Fast-Reroute (FRR) feature on the system.

This feature provides for the use of a Loop-Free Alternate (LFA) backup next-hop for forwarding in-transit and CPM generated IP packets when the primary next-hop is not available. IP FRR is supported on IPv4 and IPv6 OSPF/IS-IS prefixes forwarded in the base router instance to a network IP interface or to an IES SAP interface or spoke interface. It is also supported for VPRN VPN-IPv4 OSPF prefixes and VPN-IPv6 OSPF prefixes forwarded to a VPRN SAP interface or spoke interface.

IP FRR also provides a LFA backup next-hop for the destination prefix of a GRE tunnel used in an SDP or in VPRN auto-bind.

When any of the following events occurs, IGP instructs in the fast path on the XMAs to enable the LFA backup next-hop:

- OSPF/IS-IS interface goes operationally down: physical or local admin shutdown.
- Timeout of a BFD session to a next-hop when BFD is enabled on the OSPF/IS-IS interface

When the SPF computation determines there is more than one primary next-hop for a prefix, it will not program any LFA next-hop in RTM. Therefore, the IP prefix will resolve to the multiple equal-cost primary next-hops that provide the required protection.

The **no** form of this command disables the IP FRR feature on the system

ip-filter

Syntax

ip-filter *ip-filter-id* **entry** *entry-id* [*entry-id*]

no ip-filter *ip-filter-id* [**entry** *entry-id*]

Context

[Tree] (config>mirror>mirror-source ip-filter)

Full Context

configure mirror mirror-source ip-filter

Description

This command enables mirroring of packets that match specific entries in an existing IP filter.

The **ip-filter** command directs packets which match the defined list of entry IDs to be mirrored to the mirror destination referenced by the *mirror-dest-service-id* of the **mirror-source**.

The IP filter must already exist in order for the command to execute. Filters are configured in the **config>filter** context. If the IP filter does not exist, an error will occur. If the filter exists but has not been associated with a SAP or IP interface, an error is not generated but mirroring will not be enabled (there are no packets to mirror). Once the IP filter is defined to a SAP or IP interface, mirroring is enabled.

If the IP filter is defined as ingress, only ingress packets are mirrored. Ingress mirrored packets are mirrored to the mirror destination prior to any ingress packet modifications.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

If the IP filter is defined as egress, only egress packets are mirrored. Egress mirrored packets are mirrored to the mirror destination after all egress packet modifications.

An *entry-id* within an IP filter can only be mirrored to a single mirror destination. If the same *entry-id* is defined multiple times, an error occurs and only the first **mirror-source** definition is in effect.

By default, no packets matching any IP filters are mirrored. Mirroring of IP filter entries must be explicitly defined.

The **no ip-filter** command, without the **entry** keyword, removes mirroring on all *entry-id*'s within the *ip-filter-id*.

When the **no** command is executed with the **entry** keyword and one or more *entry-id*'s, mirroring of that list of *entry-id*'s is terminated within the *ip-filter-id*. If an *entry-id* is listed that does not exist, an error will occur and the command will not execute. If an *entry-id* is listed that is not currently being mirrored, no error will occur for that *entry-id* and the command will execute normally.

Parameters

ip-filter-id

Specifies the IP filter ID whose entries are mirrored. If the *ip-filter-id* does not exist, an error will occur and the command will not execute. Mirroring of packets will commence once the *ip-filter-id* is defined on a SAP or IP interface.

Values 1 to 65535

name, up to 64 characters

entry-id

Specifies the IP filter entries to use as match criteria for packet mirroring. The **entry** keyword begins a list of *entry-id*'s for mirroring. Multiple *entry-id* entries may be specified with a single command. Each *entry-id* must be separated by a space.

If an *entry-id* does not exist within the IP filter, an error occurs and the command will not execute.

If the filter's *entry-id* is renumbered within the IP filter definition, the old *entry-id* is removed but the new *entry-id* must be manually added to the configuration to include the new (renumbered) entry's criteria.

Values 1 to 2097151

ip-filter

Syntax

ip-filter *ip-filter-id* **entry** *entry-id* [*entry-id*] [**intercept-id** *intercept-id* [*intercept-id*]] [**session-id** *session-id* [*session-id*]]

no ip-filter *ip-filter-id* [**entry** *entry-id* [*entry-id*]]

Context

[Tree] (config>li>li-source ip-filter)

Full Context

configure li li-source ip-filter

Description

This command enables lawful interception (LI) of packets that match specific entries in an existing IP filter.

The **ip-filter** command directs packets which match the defined list of entry IDs to be intercepted to the destination referenced by the *mirror-dest-service-id* of the **mirror-source**.

The IP filter must already exist in order for the command to execute. Filters are configured in the **config>filter** context. If the IP filter does not exist, an error occurs. If the filter exists but has not been associated with a SAP or IP interface, an error is not generated but mirroring will not be enabled (there are no packets to mirror). Once the IP filter is defined to a SAP, IP interface or subscriber, mirroring is enabled.

If the IP filter is defined as ingress, only ingress packets are intercepted. Ingress packets are sent to the destination prior to any ingress packet modifications.

If the IP filter is defined as egress, only egress packets are intercepted. Egress packets are sent to the destination after all egress packet modifications.

An *entry-id* within an IP filter can only be intercepted to a single destination. If the same *entry-id* is defined multiple times, an error occurs and only the first definition is in effect.

By default, no packets matching any IP filters are intercepted. Interception of IP filter entries must be explicitly defined.

When the **no** command is executed with the **entry** keyword and one or more *entry-id*'s, interception of that list of *entry-id*'s is terminated within the *ip-filter-id*. If an *entry-id* is listed that does not exist, an error will occur and the command will not execute. If an *entry-id* is listed that is not currently being intercepted, no error will occur for that *entry-id* and the command will execute normally.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

ip-filter-id

Specifies the IP filter ID whose entries are to be intercepted. If the *ip-filter-id* does not exist, an error will occur and the command will not execute. Intercepting packets will commence when the *ip-filter-id* is defined on a SAP or IP interface.

entry-id

Specifies the IP filter entries to use as match criteria for lawful intercept (LI). The **entry** keyword begins a list of *entry-id*'s for interception. Multiple *entry-id* entries can be specified with a single command. Each *entry-id* must be separated by a space. Up to <N><n> 8 entry IDs may be specified in a single command.

If an *entry-id* does not exist within the IP filter, an error occurs and the command will not execute.

If the filter's *entry-id* is renumbered within the IP filter definition, the old *entry-id* is removed but the new *entry-id* must be manually added to the configuration to include the new (renumbered) entry's criteria.

intercept-id

Specifies the intercept ID that is inserted into the packet header for all mirrored packets of the associated **li-source** entry. This intercept ID can be used (for example by a downstream LI gateway) to identify the particular LI session to which the packet belongs. For all types of **li-source** entries (filter, nat, sap, subscriber), when the mirror service is configured with **ip-udp-shim** routable encap, an *intercept-id* field (as part of the routable encap) is always present in the mirrored packets. If there is no *intercept-id* configured for an **li-source** entry, then the default value is inserted. When the mirror service is configured with **ip-gre** routable encapsulation, no *intercept-id* is inserted and none should be specified against the **li-source** entries.

Values 1 to 4294967295 (32b) for **nat li-source** entries that are using a mirror service that is not configured with routable encap

1 to 1073741824 (30b) for all types of **li-source** entries that are using a mirror service with routable ip-udp-shim encap and no direction-bit.

1 to 536870912 (29b) for all types of **li-source** entries that are using a mirror service with routable **ip-udp-shim** encapsulation and with the **direction-bit** enabled.

session-id

Specifies the *session-id* that is inserted into the packet header for all mirrored packets of the associated **li-source** entry. This *session-id* can be used (for example by a downstream LI Gateway) to identify the particular LI session to which the packet belongs. The *session-id* is only valid and used for mirror services that are configured with **ip-udp-shim** routable encap (**config>mirror>mirror-dest>encap>ip-udp-shim**). For all types of **li-source** entries (filter, nat, sap, subscriber), when the mirror service is configured with **ip-udp-shim** routable encap, a *session-id* field (as part of the routable encap) is always present in the mirrored packets. If there is no *session-id* configured for an **li-source** entry, then the default value is inserted. When a mirror service is configured with **ip-gre** routable encap, no *session-id* is inserted and none should be specified against the **li-source** entries.

Description

This command enables mirroring of packets that match specific entries in an existing IP filter.

The **ip-filter** command directs packets which match the defined list of entry IDs to be mirrored to the mirror destination referenced by the *mirror-dest-service-id* of the **mirror-source**.

The IP filter must already exist in order for the command to execute. Filters are configured in the **config>filter** context. If the IP filter does not exist, an error will occur. If the filter exists but has not been associated with a SAP or IP interface, an error is not generated but mirroring will not be enabled (there are no packets to mirror). Once the IP filter is defined to a SAP or IP interface, mirroring is enabled.

If the IP filter is defined as ingress, only ingress packets are mirrored. Ingress mirrored packets are mirrored to the mirror destination prior to any ingress packet modifications.

If the IP filter is defined as egress, only egress packets are mirrored. Egress mirrored packets are mirrored to the mirror destination after all egress packet modifications.

An *entry-id* within an IP filter can only be mirrored to a single mirror destination. If the same *entry-id* is defined multiple times, an error occurs and only the first **mirror-source** definition is in effect.

By default, no packets matching any IP filters are mirrored. Mirroring of IP filter entries must be explicitly defined.

The **no ip-filter** command, without the **entry** keyword, removes mirroring on all *entry-id*'s within the *ip-filter-id*.

When the **no** command is executed with the **entry** keyword and one or more *entry-id*'s, mirroring of that list of *entry-id*'s is terminated within the *ip-filter-id*. If an *entry-id* is listed that does not exist, an error will occur and the command will not execute. If an *entry-id* is listed that is not currently being mirrored, no error will occur for that *entry-id* and the command will execute normally.

Parameters

ip-filter-id

The IP filter ID whose entries are mirrored. If the *ip-filter-id* does not exist, an error will occur and the command will not execute. Mirroring of packets will commence once the *ip-filter-id* is defined on a SAP or IP interface.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

entry-id

The IP filter entries to use as match criteria for packet mirroring. The **entry** keyword begins a list of *entry-id*'s for mirroring. A maximum of eight *entry-id* entries may be specified with a single command. Each *entry-id* must be separated by a space.

If an *entry-id* does not exist within the IP filter, an error occurs and the command will not execute.

If the filter's *entry-id* is renumbered within the IP filter definition, the old *entry-id* is removed but the new *entry-id* must be manually added to the configuration to include the new (renumbered) entry's criteria.

Platforms

All

ip-filter

Syntax

ip-filter *filter-id* [**name**] [**create**]

no ip-filter {*filter-id* | *filter-name*}

Context

[Tree] (config>filter ip-filter)

Full Context

configure filter ip-filter

Description

Commands in this context configure the specified IPv4 filter policy.

The **no** form of the command deletes the IPv4 filter policy. A filter policy cannot be deleted until it is removed from all objects where it is applied.

Parameters

filter-id

Specifies the IPv4 filter policy ID expressed as a decimal integer.

Values 1 to 65535

name

Configures an optional filter name, up to 64 characters in length, to a given filter. This filter name can then be used in configuration references, display, and show commands throughout the system. A defined filter name can help the service provider or administrator to identify and manage filters within the SR OS platforms.

To create a filter, you must assign a filter ID, however, after it is created, either the filter ID or filter name can be used to identify and reference a filter.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

If a name is not specified at creation time, then SR OS assigns a string version of the *filter-id* as the name.

Filter names may not begin with an integer (0 to 9).

filter-name

Specifies a string, up to 64 characters, uniquely identifying this IPv4 filter policy.

create

This keyword is required to create the configuration context. Once it is created, the context can be enabled with or without the **create** keyword.

ip-filter

Syntax

ip-filter *src-filter-id* [**src-entry** *src-entry-id*] **to** *dst-filter-id* [**dst-entry** *dst-entry-id*] [**overwrite**]

Context

[Tree] (config>filter>copy ip-filter)

Full Context

configure filter copy ip-filter

Description

This command copies an existing filter entry for a specific filter ID to another filter ID. The command is a configuration level maintenance tool used to create new entries using an existing filter policy. If **overwrite** is not specified, an error will occur if the destination filter entry exists.

Parameters

src-filter-id

Identifies the source filter policy from which the copy command will attempt to copy. The filter policy must exist within the context of the preceding keyword (**ip-filter**).

dst-filter-id

Identifies the destination filter policy to which the copy command will attempt to copy. If the **overwrite** keyword is not specified, the filter entry ID cannot already exist in the destination filter policy. If the **overwrite** keyword is present, the destination entry ID may or may not exist.

overwrite

Specifies that the destination filter entry may exist. If it does, everything in the existing destination filter entry will be completely overwritten with the contents of the source filter entry. If the destination filter entry exists, either **overwrite** must be specified or an error message will be returned. If **overwrite** is specified, the function of copying from source to destination occurs in a "break before make” manner and therefore should be handled with care.

22 i Commands – Part III

22.1 ip-filter-max-size

ip-filter-max-size

Syntax

ip-filter-max-size {*value* | **default**}

Context

[Tree] (config>service>vprn>flowspec ip-filter-max-size)

Full Context

configure service vprn flowspec ip-filter-max-size

Description

This command configures the maximum number of FlowSpec routes or rules that can be embedded into an ingress IP filter policy for a specified routing instance. FlowSpec filter entries embedded in a filter policy in this routing instance will use filter entries from the range between the embedding offset and "offset + ip-filter-max-size – 1".

The sum of this command and the highest offset in any IPv4 filter that embeds IPv4 FlowSpec rules from this routing instance (excluding filters that embed at offset 262143) must not exceed 262143.

This command can be configured to a higher or lower value at any time. If the number of IPv4 FlowSpec rules that are currently installed is *M*, and the new configured limit is *N*, where *N*<*M*, then the last set of rules from *N* to *M* (by FlowSpec order) are immediately removed, but are retained in the BGP RIB. If the limit is increased, new rules are programmed only as they are received again in new BGP updates.

Default

ip-filter-max-size 512

Parameters

value

The maximum number of FlowSpec routes or rules that can be embedded into an ingress IP filter policy.

Values 0 to 262143

default

Keyword to configure the maximum size as 512.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Platforms

All

ip-filter-max-size

Syntax

ip-filter-max-size {*value* | **default**}

Context

[Tree] (config>router>flowspec ip-filter-max-size)

Full Context

configure router flowspec ip-filter-max-size

Description

This command configures the maximum number of FlowSpec routes or rules that can be embedded into the auto-created embedded filter (fSpec- *X*). FlowSpec filter entries embedded in a filter policy in this routing instance will use filter entries from the range between "embedding offset + 1" and "embedding offset + ip-filter-max-size".

The sum of this command and the highest offset in any IPv4 filter that embeds IPv4 FlowSpec rules from this routing instance (excluding filters that embed at offset 262143) must not exceed 262143.

This command can be configured to a higher or lower value at any time. If the number of IPv4 FlowSpec rules that are currently installed is *M*, and the new configured limit is *N*, where *N*<*M*, then the last set of rules from *N* to *M* (by FlowSpec order) are immediately removed, but are retained in the BGP RIB. If the limit is increased, new rules are programmed only as they are received again in new BGP updates.

Default

ip-filter-max-size 512

Parameters

value

Specifies the maximum number of FlowSpec routes or rules that can be embedded into an ingress IP filter policy.

Values 0 to 262143

default

Keyword to configure the maximum size as 512.

Full Context

configure service vprn nat inside nat64 ip-fragmentation

configure router nat inside nat64 ip-fragmentation

configure router nat inside dual-stack-lite address ip-fragmentation

configure service vprn nat inside dslite addressip-fragmentation ip-fragmentation

Description

This command configures downstream IPv6 fragmentation behavior in DS-Lite and NAT64. IPv6 fragmentation is performed in the ISA. IPv4 fragmentation is not affected by this command. If desired, downstream IPv4 packet can be fragmented in the carrier IOM before the packet reaches ISA (and the NAT function). The IPv4 fragmentation in the downstream direction can be set by the **config>router/vprn>nat>outside>mtu** command.

DS-Lite IPv6 Fragmentation in Downstream Direction (IPv4 to IPv6)

In case that the length of the received IPv4 packet is larger than the configured tunnel-mtu value while fragmentation is allowed, the resulting IPv6 packet will be fragmented (IPv4 is tunneled within IPv6). The maximum size of the of the fragmented IPv6 packet will be 48bytes larger than the configured tunnel-mtu value. This is due to the size of the tunneling IPv6 header: 40bytes basic IPv6 header + 8 bytes of extended fragmentation IPv6 header.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

In case that fragmentation is not allowed while the IPv4 packet size is larger than configured tunnel-mtu size, the IPv4 packet will be dropped and an ICMPv4 Datagram Too Big message will be generated towards the source. The advertised mtu size in that ICMP message will be set to configured tunnel-mtu value.

NAT64 IPv6 Fragmentation in Downstream Direction (IPv4to IPv6)

In contrast to DS-Lite, NAT64 transport is not based on tunneling. Instead, IP headers are translated between IPv4 and IPv6. Consequently, NAT64 fragmentation operates based on the ipv6-mtu, as opposed to tunnel-mtu in DS-Lite which represents the size of the tunnel payload (IPv4 packet).

In case that the length of the translated IPv6 packet exceeds the size of the configured ipv6-mtu value while fragmentation is allowed, the resulting IPv6 packet will be fragmented. The maximum size of the of the fragmented IPv6 packet will be the configured ipv6-mtu value.

In case that fragmentation is not allowed while the translated IPv6 packet size is larger than configured ipv6-mtu size, the IPv4 packet (that is supposed to be translated into IPv6) will be dropped and an ICMPv4 Datagram Too Big message will be generated towards the source. The advertised mtu size in that ICMP message will be set to the ipv6-mtu value minus 28bytes. The 28bytes comes from the size of the IPv6 overhead of the translated packet (20bytes difference between the IP header sizes 40bytes in IPv6 vs 20bytes in IPv4; 8 bytes for extended IPv6 fragmentation header).

Default

disabled

Parameters

disabled

IPv6 Fragmentation is disabled. In case that the packet size is larger

than what is set by the mtu value (tunnel-mtu or ipv6-mtu) the IPv4 packet will be dropped and ICPMv4 Datagram Too Big messages will be sent back to the source.

fragment-ipv6

IPv6 fragmentation will be performed in all cases, regardless of the DF bit setting in the tunneled/translated IPv4 packet.

fragment-ipv6-unless-ipv4-df-set

IPv6 Fragmentation will be performed only in cases when DF bit in tunneled/translated IPv4 packet is cleared.

[**no**] **ip-identification-assist**

Context

[Tree] (config>app-assure>group>policy>app-filter>entry ip-identification-assist)

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Full Context

configure application-assurance group policy app-filter entry ip-identification-assist

Description

This command configures the router to perform a network IP address lookup that overrides the assigned application if it finds the network IP address in its internal application-IP database.

If an IP match is found, the application assigned from the app-filter is overridden with the application from the IP lookup. This also affects the app-group and charging group.

If an IP match is not found, the application assigned from the app-filter is not overridden and remains (including the app-group and charging group).

The **no** form of this command disables the router from performing a network IP address lookup and overriding the assigned application.

Default

no ip-identification-assist

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

configure service vprn interface ipsec ipsec-tunnel ip-mtu

configure router interface ipsec ipsec-tunnel ip-mtu

configure service ies interface ipsec ipsec-tunnel ip-mtu

configure service vprn interface sap ip-tunnel ip-mtu

Description

This command configures the IP maximum transmit unit (packet) for this interface.

Because this connects a Layer 2 to a Layer 3 service, this parameter can be adjusted under the IES interface.

The MTU that is advertised from the IES size is:

MINIMUM((SdpOperPathMtu - EtherHeaderSize), (Configured ip-mtu))

By default (for the Ethernet network interface), if no ip-mtu is configured it is (1568 - 14) equals 1554.

The **ip-mtu** command instructs the MS-ISA to perform IP packet fragmentation, prior to IPsec encryption and encapsulation, based on the configured MTU value. In particular:

If the length of a payload IP packet (including its header) exceeds the configured MTU value and the DF flag is clear (due to the presence of the clear-df-bit command or because the original DF value was 0) then the MS-ISA fragments the payload packet as efficiently as possible (i.e. it creates the minimum number of fragments each less than or equal to the configured MTU size); in each created fragment the DF bit shall be 0.

If the length of a payload IP packet (including its header) exceeds the configured MTU value and the DF flag is set (because the original DF value was 1 and the tunnel has no clear-df-bit in its configuration) then the MS-ISA discards the payload packet without sending an ICMP type 3/code 4 message back to the packet's source address.

The effective MTU for packets entering a tunnel is the minimum of the private tunnel SAP interface IP MTU value (used by the IOM) and the tunnel IP MTU value (configured using the above command and used

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

by the MS-ISA). To fragment IP packets larger than X bytes with DF set, rather than discarding them, the tunnel IP MTU should be set to X and the private tunnel SAP interface IP MTU should be set to a value larger than X.

The **no ip-mtu** command, corresponding to the default behavior, disables fragmentation of IP packets by the MS-ISA; all IP packets, regardless of size or DF bit setting, are allowed into the tunnel.

Default

no ip-mtu

Parameters

bytes

Specifies the IP maximum transmit unit (packet) for this interface.

Values 512 to 9000

Platforms

ip-mtu

Syntax

ip-mtu *octets*

no ip-mtu

Context

[Tree] (config>service>ies>aarp-interface ip-mtu)

Full Context

configure service ies aarp-interface ip-mtu

Description

This command configures the IP maximum transmit unit (packet) for this interface.

The **no** form of this command returns the default value.

Default

no ip-mtu

By default (for Ethernet network interface) if no ip-mtu is configured it is (1568 - 14) = 1554.

Parameters

octets

Specifies the maximum number of octets that can be transmitted.

Values 512 to 9786

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

ip-mtu

Syntax

ip-mtu *octets*

no ip-mtu

Context

[Tree] (config>service>ies>red-if ip-mtu)

Full Context

configure service ies redundant-interface ip-mtu

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command configures the IP maximum transmit unit (packet) for the associated router IP interface.

The configured IP-MTU cannot be larger than the calculated IP MTU based on the port MTU configuration.

The MTU that is advertised from the IES size is:

MINIMUM((SdpOperPathMtu - EtherHeaderSize), (Configured ip-mtu))

The **no** form of this command returns the associated IP interfaces MTU to its default value, which is calculated based on the port MTU setting. For Ethernet ports this will typically be 1554.

Default

no ip-mtu

Parameters

octets

Specifies the octets.

Values 512 to 9786

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

ip-mtu

Syntax

ip-mtu

Syntax

ip-mtu *octets*

no ip-mtu

Context

[Tree] (config>router>if ip-mtu)

Full Context

configure router interface ip-mtu

Description

This command configures the IP maximum transmit unit (packet) for the associated router IP interface.

The operational IP MTU that is used for the interface is determined based on both the configured IP MTU and the port MTU of the port bound to this interface.

The MTU that is used is:

MINIMUM((Port_MTU - EthernetHeaderSize), (configured ip-mtu))

The **no** form of this command returns the associated IP interfaces MTU to its default value, which is calculated based on the port MTU setting. (For Ethernet ports the default IP MTU is 1500 octets.)

Default

no ip-mtu

Parameters

octets

Specifies the IP MTU value associated with the IP interface, specified in octets. If the interface supports IPv6 packets, the IP-MTU must be set to a value greater than or equal to (≥) 1280 in accordance with RFC 2460 *Internet Protocol, Version 6 (IPv6) Specification*.

Values 512 to 9786

Platforms

ip-mtu

Syntax

ip-mtu *octets*

no ip-mtu

Context

[Tree] (bof ip-mtu)

Full Context

bof ip-mtu

Description

This command configures the IP maximum transmit unit (packet) for the management router instance.

The operational IP MTU that is used for the interface is determined based on both the configured IP MTU and the port MTU of the port bound to this interface.

The MTU that is used is:

MINIMUM((Port_MTU - EthernetHeaderSize), (configured ip-mtu))

For the management port, the port MTU is fixed at 1514 and the EthernetHeaderSize is 14 so the first element of the equation above is 1500 octets.

The **no** form of this command returns the associated IP interfaces MTU to its default value, which is calculated based on the port MTU setting. (For the management port the default IP MTU is 1500 octets.)

Default

ip-mtu 1500

Parameters

octets

Specifies the IP MTU value associated with the IP interface, specified in octets. If the interface supports IPv6 packets, the IP-MTU must be set to a value greater than or equal to (≥) 1280 in accordance with RFC 2460 *Internet Protocol, Version 6 (IPv6) Specification*.

22.10 ip-packet-length-list

ip-packet-length-list

Syntax

ip-packet-length-list *pkt-len-list-name* [**create**]

[**no**] **ip-packet-length-list** *pkt-len-list-name*

Context

[Tree] (config>filter>match-list ip-packet-length-list)

Full Context

configure filter match-list ip-packet-length-list

Description

This command configures a list of IPv4 packet lengths for match criteria in IPv4 filter policies. The **create** keyword is mandatory when configuring a packet length list.

The **no** form of this command deletes the specified list.

Parameters

pkt-len-list-name

Specifies the name of the packet length list, up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

22.11 ip-prefix

ip-prefix

Syntax

ip-prefix *ip-prefix/ip-prefix-length*

no ip-prefix

Context

[Tree] (config>subscr-mgmt>loc-user-db>ipoe>host>host-ident ip-prefix)

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Full Context

configure subscriber-mgmt local-user-db ipoe host host-identification ip-prefix

Description

This command specifies the source IPv4/IPv6 address/prefix of the data trigger packet as the host identification.

Note:
This command is only used when **ip** is configured as one of the **match-list** parameters.

The **no** form of this command removes the IP prefix from the configuration.

Parameters

ip-prefix/ip-prefix-length

Specifies the IPv4 address, IPv6 address, or IPv6 prefix.

Values ipv4-prefix a.b.c.d
ipv4-prefix-length 0 to 32
ipv6-prefix x:x:x:x:x:x:x:x (eight 16-bit pieces)
x:x:x:x:x:d.d.d.d
x to [0 to FFFF]H
d to [0 to 255]D
ipv6-prefix-length 0 to 128

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

no ip-prefix

Context

[Tree] (conf>router>segment-routing>srv6>loc>prefix ip-prefix)

Full Context

configure router segment-routing segment-routing-v6 locator prefix ip-prefix

Description

This command configures the IPv6 prefix and prefix length for an SRv6 locator.

The locator prefix length is the sum of the lengths of the block field and that of the node ID field.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **no** form of this command deletes the IPv6 prefix from this locator.

Default

no ip-prefix

Parameters

ipv6-prefix/prefix-length

Specifies an IPv6 address prefix written as hexadecimal numbers separated by colons with host bits set to 0.

Values		
	ipv6-prefix	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	ipv6-prefix-length	4 to 96

Platforms

7450 ESS, 7750 SR, 7750 SR-s, 7950 XRS, VSR

ip-prefix

Syntax

ip-prefix *ipv6-prefix*/*prefix-length*

no ip-prefix

Context

[Tree] (conf>router>sr>srv6>ms>block>prefix ip-prefix)

Full Context

configure router segment-routing segment-routing-v6 micro-segment block prefix ip-prefix

Description

This command configures the IPv6 prefix and prefix length for an SRv6 micro-segment locator.

For micro-segment SRv6, the locator prefix length must be equal to the micro-segment block length.

The **no** form of this command deletes the IPv6 prefix from this micro-segment locator.

Default

no ip-prefix

Parameters

ipv6-prefix/prefix-length

Specifies an IPv6 address prefix written as hexadecimal numbers separated by colons with host bits set to 0.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Values	ipv6-prefix	x:x:x:x:x:x:x:x (eight 4-hexadecimal pieces)
	ipv6-prefix-length	8 to 64

Platforms

7450 ESS, 7750 SR, 7750 SR-s, 7950 XRS, VSR

configure qos match-list ip-prefix-list

Description

This command creates a list of IPv4 prefixes for match criteria in QoS policies.

An IP prefix list must contain only IPv4 address prefixes created using the prefix command and cannot be deleted if it is referenced by a QoS policy.

The **no** form of this command deletes the specified list.

Parameters

ip-prefix-list-name

A string of up to 32 characters of printable ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes. The name **default** (case insensitive) is reserved by the system.

Platforms

All

ip-prefix-list

Syntax

ip-prefix-list *ip-prefix-list-name* [**create**]

no ip-prefix-list *ip-prefix-list-name*

Context

[Tree] (config>filter>match-list ip-prefix-list)

Full Context

configure filter match-list ip-prefix-list

Description

This command creates a list of IPv4 prefixes for match criteria in IPv4 ACL and CPM filter policies.

The **no** form of this command deletes the specified list.

Operational Notes:

An **ip-prefix-list** must contain only IPv4 address prefixes.

An IPv4 prefix match list cannot be deleted if it is referenced by a filter policy.

See general description related to match-list usage in filter policies.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

ip-prefix-list-name

Specifies a string of up to 32 printable ASCII characters. If special characters are used, the string must be enclosed within double quotes.

Full Context

configure application-assurance group policy app-qos-policy entry match ip-protocol-num

configure application-assurance group policy app-filter entry ip-protocol-num

Description

This command configures the IP protocol to use in the application definition.

The **no** form of this command restores the default (removes IP protocol number from application criteria defined by this app-filter entry).

Default

no ip-protocol-num

Parameters

eq

Specifies that the value configured and the value in the flow must be equal.

neq

Specifies that the value configured differs from the value in the flow.

protocol-id

Specifies the decimal value representing the IP protocol to be used as an IP filter match criterion. Well known protocol numbers include ICMP (1), TCP (6), UDP (17).

The **no** form the command removes the protocol from the match criteria.

Values 1 to 255 (Decimal, Hexadecimal, or Binary representation).

Supported IANA IP protocol names:

none, crtp, crudp, egp, eigrp, encap, ether-ip, gre, icmp, idrp, igmp, igp, ip, ipv6, ipv6-frag, ipv6-icmp, ipv6-no-nxt, ipv6-opts, ipv6-route, isis, iso-ip, l2tp, ospf-igp, pim, pnni, ptp, rdp, rsvp, sctp, stp, tcp, udp, vrrp

* - udp/tcp wildcard

ip-route-advertisement

Syntax

ip-route-advertisement [**incl-host**] [**domain-id** *global-field*:*local-field*]

no ip-route-advertisement

Context

[Tree] (config>service>vpls>bgp-evpn ip-route-advertisement)

Full Context

configure service vpls bgp-evpn ip-route-advertisement

Description

This command enables and disables the advertisement of IP prefixes in EVPN. If enabled, any active route in the R-VPLS VPRN route table are advertised in EVPN using the VPLS BGP configuration. The interface host addresses are not advertised in EVPN unless the **ip-route-advertisement incl-host** command is enabled.

The **no** form of this command disables IP prefixes advertisement in EVPN.

Default

no ip-route-advertisement

Parameters

incl-host

Specifies to advertise the interface host addresses in EVPN.

global-field:local-field

Specifies the domain ID.

Values *4byte-GlobalAdminValue:2byte-LocalAdminValue*

4byte-GlobalAdminValue:	0 to 4294967295
2byte-LocalAdminValue	0 to 65535

ipipe *service-id* [**customer** *customer-id*] [**create**] [**vpn** *vpn-id*] [**vc-switching**] [**name** *name*]

no ipipe *service-id*

Context

[Tree] (config>service ipipe)

Full Context

configure service ipipe

Description

This command configures an IP-Pipe service.

Parameters

service-id

The unique service identification number or string identifying the service in the service domain. This ID must be unique to this service and may not be used for any other service of any type. The *service-id* must be the same number used for every 7450 ESS or 7750 SR on which this service is defined.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Values *service-id*: 1 to 2147483647

svc-name: up to 64 characters

customer-id

Specifies the customer ID number to be associated with the service. This parameter is required on service creation and optional for service editing or deleting.

Values 1 to 2147483647

vpn vpn-id

Specifies the VPN ID number which allows you to identify virtual private networks (VPNs) by a VPN identification number.

Values 1 to 2147483647

Default null (0)

vc-switching

Specifies if the pseudowire switching signaling is used for the spoke SDPs configured in this service.

create

Keyword used to create the Ipipe service instance. The **create** keyword requirement can be enabled/disabled in the **environment**>**create** context.

name name

Configures an optional service name identifier, up to 64 characters, to a given service. This service name can then be used in configuration references, display, and show commands throughout the system. A defined service name can help the service provider or administrator to identify and manage services within the SR OS platforms.

To create a service, you must assign a service ID; however, after it is created, either the service ID or the service name can be used to identify and reference a service.

If a name is not specified at creation time, then SR OS assigns a string version of the *service-id* as the name.

Values *name*: up to 64 characters

ipoe

Syntax

[**no**] **ipoe**

Context

[Tree] (config>redundancy>multi-chassis>peer>sync>subscriber-mgmt ipoe)

Full Context

configure redundancy multi-chassis peer sync subscriber-mgmt ipoe

Description

This command configures the router to synchronize subscriber management IPoE information with the multi-chassis peer.

The **no** form of this command disables the router from synchronizing subscriber management IPoE information with the multi-chassis peer.

Note: The configuration of this command must match on both nodes. Otherwise, the subscriber management synchronization fails.

Default

no ipoe

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

configure service ies subscriber-interface group-interface ipoe-session ipoe-session-policy

configure service vprn subscriber-interface group-interface ipoe-session ipoe-session-policy

Description

This command specifies the IPoE session policy applicable for this group interface or capture SAP.

On WLAN GW group interfaces, it is not possible to change this value.

The **no** form of this command reverts to the default.

Default

no ipoe-session-policy ipoe-session-policy default on WLAN GW group interfaces

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

policy-name

Specifies the IPoE session policy name up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

22.29 ipoe-sub-id-key

ipoe-sub-id-key

Syntax

ipoe-sub-id-key *sub-id-key* [*sub-id-key*]

no ipoe-sub-id-key

Context

[Tree] (config>subscr-mgmt>auto-sub-id-key ipoe-sub-id-key)

Full Context

configure subscriber-mgmt auto-sub-id-key ipoe-sub-id-key

Description

This command enables certain fields to become the base for auto-generation of the default sub-id name. The sub-id name is auto generated if there is not a more specific method available. Such more specific methods would be a default sub-id name as a sap-id, a preconfigured static string or explicit mappings based on RADIUS/LUDB returned strings.

In case that a more specific sub-id name generation method is not available and the auto-id keyword is defined under the def-sub-id hierarchy, the sub-id name is generated by concatenating fields defined in this command separated by a "|" character.

The maximum length of the auto-generated sub-id name is 64 characters while the concatenation of subscriber identification fields can exceed 64 characters. Subscriber host instantiation fails if the sub-id name is based on subscriber identification fields whose concatenated length exceeds 64 characters. Failing the host creation rather than truncating the sub-id name on a 64 character boundary prevents collision of sub-ids (subscriber name duplication).

If the more specific sub-id name generation method is not available and the **auto-id** keyword is not defined under the **def-sub-id** hierarchy, the sub-id name is a random 10 character encoded string based on the fields defined under this command.

There is only one set of identification fields allowed per host type (IPoE or PPP) per chassis.

The **no** form of this command reverts to the default.

Default

ipoe-sub-id-key mac sap-id

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

sub-id-key

Specifies the auto-generated sub-id keys for IPoE hosts.

Values **mac** — Specifies that the MAC address can be combined with other subscriber host identification fields (circuit-id, remote-id, session-id, sap-id, or service-name) to form a sub-id name in a user readable format or as a random 10 character encoded value.

In case that the mac address is used as a concatenation field in the sub-id name, then its format becomes a string xx:xx:xx:xx:xx:xx with the length 17B.

The MAC address as the subscriber host identification field is not applicable to static hosts.

circuit-id — Specifies that the circuit-id can be combined with other subscriber host identification fields (mac, remote-id, session-id, sap-id, or service-name) to form a sub-id name in a user readable format or as a random 10 character encoded value.

In case that the circuit-id is used as a concatenation field in the sub-id name, then its format becomes access-node-id eth slot/port:[vlan-id] or access-node-id atm slot/port:vpi.vci with a variable length.

Note:
If circuit-id contains any non-printable ASCII characters, the entire circuit-id string is formatted in hex in the sub-id name output. Otherwise all characters in circuit-id is converted to ASCII. ASCII printable characters contain bytes in range 0x20 to 0x7E.

The circuit-id as the subscriber identification field is not applicable to ARP hosts or static hosts.

remote-id — Specifies that the remote-id can be combined with other subscriber host identification fields (mac, circuit-id, session-id, sap-id, or service-name) to form a sub-id name in a user readable format or as a random 10 character encoded value.

In case that the remote-id is used as a concatenation field in the sub-id name, then its format becomes a remote-id string with a variable length.

Note:
If remote-id contains any non-printable ASCII characters, the entire remote-id string is formatted in hex in the sub-id name output. Otherwise all characters in remote-id is converted to ASCII. ASCII printable characters contain bytes in range 0x20 to 0x7E.

The remote-id as the subscriber identification field is not applicable to ARP hosts or static hosts.

sap-id — Specifies that the sap-id can be combined with other subscriber host identification fields (mac, circuit-id, remote-id, session-

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

id, or service-name) to form a sub-id name in a user readable format or as a random 10 character encoded value.

If a circuit-id is used as a concatenation field in the sub-id name, then its format becomes: slot/mda:[outer-vlan].[inner-vlan] with a variable length.

The sap-id as the subscriber identification field is applicable to all hosts types with exception of static hosts.

dual-stack-remote-id — Specifies that the dual stack remote ID is used as the base for the auto-generated subscriber identification

service-name — Specifies that the service name that terminates the subscriber is used as the base for auto-generated subscriber identification.

Use subject to Terms available at: www.nokia.com/terms.

Description

This command specifies the lifetime of the Phase 2 IKE key.

The **no** form of this command reverts to the default, which is 3600 seconds.

Default

no ipsec-lifetime

Parameters

ipsec-lifetime

Specifies the Phase 2 lifetime for this IKE policy in seconds.

Values 1200 to 31536000

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

ipsec-lifetime

Syntax

ipsec-lifetime *seconds*

ipsec-lifetime inherit

Context

[Tree] (config>ipsec>ipsec-transform ipsec-lifetime)

Full Context

configure ipsec ipsec-transform ipsec-lifetime

Description

This command specifies the CHILD_SA. If the **inherit** parameter is specified, then the system uses the IPsec lifetime configuration in the corresponding IKE policy configured in the same IPsec gateway or IPsec tunnel.

Default

ipsec-lifetime inherit

Parameters

seconds

Specifies the lifetime of the Phase 2 IKE key in seconds.

Values 1200 to 31536000

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

inherit

Specifies that the system uses the **ipsec-lifetime** configuration in the corresponding IKE policy that is configured for the same IPsec gateway or IPsec tunnel.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

22.35 ipsec-responder-only

ipsec-responder-only

Syntax

[**no**] **ipsec-responder-only**

Context

[Tree] (config>isa>tunnel-group ipsec-responder-only)

Full Context

configure isa tunnel-group ipsec-responder-only

Description

With this command configured, system will only act as IKE responder except for the automatic CHILD_SA re-key upon MC-IPsec switchover.

Default

no ipsec-responder-only

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

22.36 ipsec-transform

ipsec-transform

Syntax

ipsec-transform *transform-id* [**create**]

no ipsec-transform *transform-id*

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Context

[Tree] (config>ipsec ipsec-transform)

Full Context

configure ipsec ipsec-transform

Description

Commands in this context create an **ipsec-transform** policy. IPsec transforms policies can be shared. A change to the ipsec-transform is allowed at any time. The change will not impact tunnels that have been established until they are renegotiated. If the change is required immediately the tunnel must be cleared (reset) for force renegotiation.

IPsec transform policy assignments to a tunnel require the tunnel to be shutdown.

The **no** form of this command removes the ID from the configuration.

Parameters

transform-id

Specifies a policy ID value to identify the IPsec transform policy.

Values 1 to 2048

create

This keyword is mandatory when creating an ipsec-transform policy. The **create** keyword requirement can be enabled or disabled in the **environment>create** context.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

configure service ies interface sap ip-tunnel ipsec-transport-mode-profile

configure service vprn interface sap ip-tunnel ipsec-transport-mode-profile

Description

This command specifies an IPsec transport mode profile name to the SAP.

The **no** form of this command removes the profile name from the service configuration.

Parameters

name

Specifies the name of an existing IPsec transport mode profile, up to 32 characters

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

22.38 ipsec-tunnel

ipsec-tunnel

Syntax

ipsec-tunnel *ipsec-tunnel-name*

no ipsec-tunnel [*ipsec-tunnel-name*]

Context

[Tree] (config>service>vprn>static-route-entry ipsec-tunnel)

Full Context

configure service vprn static-route-entry ipsec-tunnel

Description

This command creates a static route in a VPRN service context that points to the global routing context (base router). This is primarily used to allow traffic that ingress through a VPRN service to be routed out of the global routing context.

This **next-hop** type cannot be used in conjunction with any other next-hop types.

Default

no ipsec-tunnel

Parameters

ipsec-tunnel-name

IPsec tunnel name; maximum length up to 32 characters.

Platforms

All

ipsec-tunnel

Syntax

ipsec-tunnel *name* [**private-sap** [*0..4094*]] [**private-service-name** *private-service-name*] [**create**]

no ipsec-tunnel *ipsec-tunnel-name*

Context

[Tree] (config>service>vprn>if>sap ipsec-tunnel)

Full Context

configure service ies interface ipsec ipsec-tunnel

configure router interface ipsec ipsec-tunnel

configure service vprn interface sap ipsec-tunnel

Description

This command configures a secured interface IPsec tunnel. If the **private-service-name** is not specified, the private service is the secured interface service.

The **no** form of this command removes the IPsec tunnel from the configuration.

Parameters

name

Specifies the name of the IPsec tunnel.

private-sap

Specifies the private SAP ID.

Values 0 to 4094

private-service-name

Specifies the private service name.

create

Keyword used to create the IPsec tunnel instance. The **create** keyword requirement can be enabled or disabled in the **environment>create** context.

Platforms

VSR

- configure router interface ipsec ipsec-tunnel
- configure service ies interface ipsec ipsec-tunnel

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

- configure service vprn interface sap ipsec-tunnel

Context

[Tree] (config>service>vprn>bgp>multi-path ipv4)

Full Context

configure service vprn bgp multi-path ipv4

Description

This command sets ECMP multipath parameters that apply only to the (unlabeled) IPv4 unicast address family. These settings override the values set by the **maximum-paths** command.

When multipath is enabled, traffic to the destination is load-shared across a set of paths (BGP routes) that the BGP decision process considers equal to the best path. The actual distribution of traffic over the multiple paths may be equal or unequal (that is, based on weights derived from the Link Bandwidth Extended Community).

To qualify as a multipath, a non-best route must meet the following criteria (some criteria are controlled by this command):

- The multi-path route must be the same type of route as the best path (same AFI/SAFI and, in some cases, same next-hop resolution method).
- The multi-path route must be tied with the best path for all criteria of greater significance than next-hop cost, except for criteria that are configured to be ignored.
- If the best path selection reaches the next-hop cost comparison, the multi-path route must have the same next-hop cost as the best route unless the **unequal-cost** option is configured.
- The multi-path route must not have the same BGP next-hop as the best path or any other multi-path route.
- The multi-path route must not cause the ECMP limit of the routing instance to be exceeded (configured using the **ecmp** command with a value in the range 1 to 64).
- The multi-path route must not cause the applicable *max-paths* limit to be exceeded. If the best path is an EBGP learned route and the **ebgp** option is used, the *ebgp-max-paths* limit overrides the *max-paths* limit. If the best path is an IBGP-learned route and the **ibgp** option is used, the *ibgp-max-paths* limit overrides the *max-paths* limit. All path limits are configurable up to a maximum of 64. Multi-path is effectively disabled if a value is set to 1.
- The multi-path route must have the same neighbor AS in its AS path as the best path if the **restrict same-neighbor-as** option is configured. By default, any path with the same AS path length as the best path (regardless of neighbor AS) is eligible for multi-path.
- The route must have the same AS path as the best path if the **restrict exact-as-path** option is configured. By default, any path with the same AS path length as the best path (regardless of the actual AS numbers) is eligible for multi-path.

The **no** form of this command removes IPv4-specific overrides.

Default

no ipv4

Parameters

max-paths

Specifies the maximum number of multipaths per prefix/NLRI if *ebgp-max-paths* or *ibgp-max-paths* does not apply.

Values 1 to 64

egp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an EBGP learned route.

Values 1 to 64

ibgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an IBGP learned route.

Values 1 to 64

restrict same-neighbor-as

Specifies that the non-best path must have the same neighbor AS in its AS path as the best path.

restrict exact-as-path-as

Specifies that the non-best path must have the same AS path as the best path.

unequal-cost

Instructs BGP to ignore differences in the next-hop cost only when determining eligible multipaths.

configure system network-element-discovery profile neip ipv4

Description

This command configures the IPv4 NEIP for this profile. The NEIP can be configured manually or set to be automatically generated using the NEID. If the NEID option is set, the first most significant byte of the IPv4 NEIP is set to 140 and the remaining 3 bytes are set to the NEID value. The NEID can be configured with a vendor ID value, in which case the first most significant byte of the IPv4 NEIP is set to this vendor ID value.

The **no** form of this command removes the IPv4 address association for this profile.

Default

no ipv4

Parameters

ip-address

Specifies the IPv4 address of the NEIP.

auto-generate

Specifies that the NEIP is automatically generated using the NEID.

vendor-id-value

Specifies the vendor ID value.

[Tree] (config>router>bgp>group>neighbor>add-paths ipv4)

Full Context

configure router bgp add-paths ipv4

configure router bgp group add-paths ipv4

configure router bgp group neighbor add-paths ipv4

Description

This command configures the add-paths capability for unlabeled IPv4 unicast routes. By default, add-paths is not enabled for unlabeled IPv4 unicast routes.

The maximum number of unlabeled unicast paths per IPv4 prefix to send is the configured send limit, which is a mandatory parameter. The capability to receive multiple unlabeled IPv4 unicast paths per prefix from a peer is configurable using the **receive** keyword, which is optional. If the **receive** keyword is not included in the command the receive capability is enabled by default.

The **no** form of this command disables add-paths support for unlabeled IPv4 unicast routes, causing sessions established using add-paths for unlabeled IPv4 unicast to go down and come back up without the add-paths capability.

Default

no ipv4

Parameters

send-limit

Specifies the maximum number of paths per unlabeled IPv4 unicast prefix that are allowed to be advertised to add-paths peers, the actual number of advertised routes may be less. If the value is **none**, the router does not negotiate the send capability with respect to IPv4 AFI/SAFI. If the value is **multipaths**, then BGP advertises all of the used BGP multipaths for each IPv4 NLRI if the peer has signaled support to receive multiple add-paths.

Values 1 to 16, none, multipaths

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

receive

Specifies that the router negotiates to receive multiple unlabeled unicast routes per IPv4 prefix.

none

Specifies that the router does not negotiate to receive multiple unlabeled unicast routes per IPv4 prefix.

Platforms

All

ipv4

Syntax

ipv4 *max-paths* [**ebgp** *ebgp-max-paths*] [**ibgp** *ibgp-max-paths*] [**restrict** { **same-neighbor-as** | **exact-as-path**}] [**unequal-cost**]

ipv4-multicast-routing

Syntax

ipv4-multicast-routing {**native** | **mt**}

[**no**] **ipv4-multicast-routing**

Context

[Tree] (config>router>isis ipv4-multicast-routing)

Full Context

configure router isis ipv4-multicast-routing

Description

The multicast RTM is used for Reverse Path Forwarding checks. This command controls which IS-IS topology is used to populate the IPv4 multicast RTM.

The **no** form of this command results in none of the IS-IS routes being populated in the IPv4 multicast RTM and would be used if multicast is configured to use the unicast RTM for the RPF check.

Default

ipv4-multicast-routing native

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

native

Causes IPv4 routes from the MT0 topology to be added to the multicast RTM for RPF checks.

mt

Causes IPv4 routes from the MT3 topology to be added to the multicast RTM for RPF checks.

Platforms

All

22.50 ipv4-node-sid

ipv4-node-sid

Syntax

ipv4-node-sid index *index-value* [**clear-n-flag**]

ipv4-node-sid label *label-value* [**clear-n-flag**]

no ipv4-node-sid

Context

[Tree] (config>router>isis>interface ipv4-node-sid)

Full Context

configure router isis interface ipv4-node-sid

Description

This command assigns a node SID index or label value to the prefix representing the primary address of an IPv4 network interface of **type loopback**. Only a single node SID can be assigned to an interface. The secondary address of an IPv4 interface cannot be assigned a node SID index and does not inherit the SID of the primary IPv4 address.

The command fails if the network interface is not of **type loopback** or if the interface is defined in an IES or a VPRN context. Also, assigning the same SID index or label value to the same interface in two different IGP instances is not allowed within the same node.

The value of the label or index SID is taken from the range configured for this IGP instance. When using the global mode of operation, a new segment routing module checks that the same index or label value cannot be assigned to more than one loopback interface address. When using the per-instance mode of operation, this check is not required since the index and thus label ranges of the various IGP instance are not allowed to overlap.

The **clear-n-flag** option allows the user to clear the N-flag (node-sid flag) in an IS-IS prefix SID sub-TLV originated for the IPv4 prefix of a loopback interface on the system.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

By default, the prefix SID sub-TLV for the prefix of a loopback interface is tagged as a node SID, meaning that it belongs to this node only. However, when the user wants to configure and advertise an anycast SID using the same loopback interface prefix on multiple nodes, you must clear the N-flag to assure interoperability with third party implementations, which may perform a strict check on the receiving end and drop duplicate prefix SID sub-TLVs when the N-flag is set.

The SR OS implementation is relaxed on the receiving end and accepts duplicate prefix SIDs with the N-flag set or cleared. SR OS will resolve to the closest owner, or owners if ECMP is configured, of the prefix SID according to its cost.

Default

no ipv4-node-sid

Parameters

index index-value

Specifies the index value.

Values 0 to 4294967295

label label-value

Specifies the label value.

Values 0 to 4294967295

clear-n-flag

Clears the node SID flag.

Default no clear-n-flag

ipv6 max-paths [**ebgp** *ebgp-max-paths*] [**ibgp** *ibgp-max-paths*] [**restrict** { **same-neighbor-as** | **exact-as-path**}] [**unequal-cost**]

no ipv6

Context

[Tree] (config>service>vprn>bgp>multi-path ipv6)

Full Context

configure service vprn bgp multi-path ipv6

Description

This command sets ECMP multipath parameters that apply only to the (unlabeled) IPv6 unicast address family. These settings override the values set by the **maximum-paths** command.

When multipath is enabled, traffic to the destination is load-shared across a set of paths (BGP routes) that the BGP decision process considers equal to the best path. The actual distribution of traffic over the multiple paths may be equal or unequal (that is, based on weights derived from the Link Bandwidth Extended Community).

To qualify as a multipath, a non-best route must meet the following criteria (some criteria are controlled by this command):

- The multi-path route must be the same type of route as the best path (same AFI/SAFI and, in some cases, same next-hop resolution method).

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- The multi-path route must be tied with the best path for all criteria of greater significance than next-hop cost, except for criteria that are configured to be ignored.
- If the best path selection reaches the next-hop cost comparison, the multi-path route must have the same next-hop cost as the best route unless the **unequal-cost** option is configured.
- The multi-path route must not have the same BGP next-hop as the best path or any other multi-path route.
- The multi-path route must not cause the ECMP limit of the routing instance to be exceeded (configured using the **ecmp** command with a value in the range 1 to 64)
- The multi-path route must not cause the applicable *max-paths* limit to be exceeded. If the best path is an EBGP learned route and the **ebgp** option is used, the *ebgp-max-paths* limit overrides the *max-paths* limit. If the best path is an IBGP-learned route and the **ibgp** option is used, the *ibgp-max-paths* limit overrides the *max-paths* limit. All path limits are configurable up to a maximum of 64. Multi-path is effectively disabled if a value is set to 1.
- The multi-path route must have the same neighbor AS in its AS path as the best path if the **restrict same-neighbor-as** option is configured. By default, any path with the same AS path length as the best path (regardless of neighbor AS) is eligible for multi-path.
- The route must have the same AS path as the best path if the **restrict exact-as-path** option is configured. By default, any path with the same AS path length as the best path (regardless of the actual AS numbers) is eligible for multi-path.

The **no** form of this command removes IPv6-specific overrides.

Default

no ipv6

Parameters

max-paths

Specifies the maximum number of multipaths per prefix/NLRI if *ebgp-max-paths* or *ibgp-max-paths* does not apply.

Values 1 to 64

egp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an EBGP learned route.

Values 1 to 64

ibgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an IBGP learned route.

Values 1 to 64

restrict same-neighbor-as

Specifies that the non-best path must have the same neighbor AS in its AS path as the best path.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

restrict exact-as-path-as

Specifies that the non-best path must have the same AS path as the best path.

unequal-cost

Instructs BGP to ignore differences in the next-hop cost only when determining eligible multipaths.

When enabled, the Alc-App-Prof-Str VSA is ignored in a radius Accept that enables portal redirection using this redirect policy. AA functionality will be disabled during portal authentication.

The **no** version of this command allows an Alc-App-Prof-Str to be present and will enable Application Assurance during portal authentication. In this case redirection rules defined in this policy are bypassed and it is assumed the AA function is configured for portal redirection.

Context

[Tree] (config>service>vprn>pim>rp ipv6)

Full Context

configure service vprn pim rp ipv6

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command enables access to the context to configure the rendezvous point (RP) of a PIM IPv6 protocol instance.

A Nokia IPv6 PIM router acting as an RP must respond to an IPv6 PIM register message specifying an SSM multicast group address by sending to the first hop router stop register message(s). It does not build an (S, G) shortest path tree toward the first hop router. An SSM multicast group address can be either from the SSM default range or from a multicast group address range that was explicitly configured for SSM.

Default

ipv6 RP enabled when IPv6 PIM is enabled.

Parameters

ipv6-filter-id

Specifies the existing IPv6 filter policy with scope **system**. This parameter can either be expressed as a decimal integer, or as an ASCII string of up to 64 characters in length.

Values 1 to 65535 or the filter policy name

[Tree] (config>system>ned>prof>neip ipv6)

Full Context

configure system network-element-discovery profile neip ipv6

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command configures the IPv6 NEIP for this profile. The NEIP can be configured manually or set to be automatically generated. If the NEIP is set to be automatically generated, the NEID is used for the subnet and host portion of the IPv6 address and the vendor ID value is set to 140 by default. The vendor ID value can be configured.

The **no** form of this command removes the IPv6 address association for this profile.

Default

no ipv6

Parameters

ipv6-address

Specifies the IPv6 address of the NEIP.

Values

ipv6-address	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x: [0..FFFF]H
	d: [0..255]D

auto-generate

Specifies that the NEIP is automatically generated using the NEID.

vendor-id-value

Specifies the vendor ID value.

Values 1 to 255

Full Context

configure router bgp add-paths ipv6

configure router bgp group add-paths ipv6

configure router bgp group neighbor add-paths ipv6

Description

This command configures the add-paths capability for unlabeled IPv6 unicast routes. By default, add-paths is not enabled for unlabeled IPv6 unicast routes.

The maximum number of unlabeled unicast paths per IPv6 prefix to send is the configured send limit, which is a mandatory parameter. The capability to receive multiple unlabeled IPv6 unicast paths per prefix from a peer is configurable using the **receive** keyword, which is optional. If the **receive** keyword is not included in the command the receive capability is enabled by default.

The **no** form of this command disables add-paths support for unlabeled IPv6 unicast routes, causing sessions established using add-paths for unlabeled IPv6 unicast to go down and come back up without the add-paths capability.

Default

no ipv6

Parameters

send *send-limit*

Specifies the maximum number of paths per unlabeled IPv6 unicast prefix that are allowed to be advertised to add-paths peers. (The actual number of advertised routes may be less.) If the value is **none**, the router does not negotiate the send capability with respect to IPv6 AFI/SAFI. If the value is **multipaths**, then BGP advertises all the used BGP multipaths for each IPv6 NLRI if the peer has signaled support to receive multiple add-paths.

Values 1 to 16, none, multipaths

receive

Specifies the router negotiates to receive multiple unlabeled unicast routes per IPv6 prefix.

none

Specifies the router does not negotiate to receive multiple unlabeled unicast routes per IPv6 prefix.

Platforms

All

ipv6

Syntax

ipv6 *max-paths* [**ebgp** *ebgp-max-paths*] [**ibgp** *ibgp-max-paths*] [**restrict** { **same-neighbor-as** | **exact-as-path**}] [**unequal-cost**]

no ipv6

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Context

[Tree] (config>router>bgp>multi-path ipv6)

Full Context

configure router bgp multi-path ipv6

Description

This command sets ECMP multipath parameters that apply only to the (unlabeled) IPv6 unicast address family. These settings override the values set by the **maximum-paths** command.

When multipath is enabled, traffic to the destination is load-shared across a set of paths (BGP routes) that the BGP decision process considers equal to the best path. The actual distribution of traffic over the multiple paths may be equal or unequal (that is, based on weights derived from the Link Bandwidth Extended Community).

The **no** form of this command removes IPv6-specific overrides.

Default

no ipv6

Parameters

max-paths

Specifies the maximum number of multipaths per prefix/NLRI if *ebgp-max-paths* or *ibgp-max-paths* does not apply.

Values 1 to 64

ebgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an EBGP learned route.

Values 1 to 64

ibgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an IBGP learned route.

Values 1 to 64

restrict same-neighbor-as

Specifies that the non-best path must have the same neighbor AS in its AS path as the best path.

restrict exact-as-path

Specifies that the non-best path must have the same AS path as the best path.

unequal-cost

Instructs BGP to ignore differences in the next-hop cost only when determining eligible multipaths.

[Tree] (config>qos>sap-ingress ipv6-criteria)

Full Context

configure qos sap-egress ipv6-criteria

configure qos sap-ingress ipv6-criteria

Description

IPv6 criteria-based SAP egress or ingress policies are used to select the appropriate ingress or egress queue or policer and corresponding forwarding class and packet profile for matched traffic.

This command is used to enter the node to create or edit policy entries that specify IPv6 criteria such as IP quintuple lookup or DiffServ code point.

The OS implementation will exit on the first match found and execute the actions in accordance with the accompanying action command. For this reason, entries must be sequenced correctly from most to least explicit.

The **no** form of this command deletes all the entries specified under this node. When ipv6-criteria entries are removed from a SAP ingress policy, the ipv6-criteria is removed from all services where that policy is applied.

Platforms

[Tree] (config>qos>network>egress ipv6-criteria)

Full Context

configure qos network ingress ipv6-criteria

configure qos network egress ipv6-criteria

Description

IPv6 criteria-based network ingress and egress policies are used to select the appropriate ingress or egress queue or policer, and the corresponding forwarding class and packet profile for matched traffic. This command is used to enter the context to create or edit policy entries that specify IPv6 criteria such as IP quintuple lookup or DSCP.

The 7750 SR OS implementation will exit on the first match found and execute the actions in accordance with the accompanying action command. Entries must be sequenced correctly from most to least explicit.

The ingress classification only applies to the outer IPv6 header of non-tunneled traffic.

Attempting to apply a network QoS policy containing an **ipv6-criteria** statement to any object except a network IP interface will result in an error.

The **no** form of this command deletes all entries specified under this node. When IP criteria entries are removed from a network policy, the IPv6 criteria are removed from all network interfaces to which that policy is applied.

ipv6-eh

Syntax

ipv6-eh {**max** | **limited**}

no ipv6-eh

Context

[Tree] (config>system>ip ipv6-eh)

Full Context

configure system ip ipv6-eh

Description

This command defines the maximum number of IPv6 extension headers parsed in the line cards. The system parses up to six extension headers when **ipv6-eh max** is configured.

When the **ipv6-eh limited** command is configured, the system does not parse IPv6 extension headers and provides consistent ipv6-filter matches for the next-header value found in the IPv6 packet header. LAG and ECMP hashing of IPv6 packets with extension headers is limited to Layer 3 IP addresses. Layer 4 ports, TEID, and SPI values are not available for hashing. MLD snooping on Layer 2 services is also not supported in this mode.

The **no** form of this command reverts to the default value.

Default

ipv6-eh max

Parameters

max

Specifies that the maximum number of IPv6 extension headers is parsed in the line cards.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

limited

Specifies that the system does not parse IPv6 extension headers and provides consistent ipv6-filter matches for the next-header value found in the IPv6 packet header.

ipv6-filter

Syntax

ipv6-filter *ipv6-filter-id* **entry** *entry-id* [*entry-id*]

no ipv6-filter *ipv6-filter-id* [**entry** *entry-id*]

Context

[Tree] (config>mirror>mirror-source ipv6-filter)

Full Context

configure mirror mirror-source ipv6-filter

Description

This command enables mirroring of packets that match specific entries in an existing IPv6 filter.

The **ipv6-filter** command directs packets which match the defined list of entry IDs to be mirrored to the mirror destination referenced by the *mirror-dest-service-id* of the **mirror-source**.

The IPv6 filter must already exist in order for the command to execute. Filters are configured in the **config>filter** context. If the IPv6 filter does not exist, an error will occur. If the filter exists but has not been associated with a SAP or IPv6 interface, an error is not generated but mirroring will not be enabled (there are no packets to mirror). Once the IPv6 filter is defined to a SAP or IPv6 interface, mirroring is enabled.

If the IPv6 filter is defined as ingress, only ingress packets are mirrored. Ingress mirrored packets are mirrored to the mirror destination prior to any ingress packet modifications.

If the IPv6 filter is defined as egress, only egress packets are mirrored. Egress mirrored packets are mirrored to the mirror destination after all egress packet modifications.

An *entry-id* within an IPv6 filter can only be mirrored to a single mirror destination. If the same *entry-id* is defined multiple times, an error occurs and only the first **mirror-source** definition is in effect.

By default, no packets matching any IPv6 filters are mirrored. Mirroring of IPv6 filter entries must be explicitly defined.

The **no ipv6-filter** command, without the **entry** keyword, removes mirroring on all *entry-id*'s within the *ip-filter-id*.

When the **no** form of this command is executed with the **entry** keyword and one or more *entry-id*'s, mirroring that *entry-id* list is terminated within the *ip-filter-id*. If an *entry-id* is listed that does not exist, an error will occur and the command will not execute. If an *entry-id* is listed that is not currently being mirrored, no error will occur for that *entry-id* and the command will execute normally.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

ipv6-filter-id

Specifies the IPv6 filter ID whose entries are mirrored. If the *ipv6-filter-id* does not exist, an error will occur and the command will not execute. Mirroring of packets will commence once the *ipv6-filter-id* is defined on a SAP or IPv6 interface.

entry-id

Specifies the IP filter entries to use as match criteria for packet mirroring. The **entry** keyword begins a list of *entry-id*'s for mirroring. Multiple *entry-id* entries may be specified with a single command. Each *entry-id* must be separated by a space.

If an *entry-id* does not exist within the IP filter, an error occurs and the command will not execute.

If the filter's *entry-id* is renumbered within the IP filter definition, the old *entry-id* is removed but the new *entry-id* must be manually added to the configuration to include the new (renumbered) entry's criteria.

Platforms

All

ipv6-filter

Syntax

[**no**] **ipv6-filter** *ipv6-filter-id*

Context

[Tree] (config>li>li-filter-block-reservation>li-reserved-block ipv6-filter)

Full Context

configure li li-filter-block-reservation li-reserved-block ipv6-filter

Description

This command configures to which normal IPv6 address filters the entry reservation is applied.

This command is only supported in 'classic' configuration-mode (**configure system management-interface configuration-mode classic**).

The **no** form of this command removes the IPv6 filter ID from the configuration.

Parameters

ipv6-filter-id

Specifies the filter identification identifies the normal IPv6 address filters.

Values {*filter-id* | *filter-name*}

filter-id: 1 to 65535

filter-name: up to 64 characters (*filter-name* is an alias for input only. The *filter-name* gets replaced

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

with an id automatically by SR OS in the configuration).

Context

[Tree] (config>li>li-source ipv6-filter)

Full Context

configure li li-source ipv6-filter

Description

This command enables lawful interception (LI) of packets that match specific entries in an existing IPv6 filter.

The **ipv6-filter** command directs packets which match the defined list of entry IDs to be intercepted to the destination referenced by the *mirror-dest-service-id* of the **mirror-source**.

The IPv6 filter must already exist in order for the command to execute. Filters are configured in the **config>filter** context. If the IPv6 filter does not exist, an error will occur. If the filter exists but has not been associated with a SAP or IPv6 interface, an error is not generated but mirroring will not be enabled (there are no packets to mirror). Once the IPv6 filter is defined to a SAP, IPv6 interface or subscriber, mirroring is enabled (subscriber mirroring applies only to the 7750 SR).

If the IPv6 filter is defined as ingress, only ingress packets are intercepted. Ingress packets are sent to the destination prior to any ingress packet modifications.

If the IPv6 filter is defined as egress, only egress packets are intercepted. Egress packets are sent to the destination after all egress packet modifications.

An *entry-id* within an IPv6 filter can only be intercepted to a single destination. If the same *entry-id* is defined multiple times, an error occurs and only the first definition is in effect.

By default, no packets matching any IPv6 filters are intercepted. Interception of IPv6 filter entries must be explicitly defined.

When the **no** command is executed with the **entry** keyword and one or more *entry-id*'s, interception of that list of *entry-id*'s is terminated within the *ipv6-filter-id*. If an *entry-id* is listed that does not exist, an error will occur and the command will not execute. If an *entry-id* is listed that is not currently being intercepted, no error will occur for that *entry-id* and the command will execute normally.

Parameters

ipv6-filter-id

Specifies the IPv6 filter ID whose entries are to be intercepted. If the *ipv6-filter-id* does not exist, an error will occur and the command will not execute. Intercepting packets will commence when the *ipv6-filter-id* is defined on a SAP or IPv6 interface.

entry-id

Specifies the IPv6 filter entries to use as match criteria for lawful intercept (LI). The **entry** keyword begins a list of *entry-id*'s for interception. Multiple *entry-id* entries can be specified with a single command. Each *entry-id* must be separated by a space. Up to <N><n> 8 entry IDs may be specified in a single command.

If an *entry-id* does not exist within the IPv6 filter, an error occurs and the command will not execute.

If the filter's *entry-id* is renumbered within the IPv6 filter definition, the old *entry-id* is removed but the new *entry-id* must be manually added to the configuration to include the new (renumbered) entry's criteria.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

intercept-id

Specifies the intercept ID that is inserted into the packet header for all mirrored packets of the associated **li-source** entry. This intercept ID can be used (for example by a downstream LI Gateway) to identify the particular LI session to which the packet belongs. For all types of **li-source** entries (**filter**, **nat**, **sap**, **subscriber**), when the mirror service is configured with **ip-udp-shim** routable encap, an *intercept-id* field (as part of the routable encap) is always present in the mirrored packets. If there is no intercept ID configured for an **li-source** entry, then the default value will be inserted. When the mirror service is configured with **ip-gre** routable encapsulation, no *intercept-id* is inserted and none should be specified against the **li-source** entries.

Values 1 to 4294967295 (32b) For nat li-source entries that are using a mirror service that is not configured with routable encap

Values 1 to 1,073,741,824 (30b) For all types of li-source entries that are using a mirror service with routable ip-udp-shim encap and no direction-bit.

Values 1 to 536,870,912 (29b) For all types of li-source entries that are using a mirror service with routable ip-udp-shim encap and with the direction-bit enabled.

session-id

Specifies the *session-id* that is inserted into the packet header for all mirrored packets of the associated **li-source** entry. This *session-id* can be used (for example by a downstream LI Gateway) to identify the particular LI session to which the packet belongs. The *session-id* is only valid and used for mirror services that are configured with **ip-udp-shim** routable encap (**config>mirror>mirror-dest>encap>ip-udp-shim**). For all types of **li-source** entries (filter, nat, sap, subscriber), when the mirror service is configured with **ip-udp-shim** routable encapsulation, a *session-id* field (as part of the routable encapsulation) is always present in the mirrored packets. If there is no *session-id* configured for an **li-source** entry, then the default value will be inserted. When a mirror service is configured with **ip-gre** routable encap, no *session-id* is inserted and none should be specified against the **li-source** entries.

Values 1 to 4,294,967,295 (32b)

Context

[Tree] (config>filter ipv6-filter)

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Full Context

configure filter ipv6-filter

Description

Commands in this context configure the specified IPv6 filter policy.

The **no** form of the command deletes the IPv6 filter policy. A filter policy cannot be deleted until it is removed from all objects where it is applied.

Parameters

filter-id

Specifies the IPv6 filter policy ID expressed as a decimal integer.

Values 1 to 65535

name

Configures an optional filter name, up to 64 characters in length, to a given filter. This filter name can then be used in configuration references, display, and show commands throughout the system. A defined filter name can help the service provider or administrator to identify and manage filters within the SR OS platforms.

To create a filter, you must assign a filter ID, however, after it is created, either the filter ID or filter name can be used to identify and reference a filter.

If a name is not specified at creation time, then SR OS assigns a string version of the *filter-id* as the name.

Filter names may not begin with an integer (0 to 9).

Values *name*: 64 characters maximum

filter-name

Specifies a string of up to 64 characters uniquely identifying this IPv6 filter policy.

create

This keyword is required to create the configuration context. Once it is created, the context can be enabled with or without the **create** keyword.

ipv6-filter

Syntax

ipv6-filter *src-filter-id* [**src-entry** *src-entry-id*] **to** *dst-filter-id* [**dst-entry** *dst-entry-id*] [**overwrite**]

Context

[Tree] (config>filter>copy ipv6-filter)

Full Context

configure filter copy ipv6-filter

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command copies an existing filter entry for a specific filter ID to another filter ID. The command is a configuration level maintenance tool used to create new entries using an existing filter policy. If **overwrite** is not specified, an error will occur if the destination filter entry exists.

Parameters

src-filter-id

Identifies the source filter policy from which the copy command will attempt to copy. The filter policy must exist within the context of the preceding keyword (**ipv6-filter**).

dst-filter-id

Identifies the destination filter policy to which the copy command will attempt to copy. If the **overwrite** keyword is not specified, the filter entry ID cannot already exist in the destination filter policy. If the **overwrite** keyword is present, the destination entry ID may or may not exist.

overwrite

Specifies that the destination filter entry may exist. If it does, everything in the existing destination filter entry will be completely overwritten with the contents of the source filter entry. If the destination filter entry exists, either **overwrite** must be specified or an error message will be returned. If **overwrite** is specified, the function of copying from source to destination occurs in a "break before make" manner and therefore should be handled with care.

22.71 ipv6-filter-max-size

ipv6-filter-max-size

Syntax

ipv6-filter-max-size {*value* | **default**}

Context

[Tree] (config>service>vprn>flowspec ipv6-filter-max-size)

Full Context

configure service vprn flowspec ipv6-filter-max-size

Description

This command configures the maximum number of IPv6 FlowSpec routes or rules that can be embedded into an ingress IPv6 filter policy for a specified routing instance. Flowspec filter entries embedded in a filter policy in this routing instance will use filter entries from the range between the embedding offset and "offset + ip-filter-max-size – 1".

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The sum of this command and the highest offset in any IPv6 filter that embeds IPv6 FlowSpec rules from this routing instance (excluding filters that embed at offset 262143) must not exceed 262143.

This command can be configured to a higher or lower value at any time. If the number of IPv6 FlowSpec rules that are currently installed is *M*, and the new configured limit is *N*, where *N*<*M*, then the last set of rules from *N* to *M* (by FlowSpec order) are immediately removed, but are retained in the BGP RIB. If the limit is increased, new rules are programmed only as they are received again in new BGP updates.

Default

ipv6-filter-max-size 512

Parameters

value

The maximum number of FlowSpec routes or rules that can be embedded into an ingress IP filter policy.

Values 0 to 262143

default

Keyword to configure the maximum size as 512.

Platforms

All

ipv6-filter-max-size

22.81 ipv6-node-sid

ipv6-node-sid

Syntax

ipv6-node-sid index *index-value* [**clear-n-flag**]

ipv6-node-sid label *label-value* [**clear-n-flag**]

no ipv6-node-sid

Context

[Tree] (config>router>isis>interface ipv6-node-sid)

Full Context

configure router isis interface ipv6-node-sid

Description

This command assigns a node SID index or label value to the prefix representing the primary address of an IPv6 network interface of type loopback. Only a single node SID can be assigned to an IPv6 interface. When an IPv6 interface has multiple global addresses, the primary address is always the first one in the list, as displayed by the **interface info** command.

The command fails if the network interface is not of loopback type or if the interface is defined in an IES or a VPRN context. Assigning the same SID index/label value to the same interface in two different IGP instances is not allowed within the same node.

The value of the label or index SID is taken from the range configured for this IGP instance. When using the global mode of operation, a new segment routing module checks that the same index or label value cannot be assigned to more than one loopback interface address. When using the per-instance mode of operation, this check is not required since the index and thus label ranges of the various IGP instance are not allowed to overlap.

The **clear-n-flag** option allows the user to clear the N-flag (node-sid flag) in an IS-IS prefix SID sub-TLV originated for the IPv6 prefix of a loopback interface on the system.

By default, the prefix SID sub-TLV for the prefix of a loopback interface is tagged as a node SID, meaning that it belongs to this node only. However, when the user wants to configure and advertise an anycast SID using the same loopback interface prefix on multiple nodes, you must clear the N-flag to assure interoperability with third-party implementations, which may perform a strict check on the receiving end and drop duplicate prefix SID sub-TLVs when the N-flag is set.

The SR OS implementation is relaxed on the receiving end and accepts duplicate prefix SIDs with the N-flag set or cleared. SR OS will resolve to the closest owner, or owners if ECMP is configured, of the prefix SID according to its cost.

Default

no ipv6-node-sid

ipv6-source-address *ipv6-address* [**allow-connections**]

no ipv6-source-address

Context

[Tree] (config>aaa>diam>node ipv6-source-address)

Full Context

configure aaa diameter node ipv6-source-address

Description

This command configures IPv6 source address that the SR OS node will use for its peering connection.

The **no** form of this command removes the IPv6 source address from the configuration.

Parameters

ipv6-address

Specifies the source IPv6 address to use for outgoing diameter messages to an IPv6-reachable peer.

Values

ipv6-address: x:x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:x:d.d.d.d

x - [0 to FFFF]H

d - [0 to 255]D

allow-connections

Specifies to accept peering connections on the configured source IPv6 address. The peer initiating the connection can only be an inter-chassis peer.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

ipv6-source-address

no ipv6-source-address

Context

[Tree] (config>aaa>radius-srv-plcy>servers ipv6-source-address)

Full Context

configure aaa radius-server-policy servers ipv6-source-address

Description

This command configures the source address of an IPv6 RADIUS packet.

When no ipv6-source-address is configured, the system IPv6 address (inband RADIUS server connection) or Boot Option File (BOF) IPv6 address (outband RADIUS server connection) must be configured in order for the RADIUS client to work with an IPv6 RADIUS server.

This address is also used in the NAS-IPv6-Address attribute.

The **no** form of this command reverts to the default value.

Parameters

ipv6-address

Specifies the source address of an IPv6 RADIUS packet.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

ipv6-source-address

Syntax

ipv6-source-address *ipv6-address*

no ipv6-source-address

Context

[Tree] (config>service>vprn>dns ipv6-source-address)

Full Context

configure service vprn dns ipv6-source-address

Description

This command configures the IPv6 address of the default secondary DNS server for the subscribers using this interface. Subscribers that cannot obtain an IPv6 DNS server address by other means, can use this for DNS name resolution.

The ipv6-address value can only be set to a nonzero value if the value of VPRN type is set to **subscriber-split-horizon**.

The **no** form of this command reverts to the default.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

ipv6-address

Specifies the IPv6 address of the default secondary DNS server.

Values ipv6-address - a.b.c.d

Platforms

All

ipv6-source-address

Syntax

ipv6-source-address *ipv6-address*

no ipv6-source-address

Context

[Tree] (config>system>file-trans-prof ipv6-source-address)

Full Context

configure system file-transmission-profile ipv6-source-address

Description

This command specifies the IPv6 source address used for transport protocol.

The **no** form of this command uses the default source address which typically is the address of egress interface.

Default

no ipv6-source-address

Parameters

Ipv6-address

Specifies a unicast v6 address. This should be a local interface address.

Platforms

All

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

22.95 ipv6-te-router-id

ipv6-te-router-id

Syntax

ipv6-te-router-id interface *interface-name*

no ipv6-te-router-id

Context

[Tree] (config>router ipv6-te-router-id)

Full Context

configure router ipv6-te-router-id

Description

This command configures the IPv6 TE Router ID. The IPv6 TE Router ID, when configured, uniquely identifies the router as being IPv6 TE capable to other routers in an IGP TE domain.

IS-IS advertises this information using the IPv6 TE Router ID TLV.

If this command is not configured, the IPv6 TE Router ID will use the global unicast address of the system interface by default. The user can specify the system interface using this command to achieve the same result. If a different interface is specified, the preferred primary global unicast address of that interface is used instead

The **no** form of this command reverts the IPv6 TE Router ID to the default value.

Parameters

interface interface-name

Specifies the name of the interface to be added or removed. Only system and loopback interfaces are accepted.

Platforms

All

22.96 ipv6-udp-checksum-recalculation

configure subscriber-mgmt local-user-db ipoe host ipv6-wan-address-pool

configure subscriber-mgmt local-user-db ppp host ipv6-wan-address-pool

Description

This command configures the pool name that is used in the DHCPv6 server for DHCPv6 IA-PA address selection.

The **no** form of this command removes the pool name from the configuration.

Parameters

pool-name

Specifies the WAN address pool, up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

22.102 ipv6-wan-ipoe-dhcp

debug mirror-source isa-aa-group

Description

This command configures AA ISA group as a mirror source for this mirror service. Traffic is mirrored after AA processing takes place on AA ISAs of the group, therefore, any packets dropped as part of that AA processing are not mirrored.

Parameters

isa-aa-group-id

Specifies the ISA ISA-AA group ID.

Values 1 to 255

all

Specifies that all traffic after AA processing will be mirrored.

unknown

Specifies that all traffic during the identification phase (may match policy entry or entries that have mirror action configured) and traffic that had been identified as unknown_tcp or unknown_udp after AA processing will be mirrored.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

22.109 isa-aa-oversubscription-factor

isa-aa-oversubscription-factor

Syntax

isa-aa-oversubscription-factor *factor*

no isa-aa-oversubscription-factor

Context

[Tree] (config>isa>wlan-gw-group>distributed-sub-mgmt isa-aa-oversubscription-factor)

Full Context

configure isa wlan-gw-group distributed-sub-mgmt isa-aa-oversubscription-factor

Description

This command specifies by how much an AA ISA is oversubscribed when linked to a WLAN-GW group. A factor of 1 indicates that each AA ISA is linked to a single WLAN-GW ISA, while a factor of 10 indicates that each AA ISA is linked to up to 10 WLAN-GW ISAs. The factor must be an integer but poses an oversubscription limit, not an exact ratio. For example, for 2 AA ISAs and 5 WLAN-GW ISAs, a factor of 3 or higher is valid. Additional standby ISAs can be added until the oversubscription limit is reached.

The **no** form of this command resets the configuration to the default value.

Default

isa-aa-oversubscription-factor 1

Parameters

factor

The number of WLAN GW ISAs that can be served by a single AA ISA.

Values 1 to 10

Platforms

7750 SR, 7750 SR-e, 7750 SR-s

© 2025 Nokia.

no isid *start*

Context

[Tree] (config>service>system>bgp-evpn>eth-seg>service-carving>manual isid)

Full Context

configure service system bgp-evpn ethernet-segment service-carving manual isid

Description

This command configures the ISID ranges for which the PE is primary, or uses the lowest preference algorithm.

Note:
Multiple individual ISID values and ranges are allowed.

The following service-carving manual algorithms are supported for DF election:

- Manual non-preference

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

A **preference** command is not configured for this algorithm. The primary PE for the configured ISIDs is determined by the ISID range. The manual non-preference algorithm only supports two PEs in the Ethernet Segment

- Manual preference-based

  If a **preference** command is configured, the algorithm uses the configured value to determine the DF election. For ISIDs not defined in the range, the highest-preference algorithm is used. For configured ISIDs, the lowest-preference algorithm is used.

Parameters

start

Specifies the initial **isid** value of the range.

Values 1 to 16777215

to

Specifies the end **isid** value of the range. If not configured, only the individual start value is considered.

Values 1 to 16777215

Platforms

All

isid

Syntax

isid *value* [**to** *higher-value*]

no isid

Context

[Tree] (config>filter>mac-filter>entry>match isid)

Full Context

configure filter mac-filter entry match isid

Description

This command configures an ISID value or a range of ISID values to be matched by the mac-filter parent. The pbb-etype value for the related SAP (inherited from the ethernet port configuration) or for the related SDP binding (inherited from SDP configuration) will be used to identify the ISID tag.

The **no** form of this command removes the ISID match criterion.

Default

no isid

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

value

Specifies the ISID value, 24 bits as a decimal integer. When just one present identifies a specific ISID to be used for matching.

Values 0 to 16777215

higher-value

Identifies a range of ISIDs to be used as matching criteria.

Platforms

All

isid

Syntax

isid *value* [**to** *higher-value*]

no isid

no isid *value* [**to** *higher-value*]

Context

[Tree] (config>serv>mrp>mrp-policy>entry>match isid)

Full Context

configure service mrp mrp-policy entry match isid

Description

This command configures an ISID value or a range of ISID values to be matched by the mrp-policy parent when looking at the related MMRP attributes (Group B-MACs). The pbb-etype value for the related SAP (inherited from the ethernet port configuration) or for the related SDP binding (inherited from SDP configuration) will be used to identify the ISID tag.

Multiple ISID statements are allowed under a match node. The following rules govern the usage of multiple ISID statements:

- Overlapping values are allowed:
  - isid from 1 to 10
  - isid from 5 to 15
  - isid 16
- The minimum and maximum values from overlapping ranges are considered and displayed. The above entries will be equivalent with the "isid from 1 to 16” statement.
- There is no consistency check with the content of ISID statements from other entries. The entries are evaluated in the order of their IDs and the first match causes the implementation to execute the associated action for that entry and then to exit the mrp-policy.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- If there are no ISID statements under a match criteria but the **mac-filter** type is **isid** the following behaviors apply for different actions:
  - For **end-station**, it treats any ISID value as no match and goes to next entry or default action which must be "block" in this case
  - For **allow**, it treats any ISID value as a match and allows it
  - For **block**, it treats any ISID value as a match and blocks it

The **no** form of the command can be used in two ways:

no isid removes all the previous statements under one match node.

no isid *value* | **from** *value* **to** *higher-value* removes a specific ISID value or range. It must match a previously used positive statement: for example if the command **isid 16 to 100** was used using **no isid 16 to 50** will not work but **no isid 16 to 100** will be successful.

Default

no isid

Parameters

value or higher-value

Specifies the ISID value in 24 bits. When just one value is present, it identifies a particular ISID to be used for matching.

Values 0 to 16777215

from value to higher-value

Identifies a range of ISIDs to be used as matching criteria.

Platforms

All

22.120 isid-policy

isid-policy

Syntax

isid-policy

Context

[Tree] (config>service>vpls isid-policy)

Full Context

configure service vpls isid-policy

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command configures ISID policies for individual ISIDs or ISID ranges in a B-VPLS using SPBM. The ISIDs may belong to I-VPLS services or may be static-isids defined on this node. Multiple entry statements are allowed under a **isid-policy**. ISIDs that are declared as static do not require and **isid-policy** unless the ISIDs are not to be advertised.

isid-policy allows finer control of ISID multicast but is not typically required for SPBM operation. Use of ISID policies can cause additional flooding of multicast traffic.

Platforms

All

22.121 isid-range

isid-range

Syntax

isid-range *from* [**to** *to*] {**auto-rt** | **route-target** *rt*}

no isid-range *from*

Context

[Tree] (config>service>vpls>bgp-evpn>isid-route-target isid-range)

Full Context

configure service vpls bgp-evpn isid-route-target isid-range

Description

This command creates a range of ISIDs associated with a specified route-target that is advertised with BMAC-ISID and IMET-ISID routes for the ISID. The route-target can be explicitly configured or automatically assigned by the system if the **auto-rt** option is configured. Auto routes assignment is based on RFC 7623 as follows:

<2-byte-as-number>:<4-byte-value>, where 4-byte-value = 0x30+ISID

The **no** form of the command deletes the **isid-range** and its association with the **route-target**.

The **no** form is the default action, which advertises the BMAC-ISID and IMET-ISID routes with the B-VPLS configured route-target.

Default

no isid-range

Parameters

from

Specifies the start of the ISID range.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Values 1 to 16777215

to

Specifies the end of the ISID range. If it is not configured, the range is comprised of (only) the ISID specified in the *to* option.

Values 1 to 16777215

auto-rt

Automatically generates an ISID-derived **route-target** in the format: AS_number:0x30+ISID.

route-target

Specifies an explicit route target.

Values rt - target:{<ip-addr:comm-val>| <2byte-as-number:extcomm-val>| <4byte-asnumber:comm-val>}

ip-addr: a.b.c.d

comm-val: [0 to 65535]

2byte-as-number: [0 to 65535]

23 j Commands

23.1 jitter-event

jitter-event

Syntax

jitter-event rising-threshold *threshold* [**falling-threshold** *threshold*] [*direction*]

no jitter-event

Context

[Tree] (config>saa>test jitter-event)

Full Context

configure saa test jitter-event

Description

This command specifies that at the termination of an SAA test probe, the calculated jitter value is evaluated against the configured rising and falling jitter thresholds. SAA threshold events are generated as required.

Once the threshold (rising/falling) is crossed, it is disabled from generating additional events until the opposite threshold is crossed. If a **falling-threshold** is not supplied, the **rising- threshold** is re-enabled when it falls below the threshold after the initial crossing that generated the event.

The configuration of jitter event thresholds is optional.

The **no** form of the command disables the jitter event.

Parameters

rising-threshold *threshold*

Specifies a rising threshold jitter value, in milliseconds. When the test run is completed, the calculated jitter value is compared to the configured jitter rising threshold. If the test run jitter value is greater than the configured rising threshold value then an SAA threshold event is generated. The SAA threshold event is tmnxOamSaaThreshold, logger application OAM, event #2101.

Values 0 to 2147483

Default 0

falling-threshold *threshold*

Specifies a falling threshold jitter value, in milliseconds. When the test run is completed, the calculated jitter value is compared to the configured jitter falling threshold. If the test

run jitter value is greater than the configured falling threshold value then an SAA threshold event is generated. The SAA threshold event is tmnxOamSaaThreshold, logger application OAM, event #2101.

Values 0 to 2147483

Default 0

direction

Specifies the direction for OAM ping responses received for an OAM ping test run.

Values **inbound** — Monitor the value of jitter calculated for the inbound, one-way, OAM ping responses received for an OAM ping test run.

outbound — Monitor the value of jitter calculated for the outbound, one-way, OAM ping requests sent for an OAM ping test run.

roundtrip — Monitor the value of jitter calculated for the round trip, two-way, OAM ping requests and replies for an OAM ping test run.

Default roundtrip

Description

This command controls the interval between transmit opportunities that are applied to the Applicant state machine. An instance of this Join Period Timer is required on a per-Port, per-MRP Participant basis. For additional information, refer to IEEE 802.1ak-2007 section 10.7.4.1.

Default

join-time 2

Parameters

value

The interval between transmit opportunities, in tenths of a second.

Values 1 to 10

24 k Commands

24.1 kb-memory-use-alarm

kb-memory-use-alarm

Syntax

kb-memory-use-alarm rising-threshold *threshold* [**falling-threshold** *threshold*] **interval** *seconds* [*rmon-event-type*] [**startup-alarm** *alarm-type*]

no kb-memory-use-warn

Context

[Tree] (config>system>thresholds kb-memory-use-alarm)

Full Context

configure system thresholds kb-memory-use-alarm

Description

This command configures memory use, in kilobytes, alarm thresholds.

The **no** form of the command removes the parameters from the configuration.

Parameters

rising-threshold *threshold*

Specifies a threshold for the sampled statistic. When the current sampled value is greater than or equal to this threshold, and the value at the last sampling interval was less than this threshold, a single threshold crossing event will be generated. A single threshold crossing event will also be generated if the first sample taken is greater than or equal to this threshold and the associated startup-alarm is equal to rising or either.

After a rising threshold crossing event is generated, another such event will not be generated until the sampled value falls below this threshold and reaches less than or equal the falling-threshold value.

The threshold value represents units of kilobytes.

Values -2147483648 to 2147483647

Default 0

falling-threshold *threshold*

Specifies a threshold for the sampled statistic. When the current sampled value is less than or equal to this threshold, and the value at the last sampling interval was greater

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

than this threshold, a single threshold crossing event will be generated. A single threshold crossing event will also be generated if the first sample taken is less than or equal to this threshold and the associated startup-alarm is equal to falling or either.

After a falling threshold crossing event is generated, another such event will not be generated until the sampled value rises above this threshold and reaches greater than or equal the rising-threshold value.

The threshold value represents units of kilobytes.

Values -2147483648 to 2147483647

Default 0

seconds

Specifies the polling period over which the data is sampled and compared with the rising and falling thresholds.

Values 1 to 2147483647

rmon-event-type

Specifies the type of notification action to be taken when this event occurs.

Values log — In the case of log, an entry is made in the RMON-MIB log table for each event occurrence. This does not create an SR OS logger entry. The RMON-MIB log table entries can be viewed using the **show>system>thresholds** CLI command.

trap — An SR OS logger event is generated. The SR OS logger utility then distributes the notification of this event to its configured log destinations which may be CONSOLE, telnet session, memory log, cflash file, syslog, or SNMP trap destinations logs.

both — Both an entry in the RMON-MIB logTable and an SR OS logger event are generated.

none — No action is taken.

Default both

startup-alarm *alarm-type*

Specifies the alarm that may be sent when this alarm is first created. If the first sample is greater than or equal to the rising threshold value and startup-alarm is equal to rising or either, then a single rising threshold crossing event is generated. If the first sample is less than or equal to the falling threshold value and startup-alarm is equal to falling or either, a single falling threshold crossing event is generated.

Values rising, falling, either

Default either

configure li x-interfaces x3 timeouts keep-alive

Description

This command configures the X2 and X3 keep-alive timeout.

Parameters

seconds

Specifies the maximum time to wait for a LIC reply to a keep alive request. The system retries up to three more times, and if no reply is received, the system declares a connection fault and logs the failure event.

Values 300 to 600

Default 300

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

keep-alive

Syntax

keep-alive

Context

[Tree] (config>service>sdp keep-alive)

Full Context

configure service sdp keep-alive

Description

This command enables the context to configure SDP connectivity monitoring keepalive messages for the SDP ID.

SDP ID keepalive messages use SDP Echo Request and Reply messages to monitor SDP connectivity. The operating state of the SDP is affected by the keepalive state on the SDP ID. SDP Echo Request messages are only sent when the SDP ID is completely configured and administratively up. If the SDP ID is administratively down, keepalives for that SDP ID are disabled. SDP Echo Requests (when sent for keepalive messages) are always sent with the *originator-sdp-id*. All SDP ID keepalive SDP Echo Replies are sent using generic IP/GRE OAM encapsulation.

When a keepalive response is received that indicates an error condition, the SDP ID will immediately be brought operationally down. Once a response is received that indicates the error has cleared and the **hold-down-time** interval has expired, the SDP ID will be eligible to be put into the operationally up state. If no other condition prevents the operational change, the SDP ID will enter the operational state.

A set of event counters track the number of keepalive requests sent, the size of the message sent, non-error replies received and error replies received. A keepalive state value is kept indicating the last

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

response event. A keepalive state timestamp value is kept indicating the time of the last event. With each keepalive event change, a log message is generated indicating the event type and the timestamp value.

Table 54: Keepalive Interpretation and Effect of SDP Echo Reply describes the keepalive interpretation of SDP echo reply response conditions and the effect on the SDP ID operational status.

Table 54: Keepalive Interpretation and Effect of SDP Echo Reply

Result of Request	Stored Response State	Operational State
keepalive request timeout without reply	Request Timeout	Down
keepalive request not sent due to non-existent *orig-sdp-id* (This condition should not occur)	Orig-SDP Non-Existent	Down
keepalive request not sent due to administratively down *orig-sdp-id*	Orig-SDP Admin-Down	Down
keepalive reply received, invalid origination-id	Far End: Originator-ID Invalid	Down
keepalive reply received, invalid responder-id	Far End: Responder-ID Error	Down
keepalive reply received, No Error	Success	Up (If no other condition prevents)

Full Context

configure service ies subscriber-interface group-interface srrp keep-alive-interval

configure service vprn subscriber-interface group-interface srrp keep-alive-interval

Description

This command defines the interval between SRRP advertisement messages sent when operating in the master state. The interval is also the basis for setting the master-down timer used to determine when the master is no longer sending. The system uses three times the keep-alive interval to set the timer. Every time an SRRP advertisement is seen that is better than the local priority, the timer is reset. If the timer expires, the SRRP instance assumes that a master does not exist and initiates the attempt to become master.

When in backup state, the SRRP instance takes the keep-alive interval of the master as represented in the masters SRRP advertisement message. Once in master state, the SRRP instance uses its own configured keep-alive interval.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The keep-alive-interval may be changed at any time, but will have no effect until the SRRP instance is in the master state.

The **no** form of this command restores the default interval.

Default

keep-alive-interval 10

Parameters

interval

Specifies the interval, in deciseconds, between SRRP advertisement messages sent when operating in the master state.

Values 1 to 100

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

keepalive

Syntax

keepalive *seconds* [**hold-up-multiplier** *multiplier*]

no keepalive

Context

[Tree] (config>subscr-mgmt>loc-user-db>ppp>host>plcy-parms keepalive)

Full Context

configure subscriber-mgmt local-user-db ppp host ppp-policy-parameters keepalive

Description

This command configures the keepalive time interval in seconds at which LCP echo requests are transmitted for the PPP session and the number of LCP echo replies that can be missed before the PPP session is brought down. Overrides the values configured in **subscriber-mgmt ppp-policy** for PPPoE PTA sessions or in the Base router or VPRN service **l2tp group** context for L2TP LNS sessions.

The **no** form of this command removes the LCP keepalive parmeter overrides.

Default

no keepalive

Parameters

seconds

Specifies the keepalive interval in seconds.

Values 4 to 300

hold-up-multiplier *multiplier*

Specifies the number of keepalives that can be missed.

Values 1 to 5

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

keepalive

Syntax

keepalive *seconds*

no keepalive

Context

[Tree] (config>subscr-mgmt>bgp-prng-plcy keepalive)

Full Context

configure subscriber-mgmt bgp-peering-policy keepalive

Description

This command configures the BGP keepalive timer. A keepalive message is sent every time this timer expires.

The keepalive value is generally one-third of the hold-time interval. Even though the OS implementation allows the keepalive value and the hold-time interval to be independently set, under the following circumstances, the configured keepalive value is overridden by the hold-time value:

If the specified keepalive value is greater than the configured hold-time, then the specified value is ignored, and the keepalive is set to one third of the current hold-time value.

If the specified hold-time interval is less than the configured keepalive value, then the keepalive value is reset to one third of the specified hold-time interval.

If the hold-time interval is set to zero, then the configured value of the keepalive value is ignored. This means that the connection with the peer is up permanently and no keepalive packets are sent to the peer.

The **no** form of this command used at the global level reverts to the default value.

[Tree] (config>service>vprn>bgp keepalive)

Full Context

configure service vprn bgp group keepalive

configure service vprn bgp group neighbor keepalive

configure service vprn bgp keepalive

Description

This command configures the BGP keepalive timer. A keepalive message is sent every time this timer expires. The **seconds** parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). The most specific value is used.

The **keepalive** value is generally one-third of the **hold-time** interval. Even though the OS implementation allows the **keepalive** value and the **hold-time** interval to be independently set, under the following circumstances, the configured **keepalive** value is overridden by the **hold-time** value:

If the specified **keepalive** value is greater than the configured **hold-time**, then the specified value is ignored, and the **keepalive** is set to one third of the current **hold-time** value.

If the specified **hold-time** interval is less than the configured **hold-time** value, then the **keepalive** value is reset to one third of the specified **hold-time** interval.

If the **hold-time** interval is set to zero, then the configured value of the **keepalive** value is ignored. This means that the connection with the peer is up permanently and no **keepalive** packets are sent to the peer.

The **no** form of this command used at the global level reverts to the default value.

The **no** form of this command used at the group level reverts to the value defined at the global level.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Default

keepalive 30

Parameters

seconds

The keepalive timer in seconds, expressed as a decimal integer.

Values 0 to 21845

Platforms

All

keepalive

Syntax

keepalive *timeout factor*

configure router ldp targeted-session ipv4 keepalive

configure router ldp targeted-session peer-template keepalive

configure router ldp interface-parameters ipv4 keepalive

configure router ldp interface-parameters interface ipv6 keepalive

configure router ldp interface-parameters interface ipv4 keepalive

configure router ldp interface-parameters ipv6 keepalive

configure router ldp targeted-session ipv6 keepalive

Description

This command configures the time interval (in s), that LDP waits before tearing down the session. The **factor** parameter derives the keepalive interval.

The **config**>**router**>**ldp**>**if-params**>**ipv6**>**keepalive** and **config**>**router**>**ldp**>**targ-session**>**ipv6**>**keepalive** commands are not supported on the 7450 ESS.

If no LDP messages are exchanged for the configured time interval, the LDP session is torn down. Keepalive timeout is usually three times the keepalive interval. To maintain the session permanently, regardless of the activity, set the value to zero.

When LDP session is being set up, the keepalive timeout is negotiated to the lower of the two peers. Once an operational value is agreed upon, the keepalive factor is used to derive the value of the keepalive interval.

The **no** form of the command at the interface-parameters and targeted-session levels sets the **keepalive timeout** and the **keepalive factor** to the default value.

The **no** form of this command, at the interface level, sets the **keepalive timeout** and the **keepalive factor** to the value defined under the **interface-parameters** level.

The **no** form of this command, at the peer level, sets the **keepalive timeout** and the **keepalive factor** to the value defined under the **targeted-session** level.

The session must be flapped for the new settings to operate.

keepalive

Syntax

keepalive *deciseconds* **dropcount** *count*

Context

[Tree] (config>isa>nat-group>inter-chassis-redundancy keepalive)

Full Context

configure isa nat-group inter-chassis-redundancy keepalive

Description

This command configures keepalives between the CPMs residing on different chassis. The keepalives are used to detect the presence of the peering node. If the redundant peer connectivity is lost beyond the limit defined by keepalives, then each node in the redundant pair transitions into a standalone mode. Keepalives use UDP transport.

Default

keepalive 30 dropcount 2

Parameters

deciseconds

Specifies the number of keepalives that are transported periodically at intervals defined by this parameter.

Values 2 to 250

count

Specifies the drop count. If the number of consecutive keepalives defined by this parameter is lost, then the peer is considered unreachable and the node transitions into a standalone mode of operation.

Values 2 to 20

[Tree] (config>mcast-mgmt>multicast-info-policy>bundle>channel>source-override keepalive-override)

Full Context

configure mcast-management multicast-info-policy bundle keepalive-override

configure mcast-management multicast-info-policy bundle channel keepalive-override

configure mcast-management multicast-info-policy bundle channel source-override keepalive-override

Description

This command configures the keepalive timer override. The PIM (S,G) Keepalive Timer (KAT) is used to maintain the (S,G) state when (S,G) join is not received. Expiry of the KAT causes the (S,G) entry to be removed.

The KAT override configuration is performed with a multicast information policy, which must be applied to the related PIM routing instance. When a KAT override is configured under a channel (a group or a group range), it applies to all (S,G) entries that fall under it, except when the source-override is configured and a KAT override is also configured under the source-override. In this scenario, the specific KAT override must be used for the (S,G) entries that fall under the source-override, while other (S,G) entries under the bundle use the KAT override configured under the channel.

Parameters

keepalive-timer

Specifies the keepalive timer override, in seconds.

Values 10 to 86000

Platforms

All

Full Context

configure system security ssh server-kex-list kex

configure system security ssh client-kex-list kex

Description

This command configures phase 1 SSH v2 KEX algorithms for SR OS as an SSH server or an SSH client. By default, the client and server lists are empty. If the user configures this list, SSH uses the hard-coded list with the first-listed algorithm having the highest priority and so on. An empty server or client list is the default list and contains the following algorithms:

ecdh-sha2-nistp512

ecdh-sha2-nistp384

ecdh-sha2-nistp256

diffie-hellman-group16-sha512

diffie-hellman-group14-sha256

diffie-hellman-group14-sha1

diffie-hellman-group-exchange-sha1

diffie-hellman-group1-sha1

The **no** form of this command removes the specified KEX index. If all KEX indexes are removed, the default list is used again.

Parameters

index

Specifies the index of the algorithm in the list. The lowest index in the list is negotiated first on the SSH negotiation list, while the highest index is at the bottom of the SSH negotiation list.

Values 1 to 255

kex-name

Specifies the KEX algorithm for computing the shared secret key.

Values diffie-hellman-group16-sha512, diffie-hellman-group14-sha256, diffie-hellman-group14-sha1, diffie-hellman-group-exchange-sha1, diffie-hellman-group1-sha1

no key reference *reference-number*

Context

[Tree] (config>system>security>pki>ca-profile>cmpv2>key-list key)

Full Context

configure system security pki ca-profile cmpv2 key-list key

Description

This command specifies a pre-shared key used for CMPv2 initial registration. Multiples of key commands are allowed to be configured under this context.

The password and reference-number is distributed by the CA via out-of-band means.

The configured password is stored in configuration file in an encrypted form by using SR OS hash2 algorithm.

The **no** form of this command removes the parameters from the configuration.

Parameters

password

Specifies a printable ASCII string, up to 64 characters.

hash

Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified

hash2

Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

custom

Specifies the custom encryption to management interface.

reference *reference-number*

Specifies a printable ASCII string, up to 64 characters in length.

no key-value

Parameters

public-key-value

Specifies the public key value, up to 800 characters for RSA and up to 255 characters for ECDSA.

Platforms

All

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

24.20 keychain

keychain

Syntax

[**no**] **keychain** *keychain-name*

Context

[Tree] (config>system>security keychain)

Full Context

configure system security keychain

Description

This command enables the context to configure keychain parameters. A keychain must be configured on the system before it can be applied to a session.

The **no** form of this command removes the keychain nodal context and everything under it from the configuration. If the keychain to be removed is in use when the no keychain command is entered, the command will not be accepted and an error indicating that the keychain is in use will be printed.

Parameters

keychain-name

Specifies a keychain name which identifies this particular keychain entry.

Values An ASCII string up to 32 characters.

Platforms

All

24.21 keygroup-name

keygroup-name

Syntax

keygroup-name *keygroup-name*

no keygroup-name

Context

[Tree] (config>grp-encryp>encryp-keygrp keygroup-name)

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Full Context

configure group-encryption encryption-keygroup keygroup-name

Description

This command is used to name the key group. The key group name can be used to reference a key group when configuring services or displaying information.

The **no** form of the command reverts to the default value.

Parameters

keygroup-name

The name of the key group, up to 64 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

24.22 kill-session

kill-session

Syntax

[**no**] **kill-session**

Context

[Tree] (configure>system>security>profile>netconf>base-op-authorization kill-session)

Full Context

configure system security profile netconf base-op-authorization kill-session

Description

This command authorizes a user associated with the profile to send a NETCONF <kill-session> RPC. This kill session operation allows a NETCONF client to kill another NETCONF session, but not the session in which the operation is requested.

The **no** form of the command denies the user from requesting a kill-session.

Default

no kill-session

Platforms

All

25 I Commands – Part I

25.1 l2

l2

Syntax

[**no**] **l2**

Context

[Tree] (config>subscr-mgmt>wlan-gw>tunnel-query>type l2)

Full Context

configure subscriber-mgmt wlan-gw tunnel-query type l2

Description

This command enables matching on Layer 2 tunnels.

The **no** form of this command disables matching on Layer 2 access points, unless no other tunnel type specifier is configured.

Default

no l2

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

l2

Syntax

[**no**] **l2**

Context

[Tree] (config>subscr-mgmt>wlan-gw>ue-query>state l2)

Full Context

configure subscriber-mgmt wlan-gw ue-query state l2

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command enables matching on UEs in a Layer 2 wholesale state.

The **no** form of this command disables matching on UEs in a Layer 2 wholesale state, unless all state matching is disabled.

Default

no l2

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

25.2 l2-access-id-alias

l2-access-id-alias

Syntax

l2-access-id-alias *string*

no l2-access-id-alias

Context

[Tree] (config>service>vpls>sap>pfcp l2-access-id-alias)

Full Context

configure service vpls sap pfcp l2-access-id-alias

Description

This command defines a Layer 2 access ID alias for the capture SAP. It replaces the default underlying port-based or LAG-based Layer 2 access ID. Different capture SAPs on the same underlying port or LAG can have different Layer 2 access ID aliases.

The **no** form of the command removes the configuration.

Parameters

string

Specifies the Layer 2 access ID alias, up to 32 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

25.3 l2-access-points

l2-access-points

Syntax

l2-access-points

Context

[Tree] (config>service>vprn>sub-if>grp-if>wlan-gw l2-access-points)

[Tree] (config>service>ies>sub-if>grp-if>wlan-gw l2-access-points)

Full Context

configure service vprn subscriber-interface group-interface wlan-gw l2-access-points

configure service ies subscriber-interface group-interface wlan-gw l2-access-points

Description

Commands in this context configure Layer 2 access points in WLAN gateway group interfaces.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

25.4 l2-ap

l2-ap

Syntax

l2-ap *sap-id* [**create**]

no l2-ap *sap-id*

Context

[Tree] (config>service>vprn>sub-if>grp-if>wlan-gw>l2-access-points l2-ap)

[Tree] (config>service>ies>sub-if>grp-if>wlan-gw>l2-access-points l2-ap)

Full Context

configure service vprn subscriber-interface group-interface wlan-gw l2-access-points l2-ap

configure service ies subscriber-interface group-interface wlan-gw l2-access-points l2-ap

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command adds a specific SAP where Layer 2 WLAN gateway aggregation is performed. The following SAPs are supported:

- Ethernet
- LAG
- MPLS pseudowire SDPs

This command can be repeated multiple times to create multiple Layer 2 access points.

The **no** form of this command removes the Layer 2 access point. This is only allowed if the Layer 2 access point SAP is shutdown.

Parameters

sap-id

Specifies SAP to be created.

create

Keyword used to create the Layer 2 WLAN gateway aggregation instance. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

25.5 l2-ap-auto-sub-id-fmt

l2-ap-auto-sub-id-fmt

Syntax

l2-ap-auto-sub-id-fmt {**include-ap-tags** | **sap-only**}

Context

[Tree] (config>service>ies>sub-if>grp-if>wlan-gw l2-ap-auto-sub-id-fmt)

[Tree] (config>service>vprn>sub-if>grp-if>wlan-gw l2-ap-auto-sub-id-fmt)

Full Context

configure service ies subscriber-interface group-interface wlan-gw l2-ap-auto-sub-id-fmt

configure service vprn subscriber-interface group-interface wlan-gw l2-ap-auto-sub-id-fmt

Description

This command configures the contents of the auto-generated subscriber ID when the **ipoe-sub-id-key** command is set to include **sap-id** and the **def-sub-id** command is configured with **use-auto-id**. The VLANs must be configured so that the subscriber ID length is not exceeded.

This command can include either the SAP or the SAP + AP delimiting tags.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **no** form of this command reverts to the default configuration.

Default

l2-ap-auto-sub-id-fmt include-ap-tags

Parameters

include-ap-tags

Specifies that the SAP + AP delimiting tags is used.

sap-only

Specifies that the SAP only is used.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

25.6 l2-ap-encap-type

l2-ap-encap-type

Syntax

l2-ap-encap-type {**null** | **dot1q** | **qinq**}

Context

[Tree] (config>service>vprn>sub-if>grp-if>wlan-gw l2-ap-encap-type)

[Tree] (config>service>ies>sub-if>grp-if>wlan-gw l2-ap-encap-type)

Full Context

configure service vprn subscriber-interface group-interface wlan-gw l2-ap-encap-type

configure service ies subscriber-interface group-interface wlan-gw l2-ap-encap-type

Description

This parameter specifies the number of AP identifying VLAN tags for an AP. This is the default value that can be overridden per SAP. This value must be at least equal to the number of VLANs configured in the SAP or enabling a SAP will fail.

A SAP VLAN is explicitly configured, for example **l2-ap 1/1/1:25**. Other VLANs on the same port can still be used in other contexts.

The number of VLAN tags Epiped to the WLAN gateway IOM equals the **l2-ap-encap-type** minus the encaps of the SAP. Upon receipt of a packet, these VLANs are stored as a Layer 2 tunnel identifier, and are only used in context of WLAN gateway.

The **no** form of this command sets the default value.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Default
l2-ap-encap-type null

Parameters
null
Both the SAP and the AP are not VLAN-tagged.

dot1q
Either the AP or the SAP uses one VLAN tag.

qinq
Up to two VLAN tags are used by the AP or SAP.

Platforms
7750 SR, 7750 SR-e, 7750 SR-s, VSR

25.7 l2-aware

l2-aware

Syntax
l2-aware

Context
[Tree] (config>service>vprn>nat>inside l2-aware)

Full Context
configure service vprn nat inside l2-aware

Description
Commands in this context configure parameters specific to Layer2-Aware NAT.

Platforms
7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

l2-aware

Syntax
l2-aware

Context
[Tree] (config>router>nat>inside l2-aware)

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Full Context

configure router nat inside l2-aware

Description

Commands in this context configure Layer2-Aware NAT.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

l2-aware

Syntax

l2-aware subscriber *sub-ident-string* **ip** *ip-address* **protocol** {**tcp** | **udp**} [**port** *port*] [**outside-ip** *ip-address*] [**outside-port** *port*] [**nat-policy** *policy-name*] [**member** *member-id*] [**port-range-start** *port*]

no l2-aware subscriber *sub-ident-string* **ip** *ip-address* **protocol** {**tcp** | **udp port** *port*

Context

[Tree] (config>service>nat>fwd l2-aware)

Full Context

configure service nat port-forwarding l2-aware

Description

This command creates NAT static port forwards for Layer2-Aware subscribers. The ESM subscriber must be present in the system before this command is executed. The **no** form of the command deletes NAT static port forwards for Layer2-Aware subscribers.

Parameters

subscriber *sub-ident-string*

This mandatory parameter specifies the ESM subscriber for which the SPF is to be created; ESM subscriber must be present in the system before the SPF can be created.

ip *ip-address*

This mandatory parameter specifies the source IPv4/IPv6 address for which SPF will be created.

protocol {tcp | udp}

This mandatory parameter specifies the protocol to use, either TCP or UDP.

port *port*

This optional parameter specifies a source port.

Values 1 to 65535

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

outside-ip ***ipv4-address***

This mandatory parameter specifies the outside IPv4 address. If the outside IPv4 address is specified, then all other optional parameters become mandatory.

outside-port ***port***

This optional parameter specifies the outside port.

nat-policy ***policy-name***

If multiple NAT policies are used inside the routing context, then the NAT policy should be specified in the SPF request so the SPF is created in the correct NAT pool. Otherwise, the default NAT policy from the inside routing context will be used.

member ***member-id***

This optional parameter should not be used by the operator. It is used only if the command is replayed via the **exec** command or at **boot-config**. The member ID indicates the identifier of the NAT ISA group member associated with this NAT subscriber.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

25.8 l2-aware-ip-address

l2-aware-ip-address

Syntax

l2-aware-ip-address *ip-address*

l2-aware-ip-address from-pool

no l2-aware-ip-address

Context

[Tree] (config>service>ies>sub-if>grp-if>wlan-gw>ranges>range>dhcp l2-aware-ip-address)

[Tree] (config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range>dhcp l2-aware-ip-address)

Full Context

configure service ies subscriber-interface group-interface wlan-gw vlan-tag-ranges range dhcp l2-aware-ip-address

configure service vprn subscriber-interface group-interface wlan-gw vlan-tag-ranges range dhcp l2-aware-ip-address

Description

This command configures the Layer2-Aware NAT inside IP address to be assigned via DHCP on the WLAN-GW ISA.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

If the **from-pool** parameter is specified instead of an IPv4 address, a unique address is allocated to each UE. The pool used is managed by the dhcpv4-nat pool manager, configured under the same subscriber interface. This option is only available when **auth-on-dhcp** is also configured.

The **no** form of this command reverts to the default.

Parameters

ip-address

Specifies the Layer2-Aware NAT inside IP address.

from-pool

Specifies that the Layer2-Aware IP address is allocated from a pool.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

25.9 l2-aware-nat-bypass

l2-aware-nat-bypass

Syntax

[**no**] **l2-aware-nat-bypass**

Context

[Tree] (config>filter>ip-filter>entry>action l2-aware-nat-bypass)

Full Context

configure filter ip-filter entry action l2-aware-nat-bypass

Description

This command enables bypassing NAT for packets pertaining to L2-Aware hosts and matching this entry. This action is only applicable to L2-Aware NAT subscribers and it must be configured together with **action forward**. Traffic identified in the match condition bypasses L2-Aware NAT. A common use case is to bypass NAT for on-net destinations (within the customer network).

Traffic that is not classified for bypass is automatically diverted to L2-Aware NAT, unless it is explicitly configured in the IP filter to be dropped.

For selective NAT bypass to take effect, in addition to the IP filter configuration, the L2-Aware NAT subscriber must be specifically enabled for selective bypass via the **nat-allow-bypass** configuration option in the NAT CLI node in the SLA profile.

The **no** form of this command automatically diverts traffic to L2-Aware NAT, unless it is explicitly configured in the IP filter to be dropped.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

25.10 l2-aware-sub

l2-aware-sub

Syntax

[**no**] **l2-aware-sub** *sub-ident-string*

Context

[Tree] (config>li>li-source>nat l2-aware-sub)

Full Context

configure li li-source nat l2-aware-sub

Description

This command configures a Layer-2-Aware subscriber source.

The **no** form of this command removes the values from the configuration.

Parameters

sub-ident-string

Specifies a source name.

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

25.11 l2-inner-vlan

l2-inner-vlan

Syntax

l2-inner-vlan *q-tag*

no l2-inner-vlan

Context

[Tree] (config>subscr-mgmt>wlan-gw>tunnel-query l2-inner-vlan)

Full Context

configure subscriber-mgmt wlan-gw tunnel-query l2-inner-vlan

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command enables matching on a Layer 2 access point with a specified C-VLAN.

The **no** form of this command disables matching on a C-VLAN.

Default

no l2-inner-vlan

Parameters

q-tag

Specifies the *q-tag* for the C-VLAN.

Values 0 to 4095

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

25.12 l2-ip

l2-ip

Syntax

[**no**] **l2-ip**

Context

[Tree] (config>cflowd>collector>export-filter>family l2-ip)

Full Context

configure cflowd collector export-filter family l2-ip

Description

This command filters Layer 2 IP flow data from being sent to the associated collector.

The **no** form of this command removes the filter, allowing Layer 2 IP flow data to be sent to the associated collector.

Default

no l2-ip

Platforms

All

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

25.13 l2-outer-vlan

l2-outer-vlan

Syntax

l2-outer-vlan *q-tag*

no l2-outer-vlan

Context

[Tree] (config>subscr-mgmt>wlan-gw>tunnel-query l2-outer-vlan)

Full Context

configure subscriber-mgmt wlan-gw tunnel-query l2-outer-vlan

Description

This command enables matching on a Layer 2 access point with a specified S-VLAN.

The **no** form of this command disables matching on an S-VLAN.

Default

no l2-outer-vlan

Parameters

q-tag

Specifies the *q-tag* for the S-VLAN.

Values 0 to 4095

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

25.14 l2-outside

l2-outside

Syntax

l2-outside

no l2-outside

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Context

[Tree] (config>service>nat>nat-policy l2-outside)

[Tree] (config>service>nat>firewall-policy l2-outside)

Full Context

configure service nat nat-policy l2-outside

configure service nat firewall-policy l2-outside

Description

This command configures a NAT policy to be used with a Layer 2 outside service instead of a Layer 3 outside service. This command and the **pool** command are mutually exclusive.

Default

no l2-outside

Platforms

7450 ESS, 7750 SR, 7750 SR-e, 7750 SR-s, VSR

- configure service nat nat-policy l2-outside

7750 SR, 7750 SR-e, 7750 SR-s, VSR

- configure service nat firewall-policy l2-outside

25.15 l2-sap

l2-sap

Syntax

l2-sap *sap-id*

no l2-sap

Context

[Tree] (config>subscr-mgmt>wlan-gw>tunnel-query l2-sap)

Full Context

configure subscriber-mgmt wlan-gw tunnel-query l2-sap

Description

This command enables matching on Layer 2 access points active on the specified SAP.

The **no** form of this command disables matching on the SAP.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Default

no l2-sap

Parameters

sap-id

Specifies the SAP ID. For details on SAP ID parameter values, refer to section *Monitor CLI Commands* in the *7450 ESS, 7750 SR, 7950 XRS, and VSR Basic System Configuration Guide*.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

25.16 l2-service

l2-service

Syntax

l2-service *service-id*

no l2-service

Context

[Tree] (config>service>vprn>sub-if>grp-if>wlan-gw>ranges>range l2-service)

[Tree] (config>service>ies>sub-if>grp-if>wlan-gw>ranges>range l2-service)

Full Context

configure service vprn subscriber-interface group-interface wlan-gw vlan-tag-ranges range l2-service

configure service ies subscriber-interface group-interface wlan-gw vlan-tag-ranges range l2-service

Description

This command specifies the VPLS service used for L2 wholesale. When such a service is configured no other configuration is allowed under the vlan-range.

The **no** form of this command removes the L2 wholesale service, this is only allowed if the l2-service node is shut down.

Parameters

service-id

Specifies the VPLS service ID to use for Layer 2 wholesale.

Platforms

7750 SR, 7750 SR-e, 7750 SR-s, VSR

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

25.17 l2pt-termination

l2pt-termination

Syntax

l2pt-termination [**cdp**] [**dtp**] [**pagp**] [**stp**] [**udld**] [**vtp**]

no l2pt-termination

Context

[Tree] (config>service>vpls>spoke-sdp l2pt-termination)

[Tree] (config>service>vpls>sap l2pt-termination)

[Tree] (config>service>template>vpls-sap-template l2pt-termination)

Full Context

configure service vpls spoke-sdp l2pt-termination

configure service vpls sap l2pt-termination

configure service template vpls-sap-template l2pt-termination

Description

This command enables Layer 2 Protocol Tunneling (L2PT) termination on a specified SAP or spoke-SDP. L2PT termination is supported only for STP BPDUs. PDUs of other protocols are discarded.

This feature can be enabled only if STP is disabled in the context of the specified VPLS service.

The **no** form of this command reverts to the default.

Default

no l2pt-termination

Parameters

cdp

Specifies the Cisco discovery protocol

dtp

Specifies the dynamic trunking protocol

pagp

Specifies the port aggregation protocol

stp

Specifies all spanning tree protocols: stp, rstp, mstp, pvst (default)

udld

Specifies unidirectional link detection

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

[Tree] (config>service>pw-template l2pt-termination)

Full Context

configure service pw-template l2pt-termination

Description

This command enables Layer 2 Protocol Tunneling (L2PT) termination on a given SAP or spoke SDP. L2PT termination will be supported only for STP BPDUs. PDUs of other protocols will be discarded.

This feature can be enabled only if STP is disabled in the context of the given VPLS service.

Default

no l2pt-termination

Parameters

cdp

Specifies the Cisco discovery protocol.

dtp

Specifies the dynamic trunking protocol.

pagp

Specifies the port aggregation protocol.

stp

Specifies all spanning tree protocols: stp, rstp, mstp, pvst (default).

udld

Specifies unidirectional link detection.

vtp

Specifies the virtual trunk protocol.

25.19 l2tp-accounting-policy

l2tp-accounting-policy

Syntax

l2tp-accounting-policy *policy-name* [**create**]

no l2tp-accounting-policy *policy-name*

Context

[Tree] (config>aaa l2tp-accounting-policy)

Full Context

configure aaa l2tp-accounting-policy

Description

This command configures an L2TP accounting policy.

The **no** form of this command removes the policy-name from the configuration.

Parameters

policy-name

Specifies a policy name.

create

This keyword is required when first creating the configuration context. Once the context is created, it is possible to navigate into the context without the **create** keyword.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

25.20 l2tp-lns

l2tp-lns

Syntax

l2tp-lns *max-nr-of-sessions*

no l2tp-lns

© 2025 Nokia.

Context

[Tree] (config>subscr-mgmt>sub-profile>session-limits l2tp-lns)

[Tree] (config>subscr-mgmt>sla-profile>session-limits l2tp-lns)

Full Context

configure subscriber-mgmt sub-profile session-limits l2tp-lns

configure subscriber-mgmt sla-profile session-limits l2tp-lns

Description

This command configures the maximum number of L2TP LNS sessions per SLA profile instance or per subscriber.

The **no** form of this command removes the maximum number of L2TP LNS sessions limit.

Parameters

max-nr-of-sessions

Specifies the maximum number of L2TP LNS sessions.

Values 0 to 131071

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

25.21 l2tp-load-balancing

l2tp-load-balancing

Syntax

[**no**] **l2tp-load-balancing**

Context

[Tree] (config>system>load-balancing l2tp-load-balancing)

Full Context

configure system load-balancing l2tp-load-balancing

Description

This command enables the inclusion of the L2TPv2 session ID into the load-balancing hash algorithm to induce more variation and better load distribution over available links and next-hops.

The **no** form of this command disables the inclusion of the session-id.

Full Context

configure redundancy multi-chassis peer sync track-srrp-instances track-srrp l2tp-tunnel-id-range

Description

This command sets the tunnel-id range that is used to allocate a new tunnel-id for a tunnel for which multi-chassis redundancy is configured to this MCS peer.

The **no** form of this command reverts to the default.

Parameters

start *l2tp-tunnel-id*

Specifies the start of the range of L2TP tunnel identifiers that can be allocated by L2TP on this system, to be synchronized with Multi Chassis Redundancy Synchronization (MCS).

Values 1 to 16383

end *l2tp-tunnel-id*

Specifies the end of the range of L2TP tunnel identifiers that can be allocated by L2TP on this system, to be synchronized with Multi Chassis Redundancy Synchronization (MCS).

Values 1 to 16383

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

25.29 l4-load-balancing

l4-load-balancing

Syntax

[**no**] **l4-load-balancing**

Context

[Tree] (config>system>load-balancing l4-load-balancing)

Full Context

configure system load-balancing l4-load-balancing

Description

This command configures system-wide Layer 4 load balancing. The configuration at the system level can enable or disable load balancing based on Layer 4 fields. If enabled, the Layer 4 source and destination port fields will be included in hashing calculation for TCP/UDP packets.

The hashing algorithm addresses finer spraying granularity where many hosts are connected to the network.

To address more efficient traffic distribution between network links (forming a LAG group), a hashing algorithm extension takes into account L4 information (that is, src/dst L4-protocol port).

The hashing index can be calculated according to the following algorithm:

Example:

```
– If [(TCP or UDP traffic) & enabled]
    – hash (TCP/UDP ports, IP addresses)
– else if (IP traffic)
    – hash (IP addresses)
– else
    – hash (MAC addresses)
```

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

```
    – endif
```

This algorithm will be used in all cases where IP information in per-packet hashing is included (refer to "Traffic Load Balancing Options" in the *7450 ESS, 7750 SR, 7950 XRS, and VSR Interface Configuration Guide*). However, the Layer 4 information (TCP/UDP ports) will not be used for fragmented packets.

Default

no l4-load-balancing

Platforms

Full Context

configure system security management-access-filter ipv6-filter entry l4-src-port

configure system security management-access-filter ip-filter entry l4-src-port

Description

This command configures a source TCP or UDP port number or port range for a management access filter match criterion.

The **no** form of this command reverts to the default values.

Default

no l4-src-port

Parameters

port

Specifies the source TCP or UDP port number as a match criterion.

Values 1 to 65535

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Default 6 (exact match)

mask

Specifies the mask used to select a range of source port numbers. Table 56: Format Styles to Configure Mask lists the format styles to configure the 16-bit mask.

Table 56: Format Styles to Configure Mask

Format Style	Format Syntax	Example
Decimal	DDDDD	63488
Hexadecimal	0xHHHH	0xF800
Binary	0bBBBBBBBBBBBBBBB	0b1111100000000000

To select a range from 1024 to 2047, specify 1024 and 0xFC00 for the port and mask, respectively.

Values 1 to 65535 (decimal)

Default 65535 (exact match)

25.33 label-block

label-block

Syntax

label-block *name*

no label-block

Context

[Tree] (conf>router>segment-routing>srv6>loc>static-function label-block)

Full Context

configure router segment-routing segment-routing-v6 locator static-function label-block

Description

This command configures a reserved label block name to be used in the termination of services on the SRv6 FPE.

Static values of the service SID function are mapped to label values drawn from this reserved label block. A static function value of 1 maps to the first label in this label block and so on.

Dynamic values of service SID function are mapped to label values drawn from the dynamic label range.

An End or End.X function does not map to a label value.

The **no** form of this command removes the label block name from the configuration.

Default

no label-block

Parameters

name

Specifies a reserved label block name, up to 64 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-s, 7950 XRS, VSR

label-block

Syntax

label-block *name*

no label-block

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Context

[Tree] (config>router>segment-routing>srv6>locator label-block)

Full Context

configure router segment-routing segment-routing-v6 locator label-block

Description

This command configures a reserved label block name for the termination of services on the SRv6 FPE.

When an operator configures this block, the router maps both static and dynamic values of the service SID functions to label values drawn from the reserved label block. This reserved block and the block defined under **static-function** are mutually exclusive. The configuration of this block does not constrain the configuration of a particular function length.

An End or End.X function does not map to a label value.

The **no** form of this command removes the label block name from the configuration.

Default

no label-block

Parameters

name

Specifies a reserved label block name, up to 64 characters.

Platforms

7450 ESS, 7750 SR, 7750 SR-s, 7950 XRS, VSR

label-block

Syntax

label-block *name*

no label-block

25.34 label-ipv4

label-ipv4

Syntax

label-ipv4 *max-paths* [**ebgp** *ebgp-max-paths*] [**ibgp** *ibgp-max-paths*] [**restrict** {**same-neighbor-as** | **exact-as-path**}] [**unequal-cost**]

no label-ipv4

Context

[Tree] (config>service>vprn>bgp>multi-path label-ipv4)

Full Context

configure service vprn bgp multi-path label-ipv4

Description

This command sets ECMP multipath parameters that apply only to the label unicast IPv4 address family.

When multipath is enabled, traffic to the destination is load-shared across a set of paths (BGP routes) that the BGP decision process considers equal to the best path. The distribution of traffic over the multiple paths may or may not be equal. The distribution is based on weights derived from the Link Bandwidth Extended Community.

For more information about the criteria a non-best route must meet to qualify as a multipath, see "BGP route installation in the route table” in the *7450 ESS 7750 SR 7950 XRS VSR Unicast Routing Protocols User Guide*.

The **no** form of this command removes label-IPv4-specific overrides.

Default

no label-ipv4

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

max-paths

Specifies the maximum number of multipaths per prefix or NLRI. Setting this value to 1 disables multipath. This limit only applies if neither the *ebgp-max-paths* limit nor the *ibgp-max-paths* limit apply.

Values 1 to 64

ebgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an EBGP learned route. If the **ebgp** option is configured, this value overrides the *max-paths* limit. If the best path is an EBGP learned route and this value is set to 1, multipath is disabled.

Values 1 to 64

ibgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an IBGP learned route. If the **ibgp** option is configured, this value overrides the *max-paths* limit. If the best path is an IBGP learned route and this value is set to 1, multipath is disabled.

Values 1 to 64

restrict same-neighbor-as

Specifies that the non-best path must have the same neighbor AS in its AS path as the best path.

restrict exact-as-path-as

Specifies that the non-best path must have the same AS path as the best path.

unequal-cost

Instructs BGP to ignore differences in the next-hop cost only when determining eligible multipaths.

[Tree] (config>router>bgp>group>neighbor>add-paths label-ipv4)

Full Context

configure router bgp add-paths label-ipv4

configure router bgp group add-paths label-ipv4

configure router bgp group neighbor add-paths label-ipv4

Description

This command configures the add-paths capability for labeled-unicast IPv4 routes. By default, add-paths is not enabled for labeled-unicast IPv4 routes.

The maximum number of labeled-unicast paths per IPv4 prefix to send is the configured *send-limit*, which is a mandatory parameter. The capability to receive multiple labeled-unicast paths per prefix from a peer is configurable using the **receive** keyword, which is optional. If the **receive** keyword is not included in the command, receive capability is enabled by default.

The **no** form of this command disables add-paths support for labeled-unicast IPv4 routes, causing sessions established using add-paths for labeled-unicast IPv4 to go down and come back up without the add-paths capability.

Default

no label-ipv4

Parameters

send-limit

Specifies the maximum number of paths per labeled-unicast IPv4 prefix that are allowed to be advertised to add-paths peers. (The actual number of advertised routes may be less.) If the value is none, the router does not negotiate the send capability with respect to label-IPv4 AFI/SAFI. If the value is **multipaths**, then BGP advertises all the used BGP multipaths for each IPv4 NLRI if the peer has signaled support to receive multiple add paths.

Values 1 to 16, none, multipaths

receive

Specifies the router negotiates to receive multiple labeled-unicast routes per IPv4 prefix.

none

Specifies that the router does not negotiate to receive multiple labeled-unicast routes per IPv4 prefix.

Platforms

All

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

label-ipv4

Syntax

label-ipv4 *max-paths* [**ebgp** *ebgp-max-paths*] [**ibgp** *ibgp-max-paths*] [**restrict** {**same-neighbor-as** | **exact-as-path**}] [**unequal-cost**]

Description

This command configures the add-paths capability for labeled-unicast IPv6 routes. By default, add-paths is not enabled for labeled-unicast IPv6 routes.

The maximum number of labeled-unicast paths per IPv6 prefix to send is the configured *send-limit*, which is a mandatory parameter. The capability to receive multiple labeled-unicast paths per prefix from a peer is configurable using the **receive** keyword, which is optional. If the **receive** keyword is not included in the command, receive capability is enabled by default.

The **no** form of this command disables add-paths support for labeled-unicast IPv6 routes, causing sessions established using add-paths for labeled-unicast IPv6 to go down and come back up without the add-paths capability.

Default

no label-ipv6

Parameters

send-limit

Specifies the maximum number of paths per labeled-unicast IPv6 prefix that are allowed to be advertised to add-paths peers. (The actual number of advertised routes may be less.) If the value is none, the router does not negotiate the send capability with respect to label-IPv6 AFI/SAFI. If the value is **multipaths**, then BGP advertises all the used BGP multipaths for each IPv6 NLRI if the peer has signaled support to receive multiple add paths.

Values 1 to 16, none, multipaths

receive

Specifies that the router negotiates to receive multiple labeled-unicast routes per IPv6 prefix.

none

Specifies that the router does not negotiate to receive multiple labeled-unicast routes per IPv6 prefix.

label-ipv6

Syntax

label-ipv6 *max-paths* [**ebgp** *ebgp-max-paths*] [**ibgp** *ibgp-max-paths*] [**restrict** {**same-neighbor-as** | **exact-as-path**}] [**unequal-cost**]

no label-ipv6

Context

[Tree] (config>router>bgp>multi-path label-ipv6)

Full Context

configure router bgp multi-path label-ipv6

Description

This command sets ECMP multipath parameters that apply only to the label unicast IPv6 address family. These settings override the values set by the **maximum-paths** command.

When multipath is enabled, traffic to the destination is load-shared across a set of paths (BGP routes) that the BGP decision process considers equal to the best path. The actual distribution of traffic over the multiple paths may be equal or unequal (that is, based on weights derived from the Link Bandwidth Extended Community).

The **no** form of this command removes label-IPv6-specific overrides.

Default

no label-ipv6

Parameters

max-paths

Specifies the maximum number of multipaths per prefix/NLRI if *ebgp-max-paths* or *ibgp-max-paths* does not apply.

Values 1 to 64

ebgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an EBGP learned route.

Values 1 to 64

ibgp-max-paths

Specifies the maximum number of multipaths per prefix or NLRI when the best path is an IBGP learned route.

Values 1 to 64

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

restrict same-neighbor-as

Specifies that the non-best path must have the same neighbor AS in its AS path as the best path.

restrict exact-as-path

Specifies that the non-best path must have the same AS path as the best path.

unequal-cost

Instructs BGP to ignore differences in the next-hop cost only when determining eligible multipaths.

Full Context

configure router bgp next-hop-resolution labeled-routes use-bgp-routes label-ipv6-explicit-null

Description

This command allows a labelled IPv6 route with the explicit-null label to be resolved by other labelled IPv6 routes with the explicit-null label, and also by unlabeled IPv4 routes and unlabeled IPv6 routes that are resolved by static routes, interface routes, or tunnels. Up to four levels of recursive resolution are supported when the top route is a labelled IPv6 route with an explicit-null label.

Regardless of setting, a labelled IPv6 route with a regular label (other than explicit-null) is never resolved by other labelled IPv6 routes.

The **no** form of this command disables the label-ipv6-explicit-null functionality. When disabled, a labeled IPv6 route cannot be resolved by other labeled IPv6 routes.

Default

no label-ipv6-explicit-null

Context

[Tree] (config>router>mpls>interface label-map)

Full Context

configure router mpls interface label-map

Description

This command is used on transit routers when a static LSP is defined. The static LSP on the ingress router is initiated using the **config router mpls static-lsp** *lsp-name* command. An *in-label* can be associated with either a **pop** or a **swap** action, but not both. If both actions are specified, the last action specified takes effect.

The **no** form of this command deletes the static LSP configuration associated with the *in-label*.

Parameters

in-label

Specifies the incoming MPLS label on which to match.

Values 32 to 1023

Platforms

All

configure service vprn bgp group neighbor label-preference

configure service vprn bgp group label-preference

Description

This command configures the route preference for routes learned from labeled-unicast peers.

This command can be configured at three levels:

- Global level — applies to all peers
- Group level — applies to all peers in the peer-group
- Neighbor level — applies only to the specified peer

The most specific value is used.

The lower the preference, the higher the chance of the route being the active route.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **no** form of this command used at the global level reverts to the default *value* of 170.

The **no** form of this command used at the group level reverts to the *value* defined at the global level.

The **no** form of this command used at the neighbor level reverts to the *value* defined at the group level.

Parameters

value

Specifies the route preference value.

Values 1 to 255

Platforms

All

25.40 label-route-local

label-route-local

Syntax

label-route-local [{**none** | **all**}]

Context

[Tree] (config>router>ttl-propagate label-route-local)

Full Context

configure router ttl-propagate label-route-local

Description

This command configures the TTL propagation for locally generated packets which are forwarded over a BGP label route in the Global Routing Table (GRT) context.

For IPv4 and IPv6 packets forwarded using an RFC 8277 label route in the global routing instance, including 6PE, the **all** value of the command enables TTL propagation from the IP header into all labels in the transport label stack. The none value reverts to the default mode which disables TTL propagation from the IP header to the labels in the transport label stack. This command does not have a no version.

The TTL of the IP packet is always propagated into the RFC 8277 label itself, and this command only controls the propagation into the transport labels, for example, labels of the RSVP or LDP LSP to which the BGP label route resolves and which are pushed on top of the BGP label.

If the BGP peer advertised the implicit-null label value for the BGP label route, the TTL propagation will not follow the configuration described, but will follow the configuration to which the BGP label route resolves:

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

RSVP LSP shortcut:

- configure router mpls shortcut-local-ttl-propagate

LDP LSP shortcut:

- configure router ldp shortcut-local-ttl-propagate

This feature does not impact packets forwarded over BGP shortcuts. The ingress LER operates in uniform mode by default and can be changed into pipe mode using the configuration of TTL propagation for RSVP or LDP LSP shortcut listed.

Default

label-route-local none

Parameters

none

Specifies that the TTL of the IP packet is not propagated into the transport label stack.

all

Specifies that the TTL of the IP packet is propagated into all labels of the transport label stack.

Platforms

All

label-withdrawal-delay

Syntax

label-withdrawal-delay *seconds*

no label-withdrawal-delay

Context

[Tree] (config>router>ldp label-withdrawal-delay)

Full Context

configure router ldp label-withdrawal-delay

Description

This command specifies configures the time interval (in s), LDP will delay for the withdrawal of FEC-label binding it distributed to its neighbors when FEC is de-activated. When the timer expires, LDP then sends a label withdrawal for the FEC to all its neighbors. This is applicable only to LDP IPv4 prefix FECs and is not applicable to pseudowires (service FECs).

When there is an upper layer (user of LDP) which depends on LDP control plane for failover detection then label withdrawal delay and tunnel-down-damp-time options must be set to 0.

An example is PW redundancy where the primary PW doesn't have its own fast failover detection mechanism and the node depends on LDP tunnel down event to activate the standby PW.

Default

no label-withdrawal-delay

Parameters

seconds

Specifies the time that LDP delays the withdrawal of FEC-label binding it distributed to its neighbors when FEC is de-activated.

Context

[Tree] (config>lag lacp)

Full Context

configure lag lacp

Description

This command enables the LACP protocol. Per the IEEE 802.1ax standard, the Link Aggregation Control Protocol (LACP) provides a standardized means for exchanging information between Partner Systems on a link to allow their Link Aggregation Control instances to reach agreement on the identity of the Link Aggregation Group to which the link belongs, move the link to that Link Aggregation Group, and enable its transmission and reception functions in an orderly manner.

If any of the parameters are omitted, the existing configuration is preserved. The default parameter values are used if a parameter is never explicitly configured.

Default

no lacp

Parameters

mode

Specifies the mode in which LACP will operate.

Values **passive** — Starts transmitting LACP packets only after receiving packets.

active — Initiates the transmission of LACP packets.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

admin-key

Specifies an administrative key value to identify the channel group on each port configured to use LACP. A random key is assigned by default if a value is not specified when using classic CLI only.

Values 1 to 65535

system-id

Specifies the 48-bit system ID in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff, where aa, bb, cc, dd, ee and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.

Values 1 to 65535

Default 32768

priority

Specifies the system priority.

Values 0 to 65535

Default 32768

[Tree] (config>lag lacp-fallback)

Full Context

configure lag lacp-fallback

Description

This command configures the LACP fallback mode. LACP fallback allows one or more designated links of an LACP-controlled LAG to go into forwarding mode if LACP is not yet operational after a configured timeout period. Links capable of forwarding traffic assume the Ethernet and IP characteristics configured for the LAG.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Note: In the saved configuration file, the **lacp-xmit-interval** command must precede the **lacp-fallback** command. As well, to change the **lacp-xmit-interval** from **fast** to **slow**, the **lacp-fallback** command must first be changed to a **timeout** value of 90.

The **no** form of this command disables LACP fallback.

Default

no lacp-fallback

Parameters

mode

Keyword to specify the LACP fallback mode.

Values **static** — Keyword to specify that if LACP is not operational after the timeout period, a single designated LAG member goes into forwarding mode.

timeout

Specifies the timeout period in seconds. The LACP link becomes active if no LACP PDUs are received within this timeout period.

Note: Timeout range depends on the configuration of the **configure lag lacp-xmit-limit** command.

Values fast: 4 to 3600

slow: 90 to 3600

Default fast: 4

Context

[Tree] (config>redundancy>multi-chassis>peer>mc-lag lag)

Full Context

configure redundancy multi-chassis peer mc-lag lag

Description

This command defines a LAG which is forming a redundant-pair for MC-LAG with a LAG configured on the given peer. The same LAG group can be defined only in the scope of 1 peer. In order MC-LAG to become operational, all parameters (**lacp-key**, **system-id**, **system-priority**) must be configured the same on both nodes of the same redundant pair.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The partner system (the system connected to all links forming MC-LAG) will consider all ports using the same **lacp-key**, **system-id**, **system-priority** as the part of the same LAG. In order to achieve this in MC operation, both redundant-pair nodes have to be configured with the same values. In case of the mismatch, MC-LAG is kept in oper-down status.

Note that the correct CLI command to enable MC LAG for a LAG in **standby-signaling power-off mode** is **lag** *lag-id* [**remote-lag** *remote-lag-id*]. In the CLI help output, the first three forms are used to enable MC LAG for a LAG in LACP mode. MC LAG is disabled (regardless of the mode) for a given LAG with **no lag** *lag-id.*

Parameters

lag-id

The LAG identifier, expressed as an integer. Specifying the *lag-id* allows the mismatch between lag-id on redundant-pair. If no **lag-id** is specified it is assumed that neighbor system uses the same *lag-id* as a part of the specific MC-LAG. If no matching MC-LAG group can be found between neighbor systems, the individual LAGs operates as usual (no MC-LAG operation is established).

Values 1 to 800

admin-key

Specifies a 16 bit key that needs to be configured in the same manner on both sides of the MC-LAG in order for the MC-LAG to come up.

Values 1 to 65535

system-id

Specifies a 6 byte value expressed in the same notation as MAC address.

Values xx:xx:xx:xx:xx:xx - xx [00 to FF]

remote-lag-id

Specifies the LAG ID on the remote system.

Values 1 to 800

system-priority

Specifies the system priority to be used in the context of the MC-LAG. The partner system will consider all ports using the same **lacp-key**, **system-id**, and **system-priority** as part of the same LAG.

Values 1 to 65535

MAC-Lsb

Configures the last 16 bit of the MAC address to be used for all traffic ingressing the MC-LAG link(s) or if use-lacp-key option is used, it will only copy the value of lacp-key (redundancy multi-chassis mc-lag lag lacp-key admin-key). The command will fail if the *value* is the same with any of the following configured attributes:

- Source-bmac-lsb assigned to other MC-LAG ports.
- lsb 16 bits value for the source-bmac configured at chassis or BVPLS level

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The first 32 bits will be copied from the source B-MAC of the BVPLS associated with the IVPLS for a specific IVPLS SAP mapped to the MC-LAG. The BVPLS source B-MAC can be provisioned for each BVPLS or can be inherited from the chassis PBB configuration.

Values 1 to 65535 or xx-xx or xx:xx

Platforms

All

lag

Syntax

lag *lag-id* [**name** *lag-name*]

no lag *lag-id*

Context

[Tree] (config lag)

Full Context

configure lag

Description

Commands in this context configure Link Aggregation Group (LAG) attributes.

A LAG is used to group multiple ports into one logical link. The aggregation of multiple physical links allows for load sharing and offers seamless redundancy. If one link fails, traffic is redistributed over the remaining links.

Note:
For all ports in a LAG group, autonegotiation must be set to "limited" or "off".

There are three possible settings for autonegotiation, as follows:

- "on" or enabled with full port capabilities advertised
- "off" or disabled where there is no autonegotiation advertisements
- "limited" where a single speed/duplex is advertised.

When autonegotiation is enabled on a port, the link attempts to automatically negotiate the link speed and duplex parameters; the configured duplex and speed parameters are ignored.

When autonegotiation is disabled on a port, the port does not attempt to autonegotiate and will only operate at the **speed** and **duplex** settings configured for the port.

Note:
Disabling autonegotiation on gigabit ports is not allowed. This is in accordance with the IEEE 802.3 specification for gigabit Ethernet, which requires gigabyte to be enabled for far end fault indication.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

If the **config**>**port**>**ethernet autonegotiate limited** keyword option is specified, the port will autonegotiate but only advertise the **speed** and **duplex** settings configured for the port. Use the **limited** mode on multi-speed gigabit ports to force gigabit operation while keeping autonegotiation is enabled for compliance with IEEE 801.3.

The system requires autonegotiation to be disabled or limited for ports in a LAG to guarantee a specific port speed.

The **no** form of this command deletes the LAG from the configuration. A LAG can only be deleted while the LAG is administratively shut down. Any dependencies, such as IP-Interface configurations, must be removed from the configuration before the **no lag** command is issued.

Parameters

lag-id

Specifies the LAG identifier, expressed as an integer.

The LAG ID ranging from 1 to 64 supports up to 64 LAG members and LAG ID above 64 supports 32 LAG members.

Values 1 to 800

lag-name

Specifies an optional LAG name, up to 27 characters.

In model-driven interfaces, the LAG name is used for configuration references and **show** commands. A service provider or administrator can use the defined LAG name to identify and manage LAGs within the SR OS platforms.

In the classic CLI interface, the user must assign a LAG ID to create the LAG. The LAG name is optional and, if specified, must always start with "lag-”. If a name is not specified, SR OS automatically assigns a string version of the LAG ID as "lag-<lag-id>”.

Values lag-<23 chars max>

debug lag

Description

This command enables debugging for LAG.

Parameters

lag-id

Specifies the link aggregation group ID.

Values 1 to 800

port-id

Specifies the physical port ID.

Values *slot*/*mda*/*port*

all

Specifies to display all LAG information.

sm

Specifies to display trace LACP state machine.

pkt

Specifies to display trace LACP packets.

cfg

Specifies to display trace LAG configuration.

red

Specifies to display trace LAG high availability.

iom-upd

Specifies to display trace LAG IOM updates.

port-state

Specifies to display trace LAG port state transitions.

timers

Specifies to display trace LAG timers.

sel-logic

Specifies to display trace LACP selection logic.

mc

Specifies to display multi-chassis parameters.

mc-packet

Specifies to display the MC-LAG control packets with valid authentication were received on this system.

lag

Syntax

lag *lag-id*

no lag

Context

[Tree] (config>service>system>bgp-evpn>eth-seg lag)

Full Context

configure service system bgp-evpn ethernet-segment lag

Description

This command configures a LAG ID associated with the Ethernet-Segment. When the Ethernet-Segment is configured as **all-active,** then only a lag or PW port can be associated with the Ethernet-Segment. When the Ethernet-Segment is configured as **single-active**, then a lag, port or sdp can be associated to the Ethernet-Segment. In either case, only one of the four objects can be configured in the Ethernet-Segment. A specified lag can be part of only one Ethernet-Segment.

Default

no lag

Parameters

lag-id

Specifies the lag-id associated with the Ethernet-Segment.

Values 1 to 800

Platforms

lag-port-down

Syntax

[**no**] **lag-port-down** *lag-id*

Context

[Tree] (config>vrrp>policy>priority-event lag-port-down)

Full Context

configure vrrp policy priority-event lag-port-down

Description

This command creates the context to configure Link Aggregation Group (LAG) priority control events that monitor the operational state of the links in the LAG.

The **lag-port-down** command configures a priority control event. The event monitors the operational state of each port in the specified LAG. When one or more of the ports enter the operational down state, the event is considered to be set. When all the ports enter the operational up state, the event is considered to be clear. As ports enter the operational up state, any previous set threshold that represents more down ports is considered cleared, while the event is considered to be set.

Multiple unique **lag-port-down** event nodes can be configured within the **priority-event** node up to the maximum of 32 events.

The **lag-port-down** command can reference an arbitrary LAG. The *lag-id* does have to already exist within the system. The operational state of the **lag-port-down** event will indicate:

- Set – non-existent

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- Set – one port down
- Set – two ports down
- Set – three ports down
- Set – four ports down
- Set – five ports down
- Set – six ports down
- Set – seven ports down
- Set – eight ports down
- Cleared – all ports up

When the *lag-id* is created, or a port in *lag-id* becomes operationally up or down, the event operational state must be updated appropriately.

When one or more of the LAG composite ports enters the operationally down state or the *lag-id* is deleted or does not exist, the event is considered to be set. When an event transitions from clear to set, the set is processed immediately and must be reflected in the associated virtual router instances in-use priority value. As the event transitions from clear to set, a hold-set timer is loaded with the value configured by the events **hold-set** command. This timer prevents the event from clearing until it expires, damping the effect of event flapping. If the event clears and becomes set again before the hold-set timer expires, the timer is reset to the **hold-set** value, extending the time before another clear can take effect.

The **lag-port-down** event is considered to have a tiered event set state. While the priority impact per number of ports down is totally configurable, as more ports go down, the effect on the associated virtual router instances in-use priority is expected to increase (lowering the priority). When each configured threshold is crossed, any higher thresholds are considered further event sets and are processed immediately with the hold-set timer reset to the configured value of the **hold-set** command. As the thresholds are crossed in the opposite direction (fewer ports down then previously), the priority effect of the event is not processed until the hold-set timer expires. If the number of ports down threshold again increases before the hold-set timer expires, the timer is only reset to the **hold-set** value if the number of ports down is equal to or greater than the threshold that set the timer.

The event contains **number-down** nodes that define the priority delta or explicit value to be used based on the number of LAG composite ports that are in the operationally down state. These nodes represent the event set thresholds. Not all port down thresholds must be configured. As the number of down ports increase, the **number-down** *ports-down* node that expresses a value equal to or less than the number of down ports describes the delta or explicit priority value to be applied.

The **no** form of the command deletes the specific LAG monitoring event. The event can be removed at anytime. When the event is removed, the in-use priority of all associated virtual router instances must be reevaluated. The events **hold-set** timer has no effect on the removal procedure.

Default

no lag-port-down — No LAG priority control events are created.

Parameters

lag-id

The LAG ID that the specific event is to monitor expressed as a decimal integer. The *lag-id* can only be monitored by a single event in this policy. The LAG may be monitored by multiple VRRP priority control policies. A port within the LAG and the LAG ID itself are considered to be separate entities. A composite port may be monitored with the **port-down**

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

event while the *lag-id* the port is in is monitored by a **lag-port-down** event in the same policy.

Values 1 to 800 (apply to the 7750 SR and 7950 XRS)
1 to 200 (apply to the 7450 ESS)

25.62 lag-usage-optimization

lag-usage-optimization

Syntax

[**no**] **lag-usage-optimization**

Context

[Tree] (config>router>pim lag-usage-optimization)

Full Context

configure router pim lag-usage-optimization

Description

This command enables the router's usage of the LAG so traffic for a given multicast stream destined to an IP interface using the LAG is sent only to the forwarding complex that owns the LAG link on which it will actually be forwarded.

Changing the value causes the PIM protocol to be restarted.

If this optimization is disabled, the traffic is sent to all forwarding complexes that own at least one link in the LAG.

The **no** form of this command causes the traffic to be sent to all the forwarding complexes that own at least one link in the LAG.

Note:
Changes made for multicast hashing cause Layer 4 multicast traffic to not be hashed. This is independent of if **lag-usage-optimization** is enabled or disabled.

Using this command and the **mc-ecmp-hashing-enabled** command on mixed port speed LAGs is not recommended, because some groups may be forwarded incorrectly.

Default

no lag-usage-optimization

Description

This command configures the maximum response time used in group-specific queries sent in response to 'leave' messages, and is also the amount of time between two consecutive group-specific queries. This value may be tuned to modify the leave latency of the network. A reduced value results in reduced time to detect the loss of the last member of a group.

The configured **last-member-query-interval** is ignored when fast leave is enabled on the SAP or SDP.

The **no** form of this command reverts to the default value.

Default

last-member-query-interval 10

Parameters

tenths-of-seconds

Specifies the frequency, in tenths of a second, at which query messages are sent.

Values 1 to 50

25.70 last-reported-delay-hold

last-reported-delay-hold

Syntax

last-reported-delay-hold *seconds*

no last-reported-delay-hold

Context

[Tree] (config>test-oam>link-meas>template last-reported-delay-hold)

Full Context

configure test-oam link-measurement measurement-template last-reported-delay-hold

Description

This command configures the timer that specifies the wait time before the last reported delay measurement is flushed after a link measurement test enters the operationally down state. The aging timer delays the flushing of the last reported delay metric to the routing engine.

This timer starts a countdown to zero when an administrative function causes the operational state of the test on that specific interface to transition from up to down. If the timer expires before the operational state transitions to up, the previously reported value is flushed. The Delay Measurement Last Reported indicates "Cleared". The timestamp indicates the time of the clear event. The Triggered By indicates "Expired". If the administrative state recovers to operationally up before the expiration of the timer, the previous reported value is not flushed.

The aging timer does not apply to failure conditions that do not affect the administrative state of the interface, for example interface failure or routing changes.

The **no** form of this command reverts to the default value.

Default

last-reported-delay-hold 86400

Parameters

seconds

Specifies the delay measurement retention time, in seconds, after the interface on which it was collected is administratively disabled. If the configured value is reached, the last reported measurement is cleared.

A configured value of 0 indicates that the previous reported value is cleared without additional wait time.

Values 0 to 86400

25.72 latency-event

latency-event

Syntax

latency-event rising-threshold *threshold* [**falling-threshold** *threshold*] [*direction*]

no latency-event

Context

[Tree] (config>saa>test latency-event)

Full Context

configure saa test latency-event

Description

Specifies that at the termination of an SAA test probe, the calculated latency event value is evaluated against the configured rising and falling latency event thresholds. SAA threshold events are generated as required.

Once the threshold (rising/falling) is crossed, it is disabled from generating additional events until the opposite threshold is crossed. If a **falling-threshold** is not supplied, the **rising- threshold** is re-enabled when it falls below the threshold after the initial crossing that generated the event.

The configuration of latency event thresholds is optional.

The **no** form of this command disables the latency event.

Parameters

rising-threshold *threshold*

Specifies a rising threshold latency value, in milliseconds. When the test run is completed, the calculated latency value is compared to the configured latency rising threshold. If the test run latency value is greater than the configured rising threshold value then an SAA threshold event is generated. The SAA threshold event is tmnxOamSaaThreshold, logger application OAM, event #2101.

Values 0 to 2147483

Default 0

falling-threshold *threshold*

Specifies a falling threshold latency value, in milliseconds. When the test run is completed, the calculated latency value is compared to the configured latency falling threshold. If the test run latency value is greater than the configured falling threshold value then an SAA threshold event is generated. The SAA threshold event is tmnxOamSaaThreshold, logger application OAM, event #2101.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Values 0 to 2147483

Default 0

direction

Specifies the direction for OAM ping responses received for an OAM ping test run.

Values **inbound** — Monitor the value of jitter calculated for the inbound, one-way, OAM ping responses received for an OAM ping test run.

outbound — Monitor the value of jitter calculated for the outbound, one-way, OAM ping requests sent for an OAM ping test run.

roundtrip — Monitor the value of jitter calculated for the round trip, two-way, OAM ping requests and replies for an OAM ping test run.

Default roundtrip

layer-3-encap [{**ip-udp-shim** | **ip-gre** | **ip-udp-shim-sampled**}] [**create**]

no layer-3-encap

Context

[Tree] (config>mirror>mirror-dest>encap layer-3-encap)

Full Context

configure mirror mirror-dest encap layer-3-encap

Description

This command specifies the format of the routable encapsulation to add to each copied packet. Layer 3 encapsulation takes precedence over Ethernet encapsulation configuration in an LI source. No changes are allowed to the Layer 3 encapsulation once a gateway is configured.

The **no** form of this command removes the routable encapsulation.

Default

no layer-3-encap

Parameters

ip-udp-shim

Specifies that the type of Layer 3 encapsulation is an IPv4 header, UDP header, and LI shim header added to the mirrored packets.

ip-gre

Specifies that the type of Layer 3 encapsulation is an IPv4 header and GRE header added to the mirrored packets. This encapsulation type is only supported with *mirror-type ip-only*.

ip-udp-shim-sampled

Specifies that the type of Layer 3 encapsulation is an IPv4 header, UDP header, and a mirror shim header added to the mirrored packets providing direction, mirror type, filter action, interface type, and interface value.

create

Creates a Layer 3 encapsulation.

Full Context

configure service epipe spoke-sdp eth-cfm mep lbm-svc-act-responder

configure service epipe sap eth-cfm mep lbm-svc-act-responder

Description

This command enables the MEP to process service activation streams encapsulated in ETH-CFM LBM frames that are directed to the MEP. The MEP will be allocated additional resources to rapidly respond to a high-speed stream of LBM messages.

A MEP created with this option will not validate any TLVs, will not validate the ETH-LBM MAC Address, and will not increment or compute any loopback statistics. Statistical computation and reporting is the responsibility of the test head-end. The ETH-CFM level of the high speed ETH-LBM stream must match the level of a MEP configured with this command. The high-speed stream must not target an ETH-CFM level that is not explicitly configured with this option. MEPs act as boundaries for lower levels, below the configured MEP level values. Those boundary levels do not inherit this function.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

When the service activation test is complete, the MEP may be returned to standard processing by removing this command. If there is available bandwidth, the MEP will respond to other ETH-CFM PDUs, such as ETH-DMM marker packets, using standard processing.

The interaction between this command and the **tools perform service id** *service-id* **loopback eth** command must be carefully considered. It is recommended that either the **lbm-svc-act-responder** or the **tools perform service id** *service-id* **loopback eth** command be used at any given time within a service. If both commands must be configured, and the target reflection point is the MAC Swap Loopback function, the inbound stream of data must not include ETH-CFM traffic that is equal to or lower than the domain level of any configured MEP which would otherwise extract and process the ETH-CFM message. If the reflection target is a MEP configured with the **lbm-svc-act-responder** option, the mode (ingress or egress) of the SAP or SDP specified with this tools command and the MEP **direction** (up or down) must match when the functions are enabled on the same reflection point, and the domain level of the inbound ETH-LBM must be the same as that of the MEP configured with the **lbm-svc-act-responder** option. At no time should the two functions be conflicting with each other along the path of the stream. This conflict would lead to unpredictable and possibly destabilizing situations.

The **no** form of this command reverts to MEP LBM standard processing.

Default

no lbm-svc-act-responder

configure service vprn l2tp group ppp lcp-force-ack-accm

configure router l2tp group tunnel ppp lcp-force-ack-accm

configure router l2tp group ppp lcp-force-ack-accm

Description

This command enables the LCP Asynchronous Control Character Map (ACCM) configuration option. When enabled, the LCP ACCM configuration option is acknowledged during LCP negotiation between the LNS and the PPP client. The option is then ignored and no ACCM mapping is done.

By default, an L2TP tunnel inherits the configuration from the L2TP group CLI context.

The **no** form of this command disables the LCP ACCM configuration option.

Parameters

always

Specifies to acknowledge the LCP ACCM configuration option, but not to perform ACCM mapping. This option overrides the group level configuration.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

never

Specifies to reject the LCP ACCM configuration option. This option overrides the group level configuration.

ldp

Syntax

[**no**] **ldp**

Context

[Tree] (config>service>sdp ldp)

Full Context

configure service sdp ldp

Description

This command enables LDP-signaled LSPs on MPLS-encapsulated SDPs.

In MPLS SDP configurations *either* one or more LSP names can be specified *or* LDP can be enabled. The SDP **ldp** and **lsp** commands are mutually exclusive except if the mixed-lsp-mode option is also enabled. If an LSP is specified on an MPLS SDP, then LDP cannot be enabled on the SDP. To enable LDP on the SDP when an LSP is already specified, the LSP must be removed from the configuration using the **no lsp** *lsp-name* command or the mixed-lsp-mode option is also enabled.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Alternatively, if LDP is already enabled on an MPLS SDP, then an LSP cannot be specified on the SDP. To specify an LSP on the SDP, the LDP must be disabled. The LSP must have already been created in the **config>router>mpls** context with a valid far-end IP address. The above rules are relaxed when the **mixed-lsp** option is enabled on the SDP.

Default

[Tree] (config>router>mpls>lsp ldp-over-rsvp)

Full Context

configure router mpls lsp-template ldp-over-rsvp

configure router mpls lsp ldp-over-rsvp

Description

This command configures an LSP so that it can be used by the IGP to calculate its SPF tree.

When the **ldp-over-rsvp** option is also enabled in ISIS or OSPF, the IGP provides LDP with all ECMP IP next-hops and tunnel endpoints that it considers to be the lowest cost path to its destination.

IGP provides only the endpoints which are the closest to the destination in terms of IGP cost for each IP next-hop of a prefix. If this results in more endpoints than the ECMP value configured on the router, it will further prune the endpoints based on the lowest router-id and for the same router-id, it will select lowest interface-index first.

LDP then looks up the tunnel table to select the actual tunnels to the endpoint provided by IGP and further limits the endpoint selection to the ones which are the closest to destination across all the IP next-hops provided by IGP for a prefix. For each remaining endpoint, LDP selects a tunnel in a round-robin fashion until the router ECMP value is reached. For each endpoint, only tunnels with the same lowest metric are candidates. If more than one tunnel qualifies, the selection begins with the lowest tunnel-id.

25.85 ldp-shortcut

ldp-shortcut

Syntax

[**no**] **ldp-shortcut**

Context

[Tree] (config>router ldp-shortcut)

Full Context

configure router ldp-shortcut

Description

This command enables the resolution of IGP routes using LDP LSP across all network interfaces participating in the IS-IS and OSPF routing protocol in the system.

When LDP shortcut is enabled, LDP populates the routing table with next-hop entries corresponding to all prefixes for which it activated an LDP FEC. For a given prefix, two route entries are populated in the system routing table. One corresponds to the LDP shortcut next-hop and has an owner of LDP. The other one is the regular IP next-hop. The LDP shortcut next-hop always has preference over the regular IP next-hop for forwarding user packets and specified control packets over a given outgoing interface to the route next-hop.

All user and specified control packets for which the longest prefix match in RTM yields the FEC prefix will be forwarded over the LDP LSP.

When an IPv4 packet is received on an ingress network interface, a subscriber IES interface, or a regular IES interface, the lookup of the packet by the ingress forwarding engine will result in the packet being sent labeled with the label stack corresponding to the NHLFE of the LDP LSP when the preferred RTM entry corresponds to an LDP shortcut.

If the preferred RTM entry corresponds to an IP next-hop, the IPv4 packet is forwarded without a label.

When ECMP is enabled and multiple equal-cost next-hops exit for the IGP route, the ingress forwarding engine will spray the packets for this route based on hashing routine currently supported for IPv4 packets. When the preferred RTM entry corresponds to an LDP shortcut route, spraying will be performed across the multiple next-hops for the LDP FEC. The FEC next-hops can either be direct link LDP neighbors or T-LDP neighbors reachable over RSVP LSPs in the case of LDP-over-RSVP but not both.

When the preferred RTM entry corresponds to a regular IP route, spraying will be performed across regular IP next-hops for the prefix.

The **no** form of this command disables the resolution of IGP routes using LDP shortcuts.

Default

no ldp-shortcut

25.86 ldp-sync

ldp-sync

Syntax

[**no**] **ldp-sync**

Context

[Tree] (config>service>vprn>static-route-entry>indirect ldp-sync)

Full Context

configure service vprn static-route-entry indirect ldp-sync

Description

This command extends the LDP synchronization feature to a static route. When an interface comes back up, it is possible that a preferred static route using the interface as next-hop for a given prefix is enabled before the LDP adjacency to the peer LSR comes up on this interface. In this case, traffic on an SDP that uses the static route for the far-end address would be black-holed until the LDP session comes up and the FECs exchanged.

This option when enabled delays the activation of the static route until the LDP session comes up over the interface and the ldp-sync-timer configured on that interface has expired

ldp-sync-timer *seconds* [**end-of-lib**]

no ldp-sync-timer

Context

[Tree] (config>router>if ldp-sync-timer)

Full Context

configure router interface ldp-sync-timer

Description

This command enables synchronization of an IGP and LDP. When a link is restored after a failure, the IGP sets the link cost to infinity and advertises it. The actual value advertised in OSPF is 0xFFFF (65535). The actual value advertised in IS-IS regular metric is 0x3F (63) and in IS-IS wide-metric is 0xFFFFFE (16777214). This feature is not supported on RIP interfaces.

If an interface belongs to both IS-IS and OSPF, a physical failure will cause both IGPs to advertise an infinite metric and to follow the IGP-LDP synchronization procedures. If only one IGP bounces on this interface or on the system, then only the affected IGP advertises the infinite metric and follows the IGP-LDP synchronization procedures.

Next, an LDP Hello adjacency is brought up with the neighbor. The LDP synchronization timer is started by the IGP when the LDP session to the neighbor is up over the interface. This is to allow time for the label-FEC bindings to be exchanged.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

When the LDP synchronization timer expires, the link cost is restored and is readvertised. The IGP will announce a new best next hop and LDP will use it if the label binding for the neighbor's FEC is available.

If the user changes the cost of an interface, the new value is advertised at the next flooding of link attributes by the IGP. However, if the LDP synchronization timer is still running, the new cost value will only be advertised after the timer expires. The new cost value will also be advertised after the user executes any of the following commands:

- **tools>perform>router>isis>ldp-sync-exit**
- **tools>perform>router>ospf>ldp-sync-exit**
- **config>router>if>no ldp-sync-timer**
- **config>router>ospf>disable-ldp-sync**
- **router>isis>disable-ldp-sync**

If the user changes the value of the LDP synchronization timer parameter, the new value will take effect at the next synchronization event. If the timer is still running, it will continue to use the previous value.

If parallel links exist to the same neighbor, then the bindings and services should remain up as long as there is one interface that is up. However, the user-configured LDP synchronization timer still applies on the interface that failed and was restored. In this case, the router will only consider this interface for forwarding after the IGP re-advertises its actual cost value.

The LDP Sync Timer State is not always synchronized across to the standby CPM. Therefore, after an activity switch, the timer state might not be same as it was on the previously active CPM.

If the **end-of-lib** option is configured, then the system will start the LDP synchronization timer as usual. If the LDP End of LIB Typed Wildcard FEC messages are received for every FEC type negotiated for a given session to an LDP peer for that IGP interface, the **ldp-sync-timer** is terminated early and the IGP link cost is restored. If the **ldp-sync-timer** expires before the LDP End of LIB messages are received for every negotiated FEC type, then the system will restore the IGP link cost. The **end-of-lib** option is disabled by default.

The **no** form of this command disables IGP-LDP synchronization and deletes the configuration.

Default

no ldp-sync-timer

Parameters

seconds

Specifies the time interval for the IGP-LDP synchronization timer.

Values 1 to 1800

end-of-lib

Specifies that the system should terminate the **ldp-sync-timer** early if the LDP End of LIB Typed Wildcard FEC messages are received for every FEC type negotiated for a given session to an LDP peer for that IGP interface.

25.88 ldp-treetrace

ldp-treetrace

Syntax

ldp-treetrace {**prefix** *ip-prefix*/*mask*} [**downstream-map-tlv** {**dsmap** | **ddmap**}] [**fc** *fc-name* [**profile** {**in** | **out**}]] [**max-path** *max-paths*] [**max-ttl** *ttl-value*] [**retry-count** *retry-count*] [**timeout** *timeout*]

Context

[Tree] (oam ldp-treetrace)

Full Context

oam ldp-treetrace

Description

This command allows the user to perform a single run of the LDP ECMP OAM tree trace to discover all ECMP paths of an LDP FEC.

Parameters

ip-prefix/mask

Specifies the address prefix and subnet mask of the target BGP IPv4 label route.

Values ip-prefix: a.b.c.dmask, the value must be 32

downstream-map-tlv {dsmap | ddmap}

Specifies which format of the downstream mapping TLV to use in the LSP trace packet. The DSMAP TLV is the original format in RFC 4379 (obsoleted by RFC 8029). The DDMAP is the new enhanced format specified in RFC 6424 and RFC 8029.

Default Inherited from global configuration of downstream mapping TLV in option **mpls-echo-request-downstream-map** {**dsmap** | **ddmap**}.

fc-name

Specifies the FC and profile parameters are used to indicate the forwarding class and profile of the MPLS echo request packet.

When an MPLS echo request packet is generated in CPM and is forwarded to the outgoing interface, the packet is queued in the egress network queue corresponding to the specified FC and profile parameter values. The marking of the packet's EXP is dictated by the LSP-EXP mappings on the outgoing interface.

When the MPLS echo request packet is received on the responding node, The FC and profile parameter values are dictated by the LSP-EXP mappings of the incoming interface.

When an MPLS echo reply packet is generated in CPM and is forwarded to the outgoing interface, the packet is queued in the egress network queue corresponding to the FC and profile parameter values determined by the classification of the echo request packet, which

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

is being replied to, at the incoming interface. The marking of the packet's EXP is dictated by the LSP-EXP mappings on the outgoing interface. The ToS byte is not modified. Table 57: ldp-treetrace Request Packet and Behavior summarizes this behavior.

Table 57: ldp-treetrace Request Packet and Behavior

CPM (sender node)	Echo request packet: • packet {tos=1, fc1, profile1} • fc1 and profile1 are as entered by user in OAM command or default values • tos1 as per mapping of {fc1, profile1} to IP precedence in network egress QoS policy of outgoing interface
Outgoing interface (sender node)	Echo request packet: • pkt queued as {fc1, profile1} • ToS field=tos1 not remarked • EXP=exp1, as per mapping of {fc1, profile1} to EXP in network egress QoS policy of outgoing interface
Incoming interface (responder node)	Echo request packet: • packet {tos1, exp1} • exp1 mapped to {fc2, profile2} as per classification in network QoS policy of incoming interface
CPM (responder node)	Echo reply packet: • packet {tos=1, fc2, profile2}
Outgoing interface (responder node)	Echo reply packet: • pkt queued as {fc2, profile2} • ToS filed= tos1 not remarked (reply inband or out-of-band) • EXP=exp2, if reply is inband, remarked as per mapping of {fc2, profile2} to EXP in network egress QoS policy of outgoing interface
Incoming interface (sender node)	Echo reply packet: • packet {tos1, exp2} • exp2 mapped to {fc1, profile1} as per classification in network QoS policy of incoming interface

Values be, l2, af, l1, h2, ef, h1, nc

Default be

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

profile {in | out}

Specifies the profile state of the MPLS echo request packet.

Values in, out

Default out

max-paths

Specifies the maximum number of paths for a ldp-treetrace test, expressed as a decimal integer.

Values 1 to 255

Default 128

ttl-value

Specifies the maximum TTL value in the MPLS label for the LSP trace test, expressed as a decimal integer.

Values 1 to 255

Default 30

retry-count

Specifies the maximum number of consecutive MPLS echo requests, expressed as a decimal integer that do not receive a reply before the trace operation fails for a given TTL.

Values 1 to 255

Default 5

timeout

Specifies the time, in seconds, used to override the default time out value and is the amount of time that the router waits for a message reply after sending the message request. Upon the expiration of the message time out, the requesting router assumes that the message response is not received. Any response received after the request times out is silently discarded.

Values 1 to 60

Default 3

Context

[Tree] (config>router leak-export)

Full Context

configure router leak-export

Description

This command associates up to four policies to control the leaking of GRT routes into the associated VPRN.

If a route is evaluated and the action is accepted, that route is subject leaking into an associated VPRN instance, assuming the route is fully resolved and active.

This process creates the pool of routes that can be leaked. Within each VPRN, a corresponding **import-grt** policy must be configured to import select routes into that specific VPRN instance.

The **no** form of this command removes all route leaking policy associations and effectively disables the leaking of GRT routes into associated VPRNs.

Parameters

plcy-or-long-expr

Specifies the route policy name, up to 64 characters or a policy logical expression, up to 255 characters.

Values *plcy-or-long-expr*: *policy-name* | *long-expr*

policy-name: up to 64 characters

long-expr: up to 255 characters

plcy-or-expr

Specifies the route policy name, up to 64 characters or a policy logical expression, up to 64 characters long. A maximum of four policy names or policy logical expressions can be specified in a single statement.

Values *plcy-or-expr*: *policy-name* | expr

policy-name: up to 64 characters

expr: up to 64 characters

configure service vprn bgp rib-management ipv6 leak-import

configure service vprn bgp rib-management ipv4 leak-import

configure service vprn bgp rib-management label-ipv6 leak-import

Description

This command configures route policies that control the importation of leak-eligible routes from the BGP RIB of another routing instance into the unlabeled-IPv4, unlabeled-IPv6, labeled-IPv4, or labeled-IPv6 RIB of the VPRN instance. To leak a route from one routing instance to another, the origin and destination RIB types must be the same; for example, it is not possible to leak a route from an unlabeled-IPv4 RIB of a VPRN into the labeled-IPv4 RIB of the base router.

The **leak-import** command can reference up to 15 objects, where each object is either a policy logical expression or the name of a single policy. The objects are evaluated in the specified order to determine the final action to accept or reject the route.

Only one of the 15 objects referenced by the **leak-import** command can be a policy logical expression consisting of policy names (enclosed in square brackets) and logical operators (AND, OR, NOT). The first of the 15 objects has a maximum length of 255 characters while the remaining 14 objects have a maximum length of 64 characters each.

When a **leak-import** policy is not specified, no BGP routes from other routing instances are leaked into the VPRN BGP RIB.

The **no** form of this command removes the policy association.

Default

no leak-import

Parameters

plcy-or-long-expr

Specifies the route policy name (up to 64 characters) or a policy logical expression (up to 255 characters). Allowed values are any string of characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

plcy-or-expr

Specifies the route policy name (up to 64 characters) or a policy logical expression (up to 255 characters). Allowed values are any string of characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, ?, space), the entire string must be enclosed within double quotes.

Full Context

configure service ies subscriber-interface group-interface wlan-gw learn-ap-mac

configure service vprn subscriber-interface group-interface wlan-gw learn-ap-mac

Description

This command enables the sending of ARP or ND packets on the WLAN-GW GRE tunnel for certain events. The target IP address in the ARP/ND packet is the endpoint IP address of the AP. The ARP/ND response from the AP should contain the AP MAC, which subsequently can be reported in a called-station-id message. When enabled, a message will be sent for following events:

- CPM: Mobility to an AP for which the AP-MAC is not yet known
- CPM: RS-triggered authentication on an AP for which the AP-MAC is not yet known
- ISA: Any mobility event
- ISA: Any authentication where the AP-MAC is not yet known (for example, from a RADIUS proxy cache or a DHCP circuit-id). If the optional keyword **delay-auth** is configured, then the authentication will be

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

delayed until the ARP/ND is answered or timed out, after which the AP-MAC can be included in the authentication.

This configuration is ignored for L2-AP and L2TPv3 access.

Parameters

delay-auth

Specifies that authentication will be delayed until the ARP/ND is answered or timed out, after which the AP-MAC can be included in the authentication.

Full Context

configure service vprn subscriber-interface group-interface wlan-gw learn-l2tp-cookie

configure service ies subscriber-interface group-interface wlan-gw learn-l2tp-cookie

Description

This command specifies when this system will learn the cookie from L2TP tunnels terminating on this interface. Learning the cookie means that the value of the octets 3-8 of the cookie is interpreted as an access point's MAC address, and used as such, for example in the Called-Station-Id attribute of RADIUS Interim-Update messages.

Parameters

if-match

Specifies that the cookie is interpreted only if the value of the first two octets of the cookie is equal to the value of the object tmnxWlanGwSoftGreIfL2tpCookie.

cookie *hex string*

Specifies the value used to compare the first two bytes of the cookie. This parameter is only valid if **if-match** is configured.

Values 0x0000 to 0xFFFF...(4 hex nibbles)

never

Specifies that the cookie value will always be ignored.

always

Always learn the AP-MAC from the cookie, regardless of the value of the first two bytes.

configure service vprn interface dhcp lease-populate

configure subscriber-mgmt msap-policy vpls-only-sap-parameters dhcp lease-populate

configure service ies interface dhcp lease-populate

configure service vprn subscriber-interface group-interface dhcp lease-populate

Description

Commands in this context configure IPoE host parameters.

For VPLS, DHCP snooping must be explicitly enabled (using the **snoop** command) at all points where DHCP messages requiring snooping enter the VPLS instance (both from the DHCP server and from the subscribers). Lease state information is extracted from snooped DHCP ACK messages to populate lease state table entries for the SAP.

The optional *nbr-of-leases* parameter defines the number lease state table entries allowed.

- for this SAP in case of a VPLS service
- for this interface in case of an IES or VPRN interface
- for each SAP in case of an IES or VPRN group-interface
- for this interface in case of an IES or VPRN retail subscriber-interface

If the *nbr-of-leases* parameter is omitted, only a single entry is allowed. Once the maximum number of entries has been reached, subsequent lease state entries are not allowed and subsequent DHCP ACK messages are discarded.

The retained lease state information representing dynamic hosts may be used to:

- Populate a SAP based anti-spoof filter table to provide dynamic anti-spoof filtering. If the system is unable to populate the dynamic host information in the anti-spoof filter table on the SAP, the DHCP ACK message must be discarded without adding new lease state entry or updating an existing lease state entry.
- Populate the system’s ARP cache based on the arp-populate configuration. Applicable to IES and VPRN interfaces or group-interfaces.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- Populate managed entries into a VPLS forwarding database. VPLS forwarding database population is an implicit feature that automatically places the dynamic host's MAC address into the VPLS FDB. When a dynamic host's MAC address is placed in the lease state table, it will automatically be populated into the VPLS forwarding database associated with the SAP on which the host is learned. The dynamic host MAC address will override any static MAC entries using the same MAC and prevent dynamic learning of the MAC on another interface. Existing static MAC entries with the same MAC address as the dynamic host are marked as inactive but not deleted. If all entries in the lease state table associated with the MAC address are removed, the static MAC may be populated. New static MAC definitions for the VPLS instance may be created while a dynamic host exists associated with the static MAC address.
- Generate dynamic ARP replies if **arp-reply-agent** is enabled. Applicable to VPLS service SAPs

The **no** form of this command reverts to the default.

Parameters

nbr-of-leases

Specifies the number of DHCPv4 leases allowed.

l2-header

Indicates a mode of operation where anti-spoof entry associated with the given DHCP state is created based on the *src-mac* address from the Layer 2 header of the DHCP request message. The Layer 2 header flag is not set by default. This parameter is only applicable for group interfaces.

mac

Specifies that the provisioned *ieee-address* is used in the anti-spoofing entries for this SAP. The parameter may be changed mid-session. Existing sessions will not be re-programmed unless a **tools>perform>subscriber-mgmt>remap-lease-state** command is issued for the lease. This parameter is only applicable for group interfaces.

Platforms

Context

[Tree] (config>service>ies>if>ipv6>dhcp6-relay lease-populate)

Full Context

configure service ies interface ipv6 dhcp6-relay lease-populate

Description

This command specifies the maximum number of DHCPv6 lease states allocated by the DHCPv6 relay function, allowed on this interface.

Optionally, by specifying **route-populate** parameter, system could:

- Create routes based on the IA_PD/IA_NA/IA_TA prefix option in relay-reply message.
- Create black hole routes based on OPTION_PD_EXCLUDE in IA_PD in relay-reply message.

These routes could be redistributed into IGP/BGP by using route-policy, following protocol types that could be used in "from protocol”:

- dhcpv6-pd
- dhcpv6-na
- dhcpv6-ta
- dhcpv6-pd-excl

Parameters

nbr-of-leases

Defines the number lease state table entries allowed for this interface. If this parameter is omitted, only a single entry is allowed. Once the maximum number of entries has been reached, subsequent lease state entries are not allowed and subsequent DHCPv6 REPLY messages are discarded.

Values 1 to 8000

route-populate

Specifies the route populate parameter.

Values pd/na/ta — Create route based on specified option.

exclude — Create blackhole route based on OPTION_PD_EXCLUDE.

configure service vprn dhcp local-dhcp-server pool options lease-time

configure subscriber-mgmt local-user-db ipoe host options lease-time

Description

This command configures the amount of time that the DHCP server grants to the DHCP client permission to use a specific IP address.

The **no** form of this command removes the lease time parameters from the configuration.

Parameters

days

Specifies the number of days that the given IP address is valid.

Values 0 to 3650

hours

Specifies the number of hours that the given IP address is valid.

Values 0 to 23

minutes

Specifies the number of minutes that the given IP address is valid.

Values 0 to 59

seconds

Specifies the number of seconds that the given IP address is valid.

Values 0 to 59

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

lease-time

Syntax

configure service vprn interface dhcp proxy-server lease-time

configure service vpls sap dhcp proxy-server lease-time

configure service vprn subscriber-interface group-interface dhcp proxy-server lease-time

Description

This command defines the length of lease-time that is provided to DHCP clients. By default, the local-proxy-server always makes use of the lease time information provide by either a RADIUS or DHCP server.

The **no** form of this command disables the use of the lease-time command. The local-proxy-server will use the lease-time offered by either a RADIUS or DHCP server.

Default

lease-time days 7

Parameters

override

Specifies that the local-proxy-server will use the configured lease-time information to provide DHCP clients

days

Specifies the number of days that the given IP address is valid.

Values 0 to 3650

hours

Specifies the number of hours that the given IP address is valid.

Values 0 to 23

minutes

Specifies the number of minutes that the given IP address is valid.

Values 0 to 59

seconds

Specifies the number of seconds that the given IP address is valid.

25.105 least-fill

least-fill

Syntax

[**no**] **least-fill**

Context

[Tree] (config>router>mpls>lsp-template least-fill)

[Tree] (config>router>mpls>lsp least-fill)

Full Context

configure router mpls lsp-template least-fill

configure router mpls lsp least-fill

Description

This command enables the use of the least-fill path selection method for the computation of the path of this LSP.

When MPLS requests the computation of a path for this LSP, CSPF will find all equal cost shortest paths which satisfy the constraints of this path. Then, CSPF identifies the single link in each of these paths which has the least available bandwidth as a percentage of its maximum reservable bandwidth. It then selects the path which has the largest value of this percentage least available bandwidth figure. CSPF identifies the least available bandwidth link in each equal cost path after it has accounted for the bandwidth of the new requested path of this LSP.

CSPF applies the least-fill path selection method to all requests for a path, primary and secondary, of an LSP for which this option is enabled. The bandwidth of the path can be any value, including zero.

CSPF applies the least-fill criterion separately to each preemption priority in the base TE. A higher setup priority path can preemptively lower holding priority paths.

CSPF also applies the least-fill criterion separately to each Diff-Serv TE class if Diff-Serv TE is enabled on this node. A higher setup priority path can preemptively lower holding priority paths within a Class Type.

MPLS will re-signal and move the LSP to the new path in the following cases:

- Initial LSP path signaling.
- Re-try of an LSP path after failure.
- Make-before-break (MBB) due to pending soft preemption of the LSP path.
- MBB due to LSP path configuration change, that is, a user change to bandwidth parameter of primary or secondary path, or a user enabling of fast-reroute option for the LSP.
- MBB of secondary path due to an update to primary path SRLG.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

- MBB due to FRR Global Revertive procedures on the primary path.
- Manual re-signaling of an LSP path or of all LSP paths by the user.

During a manual re-signaling of an LSP path, MPLS will always re-signal the path regardless of whether the new path is exactly the same or different than the current path and regardless of whether the metric of the new path is different or not from that of the current path.

During a timer-based re-signaling of an LSP path which has the least-fill option enabled, MPLS will only re-signal the path if the metric of the new path is different than the one of the current path.

The **no** form of this command deletes a specific node entry in this database.

Default

no least-fill. The path of an LSP is randomly chosen among a set of equal cost paths.

Platforms

All

25.106 least-fill-min-thd

least-fill-min-thd

Syntax

least-fill-min-thd *percent*

no least-fill-min-thd

Context

[Tree] (config>router>mpls least-fill-min-thd)

Full Context

configure router mpls least-fill-min-thd

Description

This parameter is used in the least-fill path selection process. When comparing the percentage of least available link bandwidth across the sorted paths, whenever two percentages differ by less than the value configured as the least-fill-min-thresh, CSPF will consider them equal and will apply a random number generator to select the path among these paths

The **no** form of this command resets this parameter to its default value.

Default

least-fill-min-thd 5

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

percentage

Specifies the least fill minimum threshold value as a percentage.

Values 1 to 100%

Platforms

All

25.107 least-fill-reoptim-thd

least-fill-reoptim-thd

Syntax

least-fill-reoptim-thd *percent*

no least-fill-reoptim-thd

Context

[Tree] (config>router>mpls least-fill-reoptim-thd)

Full Context

configure router mpls least-fill-reoptim-thd

Description

This parameter is used in the least-fill path selection method. During a timer-based re-signaling of an LSP path which has the least-fill option enabled, CSPF will first update the least-available bandwidth figure for the current path of this LSP. It then applies the least-fill path selection method to select a new path for this LSP. If the new computed path has the same cost as the current path, it will compare the least-available bandwidth figures of the two paths and if the difference exceeds the user configured optimization threshold, MPLS will generate a trap to indicate that a better least-fill path is available for this LSP. This trap can be used by an external SNMP based device to trigger a manual re-signaling of the LSP path since the timer-based re-signaling will not re-signal the path in this case. MPLS will generate a path update trap at the first MBB event which results in the re-signaling of the LSP path. This should clear the eligibility status of the path at the SNMP device.

The **no** form of this command resets this parameter to its default value.

Default

least-fill-reoptim-thd 10

Parameters

percentage

Specifies the least fill reoptimization threshold value as a percentage.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command controls the period of time that the Registrar state machine will wait in the leave state before transitioning to the MT (Empty) state when it is removed. An instance of the timer is required for each state machine that is in the leave state. The leave period timer is set to the value specified for **leave-time** when it is started.

A registration is normally in an "in" state where there is an MFIB entry and traffic is being forwarded. When a "leave all" is performed (periodically around every 10-15 seconds per SAP/SDP binding - see leave-all-time-below), a node sends a message to its peer indicating a leave all is occurring and puts all of its registrations in leave state.

The peer refreshes its registrations based on the leave all PDU it receives and sends a PDU back to the originating node with the state of all its declarations.

Refer to IEEE 802.1ak-2007 section 10.7.4.2.

Default

leave-time 30

Parameters

value

The period of time that the Registrar state machine waits in the leave state before transitioning to the MT state, in tenths of a second.

Values 30 to 60

Syntax

[**no**] **ler-use-dscp**

Context

[Tree] (config>qos>network>ingress ler-use-dscp)

Full Context

configure qos network ingress ler-use-dscp

Description

This command is used to enable tunnel QoS mapping on all ingress network IP interfaces that the network-qos-policy-id is associated with. The command may be defined at any time after the network QoS policy has been created. Any network IP interfaces currently associated with the policy will immediately start to use the internal IP ToS field of any tunnel terminated IP routed packet received on the interface, ignoring any QoS markings in the tunnel portion of the packet.

This attribute provides the ability to ignore the network ingress QoS mapping of a terminated tunnel containing an IP packet that is to be routed to a base router or VPRN destination. This is advantageous when the mapping for the tunnel QoS marking does not accurately or completely reflect the required QoS handling for the IP routed packet. When the mechanism is enabled on an ingress network IP interface, the IP interface will ignore the tunnel's QoS mapping and derive the internal forwarding class and profile based on the precedence or DiffServ Code Point (DSCP) values within the routed IP header ToS field compared to the Network QoS policy defined on the IP interface.

The default state is not to enforce tunnel termination IP routed QoS override within the network QoS policy.

The **no** form of this command removes tunnel termination IP routed QoS override from the network QoS policy and all ingress network IP interfaces associated with the policy.

Default

no ler-use-dscp

25.118 less-specific

less-specific

Syntax

less-specific [**allow-default**]

no less-specific

Context

[Tree] (config>vrrp>policy>priority-event>route-unknown less-specific)

Full Context

configure vrrp policy priority-event route-unknown less-specific

Description

This command allows a CIDR shortest match hit on a route prefix that contains the IP route prefix associated with the route unknown priority event.

The **less-specific** command modifies the search parameters for the IP route prefix specified in the **route-unknown** priority event. Specifying **less-specific** allows a CIDR shortest match hit on a route prefix that contains the IP route prefix.

The **less-specific** command eases the RTM lookup criteria when searching for the *prefix/mask-length*. When the **route-unknown** priority event sends the prefix to the RTM (as if it was a destination lookup), the result route table prefix (if a result is found) is checked to see if it is an exact match or a less specific match. The **less-specific** command enables a less specific route table prefix to match the configured prefix. When **less-specific** is not specified, a less specific route table prefix fails to match the configured prefix. The **allow-default** optional parameter extends the **less-specific** match to include the default route (0.0.0.0).

The **no** form of the command prevents RTM lookup results that are less specific than the route prefix from matching.

Default

no less-specific — The route unknown priority events requires an exact prefix/mask match.

Parameters

allow-default

When the **allow-default** parameter is specified with the **less-specific** command, an RTM return of 0.0.0.0 matches the IP prefix. If **less-specific** is entered without the **allow-default** parameter, a return of 0.0.0.0 will not match the IP prefix. To disable **allow-default**, but continue to allow **less-specific** match operation, only enter the **less-specific** command (without the **allow-default** parameter).

configure port tdm e1 egress-scheduler-override level

configure port tdm e3 egress-scheduler-override level

configure port sonet-sdh path egress-scheduler-override level

configure port tdm ds1 channel-group egress-scheduler-override level

Description

This command overrides the maximum and CIR rate parameters for a specific priority level on the port or channel's port scheduler instance. When the **level** command is executed for a priority level, the corresponding priority level command in the port-scheduler-policy associated with the port is ignored.

The override level command supports the keyword **max** for the **rate** and **cir** parameter. When executing the level override command, at least the **rate** or **cir** keywords and associated parameters must be specified for the command to succeed.

The **no** form of this command removes the local port priority level rate overrides. Once removed, the port priority level will use the port scheduler policies level command for that priority level.

Parameters

priority-level

Identifies which of the eight port priority levels are being overridden.

Values 1 to 8

pir-rate

Overrides the port scheduler policy's maximum level rate and requires either the **max** keyword or a rate defined in kilobits per second to follow.

Values For Ethernet: 1 to 6400000000, **max**

For SONET-SDH and TDM: 1 to 3200000000, **max**

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

cir-rate

Overrides the port scheduler policy's within-cir level rate and requires either the max keyword or a rate defined in kilobits per second to follow.

Values For Ethernet: 1 to 6400000000, **max**

For SONET-SDH and TDM: 1 to 3200000000, **max**

pir-percent

Specifies the PIR as a percentage.

Values 0.01 to 100.00

cir-percent

Specifies the CIR as a percentage.

Values 0.00 to 100.00

max

removes any existing rate limit imposed by the port scheduler policy for the priority level allowing it to use as much total bandwidth as possible.

[Tree] (config>service>vprn>isis>if level)

Full Context

configure service vprn isis level

configure service vprn isis link-group level

configure service vprn isis interface level

Description

This command creates the context to configure IS-IS Level 1 or Level 2 area attributes.

A router can be configured as a Level 1, Level 2, or Level 1/2 system. A Level 1 adjacency can be established if there is at least one area address shared by this router and a neighbor. A Level 2 adjacency cannot be established over this interface.

Level 1/2 adjacency is created if the neighbor is also configured as Level 1/2 router and has at least one area address in common. A Level 2 adjacency is established if there are no common area IDs.

A Level 2 adjacency is established if another router is configured as Level 2 or a Level 1/2 router with interfaces configured as Level 1/2 or Level 2. Level 1 adjacencies are not established over this interface.

To reset global and/or interface level parameters to the default, the following commands must be entered independently:

- **level>no hello-authentication-key**
- **level>no hello-authentication-type**
- **level>no hello-interval**
- **level>no hello-multiplier**
- **level>no metric**
- **level>no passive**
- **level>no priority**

Default

level 1 or level 2

Parameters

level-number

The IS-IS level number.

Values 1, 2

Platforms

All

level

Syntax

level *syslog-level*

Context

[Tree] (config>service>vprn>log>syslog level)

Full Context

configure service vprn log syslog level

Description

This command configures the syslog message severity level threshold. All messages with severity level equal to or higher than the threshold are sent to the syslog target host.

Only a single threshold level can be specified. If multiple levels are entered, the last **level** entered will overwrite the previously entered commands.

Default

level info

Parameters

syslog-level

The threshold severity level name.

Values emergency, alert, critical, error, warning, notice, info, debug

Router severity level	Numerical Severity (highest to lowest)	Configured Severity	Definition
	0	emergency	system is unusable
3	1	alert	action must be taken immediately
4	2	critical	critical condition
5	3	error	error condition
6	4	warning	warning condition
	5	notice	normal but significant condition
1 cleared 2 indeterminate	6	info	informational messages

Full Context

configure router pim interface mcac mc-constraints level

configure router mcac policy bundle mc-constraints level

configure router igmp interface mcac mc-constraints level

configure router mld interface mcac mc-constraints level

Description

This command configures the amount of bandwidth available within a given bundle for MC traffic for a specified level. The amount of allowable BW for the specified level is expressed in kb/s and this can be defined for up to eight different levels.

If no bandwidth is defined for a given level then no limit is applied.

The **no** form of this command removes the level from the configuration.

Parameters

level

Specifies the bandwidth for a given level. Level 1 has the highest priority. Level 8 has the lowest priority.

Values 1 to 8

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

bw ***bandwidth***

Specifies the bandwidth, in kb/s, for the level.

Values 1 to 2147483647 kb/s

no level *priority-level*

Context

[Tree] (config>qos>port-scheduler-policy level)

Full Context

configure qos port-scheduler-policy level

Description

This command configures an explicit within-CIR bandwidth limit and a total bandwidth limit for each port scheduler's priority level. To understand how to set the level rate and CIR parameters, a basic understanding of the port-level scheduler bandwidth allocation mechanism is required. The port scheduler takes all available bandwidth for the port or channel (after the max-rate and any port egress-rate limits have been accounted for) and offers it to each of the eight priority levels twice.

The first pass is called the within-CIR pass and consists of providing the available port bandwidth to each of the 8 priority levels, starting with level 8 and moving down to level 1. Each level takes the offered load and distributes it to all child members that have a port-parent cir-level equal to the current priority level. (Any child with a cir-weight equal to 0 is skipped in this pass.) Each child may consume bandwidth up to the child's frame-based within-CIR offered load. The remaining available port bandwidth is then offered to the next lower priority level until level 1 is reached.

The second pass is called the above-CIR pass and consists of providing the remaining available port bandwidth to each of the eight priority levels a second time. Again, each level takes the offered load and distributes it to all child members that have a port-parent level equal to the current priority level. Each child may consume bandwidth up to the remainder of the child's frame-based offered load (some of the offered load may have been serviced during the within-CIR pass). The remaining available port bandwidth is then offered to the next priority level until level 1 is again reached.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

If the port scheduling policy is using the default orphan behavior (orphan-override has not been configured on the policy), the system then takes any remaining port bandwidth and allocates it to the orphan queues and scheduler on priority level 1. In a non-override orphan state, all orphans are attached to priority level 1 using a weight of 0. The zero weight value causes the system to allocate bandwidth equally to all orphans based on each orphan queue or scheduler's ability to use the bandwidth. If the policy has an orphan-override configured, the orphans are handled based on the override commands parameters in a similar fashion to properly parented queues and schedulers.

The port scheduler priority level command rate keyword is used to optionally limit the total amount of bandwidth that is allocated to a priority level (total for the within-CIR and above-CIR passes). The cir keyword optionally limits the first pass bandwidth allocated to the priority level during the within-CIR pass.

When executing the level command, at least one of the optional keywords, **rate** or **cir,** must be specified. If neither keyword is included, the command will fail.

If a previous explicit value for rate or cir exists when the level command is executed, and either rate or cir is omitted, the previous value for the parameter is overwritten by the default value and the previous value is lost.

The configured priority level rate limits may be overridden at the egress port or channel using the egress-scheduler-override level priority-level command. When a scheduler instance has an override defined for a priority level, both the rate and cir values are overridden even when one of them is not explicitly expressed in the override command. For instance, if the cir kilobits per second portion of the override is not expressed, the scheduler instance defaults to not having a CIR rate limit for the priority level even when the port scheduler policy has an explicit CIR limit defined.

The **no** form of this command returns the level to its default value.

Default

no level priority-level

Parameters

priority-level

Specifies to which priority level the level command pertains. Each of the eight levels is represented by an integer value of 1 to 8, with 8 being the highest priority level.

Values 1 to 8 (8 is the highest priority)

pir-rate

Specifies the total bandwidth limits allocated to priority-level, in kilobits per second.

Values 1 to 6400000000, **max**

pir-percent

Specifies the percent bandwidth limits allocated to priority-level.

Values 0.01 to 100.00

cir-rate

The cir specified limits the total bandwidth allocated in the within-CIR distribution pass to priority-level. When cir is not specified, all the available port or channel bandwidth may be allocated to the specified priority level during the within-CIR pass.

Values 0 to 6400000000, **max**

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The value given for kilobits per second is expressed in kilobits per second on a base 10 scale as is usual for line rate calculations. If a value of 1 is given, the result is 1000 bits per second (as opposed to a base 2 interpretation that would be 1024 bits per second).

cir-percent

Specifies the percent bandwidth limits allocated to priority-level.

Values 0.00 to 100.00

group *name*

specifies the existing group that the weighted scheduler group this level maps to, up to 32 characters.

weight

Specifies the weight of the level within this weighted scheduler group.

Values 1 to 100

Default 1

monitor-threshold *percent*

Specifies the percent of the configured rate. If the offered rate exceeds the configured threshold, a counter monitoring the threshold will be increased.

Values 0 to 100

configure router isis interface level

Description

This command creates the context to configure IS-IS Level 1 or Level 2 area attributes.

A router can be configured as a Level 1, Level 2, or Level 1/2 system. A Level 1 adjacency can be established if there is at least one area address shared by this router and a neighbor. A Level 2 adjacency cannot be established over this interface.

Level 1/2 adjacency is created if the neighbor is also configured as Level 1/2 router and has at least one area address in common. A Level 2 adjacency is established if there are no common area IDs.

A Level 2 adjacency is established if another router is configured as Level 2 or a Level 1/2 router with interfaces configured as Level 1/2 or Level 2. Level 1 adjacencies are not established over this interface.

To reset global and/or interface level parameters to the default, the following commands must be entered independently:

```
– level>no hello-authentication-key
    – level>no hello-authentication-type
    – level>no hello-interval
    – level>no hello-multiplier
    – level>no metric
    – level>no passive
    – level>no priority
```

Default

level 1 or level 2

Parameters

1

Specifies the IS-IS operational characteristics of the interface at level 1.

2

Specifies the IS-IS operational characteristics of the interface at level 2.

26 I Commands – Part II

26.1 lfa-policy-map

lfa-policy-map

Syntax

lfa-policy-map route-nh-template *template-name*

no lfa-policy-map

Context

[Tree] (config>service>vprn>isis>if lfa-policy-map)

Full Context

configure service vprn isis interface lfa-policy-map

Description

This command applies a route next-hop policy template to the IS-IS interface for the VPRN instance.

When a route next-hop policy template is applied to an interface in IS-IS, it is applied in both level 1 and level 2. When a route next-hop policy template is applied to an interface in OSPF, it is applied in all areas. However, the command in an OSPF interface context can only be executed under the area in which the specified interface is primary and then applied in that area and in all other areas where the interface is secondary. If the user attempts to apply it to an area where the interface is secondary, the command fails.

If the user excluded the interface from LFA using the command **loopfree-alternate-exclude**, the LFA policy, if applied to the interface, has no effect.

Finally, if the user applied a route next-hop policy template to a loopback interface or to the system interface, the command will not be rejected, but it will result in no action being taken.

The **no** form deletes the mapping of a route next-hop policy template to an OSPF or IS-IS interface.

Parameters

template-name

Specifies the name of the template, up to 32 characters.

Platforms

All

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Full Context

configure li li-filter-lock-state

Description

This command configures the lock state of the filters used by LI. With the configurable filter lock for LI feature an LI user can control the behavior of filters when they are used for LI.

Prior to Release 12.0.R1, when a filter entry was used as a Lawful Intercept (LI) mirror source criteria, all subsequent attempts to modify the filter were then blocked to avoid having the LI session impacted by a non-LI user.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

The **no** form of this command reverts to the default.

Default

li-filter-lock-state locked

Parameters

locked

When an li-source criteria is configured that references any entry of filter Y, then filter Y can no longer be changed (until there are no longer any li-source references to entries of filter Y).

unlocked-for-li-users

Filters can continue to be edited by LI users only even when an li-source references an entry in that filter.

unlocked-for-all-users

Full Context

configure li li-filter li-ip-filter

Description

This command creates a Lawful Interception (LI) IPv4 filter list, or enters the CLI context for a LI IPv4 filter list. LI IPv4 filters are used as a manner to create confidential IPv4 filter based li-source entries. The LI IPv4 filter entries are inserted/merged into normal IPv4 filters as configured with the **li-filter-associations** and **li-filter-block-reservation** commands, but the LI IPv4 filter entries are not visible to users without LI permissions.

The **no** form of this command removes the LI IPv4 filter name from the configuration.

Parameters

li-filter-name

Specifies the name of the IPv4 address filter. Filter names cannot start with an underscore character (for example, "_my-filter”) and cannot use the name "default”.

Context

[Tree] (config>li>li-source li-ip-filter)

Full Context

configure li li-source li-ip-filter

Description

This command enables lawful interception (LI) of packets that match specific entries in an existing LI IP filter that has been associated with a normal IP filter. The specification of an li-ip-filter entry as an li-source means that packets matching the li-ip-filter entry will be intercepted on all interfaces/saps/and so on where the associated normal ip-filter(s) are applied.

Parameters

li-filter-name

Specifies the name of the **li-ip-filter**, up to 32 characters.

li-entry-id

Specifies the entry ID in the **li-ip-filter** that is to be used as an li-source criteria.

Values 1 to 65535

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

intercept-id

Specifies the intercept-id that is inserted into the packet header for all mirrored packets of the associated li-source entry. This intercept ID can be used (for example by a downstream LI gateway) to identify the particular LI session to which the packet belongs. For all types of **li-source** entries (filter, nat, sap, subscriber), when the mirror service is configured with **ip-udp-shim** routable encap, an *intercept-id* field (as part of the routable encap) is always present in the mirrored packets. If there is no *intercept-id* configured for an **li-source** entry, then the default value will be inserted. When the mirror service is configured with **ip-gre** or **ip-udp-shim-sampled** routable encap, no intercept ID is inserted and none can be specified against the **li-source** entries.

session-id

Specifies the session-id that is inserted into the packet header for all mirrored packets of the associated li-source entry. This *session-id* can be used (for example by a downstream LI Gateway) to identify the particular LI session to which the packet belongs. The session-id is only valid and used for mirror services that are configured with ip-udp-shim routable encap (**config>mirror>mirror-dest>encap>ip-udp-shim**). For all types of li-source entries (filter, nat, sap, or subscriber), when the mirror service is configured with **ip-udp-shim** routable encap, a session-id field (as part of the routable encap) is always present in the mirrored packets. If there is no *session-id* configured for an li-source entry, then the default value will be inserted. When a mirror service is configured with **ip-gre** or **ip-udp-shim-sampled** routable encap, no session-id is inserted and none can be specified against the li-source entries.

no li-reserved-block *block-name*

Context

[Tree] (config>li>li-filter-block-reservation li-reserved-block)

Full Context

configure li li-filter-block-reservation li-reserved-block

Description

This command creates or edits an LI reserved block. An LI reserved block allows an operator to define where entries from an LI filter should be inserted into a normal filter. The block reserves a configurable number of entries in the normal filter that can only be used for entries inserted from associated LI filters. The LI filter entries that get inserted into the reserved block in each normal filter are not visible to non-LI operators. The block also defines to which normal filters the reservation is applied.

The **no** form of this command removes the block name from the configuration.

Parameters

block-name

Specifies the name of the MAC filter. Block names cannot start with an underscore character (for example, "_my-filter”) and cannot use the name "default”.

26.13 li-separate

li-separate

Syntax

[**no**] **li-separate**

Context

[Tree] (bof li-separate)

Full Context

bof li-separate

Description

This command specifies whether or not a non-LI user has access to lawful intercept (LI) information. When this command is enabled, a user who does not have LI access will not be allowed to access CLI or SNMP objects in the li context. Modifying this command will not take effect until the system is rebooted.

When the **no li-separate** command is set (the default mode), those who are allowed access to the **config>system>security>profile** context and user command nodes are allowed to modify the configuration of the LI parameters. In this mode, a user that has a profile allowing access to the **config>li** and/or **show>li** command contexts can enter and use the commands under those nodes.

When the **li-separate** command is configured, only users that have the LI access capabilities set in the **config>system>security>user>access li** context are allowed to access the **config>li** and/or **show>li** command contexts. A user who does not have LI access is not allowed to enter the **config>li** and **show>li** contexts even though they have a profile that allows access to these nodes. When in the **li-separate** mode, only users with **config>system>security>user>access li** set in their user account have the ability modify the setting LI parameters in either their own or other profiles and user configurations.

Context

[Tree] (config>qos>adv-config-policy>child-control>bandwidth-distribution limit-pir-zero-drain)

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Full Context

configure qos adv-config-policy child-control bandwidth-distribution limit-pir-zero-drain

Description

This command is used to configure the system to use the minimum configurable PIR instead of an H-QoS derived zero operational PIR. The default behavior is to allow the operational PIR of the queue to remain the last configured value while setting the queue MBS to zero (preventing queuing of newly arriving packets). Retaining the previous PIR value may cause a momentary burst above an aggregate rate associated with the queue as it drains. Using the **limit-pir-zero-drain** command causes the queue to drain at the lowest rate possible (typically 1 kb/s) that limits overrun situations.

The **no** form of this command reverts to default behavior.

configure service vprn subscriber-interface group-interface sap egress limit-unused-bandwidth

configure port ethernet access egress queue-group agg-rate limit-unused-bandwidth

configure port ethernet network egress queue-group agg-rate limit-unused-bandwidth

Description

This command specifies to limit the unused bandwidth and allow a tighter control in allocation of bandwidth by HQoS. When enabled, HQoS algorithm distributes any unused aggregate bandwidth between queues operating below their fair share rates. This allows a simplified aggregate rate protection while allocating bandwidth by HQoS.

The **no** form of this command reverts to the default.

line-length

Syntax

line-length {**110** | **220** | **330** | **440** | **550** | **660**}

Context

[Tree] (config>system>sync-if-timing>bits>output line-length)

Full Context

configure system sync-if-timing bits output line-length

Description

This command configures the **line-length** parameter of the BITS output, This is the distance in feet between the network element and the office clock (BITS/SSU). There are two possible BITS-out interfaces, one for each CPM. They are configured together, but they are displayed separately in the show command. This command is only applicable when the interface-type is DS1.

Default

line-length 110

Parameters

110

Specifies that the distance is from 0 to 110 feet.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

220

Specifies that the distance is from 110 to 220 feet.

330

Specifies that the distance is from 220 to 330 feet.

440

Specifies that the distance is from 330 to 440 feet.

550

Specifies that the distance is from 440 to 550 feet.

660

26.27 link

link

Syntax

link *port-id* {**primary** | **secondary**}

no link *port-id*

Context

[Tree] (config>lag>link-map-profile link)

Full Context

configure lag link-map-profile link

Description

This command designates one of the configured ports of the LAG to be used on egress as either a primary or secondary link (based on the option selected) by all SAPs and network interfaces that use this LAG link map profile.

Links are part of a profile When a link is added or deleted, all SAPs and network interfaces that use this link-map-profile may be re-hashed if required.

The **no** form of this command deletes the link from this LAG link mapping profile. A port must be deleted from all LAG link profiles if it is to be deleted from the LAG.

Parameters

port-id

Specifies a physical port ID that is an existing member of this LAG.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

port-id	*slot*/*mda*/*port*[.*channel*]		
	eth-sat-id	esat-*id*/*slot*/*port*	
		esat	keyword
		id	1 to 20
	pxc-id	pxc-*id*.*sub-port*	
		pxc	keyword
		id	1 to 64
		sub-port	a, b

primary

Designates one of the configured ports of the LAG to be used on egress as a primary link by SAPs/network interfaces that use this LAG link map profile.

secondary

Designates one of the configured ports of the LAG to be used on egress as a secondary link by SAPs/network interfaces that use this LAG link map profile.

Platforms

Syntax

[**no**] **link**

Context

[Tree] (config>test-oam>link-meas>template>ret-path link)

Full Context

configure test-oam link-measurement measurement-template twamp-light return-path link

Description

This command includes a return path sub-TLV link. The link sub-TLV instructs a Session-Reflector configured for type **stamp** to use the receiving logical IP interface for the transmission of the response packet from the reflector to the **session-sender**. The destination of the reflected packet must be installed in the forwarding table and reachable out the IP interface or the packet is dropped by the Session-Reflector. When there are parallel non-equal cost return paths between the Session-Reflector and the Session-Sender the response packet can only be returned on the lowest cost path.

Default

no link

configure service vprn subscriber-interface ipv6 dhcp6 relay link-address

configure subscriber-mgmt local-user-db ipoe host link-address

configure service ies subscriber-interface ipv6 dhcp6 relay link-address

Description

This command configures the link address used for prefix selection at the DHCP server.

The link-address is a field in DHCP6 Relay-Forward message that is used in DHCP6 server to select the IPv6 address (IA-NA) or IPv6 prefix (IA-PD) from a pool with configured prefix range covering the link-address. The selection scope is the pool or a prefix range within the pool.

The **no** form of this command reverts to the default.

Default

no link-address

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

ipv6-address

Specifies the link-address.

Values

ipv6-address	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x - [0 to FFFF]H

Context

[Tree] (config>port>ethernet>efm-oam>peer-rdi-rx link-fault)

Full Context

configure port ethernet efm-oam peer-rdi-rx link-fault

Description

This command defines how to react to the reception of a link fault flag set in the informational PDU from a peer.

Default

link-fault local-port-action out-of-service

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

local-port-action

Defines whether or not the local port will be affected when a link fault is received from a peer.

log-only

Keyword that prevents the port from being affected when the local peer receives a link fault. The dying gasp will be logged but the port will remain operational.

out-of-service

Keyword that causes the port to enter a non-operation down state with a port state of link up. The error will be logged upon reception of link fault event. The port will not be available to service data but will continue to carry Link OAM traffic to ensure the link is monitored.

configure service ies interface ipv6 link-local-address

configure service vprn interface ipv6 link-local-address

configure service ies subscriber-interface ipv6 link-local-address

configure router interface ipv6 link-local-address

Description

This command configures the IPv6 Link Local address that is used as a virtual SRRP IPv6 address by the Master SRRP node. This address is sent in the Router Advertisements initiated by the Master SRRP node. Clients use this address as IPv6 default-gateway. Both SRRP nodes, Master and Backup, must be configured with the same Link Local address.

Only one link-local-address is allowed per interface.

Caution:
Removing a manually configured link local address may impact routing protocols or static routes that have a dependency on that address. It is not recommended to remove a link local address when there are active IPv6 subscriber hosts on an IES or VPRN interface.

The **no** form of this command reverts to the default.

Parameters

ipv6-address

Specifies the IPv6 address in the form:

Values

ipv6-address:	x:x:x:x:x:x:x:x
	x:x:x:x:x:x:d.d.d.d
	x - [0..FFFF]H
	d - [0..255]D

dad-disable

Disables Duplicate Address Detection (DAD) and sets the address to preferred, even if there is a duplicated address.

Platforms

link-measurement

Context

[Tree] (config>test-oam link-measurement)

Full Context

configure test-oam link-measurement

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

Commands in this context configure various link measurement template attributes that are inherited on associated IP interfaces for delay reporting to the routing engine.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, 7950 XRS

26.37 link-monitoring

link-monitoring

Syntax

[**no**] **link-monitoring**

Context

[Tree] (config>port>ethernet>efm-oam>discovery>advertise-capabilities link-monitoring)

Full Context

configure port ethernet efm-oam discovery advertise-capabilities link-monitoring

Description

When the link monitoring function is in a no shutdown state, the Link Monitoring capability (EV) is advertised to the peer through the EFM OAM protocol. This may not be desired if the remote peer does not support the Link Monitoring functionality.

The **no** version of this command suppresses the advertisement of capabilities.

Default

link-monitoring

Platforms

All

link-monitoring

Syntax

link-monitoring

Context

[Tree] (config>port>ethernet>efm-oam link-monitoring)

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Full Context

configure port ethernet efm-oam link-monitoring

Description

This context contains link monitoring specific options defining the various local thresholds, port interaction and peer notification methods. In order to activate Link monitoring function, this context must be configured with the no shutdown option. Shutting down link monitoring will clear all historical link monitoring counters. If the port was removed from service and placed in a non-operational down state and a port state of link up because a signal failure threshold was crossed and link monitoring is shutdown, the port will be returned to service assuming no underlying conditions prevent this return to service.

When the link monitoring function is in a **no shutdown** state, the Link Monitoring capability (EV) is advertised to the peer through the EFM OAM protocol. This may not be desired if the remote peer does not support the Link Monitoring functionality.

This command instructs STP on the maximum number of bridges behind this SAP or spoke SDP. If there is only a single bridge, transitioning to forwarding state will be based on handshaking (fast transitions). If more than two bridges are connected via a shared media, their SAP or spoke SDPs should all be configured as shared, and timer-based transitions are used.

The **no** form of this command returns the link type to the default value.

Context

[Tree] (oam>eth-cfm linktrace)

Full Context

oam eth-cfm linktrace

Description

The command initiates a linktrace test.

Parameters

mac-address

Specifies a unicast MAC address destination.

Values xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx

remote-mepid *mep-id*

Specifies the remote MEP ID of the peer within the association. The domain and association information are derived from the **source mep** for the session. The Layer 2 IEEE MAC address is resolved from previously-learned remote MAC addressing, derived from the reception and processing of the ETH-CC PDU. The local MEP must be administratively enabled.

Values 1 to 8191

mep *mep-id*

Specifies the local MEP ID.

Values 1 to 8191

md-index

Specifies the MD index.

Values 1 to 4294967295

ma-index

Specifies the MA index.

Values 1 to 4294967295

ttl-value

Specifies the TTL for a returned linktrace.

Values 0 to 255

Default 64

Full Context

configure call-trace trace-profile live-output

Description

This command specifies a live output destination for this trace. When configured, captures will not be stored locally but sent (over UDP) to the server in the specified routing context. The destination can be specified as either an IP address or a DNS FQDN. The **live-output** and **debug-output** commands are mutually exclusive.

The **no** form of this command disables live output streaming.

Parameters

ip-address

Specifies the IPv4 or IPv6 address of the server to stream to.

fqdn

Specifies the FQDN that represents the server in DNS, up to 255 characters.

port

Specifies the UDP port on which the server is listening.

Values 1 to 65535

Default 29770

router-instance

Specifies the router instance in which the live output is forwarded.

service-name

Specifies the name of the Layer 3 service in which the live output is forwarded.

26.48 llf

llf

Syntax

[**no**] **llf**

Context

[Tree] (config>service>epipe>sap>ethernet llf)

Full Context

configure service epipe sap ethernet llf

Description

This command enables Link Loss Forwarding (LLF) on an Ethernet port. This feature provides an end-to-end OAM fault notification for Ethernet VLL service. It brings down the Ethernet port (Ethernet LLF) or sends a SONET/SDH Path AIS (ATM LLF) toward the attached CE when there is a local fault on the Pseudowire or service, or a remote fault on the SAP or pseudowire, signaled with label withdrawal or T-LDP status bits. It ceases when the fault disappears.

The Ethernet port must be configured for null encapsulation.

This feature is also supported in Epipes with BGP-EVPN enabled. In this case, upon removal of the EVPN destination, the port is brought oper-down with flag LinkLossFwd, however the AD per-EVI route for the SAP is still advertised (the SAP is kept oper-up).

The **no** form of this command disables LLF on an Ethernet port.

Default

no llf

26.51 load

load

Syntax

load *file-url* [**overwrite** | **insert** | **append**]

Context

[Tree] (candidate load)

Full Context

candidate load

Description

This command loads a previously saved candidate configuration into the current candidate. The edit point will be set to the end of the loaded configuration lines. The candidate configuration cannot be modified while a load is in progress.

Default

If the candidate is empty then a load without any of the optional parameters (such as overwrite, and so on) will load the file-url into the candidate. If the candidate is not empty then one of the options, such as overwrite, insert, and so on, must be specified.

Parameters

file-url

Specifies the directory and filename to load.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

overwrite

Discards the contents of the current candidate and replace it with the contents of the file.

insert

Inserts the contents of the file at the current edit point.

append

Inserts the contents of the file at the end of the current candidate.

[Tree] (config>service>vprn>radius-proxy>server load-balance-key)

Full Context

configure router radius-proxy server load-balance-key

configure service vprn radius-proxy server load-balance-key

Description

This command specifies the key used in calculating a hash to select an external RADIUS server from the pool of configured servers.

The key can be the source IP and source UDP port tuple, or the specified RADIUS attribute in RADIUS packets.

The **no** form of this command removes the parameters from the configuration.

Parameters

vendor-id

Specifies the vendor-id of vendor-specific attribute.

Values 0 to 16777215

attribute-type

Specifies that the key is constructed with the attributes in the RADIUS message.

Values 1 to 255

source-ip-udp

Specifies that the key consists of the source IP address and source UDP port of the RADIUS message.

Full Context

configure service vprn l2tp group load-balance-method

configure router l2tp group tunnel load-balance-method

configure service vprn l2tp group tunnel load-balance-method

configure router l2tp group load-balance-method

Description

This command is applicable only to LNS. By default traffic load balancing between the BB-ISAs is based on sessions. Each session is individually assigned to an BB-ISA during session establishment phase.

By introducing MLPPPoX, all sessions of a bundle must be terminated on the same LNS BB-ISA. This is necessary for two reasons:

- QoS in the carrier IOM has a uniform view of the subscriber
- a single BB-ISA is responsible for MLPPPoX encapsulation/fragmentation for a given bundle.

Therefore, if fragmentation is enabled, load-balancing per tunnel must be configured. In the per tunnel load-balancing mode, all sessions within the same tunnel are terminated on the same LNS BB-ISA.

In the case that we have MLPPPoX sessions with a single member link, both load-balancing methods are valid.

The **no** form of this command reverts to the default.

Default

load-balance-method per-session

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Parameters

per-session

Specifies that the traffic load balancing between the LNS BB-ISAs is based on individual PPPoE sessions.

per-tunnel

Specifies that the traffic load balancing between the LNS BB-ISAs is based on tunnels.

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

configure port sonet-sdh path load-balancing-algorithm

configure port ethernet load-balancing-algorithm

configure port tdm e3 load-balancing-algorithm

configure port tdm ds1 channel-group load-balancing-algorithm

Description

This command specifies the load balancing algorithm to be used on this port.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

In the default mode, **no load-balancing-algorithm**, the port inherits the global settings. The value is not applicable for ports that do not pass any traffic.

The configuration of load-balancing-algorithm at logical port level has three possible values:

- **include-l4** — Enables inherits system-wide settings including Layer 4 source and destination port value in hashing algorithm.
- **exclude-l4** — Layer 4 source and destination port value will not be included in hashing.
- **no load-balancing-algorithm** — Inherits system-wide settings.

The hashing algorithm addresses finer spraying granularity where many hosts are connected to the network. To address more efficient traffic distribution between network links (forming a LAG group), a hashing algorithm extension takes into account Layer 4 information (src/dst L4-protocol port). The hashing index can be calculated according to the following algorithm:

If [(TCP or UDP traffic) & enabled]

hash (<TCP/UDP ports>, <IP addresses>)

else if (IP traffic)

hash (<IP addresses>)

else

hash (<MAC addresses>)

endif

This algorithm will be used in all cases where IP information in per-packet hashing is included (refer to "Traffic Load Balancing Options” in the *7450 ESS, 7750 SR, 7950 XRS, and VSR Interface Configuration Guide*). However the Layer 4 information (TCP/UDP ports) will not be used in the following cases:

- fragmented packets

Default

no load-balancing-algorithm

Parameters

option

Specifies the load balancing algorithm to be used on this port.

Values **include-l4** — Specifies that the source and destination ports are used in the hashing algorithm.**exclude-l4** — Specifies that the source and destination ports are not used in the hashing algorithm.

26.57 load-balancing-weight

load-balancing-weight

Syntax

load-balancing-weight *value*

no load-balancing-weight [*value*]

Context

[Tree] (config>service>vprn>static-route-entry>next-hop load-balancing-weight)

Full Context

configure service vprn static-route-entry next-hop load-balancing-weight

Description

This command configures a weighted ECMP load-balancing weight for a static route next-hop.

If all of the ECMP next-hops of a static route have a configured load-balancing-weight then packets matching the route are sprayed according to the relative weights. In other words, the next-hop interface with the largest load-balancing weight should receive the most forwarded traffic if weighted ECMP is applicable.

The **no** form of this command disables weighted ECMP for the interface and effectively disables weighted ECMP for the entire static route.

Parameters

value

Specifies the cost metric value.

Values 0 to 4294967295

Platforms

All

load-balancing-weight

Syntax

load-balancing-weight [*weight*]

[Tree] (config>service>vprn>ospf>area>if load-balancing-weight)

Full Context

configure service vprn ospf3 area interface load-balancing-weight

configure service vprn ospf area interface load-balancing-weight

Description

This command configures the weighted ECMP load-balancing weight for an IS-IS, OSPF, and OSPF3 interface. If the interface becomes an ECMP next hop for an IPv4 or IPv6 route, and all the other ECMP next hops are interfaces with configured (non-zero) load-balancing weights, then the traffic distribution over the ECMP interfaces is proportional to the weights. This means that the interface with the largest load-balancing weight receives the most forwarded traffic if weighted ECMP is applicable.

The **no** form of this command disables weighted ECMP for the interface which effectively disables weighted ECMP for any IP prefix that has this interface as a next hop.

Default

no load-balancing-weight

Parameters

weight

Specifies the load balancing weight.

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command configures the weighted ECMP load-balancing weight for an IS-IS interface of the VPRN. If the interface becomes an ECMP next-hop for IPv4 or IPv6 route and all the other ECMP next-hops are interfaces with configured (non-zero) load-balancing weights, then the traffic distribution over the ECMP interfaces is proportional to the weights. In other words, the interface with the largest **load-balancing-weight** should receive the most forwarded traffic if weighted ECMP is applicable.

The **no** form of this command disables weighted ECMP for the interface and, therefore, effectively disables weighted ECMP for any IP prefix that has this interface as a next-hop.

Default

no load-balancing-weight

Parameters

weight

Specifies the load balancing weight.

Values 0 to 4294967295

Platforms

All

load-balancing-weight

Syntax

load-balancing-weight *weight*

no load-balancing-weight

Context

[Tree] (config>router>ldp>if-params>if load-balancing-weight)

Full Context

configure router ldp interface-parameters interface load-balancing-weight

Description

This command configures the load balancing weight for the LDP interface. The load balancing weight, normalized to 64, is used for weighted ECMP of LDP labeled packets over direct network IP interfaces.

If the interface becomes an ECMP next hop for an LDP FEC, and all the other ECMP next hops are interfaces with configured (non-zero) load-balancing weights, then the traffic distribution over the ECMP interfaces is proportional to the normalized weight with a granularity of 64.

If one or more of the LDP interfaces in the ECMP set does not have a configured load-balancing weight, then the system falls back to ECMP.

The **no** form of this command removes the load balancing weight for the LDP interface.

load-balancing-weight

Syntax

load-balancing-weight [*value*]

no l**oad-balancing-weight**

Context

[Tree] (config>router>isis>interface load-balancing-weight)

Full Context

configure router isis interface load-balancing-weight

Description

This command configures the weighted ECMP load-balancing weight for an IS-IS interface. If the interface becomes an ECMP next hop for an IPv4 or IPv6 route, and all the other ECMP next hops are interfaces with configured (non-zero) load-balancing weights, then the traffic distribution over the ECMP interfaces is proportional to the weights. In other words, the interface with the largest load-balancing weight should receive the most forwarded traffic if weighted ECMP is applicable.

The **no** form of this command disables weighted ECMP for the interface and therefore effectively disables weighted ECMP for any IP prefix that has this interface as a next hop.

Default

no load-balancing-weight

Parameters

value

0 to 4294967295

[Tree] (config>router>ospf3>area>if load-balancing-weight)

Full Context

configure router ospf area interface load-balancing-weight

configure router ospf3 area interface load-balancing-weight

Description

This command configures the weighted ECMP load-balancing weight for an OSPF or OSPF3 interface. If the interface becomes an ECMP next hop for an IPv4 or IPv6 route, and all the other ECMP next hops are interfaces with configured (non-zero) load-balancing weights, then the traffic distribution over the ECMP interfaces is proportional to the weights. This means that the interface with the largest load-balancing weight receives the most forwarded traffic if weighted ECMP is applicable.

The **no** form of this command disables weighted ECMP for the interface which effectively disables weighted ECMP for any IP prefix that has this interface as a next hop.

Default

no load-balancing-weight

Parameters

weight

Specifies the load balancing weight.

Context

[Tree] (config>subscr-mgmt>sub-profile>control local)

Full Context

configure subscriber-mgmt sub-profile control local

Description

This command enables a session that is set up with local control plane handling to use this subscriber profile. This command cannot be disabled.

Default

local

Platforms

7450 ESS, 7750 SR, 7750 SR-a, 7750 SR-e, 7750 SR-s, VSR

local

Syntax

local [**inherit** | **all** | **vc-only** | **none**]

Context

[Tree] (config>service>vprn>ttl-propagate local)

Full Context

configure service vprn ttl-propagate local

© 2025 Nokia.
Use subject to Terms available at: www.nokia.com/terms.

Description

This command overrides the global configuration of the TTL propagation for locally generated packets which are forwarded over a MPLS LSPs in a given VPRN service context.

The global configuration is performed under config>router>ttl-propagate>vprn-local.

The default behavior for a given VPRN instance is to inherit the global configuration for the same command. The user can explicitly set the default behavior by configuring the inherit value

Default

local inherit

Parameters

inherit

Specifies the TTL propagation behavior is inherited from the global configuration under **config**>**router**>**ttl-propagate**>**vprn-local**.

none

Specifies the TTL of the IP packet is not propagated into the VC label or labels in the transport label stack.

vc-only

Specifies the TTL of the IP packet is propagated into the VC label and not into the labels in the transport label stack.

all

Specifies the TTL of the IP packet is propagated into the VC label and all labels in the transport label stack.

All

local

Syntax

local

Context

[Tree] (config>ipsec>ts-list local)

Full Context

configure ipsec ts-list local

Description

Commands in this context configure local TS-list parameters. The TS-list is the traffic selector of the local system, such as TSr, when the system acts as an IKEv2 responder.

[Tree] (config>service>vprn>l2tp local-address)

Full Context

configure router l2tp local-address

configure service vprn l2tp group tunnel local-address

configure router l2tp group tunnel local-address

configure router l2tp group local-address

configure service vprn l2tp group local-address

configure service vprn l2tp local-address

Description

This command configures the local address.

The **no** form of this command removes the local IP address from the configuration.

Default

no local-address

Parameters

ip-address

Specifies the IP address used during L2TP authentication.

local-address

Syntax

local-address *ip-address*

no local-address

Context

[Tree] (config>subscr-mgmt>bgp-prng-plcy local-address)

Full Context

configure subscriber-mgmt bgp-peering-policy local-address

Description

This command configures the local IP address used by the group or neighbor when communicating with BGP peers.

Outgoing connections use the **local-address** as the source of the TCP connection when initiating connections with a peer.

When a local address is not specified, the 7750 SR OS uses the system IP address when communicating with IBGP peers and uses the interface address for directly connected EBGP peers. This command is used at the neighbor level to revert to the value defined under the group level.

The **no** form of this command removes the configured local-address for BGP.

The **no** form of this command used at the group level reverts to the value defined at the global level.

The **no** form of this command used at the neighbor level reverts to the value defined at the group level.

Parameters

ip-address

Specifies the IPv4 or IPv6 address of the local address.

For IPv4, the local address is expressed in dotted decimal notation. Allowed values are a valid routable IP address on the router, either an interface or system IP address.

For IPv6, the local address is expressed in semi-colon hexadecimal notation. Allowed values is an interface or a system IP address.

Values

ipv4-address:	a.b.c.d
ipv6-address:	x:x:x:x:x:x:x:x (eight 16-bit pieces)
	x:x:x:x:x:x:d.d.d.d
	x - [0 to FFFF]H
